This proceedings of the 2000 Society for Information Technology & Teacher Education International Conference contains 459 papers organized in the following sections: Concepts and Procedures (23 papers); Distance Education (24 papers); Diversity & International (9 papers); Educational Computing Course (13 papers); Educational Leadership (8 papers); Faculty Development (29 papers); Graduate & Inservice (35 papers); Instructional Design (19 papers); International (25 papers); Mathematics (18 papers); New Media (19 papers); Preservice Teacher Education (56 papers); Research (31 papers); Reading, Language Arts, & Literacy (15 papers); Science (19 papers); Simulations (10 papers); Special Needs (8 papers); Social Studies (9 papers); Technology Diffusion (26 papers); Telecommunications: Graduate & Inservice (16 papers); Telecommunications: Preservice Applications (8 papers); Telecommunications: Systems & Services (19 papers); Theory (12 papers); Young Child (5 papers); and Invited Papers (3 papers). (MES)
Proceedings of SITE 2000–February 8-12, 2000
San Diego, California

General Editors –
Dee Anna Willis
Jerry D. Price
Jerry Willis

Volume 1
2000 General Editors
Dee Anna Willis, Northwestern State University of Louisiana
Jerry D. Price, University of Houston
Jerry Willis, Iowa State University

2000 Section Editors
Debra Bauder, State University of New York, Utica/Rome
Stephanie Boger-Mehall, University of Houston
Ray Braswell, University of Alabama - Montgomery
Wren Bump, Texas Southern University
Ruth Burkett, University of South Florida
Paula Christensen, Northwestern State University of Louisiana
Mike Connell, University of Houston
Caroline M. Crawford, University of Houston - Clear Lake
Reagan Curtis, Northwestern State University of Louisiana
Nki Davis, Iowa State University
Glenn Devoogd, California State University, Fresno
Sue Espinoza, Texas A&M University - Commerce
Carine Feyten, University of South Florida
Frank Fuller, Northwestern State University of Louisiana
Bob Gillan, Northwestern State University of Louisiana
Madeline Justice, Texas A&M University-Commerce
Neelam Kher, Northwestern State University of Louisiana
Kathy Matthew, Louisiana Tech University
Kim McGAlister, Northwestern State University of Louisiana
Ron McBride, Northwestern State University of Louisiana
Karen McFerrin, Northwestern State University of Louisiana
Sara McNeil, University of Houston
Barbara Moore, University of South Florida
Dale Nederhauser, University of Utah
Linda Roach, Northwestern State University of Louisiana
Bernard Robin, University of Houston
Cathy Seymour, Northwestern State University of Louisiana
Neal Studler, University of Nevada - Las Vegas
John Tollett, Northwestern State University of Louisiana
Cameron White, University of Houston
James White, University of South Florida
Dee Anna Willis, Northwestern State University of Louisiana

Invitation to Join

The Association for the Advancement of Computing in Education (AACE) international, non-profit educational organization. The Association's purpose is to:

- the knowledge, theory, and quality of teaching and learning at all levels with technology. This purpose is accomplished through the encouragement of scholarship related to technology in education and the dissemination of research results and through AACE sponsored publications, conferences, and other opportunities for professionals from around the world to share knowledge and ideas on research, id applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities, policy decision-makers, professional trainers, adult educators, her specialists in education, industry, and government with an interest in ncing knowledge and learning with information technology in education.

Membership Benefit Highlights

- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

AACE PO Box 2966 • Charlottesville VA 22902 USA
www.aace.org

Advancing Knowledge and Learning with Information Technology
Abstracts for all journal issues are available at www.aace.org/pubs

**Educational Technology Review (ETR)**
ISSN 1065-6901
Quarterly

AACE’s member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. It’s purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. All AACE Professional and Student Members receive *ETR* as a benefit of membership.

**WebNet Journal**
ISSN 1522-192X
Quarterly

Focused on WWW, Internet, and intranet-based technologies, applications, research, and issues, the *WebNet Journal* is an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

**Journal of Educational Multimedia and Hypermedia (JEMH)**
ISSN 1055-8896
Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the *Journal* is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

**Journal of Computers in Mathematics & Science Teaching (JCMST)**
ISSN 0731-9258
Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The *Journal* offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

**Journal of Interactive Learning Research (JILR)**
ISSN 1093-023X
Quarterly

The *Journal*’s published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality based learning systems.

**Journal of Technology and Teacher Education (JTATE)**
ISSN 1059-7069
Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. *Journal* content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

**International Journal of Educational Telecommunications (IJET)**
ISSN 1077-9124
Quarterly

*IJET* serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

**Information Technology in Childhood Education Annual (ITCE)**
ISSN 1522-8185

A primary information source and forum to report the research and applications for using information technology in the education of Children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.
AACE Conferences

Details for conferences are available at www.aace.org/conf

The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

ED-MEDIA 2000
World Conference on Educational Multimedia, Hypermedia & Telecommunications

JUNE 26-JULY 1, 2000 • MONTREAL, CANADA
JUNE 25-30, 2001 • TAMPERE, FINLAND

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications

This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

WebNet 2000
World Conference on the WWW and Internet

OCT. 30-NOV. 4, 2000 • SAN ANTONIO, TX USA

WebNet - World Conference on the WWW & Internet

This annual conference facilitates the exchange of information in these major topics: Commercial, Business, Professional, and Community Applications; Education Applications; Electronic Publishing and Digital Libraries; Ergonomic, Interface, and Cognitive Issues; General Web Tools and Facilities; Medical Applications of the Web; Personal Applications and Environments; Societal Issues, including Legal, Standards, and International Issues; and Web Technical Facilities.

INTERNATIONAL CONFERENCE ON MSET 2001
MATHEMATICS/SCIENCE EDUCATION & TECHNOLOGY

MARCH 3-6, 2001 • ORLANDO, FL USA

M/SET - International Conference on Mathematics/Science Education & Technology

The conference focuses upon information technology in mathematics, science and computer science education across all levels and settings, including elementary, secondary, college, and teacher education. Learn about the current research, development, classroom applications, issues, theory, and trends.

SOCIETY FOR INFORMATION TECHNOLOGY & TEACHER EDUCATION 2001

MARCH 6-10, 2001 • ORLANDO, FL USA

SITE - Society for Information Technology and Teacher Education International Conference

This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences

ICCE/ICCAI—International Conference on Computers in Education/International Conference on Computer-Assisted Instruction

ICCE/ICCAI is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

NOVEMBER 21-24, 2000 • TAIPEI, TAIWAN

Professional & Student Memberships  
Annual membership includes a choice of AACE-sponsored journals, membership in a related Division/Society, a subscription to Educational Technology Review (member magazine), discounts for conferences, proceedings books & CD-Roms.  
Please check below the Journal(s)/membership(s) you wish to receive:  

Professional Membership  
Student Membership  

1 Journal + Ed. Tech. Review:  
$80  
$40  

2 Journals + Ed. Tech. Review:  
$135  
$70  

3 Journals + Ed. Tech. Review:  
$190  
$100  

4 Journals + Ed. Tech. Review:  
$245  
$130  

5 Journals + Ed. Tech. Review:  
$300  
$160  

6 Journals + Ed. Tech. Review:  
$355  
$190  

7 Journals + Ed. Tech. Review:  
$410  
$220  

*If you selected a Student Membership rate above, you must be registered full-time in an accredited educational institution and you must provide the following information:  
- Educational Institution:  
- Expected graduation date:  

Library/Institutional Membership  

- WebNet Journal: Internet Technologies, Applications & Issues  
- Jrl. of Computers in Math and Science Teaching (JCMT)

TABLE OF CONTENTS

CONCEPTS AND PROCEDURES ................................................................. 1

Section Editors: Deborah Bauder, Rome City School District (NY); Rosemary Mullick, SUNY Institute of Technology at Utica/Rome; Ronald Sarner, SUNY Institute of Technology at Utica/Rome

The Role of An Educational Software Clearinghouse In Undergraduate Teacher Education Programs ........................................................................... 3

Michael Shaughnessy, Eastern New Mexico University, USA; Randy Seavers, University of Houston, USA

Technology For Critical Pedagogy: Beyond Self-Reflection With Video .......................................................... 6

David McCurry, Monmouth University, USA

Model Technology Classrooms In Teacher Education ..................................................................................... 12

Kathryn Matthew, Louisiana Tech University, USA; Kimberly Kimbell-Lopez, Louisiana Tech University, USA

Defining a Distant Environment for Teacher Education .............................................................................. 16

Gertrude (Trudy) Abramson, NSU/SCIS, USA; Timothy (Tim) Ellis, NSU/SCIS, USA

Course Portfolio: A Tool for Online Teaching ............................................................................................. 22

Lissa Pollacia, Northwestern State University, USA; Richard Tarver, Northwestern State University, USA

Student Digital Portfolios on CD-ROM: Assessing Ability-Based Projects ............................................ 25

Terry Corwin, Valley City State University, USA

An evaluation methodology for computer mediated teletraining systems ........................................ 30

Francoise, Sandz-Guermond, Insa-20, Avenue Albert Einstein - Bat 401 - Ictt, France; Gerard, Beuchot, Insa-20, Avenue Albert Einstein - Bat 401 - Ictt, France

Developing an On-line Ethics Policy ........................................................................................................ 36

Jennifer Summerville, Emporia State University, USA

Ethics and the Internet ................................................................................................................................. 40

Stig R Rask, The Foundation for Knowledge and Competence Development, Sweden

CBT: The Past, Present and, Hopefully, the Future ......................................................................................... 44

Daniela Marghitu, Auburn University, U.S.A.; Roland Hubscher, Auburn University, U.S.A.

Staff Development, Distant and Direct: The Middle School Initiative at Northwestern State University .................................................................................. 50

Bob Gillian, Northwestern State University, USA; Frank Fuller, Northwestern State University, USA; Karen McFerrin, Northwestern State University, USA

A University Design Team Approach: Developing Courses for On-line Distance Education ............... 53

Timothy Youngman, University of Houston-Clear Lake, United States; Lee Gotcher, University of Houston-Clear Lake, United States; Shahrzad Vafa, University of Houston-Clear Lake, United States; Sharon Dinsmore, University of Houston-Clear Lake, United States; Orval B. Goucher, University of Houston-Clear Lake, United States

Interactive Television: The Planning Process .......................................................................................... 59

Kay Allen, University of Central Florida, U.S.A.

The Value Of Information Technology (As Difficult To Assess As The Value Of Education!) ........... 62

Alexandre Graeml, CEFET-PR/UNCENP, Brazil; Pierre Ehrlich, EAESP-FGV, Brazil

Then and Now: Technology and the Changing Face of Higher Education .................................... 68

Eric Seemann, Louisiana Tech University, USA; Walter Babolts, Louisiana Tech University, USA; Lamar Wilkinson, Louisiana Tech University, USA

Higher Level Thinking Skills and Individual Differences: Bridging Gaps with Technology ............ 74

Barbara Moore, University of South Florida, USA

Technology for Teachers: Another Perspective of the Implementation ........................................... 80

John R. Ouyang, Kennesaw State University, USA; James E. Yao, Texas A & M University – Commerce, USA
A Farewell to the Traditional Instructional Media and Technologies in the New Millennium     84

The Technology Facade     90
Lawrence Tomei, Duquesne University, USA

Technology Planning and Technology Integration: A Case Study     95
Linda Espey, Heartland Area Education Agency and Drake University, Iowa, USA

Effective Curricular Software Selection for K-12 Educators     101
James Marshall, San Diego State University, USA; Marguerite Hillman, Hillman Consulting, USA

Using Concept Mapping in the Classroom     107
F. Thomas Scappaticci, King's College, USA

Proving Competence: Integrative Assessment and Web-based Portfolio System in a Dynamic Curriculum     112
Douwe Wielenga, Amsterdam Faculty of Education, Netherlands; Rene Melisse, Amsterdam Faculty of Education, Netherlands

DISTANCE EDUCATION

Section Editors: Frank Fuller, Northwestern State University of Louisiana; Ron McBride, Northwestern State University of Louisiana

Role Modeling Critical Thinking Strategies In an Online Course for Nurse Educators     120
Gary Loving, University of Oklahoma Health Sciences Center, USA

Problems and Practical Solutions of Web Based Courses: Lessons learned from three educational Institutions     124
Marios Miltiadou, Arizona State University, USA; Marina McIsaac, Arizona State University, USA

Evaluating new ICT-based models for teacher training     130
Svein Ove Lyse, Stord/Haugesund College, Norway; Jostein Tvedte, Stord/Haugesund College, Norway

Improving Collaborative Learning by Supporting Casual Encounters In Distance Learning     136
Juan Contreras, Centro de Investigación Científica y Educación Superior de Ensenada, México; Rafael Llamas, Centro de Investigación Científica y Educación Superior de Ensenada, México; Aurora Vizzacino, Universidad de Castilla la Mancha, España; Jesús Favela, Centro de Investigación Científica y Educación Superior de Ensenada, México

Group learning through Internet     143
Antonio Vit, UFRGS, Brazil; Tarouco Liane, UFRGS, Brazil

Challenges of Using CSCL in Open Distributed Learning     148
Anders Grov Nilsen, Stord/Haugesund College, Norway; Elen Instefjord, Stord/Haugesund College, Norway

Remote Labs!     155
Khalid Hamza, Florida Atlantic University, USA; Bassem Alhalabi, Florida Atlantic University, USA; David Marcovitz, Loyola College in Maryland, USA

Online Interactive Learning: An Innovative Project of the Inter American University, Bayamón Campus, Developed with the Integration of Students, Faculty and Administrative Staff     162
Yolanda Serrano, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.; José Guillermo Santiago, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.; Reinaldo Medina, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.

An Overview of Online Educational Delivery Applications     165
George Marsh, II, The University of Alabama, USA; Anna McFadden, The University of Alabama, USA; Barrie Jo Price, The University of Alabama, USA

Teaching and Learning in An Anytime/Anyplace Classroom     171
Gertrude (Trudy) Abramson, NSU/SCIS, USA; Maxine Cohen, NSU/SCIS, USA; Timothy (Tim) Ellis, NSU/SCIS, USA; Cordelia Twomey, NJCU, USA; Mitchell Pratt, Alpine School District, USA

DEP WEB: A concept mapping based on web distance education process     173
Apuena Gomes, Universidade Federal do Rio Grande do Norte, Brasil; Márcia Gottgroy, Universidade Federal do Rio Grande do Norte, Brasil
More than Having a Connection: Qualitative Factors that Affect Learning In a Web-based University Course .......................................................................................................................... 177
Laura E. Sujo de Montes, Northern Arizona University, USA; Carmen L. Gonzales, New Mexico State University,

Content Analizing as a Tool In Evaluating the Effectiveness of Distance Learning System........ 183
Baruch Ojfir, Bar-Ilan University, Israel; Y. Lev, Bar-Ilan University, Israel

Evaluation of World Wide Web Delivered University Courseware: Creating an Instrument Appropriate For A New Course Delivery Medium ................................................................. 189
James Izat, West Texas A&M University, USA; LeAnn McKinzie, West Texas A&M University, USA; Charles Mize, West Texas A&M University, USA; Trey McCallie, West Texas A&M University, USA

Trickle Down Technology: A Distance Education Approach .................................................................. 196
Angie Parker, Gonzaga University, USA

Shifting focus from teaching to learning - ICT as an incentive to reform teacher education........... 204
Harald Haugen, Stord/Haugesund College, Norway; Svein Ove Lysne, Stord/Haugesund College, Norway; Lars Vavik, Stord/Haugesund College, Norway; Bodil Ask, Agder College, Norway; Birgit Bratseth, Stord/Haugesund College, Norway

New Horizons In Distance Education: Re-mapping the Pedagogical Terrain .............................. 210
Jeannine Hirtle, Sam Houston State University, USA; Robin McGrew-Zoubi, Sam Houston State University, USA; Christopher Scofield, St. Martin's University, USA

Three community building strategies and their Impacts In an on-line course: A case study .......... 216
Joy Egbert, Indiana University, USA; Chin-Chi Chao, Indiana University, USA; Karen Ngeow, Indiana University, USA

Technology in the classroom: Implications for Teacher Education .................................................. 222
Warren Wessel, University of Regina, Canada

Introducing ODL In Teacher Education - on on-line course on how to create on-line learning environments .................................................................................................................. 228
Harald Haugen, Stord/Haugesund College, Norway; Bodil Ask, Agder College, Norway

A new program for the Inservice training of Computer studies teachers through distance education ................................................................. 233
Elsa Naude, University of South Africa, South Africa

Meeting the needs of Distant Learning through the use of PowerPoint and RealPresenter .......... 239
David Cary, CSU Northridge, USA; Wayne Smith, CSU Northridge, USA

New tools for assessment In distance education .............................................................................. 241
Luciano Hack, Universidade de Santa Catarina, Brazil; Liane Tarouco, Universidade Federal do Rio Grande do Sul, Brazil

Distance education insights from eight case studies In TESOL teacher preparation ....................... 245
Lynn Henrichsen, Brigham Young University, USA

DIVERSITY & INTERNATIONAL ................................................................. 248
Section Editor: Madeline Justice, Texas A&M University-Commerce

"At-Risk" Learners and the "Digital Divide": Exploring the Equity In Access Issue ...................... 249
Jeanne Foster, Texas Woman's University, USA; Sharla Snider, Texas Woman's University, USA

Integrating Standards-Based Instructional Technology ............................................................... 256
Nicole Snow, Northern Arizona University, USA

Technology and the Navajo - Its Time Has Come ........................................................................ 262
Jerry A. Bennett, Navajo Education Technology Consortium, USA

A Multifaceted Approach to Integrating Computers In Multicultural Preservice Teaching ........ 264
Inés Márquez Chisholm, Arizona State University West, USA

"From Tatters to Tapestry": Technology and the Weaving of Cultural Education In the Mainstream Classroom............................................................................................... 270
Debra A. Suarez, The University of Alabama, USA

Gender Representation In Visuals on School Web Pages ............................................................... 276
Wendy Maboudian, University of Houston, USA
Within Student Comparison of ESL Acquisition-Through Content Between Virtual F/F Seminar for ESL and Native Speakers' Negotiated Meaning ................................................................. 282
Stephen Carey, University of British Columbia, Canada

Virtual Interactive Workshop: a pedagogical art education view into the computer lab ........................................... 285
Maria Cristina V. Biazus, Universidade de Caxias do Sul, Brazil

Fostering Equity in Pre-College Computing Classrooms ................................................................. 290
Sandra Madison, University of Wisconsin-Stevens Point, USA; James Gifford, University of Wisconsin-Stevens Point, USA; Min Deng, University of Wisconsin-Stevens Point, USA

EDUCATIONAL COMPUTING COURSE ................................................................. 296
Section Editor: Wren Bump, Texas Southern University

Insuring the Future: Development of an Exemption Exam for an Introductory ................................................................. 298
William Wiencke, State University of West Georgia, USA; Leticia Ekhaml, State University of West Georgia, USA

How Can We Help Johnny Compute? ................................................................. 302
Gail Ring, University of Florida, USA; Sebastian Foti, University of Florida, USA

Technology for Preservice Teachers: What Is It? ................................................................. 307
John Bailey, Brigham Young University - Hawaii Campus, USA

Preparing Pre Service Teachers to Use Technology to Teach the Content Areas In Elementary Schools ................................................................. 311
Maria Bhattacharjee, University of Houston Downtown, USA; Linlin "Irene" Chen, University of Houston Downtown, USA

The Impact of Theory on Technology Use In the Classroom ................................................................. 316
Alec Couros, University of Regina, Canada; Carol Fulton, University of Regina, Canada; Vi Maeers, University of Regina, Canada

Constructing Technology-based Constructivism: A New Approach to the Educational Computing Course ................................................................. 322
Edwin J. George, Florida Gulf Coast University, Fort Myers, FL, USA; Jennifer Sparrow, Florida Gulf Coast University, Fort Myers, FL, USA

Collaborative Team Teaching Approach In a Technology Course ................................................................. 329
Seung Jin, Cleveland State University, USA; Abu Nasara, Cleveland State University, USA

Beyond Applications to the Essential Processes of Technology Integration: Designing an Educational Technology Course to Reflect ISTE Standards and to Model Best Practices for the Future ................................................................. 335
Margaret Ropp, University of New Mexico, USA; Jill R. Brown, University of New Mexico, USA

Integrating Electronic Portfolios Into Undergraduate and Graduate Educational Technology Courses at the University of Florida ................................................................. 339
Colleen Swain, University of Florida, USA; Gail Ring, University of Florida, USA:

Teachers' Comfort Level, Confidence, and Attitude toward Technology at a Technology Course ................................................................. 343
Amy S. C. Leh, California State University San Bernardino, USA

A Comparison Of Student-Teachers' Attitudes Toward Computers In On-Line And Traditional Computer Literacy Courses: A Case Study ................................................................. 348
Tarkan Gurbuz, Middle East Technical University, Turkey; Soner Yildirim, Middle East Technical University, Turkey; M. Yasar Ozden, Middle East Technical University, Turkey

What are we talking about? The Impact of Computer-mediated Communication on Student Learning In an Educational Technology course ................................................................. 354
Sarah Irvine, American University, USA

Information System Design of Undergraduate Education: Combining Lectures with Practice ................................................................. 359
Yoshinori Fujio, Prefectural University of Kumamoto, JAPAN
EDUCATIONAL LEADERSHIP

Section Editor: John R. To llett, Northwestern State University

Technology Standards for School Administrators: Implications for Administrator Preparation Programs

Warren Hope, Florida A&M University, USA; Bernadette Kelley, Florida A&M University, USA; Janet Gayden, Florida A&M University, USA

Information Technology and the transformation of leadership preparation programs: A response to calls for reform in educational practice.

Ian Gibson, Wichita State University, USA

Graduate Technology Coursework in a Framework of Professional Leadership

Perry Rettig, University of Wisconsin Oshkosh, USA; Penny Garcia, University of Wisconsin Oshkosh, USA; Scherie Lampe, University of Wisconsin Oshkosh, USA

Stephen Best, University of Michigan, USA; Ronald Marx, University of Michigan, USA; Barry Fishman, University of Michigan, USA; Deborah Peek-Brown, Detroit Public Schools, USA

TLI: Recreating University Programs to Meet School District Needs

Carolyn R. Parkins, University of Louisville, USA

“The Usual Suspects”: Explaining Success and Failure in Instructional Technology Consortia

Steven Jackson, Indiana University of Pennsylvania, USA; Dolores Bryzcki, Indiana University of Pennsylvania, USA; Mary Ann Cessna, Indiana University of Pennsylvania, USA

ICT Training and Implementation: Inseparable activities

Reg North, University of Ulster, U.K.

Attitudes Towards Using Computers in Administration Among School Administrator

A. Rafee C. Kassm, Universiti Utara Malaysia, Malaysia; Hatim M. Tahir, University Utara Malaysia, Malaysia

FACULTY DEVELOPMENT

Section Editors: Bob Gillan, Northwestern (LA) State University; Karen McFerrin, Northwestern (LA) State University

Involving Faculty in Faculty Development: A Recursive Model

Kristine Blair, Bowling Green State University, USA; Dan Madigan, Bowling Green State University, USA

Technology Use in Higher Education: A faculty development model

Jessica Kahn, Chestnut Hill College, USA; Robert Pred, Chestnut Hill College, USA

A Faculty of Education as a Community of Learners: Growing to Meet the Demands of Instruction and Technology

Nancy Browne, University of Regina, Canada; Mhairi Maeers, University of Regina, Canada; Elizabeth Cooper, University of Regina, Canada

Faculty Development: From Computer Skills to Technology Integration

Karen Milligan, Carson-Newman College, USA; Stephanie Robinson, Carson-Newman College, USA

Technology Mentorships in Higher Education: An Optimal Match for Expanding Educational Computing Skills

Sally R. Beisser, Drake University, USA

Constructivist Learning: Also For Faculty

Simone Terwindt, Amsterdam Faculty of Education, Netherlands

Building a Vision for Technology Integration

Ann McCoy, University of Alaska Anchorage, USA

Teaching Well With Technology: An Educators Guide to Wise and Time-Efficient Use of Instructional Technology

Kevin Barry, University of Notre Dame, USA; Thomas Laughner, University of Notre Dame, USA; Barbara Walvoord, University of Notre Dame, USA
Ten Years of Technology Training for Faculty ................................................................. 463
Neal Topp, University of Nebraska at Omaha, US; Robert Mortenson, University of Nebraska at Omaha, US

Teachers' Distance Professional Development And Support Model .................................. 469
Peter Serdiukov, University of Utah Reading Center, USA; Dale Niederhauser, University of Utah Reading Center, USA; Ralph Reynolds, University of Utah Reading Center, USA

Teaching the Teachers: Faculty Development Institutes at Two Universities .................. 474
Marc Childress, Old Dominion University, USA; Ray Braswell, Auburn University Montgomery, USA

The Evangellist and the Conscientious Objector - Lessons Learned from Faculty Development .............................................................. 479
Lawrence Baines, Berry College, USA; Lynnwood Belvin, Berry College, USA

Puzzled by Technology Professional Development? Which Pieces Fit In Higher Education? ...... 483
Ellen Newcombe, West Chester University, USA; John Kinslow, West Chester University, USA

Aids and Cautions for Developers of Web Pages to Supplement Courses In Higher Education .......................................................................................... 487
Cleborne Maddux, University of Nevada, Reno, USA

Power Web Searching Techniques for Teacher Educators .................................................. 492
Judi Repman, Georgia Southern University, USA; Randal Carlson, Georgia Southern University, USA; Elizabeth Downs, Georgia Southern University, USA; Ken Clark, Georgia Southern University, USA

Interactive PowerPoint for Teachers and Students ......................................................... 496

Preface to the Millennium Edition!

Now that we have had our celebrations about the coming of a new century and a new millennium, purists are pointing out that we are not really in the first year of the new millennium but in the last year of the old one. "What?", you say. I vacationed in Turkey this Christmas (thanks to Dee Anna Willis being willing to shoulder most of the load for getting the section leaders' comments in and organized) and the English language paper in Turkey ran an article about the way the monk who organized the calendar we use today started it. Instead of making the first year, 0, he made it year 1. Thus, the year 2000 is actually not the two thousandth year, it is the 1999th year. So, if we want to do the whole thing over again next year, we can.

What about the Annual? Is this the 9th or the 10th year of the Annual? That too is a bit complicated. The first conference was held in 1990 which means this is the 11th conference. (We did not think far enough ahead to hold the first conference in 1991 instead of 1990 so it would be easy to keep up with.) Everything being equal this should be the 11th Annual, right? Well, not quite. The papers presented at the first conference were not published in an Annual. Instead, they were Issues 1, 2, and 3 of the 1990 volume of the journal, Computers in the Schools. So, when it comes to Annuals, the year and the number of the Annual is consistent. This is the tenth Annual.

Ten years! For the Annual. And eleven for the conference! Not long in the grand scheme of things but a long time when it comes to conferences. I would estimate that there are 80% more "First Annual" conferences than "Second Annual." And, if we extrapolate a bit my guess is that less than 5% of the academic conferences are around for an eleventh incarnation. SITE is a survivor for several reasons. One is that it does a good job of meeting a need. There is a growing community of scholars and professionals who have a strong interest in technology and teacher education. SITE is THE conference if that is your interest. A country singer whose name eludes me had a popular song a few years ago that had the lyric, "I was country before country was in." SITE was here, with a focus on teacher education before that was an "in thing."

Today, technology and teacher education is an in thing. The U.S. Department of Education's $75 million dollar grant program on preparing teachers to use technology has raised the interest level and attention of teacher education, as have a number of other activities such as the AACTE report on technology in teacher education. Technology was not always in the limelight of teacher education, however. In introducing the special issue of Educational Technology Research and Development on technology and teacher education, Bob Hannafin (1999) commented that in the past teacher education and instructional technology "lived quite happily in separate worlds, neither really knowing - or caring to know - what the other was doing" (p. 27). Hannafin edited the special issue of ETR&D on technology and teacher education because he felt this was an emerging field that deserved the attention of the IT community. I am happy to say that of the seven authors involved in writing articles for that special issue, all except one are regular participants in SITE. Two have been or are presidents of the organization and several others have won awards for their papers at SITE.

The USDOE grants program, the work of NCATE, ISTE, and AACTE; and special issues of journals like ETR&D, are all indicators of the changing landscape of technology and teacher education. SITE and its membership has many opportunities to form collaborative relationships with other organizations. The time is right for that, thus the theme of the conference, Bridges Among Professional Associations. I hope you have a productive and enjoyable conference and that you become an active and energetic part of the process of building bridges in this time of high interest and attractive possibilities.

This year's papers tend to cluster into three broad areas: (1) teacher preparation, (2) distance learning, and (3) integrating technology.

The teacher preparation group consists of three selections. Michael Shaughnessy of Eastern New Mexico University notes the importance of preparing teachers to use educational software effectively and describes a software clearinghouse to encourage entering professionals to evaluate a variety of computing applications. In the second selection, David McCurry of Monmouth University (NJ) describes the use of videotaping, not only for purposes of self-reflection, but notes that it can also be used for a sociological assessment of teaching practices in a broader sense. In the final paper in this cluster, Kathryn Matthew and Kimberly Kimbell-Lopez, both of Louisiana Technical University, describe the importance of model technology classrooms that are used in their teacher preparation program.

Twelve papers in this section deal with aspects of distance learning, including the use of portfolios, ethics, and descriptions of ongoing projects. Gertrude Abramson and Timothy Ellis from Nova Southeastern University provide an excellent overview of the role and challenges of distance education in teacher preparation. In particular, Abramson and Ellis take pains to establish differences in attitudes and priorities between adult learners and traditional age college-students. We would do well to remember these differences as we read the other papers in this section.

The use of portfolios to organize a course and to document student achievement generates considerable interest. Lissa Pollacia and Richard Tarver from Northwestern State University (LA) present a course portfolio, “a coherent set of materials, compiled by the instructor, that provides insight into how a course is being managed and/or facilitated.” The authors provide guidelines for compiling a course portfolio, and describe accommodations that are necessary for on-line courses. The paper by Douwe Wielenga from the Amsterdam (Netherlands) Faculty of Education is an overview of the role of integrative assessment. Terry Corwin from Valley City (ND) State University describes an interesting project through which students are required to compile a digital portfolio and, as a capstone experience, complete the portfolio by burning it onto a compact disk. Françoise Sandoz-Guermond and Gérard Beuchot, both from INSA de Lyon (France) describe a method for evaluating computer-mediated training.

Two selections deal with computer ethics. Jennifer Summerville from Emporia State University (KS) cites the need for an explicit ethics policy for on-line college courses and describes some of her experiences. Stig Rask from the Foundation for Knowledge and Competence Development in Sweden provides guidance on ways to instill ethical internet behavior among elementary and secondary school children.

Daniela Marghitu and Roland Hübscher from Auburn University discuss lessons learned from their use of computer-based training (CBT) applications. Robert Gilian, Karen McFerrin, and Frank Fuller from Northwestern State University (LA) report on a middle school staff development initiative, and the conversion of their materials to the world wide web. In “A University Design Team Approach: Developing Courses for On-line Distance Education, Timothy Youngman, Lee Gotcher, Shahrzad Vafa, Sharon Dinsmore, and Orval Goucher all from the University of Houston - Clear Lake present a team-based systematic course design process. Finally, Kay Allen from the University of Central Florida provides guidance for planning an interactive television course.

The final group of papers deal with the integration of technology and instruction. Alexandre Graeml from Centro Universitário Positivo in Brazil and Pierre Ehrlich from Escola de Administração de Empresas de São Paulo in Brazil present an insightful literature review comparing attempts to evaluate the return on investment in information technology with ways of assessing the benefits of formal education. Eric Seemann, Walter Buboltz, and Lamar Wilkinson of Louisiana Tech University present a reflective paper assessing changes to student and faculty demographics over the last generation or two. From the demographic changes flow changes in skills, attitudes and beliefs on the part of students and faculty alike.
Another aspect of change in the educational landscape—the need to deal with students with individual differences—is the subject of a paper by Barbara Moore from the University of South Florida. Moore argues that technology, in the form of a web-based resource termed a “digital bridge,” is the key to dealing with students with gaps in content knowledge.

John Ouyang from Kennesaw (GA) State University, James Yao from Texas A&M, and Henry Wang from Lon Morris College (TX) have two selections. In the first, “Technology for Teachers: Another Perspective of the Implementation,” the authors review teacher computing literacy training, providing a historical overview that traces programming-centered training to a computing-curriculum focus and finally to a problem-solving approach. Their other paper, entitled “A Farewell to the Traditional Instructional Media and Technologies in the New Millennium,” concludes that “computer-based instructional media and technology has far more greater advantages over traditional media and instructional technology in almost all the aspects,” and suggests that now is an appropriate time to abandon “traditional media and technology.”

Lawrence Tomei from Duquesne University seems less anxious to declare new technologies victorious. His paper entitled “The Technology Facade” is an indictment against the “use of technology in a school without benefit of a necessary infrastructure of support its application as a viable instructional strategy.”

Linda Espey from Heartland Area Education Agency 11 and Drake University (IA) presents a case study of the Boone (IA) Community School District that explores whether the development of a technology plan facilities meaningful use of technology in the classroom. She concludes that the Boone CSD was very successful in developing and implementing a technology plan, but that more work remains before teaching and learning change significantly.

In “Effective Curricular Software Selection for K-12 Educators,” James Marshall from San Diego State University and Marguerite Hillman from Hillman Consulting outline a model, which they term 4DIEM (the four Ds are Describe the objective, Determine if software exists and if so, what type is required, Decide on which appropriate titles to review, test Drive - followed by Integrate, Evaluate, and Modify) that is used to evaluate educational software.

In the final selection Thomas Scappaticci from King’s College describes the technique of “concept mapping” and its implementation in a product called Inspiration Software.
The Role of An Educational Software Clearinghouse in Undergraduate Teacher Education Programs

Michael F. Shaughnessy
Eastern New Mexico University
School of Education
Portales, New Mexico 88130
Michael. Shaughnessy@enmu.edu

Abstract: As teaching and technology changes, access to educational resources and technology becomes increasingly imperative in order to prepare pre-service teachers to work in an increasingly technologically rich environment. This paper discusses the importance of an educational software clearinghouse in the preparation of undergraduate teachers. The paper will discuss the critical elements of exposure to educational software and educational and assistive technology.

As we enter the new millennium, colleges and universities are increasingly confronted with the problem of training pre-service teachers in methodology, assessment, classroom management, special education, inclusion and school law. Colleges and universities are increasingly confronted with students who are academically unprepared and computer illiterate. University instructors are confronted with transfer students who have minimal skills in educational technology, and who may need orientation to a vastly different modality of teaching.

At the same time, companies are increasingly putting educational software and educational products on the market for parents, teachers and librarians to purchase. However, prior to purchasing, what is often very expensive software, the buyer must be able to ascertain if the software is appropriate for the specific use, appropriate to the reading level of the student, and whether the software is easily accessible and what the strengths and weaknesses of that software are.

Several years ago, the New Mexico Educational Software Clearinghouse was established by Mark Isham and Janna Siegel to provide teachers in the State of New Mexico with a centrally located facility to review software prior to purchase. The NMESC is currently directed by this writer and its functions have expanded to expose pre-service teachers to educational software and educational technologies that may be useful to them in the future.

The realm of education and teaching training has expanded considerably in the past two decades. Increasingly, teachers are responsible for multiply handicapped children that are being included or "mainstreamed" into regular education classes (Shaughnessy, 1996). At the same time, parents are increasingly concerned about their children's test scores and progress in their schools.

Teachers are also dealing with students who have been raised in a very visual medium, with some sources indicating that many children watch as much as seven hours of television a day.

Teachers must be first aware of the educational technology available to them. They must be able to quickly load software onto the computer and deal with any glitches that they may encounter. Teachers must use instructional time wisely and be able to incorporate Educational Software into their classes for review, and also for the incorporation of higher order thinking skills as well as critical thinking skills. At the same time, they must be able to help students master certain basics, such as addition, subtraction, multiplication and division. There are a number of viable C.D.'s available for this purpose. In addition, teachers want to expose children to reading and enhance their reading skills and abilities as well as their comprehension. Teachers must be able to procure appropriate software quickly and have students able to "log on" rapidly and begin at a level of difficulty that is appropriate for them.

Teachers need to be able to critically distinguish between educational software that is challenging and enlightening, as opposed to software that is simply visual and loaded with a number of "bells and whistles". All too often, many software companies overdo the colorful aspect to the neglect of actual learning and information procuring and dissemination.
In order to be able to distinguish between the wheat and the chaff so to speak, teachers need to be exposed to a wide variety of educational products. There are a number of companies that produce excellent, thought provoking software products that will enhance the cognitive abilities and cognitive growth of their students. On the other hand, there are a number of companies that misrepresent their products and alienate parents and teachers with false claims. In fact, some educational software is not "field tested" on the groups of children that they have been designed for.

Teachers need to be sensitive to programs that "freeze" or "lock up" or force students to review four to five minutes of credits at the end of the program. Students are not always interested in who produced, directed and did the art work for various software products. Much time is wasted and educational time and instructional time is a very valuable commodity. Increasingly, teachers are being asked to cover more and more material in the same space of time. And, many teachers and students abhor the concept of homework. By the same token, an educational C.D. may prove engaging, challenging and stimulating and may not be onerous to the child.

Preparing Teachers to Use Educational Software

Teachers need to be able to employ educational software either in large group settings or individually. Some software packages require extensive amounts of time to become familiar with. Other software packages are very simple and easy to load and require very little prompting or assistance. Teachers need to be able to quickly review the documentation that comes with software and find the "gist" of the program quite rapidly.

Some educational software companies now advertise on the world wide web and teachers can sometimes purchase software at greatly reduced prices, if they know what companies are reputable and reliable and have return plans and which companies are new and developing, but may have educational materials that are not "user friendly".

While there is a presumption among many administrators that all college students are computer literate, there are some students who have never turned on a computer. Such students are going to need to learn some computer basics. This takes instructional time away from other areas of interest. In effect, the instructor in undergraduate teacher education programs must make very wise prudent, judicious decisions about what is to be taught and how much time to spend on certain topics. An educational software clearinghouse is a valuable resource since students can spend as much time as they want reviewing software that is of interest to them and relevant to them, rather than having to sit through demonstrations of math or science software, when their instructional areas may be language arts or social studies.

Educational Decisions

Teachers must make many educational decisions as they enter the classroom. One such decision is when to use what type of software, to teach what type of lesson to what type of student. Embedded in this question is the issue of inclusion, where a teacher may have a very heterogeneous group of students. They may not all relate to the same software, nor will they have the reading comprehension skills to master the software or even keep up with the program. If there are gifted children in the class, the software may actually be boring. In such cases, teachers may need to send that child to an individual computer so that child will be challenged at a level commensurate with his ability. There are learning disabled students who may benefit greatly from educational software, if the reading level is appropriate. If the reading level is too difficult, the child will be frustrated. If the reading level is too simple, then instructional time is wasted and the child will be bored.

Some children may enjoy the stimulation from some educational software, but children also need to learn to concentrate, pay attention, participate in class and engage in classroom discussions. Teachers need to heed these aspects of instructional pedagogy and not overuse educational software. As with any new aspect of technology, there is a bandwagon effect. Curiously, many administrators believe that educational software is going to play a major role in remediation of students with deficits. While that may in part be true, in order to ameliorate some academic deficiencies, good old fashioned hard work may also be needed.

Incorporating Educational Software
Teachers must be trained as to when to use educational software, just as they need to be trained as to when to use a movie, slides, a filmstrip or any other educational aid. However, this is an art, and not a science as some currently believe. When instructional time is used for the presentation of software, the educational software should be relevant, appropriate and contain content that directly relates to the topic or lesson.

With the advent of the Individualized Educational Program or Plan, some educational teams may actually advocate for specific educational software to be used as part of a student's educational plan. In some instances, with students with specific special needs this may be most appropriate. However, the team must be sensitive to the fact that there may be a "boredom" factor after repeated viewings of a certain educational software program. We must all be sensitive to these issues and bear in mind that students do grow, develop and mature over time.

An Educational Software Clearinghouse in Your University?

Should your college or university develop a software clearinghouse to allow students to preview software prior to purchase or prior to use? There are a number of factors to take into consideration.

1. Space- Computers and storage for the Educational Software and the disks is needed. In many universities, office and storage space is at a minimum.
2. Paper- Letterhead, envelopes and postage will be required to request software to be placed in the clearinghouse.
3. Computers- Educational Software typically consumed a good deal of space on the hard drive and instructors must be aware that other items such as word processing programs may have to be deleted.
4. Labor- A graduate student or a work study student or a volunteer may be necessary to insure that educational software is not stolen or removed without permission. Theft is a major problem. Some students who check out software for use at home may never return the software and may never return to school. This is a problem.
5. Administrative understanding. Administrators do not often understand the changing nature of technology in education and are often oblivious to the fact that there are dictionaries and encyclopedias and art galleries on educational software disks. A tour of a software clearinghouse may help convince them of the usefulness of this endeavor.
6. Instructional Resource Centers can often provide some assistance to Software Clearinghouses. Basically, they are very much in the same situation and deal with the same complexities.
7. Some State Departments of Education may have grants to help subsidize or assist with the growth and development of a software clearinghouse. They may be very supportive and may actually offer suggestions and ancillary items to be requested or purchased.
8. Once established, and once on a mailing list, the Educational Software Clearinghouse tends to take on a life of its own as brochures and catalogs begin to pour into the Clearinghouse.

In conclusion, an educational software clearinghouse or some facility for the preview and review of educational software is becoming increasingly necessary in today's world. Just as libraries were of critical importance in the last century, so do will software review centers become critical in the new millenium.

Technology for Critical Pedagogy: Beyond Self-Reflection with Video

David S. McCurry
Curriculum and Instruction Department
Monmouth University, New Jersey, New Jersey
United States
dmccurry@monmouth.edu

Abstract: This paper opens with a story of what was once cutting-edge, state-of-the-art technology and its integration into preservice teacher preparation. It is a story of the technology, in this case video recording, the theories applied to its educational use and a specific teacher training method—microteaching. The historical context of microteaching with video recording feedback is presented. The further evolution of this technology in self-reflective methods is explored by considering the combination of inner development of the individual teacher with the outer, critical examination of social contexts of teaching. The final part of the paper attempts to construct a critical framework for utilizing both inner, self-reflective models of video feedback with models of critical video ethnography, used by the author in overseas educational development work in Africa, that examine situational practice. This paper will explore the theory foundation of these models in search of common principles to inform the practical use of video in new models of critical inquiry and reflection in professional development.

Once upon a time in teacher education...

In the mid 1960s a group of pioneering teacher educators at Stanford University in Palo Alto, California began an experimental use of a new technology, video tape recording. At roughly the same time, among the ferment of ideas contributing to many facets of academe, processes of group interaction and the boundaries of individual growth and human potential were being explored. How do people effectively communicate in groups? How do individuals relate to one another in group settings to accomplish group oriented tasks? The fields of social and humanistic psychology were at this time generating relatively new ideas related to everyday activity in the workplace. Therapy groups, transactional analysis, creative problem solving (i.e. Synectics, see Gordon, 1971) and social learning theory formed a conceptual environment which some would use to apply to the process of teacher training. While various approaches situated in humanism contributed ideas about the development of the individual, other approaches to increasing the threshold of human behavioral efficiency also influenced inquiry directed towards learning and knowledge transfer. Sub-fields such as cybernetics and computing technology were beginning to influence practice through research into learning, cognition, training and the use of technology, largely from an efficiency model (how to increase learning with the least possible input of resources in the least amount of time). Research supporting these latter models were often funded by the US government through Department of Defense related contracts in search of more efficient training systems.

It was in this context that teacher educators would develop a process called microteaching, predicated on a few specific concepts. First, teaching behavior, and all complex behaviors for that matter, can be identified as a stream of activity which can be further atomized into discrete “micro” behaviors and that, once identified, can be studied, modified, practiced and learned (Acheson, 1964). Second, a powerful force in changing one’s behavior is an external application of feedback, through peer interaction and internalized through personal, self-critique. A necessary set of pre-conditions is assumed to exist in that one has to be willing to accept the input of feedback towards the process of self-improvement and development. A central psychological concept, self-confrontation, is applied to this process of teacher training in small groups through peer feedback and self-analysis.
Self-confrontation then, just as now, is a process where individuals are exposed to information about how others see them in an "external" view. Theoretical antecedents are positive and negative feedback, feed-forward models, and behavior modification. In these models, one's own behavior or actions are re-introduced through some form of "feedback" (in this case, through videotape and verbal feedback in peer-critique). The very nature of such feedback is necessarily taken in "critically" by the individual and assumed to influence desired changes in behavior based on suggested or modeled practice (Nielsen, 1963).

As a general practice of professional development, however, such methods are highly limited to the individual (and often emotionally coupled to his or her own personality and ego development) and to the immediate context of the environmental variables present at the time of observation or recording. Social contexts and their influence on behavior are intentionally minimized as variables affecting the subject or simply not dealt with. In traditional models of microteaching this often has meant using other students in the class as "surrogate" pupils when modeling practice lessons. Microteaching then and now, attempts to develop improvement in discrete teaching behaviors by a process of focussed observation, feedback and modification of isolated teaching behaviors. Thus the process of teaching and learning, through these various influences, became "technologized." In the 1980's, teacher "training" gave way to teacher "preparation" with associated models built on reflective practice and constructivist educational theories.

**Video in a Reflective Practice World**

Certainly linked to Dewey's notion of critical reflection informing practice and following the influence that Donald Scöhn's work has had on the profession, it can be said that we in the field of teacher preparation live, to varying degrees, in a "reflective practice world" (Scöhn, 1983). The "reflective practitioner" is a stated goal of many teacher preparation programs and appears in the discourse on nationally proposed standards (Chiarelott and Klien, 1996). Given the different theoretical underpinnings of current approaches to teacher development (holistic, authentic and socially constructed) one may ask "does microteaching have a place in a reflective practice world?" Microteaching, as a specific method of teacher "training", is also still used in teacher education programs although to what extent is difficult to document. Carlgren (1998) has pointed out a need to further explore both the theory and practice of "doing" reflective practice. Video technology is also described as a useful tool for self-reflection models in teacher development and assessment (Holodick, Scappaticci & Drazdowski, 1999).

Self-reflection is a proven way of extending the feedback models used in earlier approaches to professional skills development, including microteaching (Frieberg & Waxman, 1988). Here again the emphasis is on the "self" in relation to professional contexts involving negotiated behavior among colleagues, students, parents and the community. While the encouragement of self-reflective practice lead to better understanding of the self in these contexts, they do not necessarily help the individual form a critical approach to understanding those contexts. The result may be teachers who are competent and comfortable with their own growth and development, albeit in a relatively static reality that they are unprepared and unequipped to engage in proactive ways. The improvement of individual practice through self-reflection and self-assessment models is assumed to lead to the macro-improvement of social and institutional settings for education. This is to be accomplished (or so it is assumed) by raising the individual quality of instruction in the classroom as a unit of evaluation. Such approaches to quality improvement are dependent on quantity effects achieved through, among other things, coherence with national standards or criteria for professional growth and entry into the profession itself. Reflective practice as a goal of teacher development is echoed in the national standards (NCATE, 1997) for teacher education programs.

The uses of video in these models largely reflect the same framework for self-reflection as an extended form of peer-feedback. Video offers the reflective practitioner a tool to gather information about the self in authentic practical settings. Video technology is now used in a wide range of existing and emergent models of professional development, founded on theories of self-assessment and self-reflection with recording of practice for further analysis and reflection occurring in the field. Concurrent with the professional development models used is newly embraced constructivist theories of teaching and learning that are primarily represented by the work of Vygotsky (1978).
Through the looking glass: Beyond self-reflection as a professional development model

Critical self-assessment and self-reflection are powerful tools in the development of professional teachers who are committed to lifelong learning and continuous improvement of their skills. Self-reflection models and associated practices (reflective journals, reflective group discussion and feedback) are now very common in teacher preparation and development programs. Such models have followed holistic approaches that seek to overcome limitations inherent in technical skills related methods such as microteaching. The professional development of the “self” should always be part of programs that seek to foster improvement among those who desire to engage in a profession. There is a distinction, however, between process-oriented constructivist and social-constructivist paradigms which apply not just to professional development models but to the theories of classroom teaching which professional development models are aimed (Hung & Chen, 1999).

Amidst new reforms in education there are emergent models of professional development which focus not just on the individual in a type of setting (classroom teaching) but examine a more complex range of professional development characteristics across social and community boundaries. Schools, and the processes of teaching and learning, are only one part of this model. In these models, the individual is an actor in a rich and complex social and cultural milieu that forms the context of the professional development activity. A new paradigm for professional development includes a critical dialogue with a broad population of stakeholders such as parent groups, professionals from other fields (academic discipline experts from university settings), community organizations and local business and include learning theories with social and organizational dimensions in addition to theories which are largely concerned only with the individual. In particular, expectations for teacher educators will now focus on developing the ability to work with groups of teachers as organized professional units in the school. Associated skills would include group feedback and critique and the ability to continue their professional development through inquiry models in their own professional settings (Stein, Smith & Silver, 1999).

Such changes are a challenge for professional development programs which in the past typically attempted to impart the “pedagogy of teaching” as sets of technical skills in higher education settings. Video technology has been used in various forms throughout this evolution. Although it is far from a “neutral tool”, neither is video deterministic in nature. Characteristics of video recording and data collection need careful analysis related to the intended field setting. Video recording (and the use of the resulting data) carries potential in a new paradigm of professional development. Its use in models of professional development that go beyond technical “micro” skills development or self reflective, personal assessment models will depend on being able to widen the “field of view” beyond the limitations of a single teacher standing in front of a classroom of learners and beyond the inner-reflective use of “video journals”. Models of use that fit with inquiry-based approaches to “wide-field” analysis of social contexts already exist in ethnography and could provide powerful frameworks for the incorporation of video technology into new paradigms of professional development for teachers.

The brief foray into the historical context of one technology innovation in teacher training and its subsequent evolution as a tool for teacher development is simply pointed at the axiom: It is not so much what tools are available as what we do with them. If we desire new activity or constructions, based on new paradigms for teaching and learning, then we will use available tools, adapt them and re-shape them if they do not “fit” or create entirely new tools to accomplish the desired actions. In terms of preparing new teachers, there is now a mandate, reflected in the ISTE (1996) technology standards for teacher education to expose them to the possibilities which new information technologies seem to hold. We assume in the discourse on technologized education, that value and “power” are intrinsic in the mere access to information, not in the active use of information for processes of social justice, environmental preservation and economic equity. Active processes of learning require being able to use information in new ways, integrated with and built upon prior knowledge in the minds of the learner and framed by a critical analysis of the social construct in which the knowledge is formed and used. The use of this technology and all of the “new information technologies” which teachers have now or will have at their disposal will not amount to much unless they are grounded in a theory of application, itself part of a general theory of education.

As world problems mount, precisely at a time when information technology is creating shorter paths to wider communication and information exchange, the focus of education should rightfully be on
providing the information and skills necessary for present and future generations of learners to engage these problems and form solutions which are viable in a democratic and culturally diverse society. Critical pedagogy, which forms a theory-based practice of teaching and learning directed at the critical analysis and "discovery" of social and political inequity at the root of society ills, provides one theory-context for pursuing the "meaningful use" and integration of new information technologies into teaching and learning. In short, the past uses of technology (like video) in teacher development have been directed at improving the individual as an autonomous entity, capable of "improving" and modifying behavior towards an accepted or demonstrated ideal state. Reflective practice provides a rich extension of this mechanistic model to "skills development" but is still highly individualistic in nature. For models and theory that provide a greater sense of purpose and meaning for educational activity educators need to look farther afield. Arthur Pearl and Tony Knight (1999) have offered a convincing "general education theory" for democratic education, in which the use of technology, especially information technologies, would make sense. They posit four general requirements of a general democratic education theory:

1. Knowledge should be universally provided to enable all students to solve generally recognized social and personal problems.
2. Students should participate in decisions that affect their lives.
3. Clearly specified rights should be made universally available.
4. Equal encouragement should be given for success in all society's legal endeavors.

(Pearl & Knight, 1999, p. 2)

Critical discussion of how the current push for technology integration into teacher education and teaching in general will benefit society as a whole is sorely missing from much of the discussion in the literature. Most accounts focus on the practical, myopic view of what works (within limited definitions of evaluation criteria) or simply examine what is possible through a limited demonstration of "cutting-edge" uses and re-configuration of existing technology. Pearl and Knight further elaborate a 9 point model for problem-solving curriculum directed at building competence for dealing with social and personal problems. These range from environmental issues to economic justice and inequality to workplace democracy and human rights, nonviolence, elimination of world poverty and, in discussing technology, challenge curriculum in a democratic education to [Marshal] technology for socially useful purposes. Technology has intended and unintended consequences. Most current presentations of a high technology future are dystopic. Students need to examine how technology can be organized to better serve humanity. Students need to distinguish myth from reality in the highly promoted "information society." They need to be given the opportunity to perform research that will enable them to distinguish information from disinformation. Students need to be able to weigh the difficult ethical issues related to the use of technology. (p.38-39).

Quite a departure from the current discourse on integration standards most frequently cited in technology in teacher education forums.

Towards a Model for Using Video in Self and Situational Critical Reflection on Practice

Given its historical role and limitations in earlier microteaching approaches as well as in more recent reflective practice models, can video still be considered a useful tool in alternative approaches to teacher development? Turning the camera around to explore the context and setting of the classroom is a daunting task. Videotaping practitioners in situ can reveal rich data for analysis both by the subject (the teacher engaged in teaching practice), by peers (degree program candidates and colleagues) and by other participants like students and community members with an interest in the process of education in specific settings (Karasati, 1997).

A further extension of this practice which incorporates a critical awareness of the classroom as a setting for social and cultural development would be to create video data which examines not just the individual as an "actor" in the setting but as a participant in the setting itself. In this model, ethnographic
video methods can be used as a method of data gathering and analysis (McCurry, 1995). At least a few areas of activity associated with teacher development overlap with video ethnography and ethnographic field methods in general: authenticity (data collected in real settings), contextualization of experience (placing events and their analysis in the broad social and cultural context in which they occur), iterative processes of producing "meaning" (sharing observations to confirm or refute assumptions and ascribed meaning to actions) and the formation of an inquiry approach to practice that encourages teachers to actively pursue understanding the "field reality" of their own life and professional circumstances. Further thoughts on some of these areas in relation to the use of video technology are considered below.

**Authenticity:** Video recorded for the purposes of modeling behavior for any type of further analysis should be collected in real environments. Simulations have some utility but their unauthentic nature will always be a distraction.

**Digital video data:** Video data, whether originating in analog or digital formats, offers the possibility for inclusion in portfolio for assessment or to demonstrate performance. This is a particularly interesting area since little is available on protocols for collecting such data and using it for auto-analysis or as part of peer or colleague mediated assessment. Data needs to be gathered in authentic environments, edited into "exemplary moments" based on critical judgement about one's development and performance.

**Shared communication of feedback:** Traditional peer feedback models developed over three decades ago need to be revisited given a new purpose to self-reflective models of teacher development. Perhaps mentor or colleague support systems in the school environments could accommodate video data gathered at the learning site for purposes of improving practice. Interpersonal communication models still seem to be a valid form but are not made explicit in many programs.

**Contextualization of the data:** Focussing less on the individual's behavior in isolation and more on the observed practice in real settings.

**Participatory video production for reflective practice and practitioner inquiry:** Based on models developed in international development education, video production is a yet to be exploited potential tool for the development of practitioner knowledge with preservice teachers.

**Conclusion**

Video, as one technology with its own evolution and characteristics, has been used successfully in support of differing approaches to teacher training and development. It has supported the use of micro-behavioral training methods as a feedback tool and has been used in constructivist models as a presentation media and tool for knowledge construction. Underlying these uses are broad, and quite divergent, theories of teaching and learning to which the technology, as a fundamental telecommunications tool, has been adapted. The more important consideration of the specific characteristics of any technology should be with these prevailing theories and the way methods and media based on these models are supported by the current state of the technology itself. In this paper, I have attempted to derive a framework for using video to support a socially constructive teacher development model that further supports a theory of democratic education. Such a framework and model for teaching includes the necessary broadening of the "field of view" of video use beyond the individual behavior of the teacher as a subject towards the complex social and cultural environment in which the teacher practices the art of teaching. Such an approach engages the teacher as a critical inquirer not just of his or her own practice but of the entire process and context of education, in all its complex social and cultural dimensions. Implications for the use of technology in teacher professional development under this approach are substantial.

Abstract: Model technology classrooms at the university and in local schools provide preservice teachers with opportunities to see technology use modeled and to practice teaching with technology. Observing technology being used in classrooms and teaching with technology assures that new teachers will infuse technology in their classrooms. Since teachers teach the way they were taught, it is essential that they be taught with technology. However, since the majority of teacher preparation faculty were not taught with technology, they need resources and support as they learn to integrate technology into their teaching and change from teacher-directed to student-directed learning.

A report compiled by the American Council on Education's (ACE) Presidents' Task Force on Teacher Education (1999) stated that college presidents must either make teacher preparation a top priority or get out of the business of preparing teachers. Based on the task force's findings they proposed an action agenda for university presidents. One component of the action plan calls for universities to provide the equipment, the facilities, and the personnel required to teach preservice teachers to integrate technology into their teaching. Further, university professors must be encouraged to model teaching with technology in their teacher preparation classes, and they must be given the resources and training they need to be able to do this effectively.

A national survey conducted by the International Society for Technology in Education (ISTE) commissioned by the Milken Exchange on Education Technology found that teacher preparation programs are not preparing teachers to effectively teach with technology (Moursund & Bielefeldt, 1999). Results of this survey indicate that teacher preparation faculty do not model technology use in part because they lack the skills to do so, and they lack the necessary hardware and software. The results also indicate that methods and curriculum courses that integrate technology into the curriculum impact new teachers' use of technology in their classrooms more than stand alone technology courses. Additionally, student teachers need opportunities to use technology in their student teaching under the supervision of classroom teachers who effectively integrate technology into their teaching.

To prepare preservice teachers to meet the expectations of the school districts that hire them, it is essential for students to have technological expertise and opportunities to use technology to teach in their preservice education (O'Bannon & Matthew, 1998). These opportunities must be available at the university level throughout preservice teachers' curriculum and in classrooms where they have opportunities to work with inservice teachers and their students. For preservice teachers to become technology proficient they need a wide variety of technological resources at the university and in schools where they observe and teach. These resources must be relevant to the planning, development, management, and evaluation of instruction. Preservice teachers must participate in classroom activities designed to provide experiences in enhancing instruction with technology to meet the individual needs of students.

Preservice Teachers and Technology
In P-12 schools technology has moved from the periphery to the center of instruction, the same must happen in teacher preparation programs (NCATE, 1997). In order for preservice teachers to integrate technology into their classrooms, they need to see it modeled in the university classes they are taking. If they are not required to use technology in their teacher preparation classes and they do not see it modeled by professors in their classes, they will not use technology in their classrooms. Preservice teachers will teach tomorrow the same way they are taught today (NCATE).

Teacher centered lectures are one challenge facing the integration of technology into the classroom (Ritchie & Wiburg, 1994; White, 1999). The successful integration of technology into teacher preparation programs requires student-centered constructivist teaching. Educational reform requires changes in the core relationship between teachers and students. This core relationship requires teachers and students to become learning partners. Together these partners construct knowledge, rather than students being the passive recipients of knowledge transmitted by the teacher. In order to do this teachers must focus on how students learn rather than what is taught (Johnson & Blair, 1999). Rather than the textbook as the sole source of knowledge, students and teachers need to explore multiple sources of information as they work together to construct knowledge. These student-centered classrooms allow students to use a collaborative, hands-on approach to learning as they question, explore, organize, and reflect on problems (Cohen, 1997; White). Technology provides students with the tools necessary to construct their own knowledge as they ask questions and conduct research to find the answers.

A single technology class in the teacher preparation program is not sufficient to assure that new teachers will be able to successfully integrate technology into their classrooms. Halpin (1999) found that preservice teachers who participated in a methods course that integrated technology into the curriculum were more likely to use technology in their classroom during their first year of teaching when compared to students who learned computer skills in an isolated technology class. Preservice teachers need opportunities throughout their teacher preparation program to observe professors modeling the use of technology in model classrooms with a rich collection of electronic resources.

Preservice teachers need opportunities to learn to use educational technology in realistic school settings (Pan, 1998). To foster changes in how teachers use technology in the classroom, universities and schools must form partnerships to ensure that preservice teachers have opportunities to integrate technology into instruction in classrooms (White, 1994). Universities need to provide leadership for schools as they work to integrate technology (Pan). This collaboration between universities and schools will assure that novice teachers transfer their technology knowledge and skills into their classrooms (Bennett & Daniel, 1999). Preservice teachers who are required to use technology in their courses, who see technology use model in their classes, and who have opportunities to teach with technology will use technology to teach in their own classrooms.

Teacher Preparation Faculty and Technology

Since the majority of teacher preparation faculty do not use technology for their own research and teaching, they do not know how to teach preservice teachers to infuse technology into their teaching (NCATE, 1997). Only if professors learn to use technology and model the use of technology are preservice teachers going to transfer their learning from the university to their classrooms (Bennett & Daniel, 1999). In order to model technology use, university professors must know about current hardware and software available for use in the classroom. Hence, there are several challenges to overcome if university faculties are to use and model technology in their teaching.

Dusick's (1998) review of literature revealed that several factors impact whether or not faculties use computers for instruction. These factors include: 1) administrative support, 2) computer availability, 3) resources, 4) support staff, and 5) training in the use of computers. Reporting on a three-year program focused on infusing technology into a teacher education program Thompson, Schmidt, and Hadjiyianni (1995) identified these essential factors for success: 1) easy access to technology; 2) allowing faculty to become personally comfortable with technology before using it for instructional purposes; 3) having technology integration as a department goal; 4) receiving strong support from the administration; 5) inviting participation in the program; and 6) one-on-one mentoring for faculty. Drazdowski, Holodick, and Scappaticci (1998) faced similar challenges during a three-year plan to infuse technology into their teacher preparation program. Additionally, they concluded that: 1) long range planning, 2) curriculum development, 3) faculty support and willingness to try new technology, and 4) the patience of the faculty member responsible for the changes were essential to achieving their goals.

One-on-one mentoring of faculty assures that their individual technology needs are addressed. Stewart (1999) describes a one-on-one mentoring program that paired a college of education faculty member and a doctoral student in the college technology program. The faculty member's increased comfort level with technology led her to encourage her students to use a variety of hardware and software for their class assignments. Receiving
individualized attention focusing on what the faculty member wants to learn, a self-paced approach to learning, learning in a comfortable setting, and ongoing support during the learning experience make mentoring a viable option for teaching university faculty to use technology.

Overcoming challenges to the integration of technology into teacher preparation courses requires resources and support. Resources are needed in the form of hardware and software in faculty offices, university classrooms, and school classrooms where preservice teachers observe and teach. Administrative support and technical support are essential. Faculty also need support in the form of ongoing faculty development in the use of technology as well as support in curriculum development as they restructure their classes to include technology.

Model Technology Classrooms

Two recent grant awards have provided needed resources to enhance the integration of technology into our teacher preparation program. The Louisiana State Board of Regents Support Fund provided a literacy/technology model classroom in the College of Education and a United States Department of Education Capacity Grant provided three model technology classrooms at the university lab school, as well as, faculty technology coaches. The resources and support provided through these grants in combination with other technology initiatives in the College will assure that our teacher preparation students see technology modeled in their university classes and practice teaching with technology at the university and in the lab school. Providing model technology classrooms and support for faculty as they model technology integration assures that our preservice teachers have opportunities to not only master basic technology skills but also to be able to transfer their use of technology across contexts for collaborative problem solving in classrooms with students.

The model technology classrooms contain at least five multimedia computers with Internet access, printers, a scanner, a digital camera, projection system, a document camera and open-ended software such as Microsoft Office, HyperStudio, and Inspiration. Further, the literacy/technology classroom at the university contains a wide array of print materials and software to enhance literacy development. Preservice teachers see technology infusion modeled in their methods classes as they use multiple sources to question, research, and reflect on the best ways to teach students. Then, they have opportunities to use these resources as they work with students in similarly equipped lab school classrooms under the direction of teachers who have successfully infused technology across their curriculum. The model classroom at the university is also available to faculty in the arts and sciences who teach courses required in the teacher preparation program.

Grant funds have also provided ongoing technology professional development for faculty in the College of Education, faculty in the arts and sciences, and faculty at the lab school. The content of these professional development sessions are determined by faculty input and are scheduled at a variety of times to assure that all faculty members have opportunities to attend. Faculty feedback at the end of the sessions is used to make changes in the presentations to assure that the sessions meet the needs of the faculty. As faculties in other colleges across campus have learned of the sessions, they have requested that sessions be held for them, too.

Thompson, Schmidt, and Hadjiyianni (1995) and Stewart (1999) discussed the importance of one-on-one faculty mentoring sessions and grant funds have provided technology coaches for faculty directly involved in teacher preparation courses. These technology coaches are available for one-on-one technology mentoring and support in faculty offices and during classes. These technology coaches are education majors who are paid a stipend for their work and receive additional technology training to be able to assist faculty. Using education majors as technology coaches gives them additional opportunities to use technology for teaching and learning.

Summary

If new teachers are going to teach with technology, then it is essential that teacher preparation faculty model technology use in their teaching and that preservice teachers practice teaching with technology in authentic classroom settings. Teacher preparation programs often lack the resources and support needed to model technology integration in their teaching. As the resources and support become available there are still challenges to overcome as university faculty learn to use the new technology and change the way they teach. Faculties need one-on-one, ongoing support to learn to use technology. Then, they need assistance as they change from teacher-centered to student-centered classrooms where students use multiple sources to question, collaborate, research, organize, and reflect on their own learning. Universities must collaborate with local schools to assure that preservice teachers practice teaching in technology-rich classrooms under the guidance of teachers who infuse technology in their
teaching. A concerted effort is needed to assure that new teachers will be prepared to teach effectively with technology.

Defining a Distant Environment for Teacher Education

Gertrude (Trudy) Abramson
abramson@scis.nova.edu
Nova Southeastern University, United States
School of Computer and Information Sciences

Timothy (Tim) Ellis
ellist@scis.nova.edu

Abstract: Virtual classrooms are rapidly becoming alternate acceptable delivery systems. One of the major challenges facing professors in higher education today is the creation of the best possible adult learning environment in our cyberspace classrooms. This paper describes some of the issues involved in refining Internet-based, asynchronous conference forums to meet the learning needs of adult students in distant inservice and graduate courses.

Introduction

At the crossroads of real and virtual colleges, limitless opportunities for professional development and lifelong learning are made possible. Academic institutions are faced with decisions about where to focus their human and fiscal resources. Every instruction delivery system (IDS) has its strengths and weaknesses. This paper will focus on an analysis of existing IDSs and attempt to make strides toward the identification of optimal environments for in-service professional development courses. We are addressing the needs of classroom teachers/graduate students who have selected to take part in the learning process based upon a job requirement or a personal want. These remarks may be generalized to most adult post-baccalaureate learning environments.

Traditional Campus

The traditional college campus is located in buildings to which students must drive or take a bus or train assuming they do not live on campus. Classroom instructors generally require that students be present at specified times and dates for at least 14 meetings per term. Even when attendance is optional, there is an expectation that students will attend class. Libraries, bookstores and administrative offices, where matters of registration, financial aid, and record maintenance are attended to are other familiar components.

Traditional, gainfully employed graduate students live within commuting distance of the campus. They invest time and money in travel, parking, and in walking to the classroom. Most are classroom teachers or substitutes; some serve in administrative capacities. Students whose job responsibilities or time frames change during a term are often forced to withdraw from classes. Students whose jobs end during a course of studies must choose between keeping job searches local or abandoning the program. Once a commitment is made to pursue a degree program, the student is "planted" in the physical location. In today's world of rapidly changing jobs, this is a frequently occurring conundrum. Many adult students have child-rearing responsibilities as well. Going to the campus makes it necessary to hire and train a caretaker. An element of stress exists as the student waits each week for the caretaker to show up. Many students report that they dash home from work, make supper, supervise homework, and only then begin the process of being students.

Class organization takes several forms. Graduate education classes are best when limited to no more than 24 students. However, class size is often dictated by enrollment not best practice. Classes with approximately 30 students and one professor enable some interaction mostly for the more aggressive and/or articulate students. Large lecture classes with up to hundreds of students are strictly professor to student delivery systems. In some places, members of these very large groups, divided into breakout or recitation groups, meet with a doctoral student who works under the direction of the lecturing professor. Lab classes provide hands-on learning with and without instructor guidance. Almost all on-campus courses are time bound.
Virtual Campuses

Distance learning has taken a variety of forms over the years. Recently, the focus appears to be on web-based courses using text-only, text and still images, or in some cases, text, video and audio (Abramson, 1998). A common thread obtains whether one uses one of these Internet-based forms or the older videotape, television, satellite broadcasting or even posted mail for distance learning. That is, the student does not need to be in the same physical space as the professor. Also, increasingly, course offerings are asynchronous, meaning that the student may "attend" at a different time than the instruction is presented. Anytime/anyplace learning has become a major player in adult education (Gibson, 1998), in general, and in teacher education to a lesser degree.

Much has been written and discussed about the learning needs and learning styles of the distant student and how curriculum may be presented and revised to meet these needs. The literature is replete with concerns over the loss of the personal touch and real-time teacher/student interaction. Issues such as technical support, faculty preparedness, copyrights, testing, attendance, class size and authenticity of authorship are under heavy discussion alongside course delivery and quality of interactivity. The fact remains that there is a new player in the game so our options are to master the rule or be left on the sidelines.

The Adult as a Student

All classroom teachers involved with in-service professional development may be classified as adult learners. However, just because most professional development takes place in a college or university does not mean that the teachers become college students. Differences between traditional college students and adult learners will be approached from four perspectives: age, needs, desires, and goals (Bowden & Merritt, 1995). The traditional college student is an 18 to 25 year old person who continued on to higher education immediately or very shortly after completion of high school. "Adult" students can range in age from their late 20s through their 70s or beyond and typically have been separated from an educational environment for a number of years (McNair, 1994).

The needs of these older students are influenced by a constellation of factors, including relationship responsibilities as parents and spouses, organizational affiliations, and commitments that place demands on their time and financial resources (Boucouvalas & Krupp, 1989). Perhaps as a result of these multiple and often conflicting needs, adults as students typically desire two things from their learning environment: a direct connection to their past experiences or current concerns, and a pragmatic, problem-solving approach within the learning environment (Brookfield, 1989).

Adults perhaps can best be understood as students in terms of their goals for participating in an educational program. Although the specific goals cover a very wide spectrum, in general, the immediate, practical applicability of material is extremely important to the older student (Bowden & Merritt, 1995). Knowles (1977) observed that, for the adult student the "...time perspective changes from one of postponed application of knowledge to immediacy of application, and accordingly his orientation toward learning shifts from one of subject-centeredness to one of problem-centeredness" (p. 39).

The educational requirements of the adult learner extend beyond the rather practical considerations identified by Bowden and Merritt (1995), Boucouvalas and Krupp (1989), and Brookfield (1989). There is evidence that the process of assimilating knowledge is different for the older learner than for the younger student. Adults approach the learning environment in a different fashion, expect different things from that environment, and react to the various aspects of the environment differently than the traditional college student. Zemke and Zemke (1995) observed that, although a single-faceted theory was inadequate for identifying the unique needs of the adult as a learner, some general principles regarding the adult as a student are apparent. Timing is vital in adult education; adults usually have rather small 'windows-of-opportunity' during which they are receptive to learning a new task. The learning process must incorporate practical application of the subject matter and be problem-centered. Finally, facilitation, as opposed to the lecture approach, is much more likely to be successful for the older student.

Self-directed, autonomous learning is important to the adult student and should be acknowledged by the actions of the professor (Tennant, 1991). Although the need for self-directed learning is widely accepted within the literature, Griffin (1991), in an exploration of the impact of social theory on adult learning, identified a very interesting paradox regarding the goals for adult learning. The impetus for an adult to return to an educational setting is often related to the need to adapt to changing circumstances in the workplace or greater environment. At the same time, adult learning practices are predicated on the need for self-direction. An adult learning environment often must meet the somewhat contradictory goals of addressing the needs presented by external forces such as employers while at the same time affording the student maximum control over the learning process.
The Adult as an Online Learner

In general, the needs of the adult as a student potentially match well with the strengths of an Internet-based online learning environment. A point-by-point comparison of the general needs of adult as learners as outlined above with the characteristics of an online learning environment follows.

Flexibility of Schedule. An online environment can offer the student a time- and place-independent academic setting. Owston (1997) reviewed the online offerings available from several institutions of higher education located in both Europe and the United States. He uncovered numerous examples of programs specifically targeted at providing adult students with educational opportunities that could be accommodated within a busy schedule of family, social, and work responsibilities.

Direct and Immediate Applicability of Material. Computer-enhanced learning environments can simulate the application of material that would be impossible to include in a traditional classroom setting because of safety, cost, or moral issues. Hatfield (1996) described the use of computer-simulated environment used to help pre-service mathematics teachers experiment with teaching approaches they would have been hesitant to try if working with live students. In a virtual classroom setting, these prospective teachers were able to experiment with the effective use of educational approaches such as mathematical modeling, group problem solving, and the use of manipulatives. This virtual experience enabled the students to grasp the concepts and internalize the thought processes underlying the application of these pedagogical approaches more thoroughly than students learning the same material in a traditional setting. The multimedia-based virtual classroom offered a realistic setting in which the student felt safe to experiment with new approaches, thereby promoting greater personal involvement in the instruction.

Positive Connection to Previous Experiences. Internet-based online environments significantly change the role of the student in the educational process. The relationship between instructor and student is altered; Kilian (1997) observed that Internet-based education is, in fact, changing traditional academic roles by encouraging an egalitarian, mentor-apprentice relationship between teacher and student. Perhaps more significantly, the relationship between student and subject matter is modified significantly within this environment. Dyrli and Kinnaman (1996) observed that in the Internet-based online environment students can become much more involved as information producers rather than information users as is typical in the conventional classroom setting.

Problem-Solving Orientation. An Internet-based online learning environment is essentially problem-oriented and active in nature. Hazari and Schno (1999) outlined how the interactive tools such as forms, threaded discussion forums, and interactive 'chat' rooms available in a World Wide Web based environment can promote a problem oriented environment by stimulating interaction with course content, instructor, and other students.

Self-Direction. The role of the learner in an Internet-based online environment is inherently one of increased power and control. As detailed above, the increased flexibility in scheduling, capacity to experiment in a safe, virtual environment, and active orientation combine to make the student more a partner in the learning process than a passive recipient of knowledge. The nature of personal computer systems in general and the Internet in particular, furthermore, promote personal independence by the control in sequencing and pacing they afford the user.

Dangers Inherent in an Online Environment

Each of the characteristics of the adult learner discussed above can present challenges to the instructor, especially in an online environment. The need for flexibility in scheduling often manifests as missed assignments, inability to participate in group learning experiences, and deferred completion of courses. The demand for direct and immediate applicability of material may, in fact, be a retreat into concreteness, while the desire for a positive connection to past experiences might mask a resistance to new ideas. The need for a problem-solving orientation, often expressed as, I'm a 'hands-on' learner, can be an unwillingness to engage in a rigorous thought process. Similarly, the demand for a self-directed learning environment might be a sophisticated term to describe a power struggle between student and teacher.

The online learning environment is not a panacea for the adult student. Although an Internet-based delivery system may address many of the needs of the older student, this approach to education raises concerns as well as offers solutions.

Many of the challenges the older learner presents as a student are potentially aggravated by the online environment. Brunt (1996) emphasized the need of adult learners for personal support, especially early in the
learning process. Since adult students bring with them baggage, such as personal difficulties, financial hardship, lack of confidence and negative memories of previous learning experiences, the need for personal support can be crucial. He warned that, although distance approaches enhanced by technology such as the Internet, might be attractive to the adult student for several reasons, many adult students might not be able to benefit because of the lack of meaningful, personal support.

A headlong rush into replacing traditional classrooms with online learning environments for adult students is certainly unwarranted. Hara and Kling (1999) quite effectively cataloged the potential frustrations for both students and instructors involved in a Web-based online learning environment. Although online environments present the potential to quite effectively meet the needs of the older student, there do appear to be an equal number of potential hazards.

Graduate Education Programs at SCIS

Let us look at the environments within which we teach across distances. Although our graduate programs are all distant ones, we have a real campus at which most of the professors may be found daily. While the students are distant, the faculty is remarkably collaborative. We network extensively and support one another as we strive to build the best possible programs for learning. Our classes are presented in three different formats.

- MCTE is a totally on-line masters program in computing technology in education. At this writing, even orientation is an on-line experience. Faculty and students never meet face-to-face and students do not know one another. There are four 12-week terms each year. Students who take two courses each term can complete the program in 18 months.
- DCTE Institute is a partially on-line doctoral program in computing technology in education. Faculty and students meet for one week (forty hours) each five-month term. There are two terms each year, separated by a month. Students take two courses and one project course for four terms before beginning the dissertation phase of the program. The day before a student's first term is an on-campus orientation experience. All further interaction is computer-based.
- DCTE Cluster mirrors the Institute with one exception. Instead of the two weeks on campus, students and faculty meet for four weekends, at the beginning and middle of each term (20 hours plus 20 hours).

The Learning Place at SCIS

The physical entity that replaces the classroom during distant course components is the computer. Each professor has an office and a resource center located on his/her home page. See, for example, http://www.scis.nova.edu/~abramson and http://www/scis.nova.edu/~ellist. There, one may find a photo of the professor, and, for some courses, link to images of classmates, thus reinforcing "real people" identities. Syllabi are available so students may preview a course before signing up and may download clean copies should theirs become lost. PowerPoint slide shows created to support classroom presentations are easily saved as html documents and linked to the home page. Alternately, useful links to research gateways may be provided for student research.

Our classrooms in cyberspace are multi-threaded forums, which are elaborate, interactive bulletin boards. When the professor has the time to set up properly, classes begin with established sets of discussion topics to which students may respond on an as-needed basis. The beauty of the system is that it is there whenever it is looked for; it cannot be accidentally erased. All remarks posted to the forum are available to everyone in the class. If anyone wishes to retract a posting, the professor can do it with a delete command. The professor may also correct spelling and punctuation if indicated. The intrinsic value of the forum is identical to any class: It is a combination of the professor and the students and the efforts put forth in the learning process.

Keeping within the guiding principle of computer-based, distance learning, there is a vehicle for submission of homework assignment electronically called Electronic Student, Electronic Teacher (ESET). This application allows students to upload (and thus submit assignments electronically) different kinds of documents. It also provides for acknowledgement and grade tracking. Importantly, should an instructor even misfile or misplace a student assignment, another copy may be downloaded since everything is archived.

Another heavily used tool is electronic mail (e-mail). At the beginning of each new class, an Address Book is set up so that messages may be sent to the entire group by typing the class alias in the TO: line (e.g. IDS0399). Of course, personal communications and assignment feedback are easily carried out with e-mail. It is a real thrill to send a message to Japan or Israel and to find a response from the student the next morning. These asynchronous
(anytime) tools make for much more immediate satisfaction than do setting and keeping mutually acceptable meeting times (Abramson, 1999).

How do students feel about these options? Student satisfaction runs extremely high as do completion rates for all programs. All three formats have grown in double-digit rates since 1995.

**Distant Instruction at SCIS**

SCIS, as a graduate school, is less than 15 years old. We like to believe that we move with the times and that our use of distant modalities is state-of-the-art. One of the unwritten rules that has been handed down anonymously is that the computer (and not video or TV) is our instruction medium. That does not rule out the use of textbooks or other ancillary materials. As Feenberg (1999) reports, writing is the basic medium of online expression, the skeleton around which other technologies and experiences must be organized to build a viable learning environment. Each course is accompanied by a syllabus that explains required work in very great detail. Syllabi are updated constantly to reflect student feedback and technology changes.

The masters courses tend to be subject-content oriented and the forums structured. Commonly, the professor will post questions relating to the different readings and students are expected to respond, amplify and extent the thoughts of others. Doctoral forums tend to be more flexible. The professor or any student may open a discussion and everyone is then free to jump in. Our experiences have shown two very important constants: The quality of the interaction is a direct function of the quality of students in that particular section. Also, the seriousness with which students approach the collaborative explorations is a function of how their contributions relate to the course grade.

For the most part, student work is evaluated by performance in the form of written documents and/or computer product development depending on the particular course. Using constructivist, performance evaluations largely negates questions that are often raised about cheating and integrity in distance learning.

**Moving Toward Optimization**

To summarize, let us repeat some assumptions about adult learners that hold true for classroom teachers seeking professional development:

- Students enroll in classes because of a perceived need or want.
- Mastery of course material is essential if the need or want is to be met.
- Nothing magic occurs by bringing one's body to class.
- Different people have different communication and interaction needs.
- Time spent in traffic is better spent doing homework.
- When stress is minimized, receptivity to new material is greater.
- Job requirements take precedence over school requirements.
- Home demands compete with school demands.

We concur with Phipps and Merisotis (1999) that technology cannot replace the human factor in higher education and hope that our face-to-face meetings provide enough real contact to "carry" the learning process. Over the years, we have learned to read emotional needs within printed messages (Feenberg, 1999) as we might from student facial expressions. As a collaborative faculty, we work to develop the qualities that make a good distance-learning teacher (Roblyer, 1998). Despite our best efforts, we are still unable to define optimal environments.

Nevertheless, we hope the variables identified and discussed will move the profession in the direction of best practices for the distant, professional development of teachers.

COURSE PORTFOLIO: A TOOL FOR ONLINE TEACHING

Dr. Lissa F. Pollacia, Computer Information Systems, Northwestern State University, USA

artarver@alpha.nsula.edu

ABSTRACT: A course portfolio consists of materials that instructors collect and organize to demonstrate how a course is taught and facilitated or managed. A course portfolio can include any relevant documentation such as the syllabus, exams, exercises, problem sets, samples of student work, etc. It is important to include a framing statement that places the course in its institutional context and summarizes the major aspects of the course.

In addition to the advantages of maintaining a course portfolio for a traditional class, a course portfolio for the online instructor provides many more advantages. It can help to prevent "academic amnesia" (what did I do last term?), it can help the instructor reflect on aspects of the course, and it can provide a means for assessment of the course by an academic administrator. Administrators are generally unfamiliar with the online environment, thus a portfolio provides documentation in a familiar printed format.

1. The Course Portfolio

A course portfolio is a coherent set of materials, compiled by the instructor, that provides insight into how a course is being managed and/or facilitated. The course portfolio may cover an entire course or a subset of the course. The term course portfolio used here is to be distinguished from a student portfolio, which we mean to be one developed by a student to demonstrate knowledge or skills within a particular course. In this paper, the term course portfolio will mean materials collected by the instructor to summarize the teaching and learning that takes place in his/her course.

Compiling a course portfolio to explain what we, as instructors, do in a course helps us eliminate the problem of "academic amnesia". We often have a good idea during the course of a semester but by the time next semester rolls around, we remember that idea just as we're in front of the class teaching it again. Developing a portfolio encourages us to pause and reflect upon our teaching and how we can improve the quality of instruction and learning. It provides a mechanism by which others in our field may review our teaching, and it allows us to share successful approaches.

2. Guidelines for Compiling a Course Portfolio

Although there are no hard and fast rules about what should be included in a course portfolio, the instructor will want to include materials that illustrate the three aspects of teaching:

- Preparation
- Process
- Product

For preparation, include a document that describes any preparation work that went into a unit or lesson. For illustrating the process of instruction, include tests, activities, problem sets, lab exercises, and any other materials that provide insight into how you go about achieving the learning objectives. Provide comments for an external reader where you feel additional explanation is appropriate.

The product is, of course, student learning. This is demonstrated by including samples of students' work, from A+ to failing level. This could be students essays, e-mail messages, projects, test papers, etc. The project/papers should show graded comments, if applicable. You must get the students permission to use their work.
Instructors usually have the majority of these kinds of documents together in a file box or filing cabinet. What is missing is the organization of these documents into some sort of easily viewed format, and a framing statement that will give an overview of the course and the institutional context. In the framing statement, summarize the curriculum of the course and your approach to teaching it. Describe the students who populate the course, and any special problems, e.g. the course is Freshman-level with very large sections. The framing statement should be written so that it is understandable by a person from outside of your field of expertise.

At any place in the portfolio, you may also include a reflective statement that describes your views on an activity, lesson, unit, etc. This statement allows you to think about the success (or lack thereof) of this particular activity, lesson, or unit. Did this activity meet your expectations? What would you do the same next term and what would you change? How did you address special problems or challenges? The reflection may or may not include a solution to the problem. The key here is to document—write it down so that you can continue to improve and others can become aware of any problems.

Some useful DO's and DONT's in compiling a course portfolio: [WWW1]

- DO be succinct in your writing and selective of the documents
- DO use your portfolio to develop, reflect upon, and improve your teaching
- DON'T include all of your course materials—it will become too cumbersome even if it is organized

Some institutions have gone so far as to recommend that the portfolio be tailored to its specific usage, i.e. development (improvement of instruction) vs. evaluative (promotion/tenure/merit decisions) [WWW1]. However in most instances, a well-organized portfolio can suffice for both purposes. For more information on constructing a course portfolio, the interested reader can refer to [WWW2] and [Dunbar et.al.].

3. Special Case of the Online Course

The case for developing a course portfolio for an online course is even more compelling than that for a traditional course, particularly with respect to evaluation. Traditional sources of information for evaluating an instructor's teaching effectiveness are: classroom visitations, systematic student ratings, opinions of colleagues and administrators, and self-evaluation [Cashin, 1978].

The online course presents special problems and challenges for the evaluator, many of whom are not yet familiar with electronic learning and the online environment. How does one conduct an online "classroom visitation" to an asynchronous class? How will other colleagues and administrators form a valid opinion of the teaching effectiveness for online classes?

As online facilitators for over two years, it has been our experience that the evaluator is reluctant to engage in an online classroom "visit". We have provided department heads, deans, and other administrators with username, password and written instructions about how to proceed; but we have met with very little success. Unless we sat with the administrator and walked them through it, they would not even attempt to view the class. Even if they had succeeded in entering the class, to someone unfamiliar with electronic learning, it seems as if "nothing" was going on.

This is where the portfolio, with concise well-written explanations, can be invaluable. It provides the evidence of how we are teaching and facilitating our students' learning. It gives the administrator or evaluator sense of what the instructor is thinking about concerning the various aspects of the course. Samples of student work validate the achievement of the learning objectives. In addition, the printed material provides the administrator with a familiar medium so that s/he can concentrate on the teaching/learning—not on using the technology.

4. Conclusions

Keeping a course portfolio has been extremely useful in the development and continued enhancement of our online courses. We have included such items as class announcements, assignments, as well as any other type of communication that we use over and over each semester. There is even a section
containing instructor responses to common mistakes. By saving these communications as word processing documents, they can be re-used next term. This will save you some time, which is very important for a time-hungry online course.

Our idea of a portfolio is an organized three-ring binder containing printed materials, but some have proposed taking the portfolio idea one step further: the electronic portfolio [Barrett, 1999] and [Aschermann, 1999]. Although these ideas are proposed for preservice teachers, the concept is the same. The portfolio can be created using authoring software, utilizing various forms of media, and creating hyperlinks between the various components, as in a web document.

5. References

Abstract: The paper describes the diffusion of an innovation, digital portfolios on CD-ROM, into the curriculum. During the completion of each student's degree requirements, the student compiles projects that demonstrate the eight Abilities endorsed by the university. The projects are created within the courses completed for general education and the student's major. Each project demonstrates content knowledge and one of the eight Abilities. The student decides which projects to include in the final Senior portfolio. The framework for the portfolio is determined by the Abilities emphasized in each academic program.

Outcome

Beginning in 2002, each graduating senior will organize a digital portfolio and burn a CD-ROM for program assessment purposes and for use by prospective employers. The Division of Education, as a leader on the campus, presently offers students the option of completing a paper or digital portfolio. Beginning in the spring of 2001 all Education graduates will be required to complete digital portfolios. At present, graduates have completed approximately fifty CD-ROM portfolios.

Problem Statements

Over the past three years the faculty of Valley City State University have endeavored to modify the general education objectives. The purpose of the change was two fold: 1) to make the objectives more assessable and observable and 2) to help student understand the connection of general education courses to their major curriculum. To facilitate these changes, a campus wide committee of faculty was formed. The committee identified a set of eight abilities from the existing objective statements see [Table 1]. It was determined that students should demonstrate the eight abilities not only in the general education courses but throughout the undergraduate's academic career. The Abilities were each assigned skills that could be demonstrated and five levels of difficulty were determined for each of the skills. Projects created in the academic classroom are based on content knowledge and also demonstrate the student's level of competency in a given Ability.

Table I: The Eight University Abilities

Documenting and assessing these Abilities became a topic of discussion on the campus. The portfolio assessment process was seen as a practical tool that would allow students to demonstrate competence levels in the eight abilities.
Process

Two changes occurred on the Valley City State campus that allowed the faculty to choose the CD-ROM format for the portfolios. First, in the spring of 1995 a campus technology committee made the decision to create one of the nation’s first notebook computer campuses. Beginning in the fall of 1996, every full time student and faculty member received an IBM notebook computer. The notebooks allow students to create and save materials on their own hard drive. The campus network also allows for fairly simple movement of large files from computer to computer. Both make the saving of materials and creation of the CD-ROMs feasible for a large number of students (Tykwinski, Brown, & Holleque, 1997).

Second, in 1996 the campus secured a five-year Title III grant from the Federal Government. It funded equipment and support for faculty training. The grant enabled the CD-ROM portfolios process to become a campus wide initiative (Figure 1).

Figure 1: The Campus Process

Diffusion into the Curriculum

Faculty

To begin the process with the faculty, a ten member learning team representing every academic division was created. These individuals began discussing the portfolio process and making decisions concerning the purpose, audience and expectations for the senior portfolio. Among the articles read and discussed by the team were Shiengold & Frederiksen, 1995 and Gillespie, Ford, Gillespie and Leavell, 1996. The members of the group also received training on hardware and software needed to create multimedia projects. The second year of the implementation process included one-on-one mentoring for ten more faculty. The process continued until, by the end of the fourth year, 85% of the faculty had been involved in the process. In the fifth year a priority was placed on mentoring new faculty. Also during the fourth year of the process, faculty stipends were provided for those who wished to create Ability based projects in their courses or to create program assessment plans that included the abilities and portfolios.

Students

During freshman orientation following the distribution of the notebook computers, a four-hour computer basics session is held. The senior portfolios are demonstrated at this time. Hardware and software skills necessary for multimedia projects are included in a required general education course taken by 95% of freshmen. These skills include web page creation, scanning, and audio & video capture. All other necessary skills are integrated into existing curriculum and are included in the course content as needed for the projects. Each division determines how and
where their students begin to develop the portfolio and which of the Abilities are be included in the senior portfolio. The projects are created with assessment indicators that students must respond to when completing the project. The faculty in each academic program determine the assessment of Senior portfolios however, using a day during finals week seems to be the prominent choice. At the present time portfolio courses are available for students who wish extra help in completing their portfolios. As the portfolios become required for all seniors, portfolio seminars in each division will meet the needs of the students. The process is outlined below in Figure 2.

![Integration of the Digital Portfolio into the VCSU Curriculum](image)

**Figure 2: Curriculum Integration for Students**

**Tracking Student Progress**

A web based tracking software is currently being considered for use. The web site is connected to a database that allows students to submit their best work in each of the Abilities. A checklist of completions is then available to the students and advisors and individual projects can also be accessed. Assessment committees both on the campus and off can also access student work. A demo of this software is available on the Rose-Human Institute of Technology website at this address: http://www.rose-hulman.edu/ira/reps/.

**Expected Outcomes of the Portfolio Process**

1. VCSU students will become self-directed, self-assessing learners. The use of portfolios in general classes and the completion of a CD-ROM portfolio gives students more ownership in their own assessment.

2. VCSU will increase the appropriate use of instructional technologies, including notebook computing for improving teaching and learning. The student notebook computer initiative is central to the creation and saving of portfolio materials.

3. VCSU will produce graduates who demonstrate that they meet established standards of knowledge and skills. The demonstration of the eight abilities through the CD-ROM portfolio provides the vehicle. VCSU will streamline and reduce duplication courses by focusing each course on unique contributions to expected competencies for graduation.
4. The ultimate aim of the CD-ROM portfolio project is to complete a major transformation of institutional culture and practice that began with a mandate from the State Board of Higher Education in 1990, from a traditional teaching institution to a student-centered, innovating, technology based institution.

5. Students are increasingly perceived and treated as full partners in the learning process and institutional governance. A strong emphasis on what students must know and be able to do is surmounting traditional orientation toward courses and credit hours as the measures of learning achievement.

6. Faculty are diversifying toward innovative teaching strategies. For example, a 1994 survey showed that a minimum of half the faculty used behavior modification, futuristic forecasting, independent study, field trips, role-playing, and student journals.

7. Daily faculty use of computers for instruction is more than double the national average rate (Green 1996). Nearly all are integrating technology-based instruction into their courses. A new multimedia classroom is used several hours each day.

Assessment of the project:

1. A faculty survey conducted yearly since the 1996 indicates that in 1999:
   - 30% of faculty require multimedia use in their courses
   - 48% of the faculty use multimedia in their teaching.
   - 30% of faculty require students to use CD-ROMs in their courses.
   - 81% use CD-ROMs in their teaching.

2. The faculty’s use of technology has continued to rise significantly each year since 1996. The 1999 percentages of use are as follows:
   - 77% of faculty reported that their computer is essential to their teaching (Marcinkiewicz, H. & Welliver, P. 1993)
   - 67% of the faculty reported that they require students to use 5 or more types of technology as part of their course requirements.
   - 74% of the faculty reported using 7 or more types of technology in preparation for their teaching or as part of the in class activities.

3. A student survey given for a third year in 1999 reports the in-depth opinions of our students concerning their learning and the use of technology as part of that learning. The Survey was created and correlated by Dr. Kathryn Holleque, 1999 Division of Educational & Psychology. Highlights are listed below and complete results may be found on the VCSU web site
   - Using a computer increases my communication with other students. 93%
   - Having my own computer broadens ways for me to receive and/or present information. 97%
   - Having my own computer saves me time. 95%
   - It is important to me to have computer access at any time, day or night. 90%
   - Using various technologies enhances my learning experience. 90%
   - I use my computer daily. 90%
   - Using a computer provides a variety of settings for learning (e.g., working by myself, working with others, working as a member of a team). 90%

Abstract: We propose here a contextual evaluation method. The difficulty of this kind of evaluation comes from the complexity of the real situation to which it applies: the procedure being contextual, it is practiced on the situation, in real time and not in condition of laboratory where one observes some critical factors by neglecting others and often the finality of the task. Consequently, we have sought to understand the context of each computer mediated training systems situation. Methods that we propose are based on a quantification of results of the work in order to evaluate performance reached by the trainees following the achievement of the training task, analysis of communication types used during each activity to resolve the task, and questionnaires on the perception and the usage of the different items of the environment in order to evaluate the satisfaction of actors.

1. Introduction

We propose here a contextual evaluation method. This type of evaluation is carried out step by step, by following the evolution of each group of trainees under observation in the experimental framework. In the taxonomy of evaluation methods, the contextual evaluation is an experimental evaluation because users are wanted to perform it.

The difficulty of the contextual evaluation comes from the complexity of the real situation to which it applies: the procedure being contextual, it is practiced on the situation, in real time and not in condition of laboratory where one observes some critical factors by neglecting others and often the finality of the task. Techniques of evaluation have to be really adapted to the context and to objectives to reach. Consequently, we have sought to understand the context of each computer mediated training systems situation to seek there directly measurable characteristics (observations, measures) or there indirectly measurable characteristics (interviews, free discussions, results of the work, measures). Methods that we propose are based on:

- quantification of results of the work on a generally recognized scale (for example, for the apprenticeship, notes granted by the trainer at each evaluated stage) in order to evaluate performance reached by the trainees following the achievement of the training task.

- analysis of communication types used during each activity to resolve the task. In this aim, we suggest to conduct objectives observations make by human observers and measures on the level and the content of the communication, during each session of apprenticeship (course, practical work and collaborative project. The measures are collected by software sensors in order to evaluate the behavior of actors and the behavior of the socio-technical system during each training session.

- questionnaires on the perception and the usage of the different items of the environment that make easy the communication during the training session (for example, the artifacts of telepresence, the multimedia...
representation of concepts to learn,….) in order to evaluate the satisfaction of actors with working in the
mediated environment and with the proposed role.

According to the specificity of each of these three sources of information, we have built tools to obtain necessary
data for the evaluation. We present below this procedural approach.

2 Techniques and Tools of Evaluation

2.1 Evaluation of the Performances of the Trainees

The performances reached by the trainees (training outcomes) following the achievement of the pedagogical task
are evaluated according to psycho-pedagogical evaluation methods. These methods are currently practiced in the
training of engineers. In collaboration with the trainer, we orient the evaluation of the targeted cognitive level in
collaboration with cognitive technology properties used for the communication in each type of session. The
method of evaluation is the test for course and practical works sessions and a synchronous and continuous
evaluation of the work for collective project sessions.

The evaluation by test is traditional for the classical training and is based on the measure of three distinct
cognitive activities we can evaluate during training sessions. It concerns knowledge memorization,
understanding and mastery levels. The test is filled by each trainee after the chained training session "course -
practical works". It is built by the trainer and contains questions related to the three cognitive activities (Sandoz
& al. 97):
The memorization of information is linked to the perception of visual information presented during the course in
the textual or graphic form, hearing information transmit by oral way, by the trainer, during the course and visual
and hearing information (information presented in the textual or graphic form and commented by oral way).
The understanding is the capability to solve identical problems (mainly in the context of practical works) where
the trainee has to show that he has assimilated concepts by solving problems (a question or a problem similar to
one met during the practical work).
The mastery is the capability to treat a new problem with the totality of knowledge acquired during the course
and practical works session (a question - new problem, that requires a reasoning process on the totality of
knowledge).

The pedagogical strategy of collaborative project aims to increase the knowledge level of trainees, their
capability to analyze a problem, to apply knowledge in order to solve a problem, to synthesize and to evaluate
the exactness of a solution. A multicriteria qualitative, quantitative and pedagogical evaluation is necessary. The
trainer applies an evaluation to different stages of the project (failed stage or stage succeeded without faults,
succeeded without fault but with suggestions by the trainer, succeeded but with small faults, initiated stage only)
and graduated according to the quality and the independence of each group during the project).

2.2 Evaluation of the Actors Satisfaction

The satisfaction of actors that interact with and via a computer system is intuitively correlated with the quality
of usage of the system. There are elements or states of the environment that stimulate or that inhibit the
interaction. Although all experimental and contextual evaluation methods recommend interviews, free
discussions and questionnaire as efficient means to appreciate the satisfaction, the majority of them makes no
recommendation on theoretical aspects about the content of these means neither on methods of data analysis thus
obtained. The experimental evaluation of the satisfaction is often an empirical approach.

To built a body of evaluation means efficient and helpful both for collecting data and for data analysis and
interpretation related to the satisfaction of actors is not possible without an explanation of the concept of
satisfaction by items, factors and process depending on the context of work and the activity of the actors. In this
explanation, we make abstraction of the type of satisfaction (for example: satisfaction towards the
communication with the other colleagues in the group, satisfaction towards the affluence and the performance of
software tools, etc.) to deepen its production mechanism.
The satisfaction is a mental state that appears in response to an achievement (internal or in the external world) or to an interaction with the external world. This explanation of the satisfaction offers us the possibility to estimate the satisfaction as compared to the real quality of the achievement or the interaction, but it does not explain the relationship that is established between the satisfaction and process and factors that affect the achievement or the interaction targeted by the individual (Hecht 78). It introduces the role of the discriminating stimuli, or stimuli that make the difference (concept belonging to the behaviorist theory of Skinner) that exist in the environment of work of the user and that can strengthen or decrease the satisfaction. Thus it is possible to construct a strategy of measure of the satisfaction from observable categories: stimuli, behavior and strengthening. The research of Hecht has been oriented to the satisfaction towards the communication (Hecht 78). It has found a totality of items (questions to ask) including the discriminating stimuli that predict better the satisfaction towards the interpersonal communication: the personal interest in the content of the communication, the feedback of the partner, etc. (in total 19 questions). Its contributions to the conceptualization of the satisfaction are:

- the usage of the factorial analysis to determine dimensions of the satisfaction. He finds that the satisfaction with the interpersonal communication is a unidimensional category (the result of the factorial analysis on the totalty of questions posed in a number of observations enough great to obtain a representative sample, especially 10 time the number of variables)
- the utilization of the scale to seven levels of Likert to quantify the contribution of each stimuli in the satisfaction. This scale allows to take into account the neutrality and the positive (strengthening) or negative (diminution) effect graduated on the satisfaction felt by each actor in the activity of the group.

These studies show that the satisfaction can be conceptualized and that questions for asking to users in order to measure their satisfaction do not have to be chosen at random. They have to be about decisive factors (although each new situation asks a" intuition "of these factors that has no always theoretical foundations). On the basis of anterior experiences, we have led our personal exploratory analysis on the satisfaction of actors in computer mediated training situations and we propose questions concerning some stimuli of satisfaction as the perception of teletraining environment; technical tool performances, the personal investment: concentration, motivation, the interaction with the other actors of the situation, the availability of information, the perception and the role of the telepresence.

Due to the increasing complexity of the task to achieve, we have to complete these questions in the situation of collaborative project, with others stimuli as the organization of the work, the absence of the paper support, the differentiated quality of the media according to their functional role in the execution of the task (video for the simulation, video of colleagues, audio to take a collective decision, etc.), the multimodality in the execution of the work (to analyze and plan, write and correct by using simultaneously several modes of computer real time mediated communication).

In phase of experimentation, if the mediated situation is completely new for the totality of the actors (they don't normally work in a such environment), the suggested questions are almost all based on a comparison with the traditional teaching. We give them nevertheless the possibility to express their personal opinions on the new environment.

Questionnaires used after course, practical work and collaborative project sessions are described in the annex. It presents the content of these questionnaires and points attached to each response according to the scale of Likert: low values indicate that the user is satisfied with the situation and the environment, medium values indicate a neutral viewpoint (or a normal situation) and raised values indicate the dissatisfaction (see Coutaz & Balbo 94).

### 2.3 Evaluation of the actors behavior and of the system behavior

The analysis of the communicative behavior and of the system performances during each session provides a lot of formative and summative information about the communication of the group in the mediated environment. Our methodological approach to undertake this evaluation is a type « quick and dirty ethnography » method [HKA94], issued of the ethno-methodology (Hughes et al. 1991) and motivated by the lack of time and humans means. By a triangulation of competence and views, we propose the following factors as being relevant for objectives of our evaluation and we observe them in each session context according to criteria presented Tab.1.

Table 1: Important Factors and Criteria in the evaluation of actors and system behavior

These methodological approaches of the experimental evaluation in our framework imply that the evaluators use different techniques of quantitative and qualitative data collection classified hereafter:

Measures (quantitative results) require instruments and strategy development in order to quantify results of the training (notes and appreciation of the trainer for each trainee), critical temporal factors (period of reply in the human interaction, length of activities), software failure and the consumption of CPU and network resources for each activity.

Predictive or "ad-hoc" observations (qualitative results) are provided by grilles of observations during each session. They are related to the human behavior in situation, the system behavior, social relationships in the group and their dynamics, the organization of the work adapted to the situation created in the environment and to capabilities of actors and the feasibility of the task regarding functionalities and interface of the environment. The human behavior is observed in different situations: failure (system, application or equipment), locking (impossibility to know what to do), difficulty (not to know how to do) or reply periods, organization of the space of work, research for help, collective decision, co-operative execution.

Several factors as quality of the equipment, of the operating system and of the graphic manager, quality of the applications, quality of the network characterize the system behavior.

Typical questionnaire interviews (quantitative and qualitative results) are constructed from items that can discriminate different levels of satisfaction or need in the context of each situation (see Rao 94).

3 Considerations on the analysis of data and the validation of results provided by the evaluation

An other point which is seldom precise in studies about the experimental evaluation is how to analyze series of data and observations to which we attach different significance and which don’t have the same nature when the evaluation methodology of evaluation is based on a multiplicity of methods.
The current tendency in the research on methods of evaluation is the adaptation to the situation with the exploratory analysis. This orientation presents advantages and disadvantages beside the probability to obtain valid results (results which could be used faithfully in similar cases).

The methodology of evaluation adapted to the situation is the result of the reasoning of the evaluators from the contextual situation and the objectives to reach. Therefore, it will depend a lot on information and knowledge a priori of the evaluators. Consequently, in a complex and new situation it is always desirable to use several methods and several sources of information to evaluate the same objective, and several populations which carry out the same task in the same environment.

The experimental evaluation has the advantage of the multiplicity of methods (redundancy of the information) and the incremental approach (to understand increasingly complex situations). The redundancy results of several sources of information on the same situation and nears us the truth on the reality. The incremental approach allows us to make inferences and then to generalize a conclusion based on knowledge of specific situations very specific and individual. These observations have been built to underline the importance of analysis techniques of results of evaluations and how to present these results. Techniques refer triangulation of different nature data (qualitative or quantitative) and expressing different viewpoints (different roles of actors, the pedagogical evaluator, the neutral observer of the session, etc.). This variety involves an interpretative approach in the data in order to synthesize results.

In the analysis of the training outcomes, it is necessary to interpret the cognitive level evaluation according to the characteristic of the trainee population and to cognitive properties of the media used in the training.

In the analysis of the satisfaction it is necessary to interpret answers to questionnaires that represent personal actor pedagogical and technical viewpoints.

The analysis of consummated resources has to be made on different temporal scales according to whether one takes in consideration the supplier (machine, network which requires analysis to the second or in under) or the consumer (a group activity, an intervention of the trainer or a session which requires an analysis where the second is the less significant unit).

It is relevant to analyze each source of information. Thus, for training outcomes, we propose a statistical analysis from trainee marks at a first level (averages, distribution of values) to compare these results with training objectives. If the number of trainees is small, two strategies can be adopted to increase the faith in results: to test two populations with different level of initial knowledge but with the same general profile (for example, engineer students), or to analyze results in comparison with a well-informed population doing training in a traditional situation.

In order to analyze responses to questionnaires about the actors satisfaction with the environment, we propose an analysis in different level. The analysis of unity of the tested population defines the correlation between actors and, between each actor and the other members of the group. The aim of a discriminating analysis of identified satisfaction levels is the verification of the clusters (hypothesis test on equality of averages clusters), the identification of discriminating factors (linear combination construction of items - questions that summarize at best the difference between clusters). The pedagogical and technical quality of the experimental framework is analyzed from marks assigned to discriminating and not discriminating items of the satisfaction.

For analysis of actors and system behavior, we can interpret measures and observations to get a formative evaluation on the behavior of actors and on the quality of the system (the reaction and the knowledge support) in order to improve the design of the training environment, and a summative evaluation on economic criteria such as the time of work and resources consumed for this work in order to the concrete limit of distance training sessions and to better understand where and how we can consider optimization.

**4 Conclusion**

Evaluation is no good if it just considers the computer. The situation is also up for evaluation. Therefore we had to build an efficient and helpful body of evaluation means both for collecting data and for data analysis and interpretation. These means are: test of student achievements with training in CETTE environment (Gradinariu 99), questionnaires on actors satisfaction and on their opinion with this style of training, measurements to characterize tools, computer system and network utilization, measurements and observations of on-going sessions (actor's behavior and external, unpredictable perturbations).

Our works, we retain an analysis of the relationship that exists between the technical means quality and the quality of strategy results pedagogical that these means can support. This duality is classic in the theory of the evaluation of learning systems (Scriven 67) that anticipates as objective a quantitative evaluation (the validation...
of the good usage of the technology) and formative-evaluative (analysis of means and pedagogical strategies when the both are in relationship of usage).

References

Abstract: There are an increasing number of classes being offered via the World Wide Web. Although much of the information that we review regarding on-line learning seems positive, difficulties can arise. In particular, the anonymity that a web course can provide can be a blessing and a curse. In this article, the author suggests developing an on-line ethics policy detailing proper and improper conduct for the course. The author details prescriptions for the design and development of such a policy and how to manage potential problems before they begin.

Introduction

On-line classes have become a reality of our worldwide culture. Just two years ago, the National Center for Educational Statistics conducted a survey of various institutions of higher learning involved in some form of distance education. At the time of the survey, 62% of public four year institutions were offering courses via a distance, 23% planned to offer courses within the next three years and 14% were not offering courses and did not plan to offer courses in the future (http://nces.ed.gov/pubs98/distance/index.html).

Today, all one has to do is perform an Internet search using the terms “Distance Education” to discover what is available to students and faculty members alike in the way of courses and resources. A person can literally find everything from a web course in statistics, to textbooks, to articles touting the virtues of the on-line classroom. Much of the information that we review regarding on-line learning seems positive.

However, we may not hear of the “horror stories”. We may not realize that at a distance, students can find a certain degree of anonymity—which has both advantages and disadvantages. These stories have almost become “urban legends” of a sort to those of us who teach via a distance. “Did you hear about the student who cursed at a professor in a chatroom?” Or possibly “Oh! I heard about a student who was so rude to other students on a listserv that no one wanted to post messages!”
Background Information

Unfortunately, stories such as these are often only told at conferences, meetings and informal gatherings of distance educators. Although they may be more the exception than the rule, nothing can be more damaging to a class that requires interaction than a belligerent student. A barbed tongue can literally shut down listserv, threaded-discussion, and chatroom conversations. Unfortunately, if group interaction is a part of student’s grades, improper student behavior is something that can have a tremendous impact on course satisfaction, willingness to take/teach another course and even on individual student course grades.

Student handbooks are written to describe behavior that is acceptable on campuses. However, the virtual university is often times campus-free. Many students are unaware of how to act or behave in this new Cyberworld. Students may use the “ignorance” excuse for why they acted inappropriately or even why they neglected to ask questions. Things would be “different” if they were in a “real” classroom.

After one such incident involving this author and an on-line student, this author decided to develop an on-line ethics policy so that the danger of class discussion deterioration would be minimized. The purpose of this paper would be to help other professionals and/or institutions develop similar policies for their own on-line classrooms.

Prescriptions

To begin, an on-line educator should first consider the nature of his or her own classroom. If, for example, interaction is not a major component of the on-line class then perhaps only a “cheating policy” is necessary. On the other hand, if interaction is necessary and a requirement, it may be important to detail the consequences of destroying that interaction.

It is this author’s experience that students are very appreciative when they know their rights and what is expected of them at the beginning of any class. Since the implementation of this author’s own policy, there have been many instances where students have sent “thank-you” messages regarding the ethics policy. They seem to appreciate knowing both communication etiquette specifics and that their own rights as distance learners are being protected.

The next step is to find out if an ethics policy is already in place at the educator’s institution. Often times there is a university or college policy on that which constitutes unethical behavior. This
becomes a simple base on which one can develop a policy. It is important for this institutional policy to be made available on-line to which the students can refer.

As an example, the Teacher's College at Emporia State University has an ethics policy detailing appropriate and inappropriate student behavior. In particular, academic dishonesty (plagiarism and cheating) and disruptive behavior are cited as being a serious breach of ethics and professional behavior. This document was used as the foundation for the ethics policy developed for this author's on-line classes. A copy of the document can be found at the following URL: http://www.emporia.edu/idt/id/tcpoeap.htm.

Further, consequences of such behavior must be made clear to the students. It is unrealistic to expect students to follow a weak policy. If a policy is developed that states that unethical/unprofessional behavior will not be tolerated but consequences of such actions are not detailed, then the implementation of consequences will be difficult, if not impossible. A copy of this author's ethics policy can be found at the following URL: http://www.emporia.edu/idt/id/ethics2.htm.

For example, in this author's class, if you disrupt the class by being belligerent or abusive to other classmates, students, colleagues, or teachers you will be removed from the class immediately. This is clearly stated, in writing, and becomes a part of the syllabus—a contract with the students.

There have been occasions where this author has had to warn students about their behavior but has yet to remove an individual from the class. Usually, these students do not violate the policy again but as a general rule do test the limits of proper behavior.

The students should also be told that it is improper to discuss personal issues regarding course content, amount of work, grades, etc. via open class communication. They should be directed to send such comments to the instructor instead of the class discussion forum. It is suggested that students refrain from using words such as "offends, insults, or angers" to get their point across. Students should be reminded that everyone is entitled to his or her opinion, not matter how "wrong" that opinion might be.

It is important to note that a student who has a propensity to violate the policy may still send the instructor offensive e-mail messages. As an instructor, you may receive e-mail that is difficult to read and is highly unprofessional. However, the goal of an on-line ethics policy is to create a safe and healthy learning environment for students in the class. You may choose to include personal e-mail under the umbrella of an on-line ethics policy. In this case, this inclusion needs to be detailed within the policy itself.
The final component is a disclaimer of sorts. It is imperative that the student realizes that he or she cannot use the ethics policy as an excuse for not participating in discussions. Students must be aware that they are responsible for their own learning.

It is this author's experience that on occasion, students have said that they were "afraid" to post because they might violate the ethics policy. The times that this has occurred, this "fear" has been an excuse. Even when the policy has been explained to these "fearful" individuals, they have continued to not participate in class discussions. It is important to note that students who are unwilling to participate might not simply be poor students. They may be fearful of an on-line learning experience itself. Again, this is where a detailed policy can help reduce these fears.

Conclusion

All of the information detailed above provides a rationale for using an ethics policy. The policy can help you as an educator keep order and peace in an on-line, discussion-based class format. An ethics policy can help classmates understand what is expected of them and that they are able to voice opinions without fear of peer insults. Finally, the policy can help foster a positive learning environment for each member of the class community and give that class a positive reputation for students of the future.

Ethics and the Internet

Stig Roland Rask

The Foundation for Knowledge and Competence Development, Sweden

Abstract: Even recognizing cultural differences, there is content on the Internet that most people would consider questionable for children? What options do we have for addressing this problem? Are censorship or filtering a good way of dealing with this problem, or will they just cause us to naively lean back and shirk our responsibilities?

I believe that the development of the Internet necessitates that ethical issues must be given greater consideration. Developing methods that will develop the ethical awareness of the students is one of the most important tasks for a school today. Our experience tells us that the use of new technology can be one of the pieces in this very important puzzle. The Internet could be the solution to its own problem, the answer to its own question.

Introduction

My name is Stig Roland Rask, I was born in 1953 and have been working as a teacher in Music, Social Society and Religious Education at Fredriksdalskolan (Fredriksdal School) in Lidköping since 1980.

1997 I became the manager of a project named “Ethics and the Internet – soft issues and hard wares” which receives support from the Swedish Foundation of Knowledge and Competence Development. This foundation was established in 1994 by the Swedish government, and was endowed with over $450 million to promote the use of IT, to stimulate research in new areas at universities and to create knowledge transfer. Over $100 million of these funds are being invested in primary and secondary schools. The goal is to obtain concrete results and spread these results to the entire educational system to create a long-term ripple effect. Ethics and the Internet has developed into a special project area among the Foundation school project, and the students at Fredriksdal’s School have become pioneers in this field. I am proud to say that our project “Ethics and the Internet” is one of the projects in this program that has attracted the most attention. Our idea of combining traditional and eternal ethical issues with modern technology has been viewed as surprising, exiting and interesting. Today I am working full time for the Foundation, trying to share my ideas and experiences to other schools.

Internet – the ethical marketplace

New technology always challenges our ethical views and the Internet is certainly no exception. Does not necessarily mean that we need to create new ethical opinions – our old system of ethics is still valid – but perhaps we need to re-express and reformulate our common foundational values, and apply our conclusions to this new area that the Internet has created.

The overall aim of the project “Ethics & Internet – soft issues & hard wares” is to develop pedagogical methods that will make it possible for questions of democracy, humanism and ethical values to find their place in a modern school. The appearance of the Internet just gives us one more reason to take these issues seriously. As a teacher I have a responsibility not only to transmit facts, but also to help the students in their emotional development and their growth into social maturity. I think that the way to understand oneself, society and the world we live in arises from a combination of theoretical knowledge, emotional ability, social maturity and ethical awareness. That’s why we must involve both the brain and the heart in our considerations and try to pay attention to all of these aspects in our pedagogical plans.

I think that the best way to stimulate these ambitions is to bring the students face to face with ethical standpoints and let them take part of the debate. During this process we have found that the best way of getting in contact with all kinds of opinions is to use – the Internet! In a few years Internet has grown to become the main meeting place for ethical discussion. The Internet is the ethical marketplace where every kind of opinion, attitude and
view can be found. This means that in the same time as the Internet challenges our ethical viewpoints – it offers us a superior tool for developing methods that will stimulate our ethical education.

**Soft Issues and Hard Wares**

In the most concrete part of the project we let the pupils chose an ethical question that they are interested and engaged in. It could be everything from abortion to euthanasia, from child labor to animals rights, from weapon export to genetic engineering, etc.

The student’s task is to produce a report based on seven given subheadings…

- presentation of the issue
- facts
- arguments for…
- arguments against…
- the actors in the discussion
- something about their own thoughts, ideas and reflections
- sources

If, for example, the students are interested in the issue of child labor they may want to visit the homepage of UNICEF, if they have chosen to study death penalty a visit to Amnesty Internationals homepage could be interesting, and if they engaged in environmental issues perhaps Greenpeace could offer one point of view. To help the students we have established a collection of links that will connect them to the ethical debate in a number of areas. This link collection is dynamic and new useful sites found by the students are immediately added to the list.

Their report becomes one chapter in an ethical book that every class produces, and this book will be the basis for a debate that takes place in the classroom. Our experience is that whatever ethical issue the students choose to study, the Internet offers them facts and opinions in seemingly endless ways.

**The eight targets**

We have formulated eight targets that we hope our project will help the students achieve:

1. Ethical awareness – the students will be aware of that life contains a vast number of ethical issues that sometimes demand personal decisions and selections.
2. Computer competence – more a side effect than a goal, it is interesting to see how the Internet has changed the role of the computer from being a closed room to become the door to the outside world.
3. Pedagogical progression – optimal learning ability is reached when the students are searching for answers to questions that have been formulated by themselves. Establishing this pedagogical situation in the classroom is critical.
4. Increased international perspective – Internet has no geographical borders.
5. Awareness of the necessity of languages – The need to study English goes beyond the next English exam.
6. Social maturity – developing maturity requires tasks that demand maturity.
7. Emotional intelligence – information is not equivalent to knowledge - and knowledge is definitely not equivalent to wisdom.
8. Increased equality – we must offer reasons for both the girls and the boys to sit down the computer. Ethical issues on the Internet are an example of such a good reason.

**The Answer to its own Question**

Our experience tells us that if the ethical issues will show the way to Internet, the attitude and knowledge the students receive will follow them throughout their future use of Internet. This is an important and very positive effect. It is crucial for Internet users to develop their ability to be critical of the opinions and attitudes behind the information they have researched. It has been our experience that the students learn to be more critical of their sources if they are allowed to work this way. If the students use the Internet when they are reflecting on ethical
issues, they will achieve a new awareness through the information provided. The pupils will learn that the Internet is a medium providing subjective information, which need to be carefully reviewed. That is why we have come to this simple but perhaps slightly paradoxical and surprising conclusion that the solution to the ethical problems of the Internet is the positive use. The Internet is the answer to its own ethical question.

Protection and Preparation

So far I have only described Internet as an ethical possibility. But you can not avoid the fact that the Internet also contains information that is definitely dubious from an ethical point of view. Just a mouse-click away from a good and useful site, you can find another site that shares disinformation or even destructive material.

As far as I can see there are only two ways to protect from the Internet’s dark sides: Isolation or vaccination. The same methods that we have at our disposal in the face of approaching disease. Both methods offer protection, but the problem with isolation is that its effects are not lasting. Vaccination, however, allows the disease to be faced without getting infected. There is just one problem left to solve – developing the vaccine! I consider the development methods to vaccinate our teenagers against the different destructive components in the information society, to be one of the most important questions that a modern school has to handle. We hope that our project in some way will contribute with useful ideas.

I think that it is a good idea to compare a good attitude toward the Internet with a good attitude toward deep water. When our children are small, we bring them carefully to the quay or the riverside. We hold their hand firmly, show them the deep water and tell them about its danger. After some years they begin to develop their own awareness. We can let them go on their own, but we still follow them with watchful eyes. Likewise, we put our children into swimming lessons. The best way of protecting our children from the danger of deep water is to teach them to swim. The water will be used as a pedagogical tool to solve its own problem. You can look upon our project analogously. We use the Internet in our ethical education in the same way a good swimming teacher uses the water in his swimming education. It seems like a good idea – doesn’t it! Sitting on the beach and learning how to swim will be boring after a while.

The three levels

Even recognizing cultural differences, there is content on the Internet that most people would consider questionable for children? What options do we have for addressing this problem? Are censorship or filtering a good way of dealing with this problems, or will they just cause us to naively lean back and shirk our responsibilities?

From my point of view you can find three levels in this debate. The first one is censorship and different kinds of technical filtering, the second one is about developing AUP:s (Acceptable Use Policy’s) and the third level talks about how to give proper guidance and ethical education.

Let me illustrate this discussion by this little story...

“The park was a popular outing for groups of children from nearby preschools and kindergartens. The only thing that concerned the teachers was the nearby stream. It demanded great their utmost caution and there was no room for inattention. The children were made aware, through persistent lectures about the risks, that they were expected to take responsibility for their own safety.

The day the fence was nailed up as a shield against the threatening water felt liberating. The teachers could relax and no longer did they have to nervously follow every step the children took. The need for warnings subsided and the responsibility for the children’s safety was turned over to the fence.

When the cause of the accident was investigated one came to the conclusion that the fence was defective and had several openings through which the children could climb. The feeling of safety that people had been lulled into had been deceptive and wrong. Rather they realized that the fence’s inadequate construction had presented an obstacle to the children’s safety, since its promise of safety had lead to passiveness and had reduced the sense of responsibility among both the children and the adults. Some even felt that the mere presence of the fence had challenged the children to search for its holes. The question of guilt was debated for a long time and bounced between those who decided to build the fence, the suppliers, the installers, and the inspectors without result any
result. How the fence had resulted in a reduced assumption of responsibility among other parties was also discussed.

Together with the introduction of Internet into the school system, a heated debate has risen about its dark sides. It has swung between impassioned cries for censorship and a rather naive lightheartedness. Whatever standpoint one takes on this issue, I think it is very important to realize that there are no fences, in the form of a censor or filtering programs, that can offer us a degree of protection that frees us from responsibility. Indeed, perhaps the fences just cause us to naively lean back and shirk our responsibilities. There is also cause for concern in the long run when one considers to the students’ views of their own rolls in the question of personal accountability.

My cynicism toward technical filters is not based solely on principals. I’m concerned about their effects from a wider perspective. Above all, I am worried because they lead to passiveness and a reduction in culpability for one’s own behavior. The adult world’s obligation to oversee ethical and social development of the next generation can not be delegated to technology. The answers to ethical questions seldom lie in technical solutions.

Besides, if we equip our children with too many bike helmets, kneepads, lifejackets, parachutes, airbags, chastity belts, and all kinds of safety nets, there is of course a chance that we will forget to tell them that life is dangerous. Our good intentions can lead to a shift in accountability away from the individual toward the safety net system.

The day will come when our children leave the protection of the home and school environment. Outside waits a rough world full of temptations and pitfalls. If our children meet this world without having developed the necessary tools and awareness, they will be very vulnerable.

The question is not which ethical filters we can install in the computers, but rather which ethical filters we can install in the students.

New Technology Necessitate Ethical Guidance

As a teacher I have a responsibility not only to put ethical discussions on the agenda, but also to give ethical guidance. There are components in a democracy that are so fundamental that they should not only be discussed - they should be transmitted. Experience has shown that many young people view the adult world as unclear and lacking when it comes to providing the guidance they need. Has the school failed to live up to its responsibility of providing guidance concerning the ideals that make up our democratic society? I believe that the development of the Internet necessitate that ethical issues must be given greater consideration. Developing methods that will make this mission possible and successful is one of the most important tasks for a school today. Our experience tells us that the use of new technology can be one of the pieces in this very important puzzle. The Internet could be the solution to its own problem, the answer to its own question.
CBT: The Past, Present and, Hopefully, the Future

Abstract: Computers are established today as a part of our day to day life. They are no longer just a professional tool but rather a commodity that helps people to work, communicate, shop or trade on line and at last, but not least, to improve the educational process. In this paper, we will discuss the lessons learned from our use of early state of the art Computer-Base Training (CBT) applications and what we hope to see in the future. Our presentation is based on the experience of the first author with large classes with over 700 students that used CBT like Virtual Tutor and PinPoint. Although our experiences are tied to specific tools, the lessons learned can be applied to a wide variety of similar tools. Actually, these tools tend to be more similar than not, which is rather disappointing considering there is not one approved way of "doing it right."

Introduction

Computers are established today as a part of our day to day life. They are no longer just a professional tool but rather a commodity that helps people to work, communicate, shop or trade on line and at last, but not least, to improve the educational process.

The easy access to computers suggested the obvious educational application: automated training and testing. This technology-driven approach to computer supported training resulted in some early products that were not based on pedagogical theories (Docent, 1998), (VirtualTutor, 1999). The results were, not very surprisingly, rather disappointing. The situation has been gradually improving since then, yet there is still a long way to go.

Given the continuous increase in demand and the high level of expectations in the educational sector of our society regarding the educational potential of CBT applications, more and more companies are venturing into designing and implementing these type of applications. Actually, these tools tend to be more similar than not, which is rather disappointing considering there is not one approved way of "doing it right." However this large selection of CBT applications can rather confuse than help educators in choosing the "right one." Based on our theoretical and practical experience regarding CBT applications we address some of the questions educators might have in this regard and finally suggest some directions for further developments of CBT applications.
Study
The Past

In the early years of CBT, the approaches were rather technology-driven using simple technology and were often consistent, planned or by accident, with instructionism. The CBT applications did not provide much interaction and feedback was lacking to help students judge the effectiveness of their learning. Often, these systems were simply presenting a computerized version of a textbook, which often is much less useful than the actual book. Actually, this approach is still taken today by some publishers but can result in disastrous CBT.

The early systems were also lacking tools for managing the classroom. They did not include the students’ records of grades and activities. They weren’t portable but tied to a specific platform or networked. Single user systems available on floppy disks and later on CD-ROMs was the state of the art.

The Present

Many tools have been improved pedagogically (CBT Systems, 1999). They are interactive and help the students judge their own progress and how effective their learning is. However, since web based approaches are so fashionable now, we need to stress that these systems still tend to be inappropriate to support the learning process.

The current systems excel at helping manage the classroom in various ways. Many of the systems are networked and have many integrated functions. The systems record the dates when the tutorials were taken and also automatically grade multiple-choice tests and record the results. Thus, they help the instructors “peek over the students’ shoulder” to see if they are doing the work and if the students are on track, e.g., by checking how much time the students spend on taking a tutorial and how good their test results are.

Unfortunately, these systems are only available for introductory courses that do not require too much flexibility. Also, they are often not comprehensive and stable enough to run easily with many students. Furthermore, the procedures for setup and the maintenance are quite complicated. So it might be difficult to find the faculty and staff to run such a system in a non-technical department. There are also no good tools to aid an instructor in creating educationally effective web sites. The systems are only minimally adaptive based on some pretest and they don’t take much advantage of the possibilities of hypermedia. They don’t allow for much exploration, i.e., they are quite linear forcing the students to go along with one of the few predetermined paths.

More and more systems are working in a simulated environment (in part to eliminate any incompatibilities between the lab networks and/or computers configurations and the requirements of the systems). Another reason for a strong trend in developing these type of systems is the increased chance of students to use it on their own personal computers without having to purchase the required software application.

There is also a strong movement toward developing integrated learning environment including training, evaluating, assessment and testing computer base application. These integrated learning environments can be Server-based or Web-based and tend to be pedagogically inadequate. Whereas the technology might have moved one step forward, the pedagogy of went two steps backwards (Mioduser, 1999).

The Future

So what would we like to see in the future based on our experience with these tools in the classroom and based on studying some related issues from a more research point of view (Hmelo, 1996, Hübscher, 1997, 1999).

We would like to see more adaptive tutorials based on preassessment and other feedback from the student with the goal of keeping the student in the zone of proximal development (Vygotsky, 1962). This would result in more individualized courses, more effective learning, and allow more self-directed path through the
learning material. If the student is kept in the zone of proximal development, it will also result in a more interesting and less frustrating learning experience for the student.

Support for content authoring that helps develop educationally effective presentations is desired. HTML editors surely don't do that.

Findings

In order to better evaluate the PinPoint CBT application (Kelly Services Co, 1999), before using it for our “Introductory to Personal Computer Applications” course (Marghitu, 1999) we ran a pilot test during one quarter. At the end of the quarter we used on line class evaluation involving students of the pilot test section and a regular section of the course as control group. These are the results of the evaluation.

Student Previous Computer Experience

All the students were non-engineering students with relatively little computer experience. The self-evaluation for the level of the students' previous computer experience was lower for the regular section (1.60) than for the PinPoint section (2.05). Figure 1 shows the results of the students' self-evaluation, on a scale of 1 to 5, for the level of previous computer experience (in percentage).

![Student Evaluation Chart](image)

**Figure 1:** Chart representing the results of the students' self-evaluation for the level of previous computer experience

Student Evaluation

After the students had used the CBT system, we asked for their feedback. The questions we asked were:

- How would you rate your opinion of PinPoint?
- How would you rate your opinion of the COMP0100 WEB PAGE?
- How would you rate your opinion of COMP0100 TEXTBOOK?
- How would you rate your opinion of how much you have accomplished in COMP0100?

Figure 2 shows the results. Although there is a slight tendency in favor of the CBT, it is statistically not significant.
We asked two more questions to find out how valuable they thought the PinPoint tool was with the following two questions. The results can be seen in Figure 3.

- Do you think you need more assistance from your instructor is required?
- Would you like to learn, in the near future, more about programming and/or using software applications?

Instructor's evaluation

After using PinPoint in one section (out of a total of eighteen sections) we have started using PinPoint in all eighteen sections. Below are the conclusions reported by approximately ten instructors of these sections. We are planning to collect more data to find out whether the instructors' subjective reports match the actual performance of the students. The data reported is statistically not significant. The instructors are graduate
students of the Computer Science and Software Engineering department.

1. The interaction with PinPoint proved to contribute to successful learning (reading, typing, using the mouse, answering questions, and thinking). However, the use of too much video in a CBT product caused the students' brains to go into passive mode, thus reducing the effectiveness of the CBT:
   - the average grade of the students using a more dynamic & interactive upgraded CBT was higher
   - students using the upgraded CBT were more independent in doing the hands on projects so instructors could spend more time on pedagogical issues

2. CBT can be used effectively in small or large classes if they are customizable (or even minimally adaptive). They are good in creating richer learning environments and allowing students to learn at their own speed:
   - a customizable CBT helps instructors to create training modules that better match the student's background and goals, the textbooks (or concepts book) used, and the training modules and hands on projects selected
   - based on the results of a pre-test, a customizable CBT can help instructors create different learning paths for students helping students to be more effective. This includes
     - a self-paced multimedia approach for the students with an “above average” computer background
     - or a “CBT instructor-led classroom” approach for the students with a “below

3. CBT eases students' inhibitions about using and learning technology:
   - by helping students to become more independent in lab and also increasing their self-esteem
   - a good CBT can also reduce students' inhibitions about using computers and their software applications

4. CBT can be very efficient learning tools in a classroom without taking away the vital importance of the instructor:
   - the results of the survey show clearly that students felt strongly about the necessity of instructor assistance
   - based on the detailed training reports provided by the management component of a competitive CBT, (see Figure 4) instructors can realize which subjects represent a real challenge

**Conclusions**

We have been somewhat critical about the past and present CBT systems. However, we feel that quite a
few systems are on the right track but are still lacking many elements directly related to pedagogy. For somewhat understandable reasons, these parts that are implemented are not difficult to do in principle, especially helping managing of classes and now also networking.

Nevertheless, an experiment in our 700-plus student classes to figure out the effectiveness of a CBT system (PinPoint) showed quite favorable results and we will keep continuing using CBT systems for our large introductory classes.

The results of the experiment suggest the following. Interaction with the system (reading, typing, using the mouse, and answering questions) contributed to successful learning. The use of too much video in a CBT product causes students to go into a passive hands-off mode reducing its effectiveness. CBT eases student's fear of using and learning with computer technology. This is apparently still a problem for many students—not all of them grow up with a computer under the pillow.

CBT can be a very efficient learning tool in classroom without taking away the vital importance of the instructor. We believe that CBT can be used even more effectively in small and large classrooms if they become more adaptive to the individual student and provide a richer learning environment allowing the students to learn in a more individualized fashion supporting the students needs.

Abstract A new project, headquartered at Northwestern State University of Louisiana, offers comprehensive training for middle school teachers, supervisors, and university faculty through a series of workshops, Web discussion groups, and summer institutes. Participants may enter the training at several points, and interpersonal collaboration among participants is encouraged, both in face to face and Internet settings. Learners will have the option of participating in a variety of levels, and discourse among both program authors and participants through Web based training and discussion is integrated into the latter phases of the project.

This project is directed to the particular needs of middle school professionals, both in the subject matter of the instruction and in the style of organization and participant involvement. Though focused on state standards of accomplishment, the project and its World Wide Web focus will be both accessible and valuable to participants from other places, as well.

It seems almost to be a cliché: the middle grades are so easy to overlook. In a climate of policy and debate focused on the earliest stages of schooling, and on the transition from school to work or college entry, the middle grades rarely appear in the debate.

The situation isn’t new, for a decade ago the Carnegie Commission (1989) deplored the nation’s ignoring education in the middle years. We overlook these students at our peril – and theirs – “just as they are reaching a vulnerable and confusing crossroads. Young adolescents feel the tug of physical growth, emotions, social development, and academic needs.... Early adolescence offers opportunities to choose a path toward a productive and fulfilling life. The wrong choices, or the absence of the right opportunities and support, mean a greatly diminished future” (National Staff Development Council, 1997).

Teachers in the middle schools often feel as overlooked as their students. Prepared to teach either elementary or high school, few find themselves teaching in either the place or subject area of their first choice. Many, indeed, are dealing with environs, developmental stages, and subjects that are all foreign, and sometimes formidable, to them (Scales, 1994).

“Middle grade students exhibit a range of physical, intellectual, emotional, and social development unmatched in other grades. To meet these developmental demands, their teachers must engage in staff development that increases their knowledge and skills, challenges their beliefs and assumptions about education, provides support and coaching to develop comfort with new practices, and engages them as active participants in the study and reform of the school culture” (National Staff Development Council, 1997). This
national challenge has local implications in Louisiana. Teacher preparation for the middle grades has been identified by the Louisiana State Superintendent, Cecil Picard, as a targeted area for concern.

To describe the situation of the middle school does not, however, require one to deplore it. The middle school teacher often greets the placement with enthusiasm, even in states that do not allow teachers to seek certification for teaching in the middle grades. The rewards of being part of "the last, best chance," as the Carnegie Commission (1989) described middle school teaching, are plentiful. In many ways, the task of middle school staff development is simply the task of letting the staff share among themselves and advertise to the world the joy of success in their particular realm.

The project at hand explores one way to celebrate the task, the challenge, and the special skills of middle school education. To meet this need, the NSU College of Education and its educational partners established a Web-based on-line professional development workshop series addressing the three areas of change identified with successful middle schools.

The Web-based professional development model seems to be particularly appropriate for middle school staff development for several reasons. The presence of the technology itself, as part of the training, has a heuristic effect, requiring participants to use perhaps to master skills identified as necessary to their practice. Such mastery is daily more important, for the Web's "value as a learning tool is a reflection of the teacher. The teacher must possess, among many other skills, considerable web expertise and the ability to plan individualized learning experiences" (Maxwell, 1997, 10).

More important, Web-based development means Web-based conferencing, and collaborative activities have been incorporated into every module. The best resource for any middle school – and any middle school teacher – is the company of professional colleagues who know and love children and learning in the middle years. This project is designed to have them working and learning together as much as possible.

The relative calm of middle education in the maelstroms of educational attention and reform are not the only reason to focus on collaboration, however. The NSDC Standards for Staff Development lists the outcomes that comprehensive school staff development should address, in context, process, and content. Among the twenty-seven standards, only one is identified as exclusively appropriate for middle schools. "Effective middle level staff development increases staff knowledge and practice of interdisciplinary team organization and instruction" (Hatch & Hytten, 1997). Collaboration, long identified as an important part of teaching with technology in any classroom (Koschmann, T. D., et al. 1994), acquires a signal importance in middle school classrooms when technology and the Web are used to teach and learn (Fuller, 1998).

The professional development series focuses on

- A Blueprint for Quality Middle Schools,
- Technology Integration in the Classroom, and
- Supporting New Academic Curriculum Standards.

The individual modules in each workshop series will be developed by leading middle school educators and technology experts throughout the state who are associated with or directing successful programs. Their efforts will be reviewed by a panel of experts comprised of outstanding teachers, administrators, SDOE, and college faculty.

The form of the each workshop follows a template that includes an Overview and Objectives, Introduction, Outcomes, Topic Information and links to examples and extension, FAQ's, Review, and Activities. The Activities are designed for individuals, small groups, and large groups to promote interaction with the module topic and preparation for the next module. Training was designed to reflect the middle school experience, the exigent elements of Louisiana education policy, and the expressed needs of teachers. The 26 training areas are listed in Table One.

The NSU faculty and graduate students will convert the modules to an interactive Web Format supporting on-line learning using ASP. Active Server Page Programming was chosen for its support of streaming video and database applications central to the large banks of information needed to support the site. The modules will then be piloted with focus groups from a target population, including NSU undergraduate teacher education students and in-service middle school educators at three middle school sites. Feedback for module refinement and development of support materials for local facilitators will be gathered.

Once a workshop is completed, it will be placed on a server. In its final form each module will have a companion Web conference to support interaction with the author, participants, and local leaders. As each on-line series is completed, a regional in-service presentation will introduce the workshop to local school districts and state college of education faculties. These workshops will provide an overview of the modules and supporting leader materials as well as promote the use of the modules.
An intensive workshop will be conducted during the summer of 2000 to assist school district coordinators/leaders and college faculty in the planning and implementation of selected modules or an entire workshop series. This summer session will also provide district middle school coordinators the opportunity to meet and interact with many of the program developers and experts in middle school education.

During the implementation phase in year two, the project staff will continue to provide technical assistance, follow-up support, maintenance and upgrade. They will disseminate information and establish a telephone help-line. Authors of the modules will also serve as technical advisors by responding to email inquiries and by participating as consultants at scheduled workshops and institutes. By project completion, teachers, district coordinators and curriculum leaders, and the education faculty of the state’s teacher education programs will have participated together in a project that both enters each participant’s classroom and knits together the community of interest statewide.

In the end, there is an ironic permanence about a training series built so completely out of apparently evanescent materials such as conversation, collaboration, and the World Wide Web. The resonating effects of two year’s collaboration among so many middle school professionals will be captured, amplified, and – possibly – institutionalized through Web-based focus groups and a continued need to use and develop the modules created during the project’s scope.

No staff development lasts forever. Indeed, no staff development should last very long, for good development is individualized, specific, and changing. Nonetheless, the continuing nature of both the network of participants and the nexus of a discussion server may prove a kind of longevity and usefulness to this project that outdistances its life on paper.

Abstract: The University of Houston-Clear Lake has developed a systematic design process to use in facilitating the development of on-line distance education courses. The process incorporates three semesters, and during which, faculty members have the opportunity to consult with a design team that consists of instructional designers, web developers, graphic artists, media specialists, and instructional programmers. This paper presents an outline of the process, describes each step in detail, and provides a framework for formative evaluation.

Introduction

This paper addresses the implications for redesigning traditional university courses for delivery over the Internet. The University of Houston-Clear Lake has adopted a unique perspective whereby faculty members have a team of professionals who serve as consultants throughout a three-semester design process. Within this framework, a systematic procedure has been developed to facilitate the refashioning of the courses. Specifically, this paper outlines a theoretical perspective for the development of on-line distance education, discusses who should be involved in the process, presents a systematic procedure for development, and discusses methods for evaluating the effectiveness of the course.

Theoretical Background

Over the past several years an increasing number of educational institutions have begun to offer on-line distance education as a viable alternative to more traditional forms of classroom instruction. There has been a great deal of discussion about which pedagogical foundation is appropriate for classes delivered over the Internet. Historically, this debate has focussed on the differences between the Instructivist and Constructivist approach. This is a meaningful consideration since classes that were originally designed for the traditional setting are afforded different instructional activities and learning opportunities that were not perceived or even possible before Web-based instruction (Dabbagh & Schmitt, 1999). Accordingly, many classes will undergo pedagogical reengineering as the process of learning over the Internet is examined more closely (Dabbagh & Schmitt, 1999). Because of such Web features as synchronous and asynchronous communication, searchability, global accessibility, and interactivity (Dabbagh & Schmitt, 1999), it can be argued that a movement toward a more Constructivist approach can easily be facilitated. Constructivism recognizes that learning is an active process in which learners construct their own concepts rather than acquire knowledge directly from an instructor (Duffy & Cunningham, cited in Dabbagh & Schmitt, 1999). According to this perspective, the on-line course should create an atmosphere that recognizes the needs of the learner rather than those of the instructor (Berg, 1999).

Without a well-developed design process, the on-line curriculum becomes little more than a replication of traditional Instructivist-based curriculum. Accordingly, tools and strategies such as videoconferencing, file exchange, electronic libraries, virtual cafés, whiteboards, role-taking activities, and student dialogues should be integrated to encourage and support tele-apprenticeship (Bonk & Cunningham, 1998). But integrating these technologies within the framework of a well-designed instructional program can be difficult even for the most
experienced faculty member. Accordingly, a systematic process is necessary to ensure a focus on all of the elements of Internet-based instruction. There are concerns about whether or not a systematic design approach can be used to develop classes that rely on more Constructivist pedagogy. However, it can be argued that Constructivist values such as collaboration, personal autonomy, reflectivity, active engagement, personal relevance, and pluralism are objectives often overlooked by instructional designers (Lebow, 1993). In essence, Constructivism is often treated as a method when in fact it is really a philosophy, and instructional systems design is seen as a philosophy when it really is a method (Lebow, 1993). Therefore, the principles of instructional design based on Constructivism emphasize the affective domain, make instruction relevant to the learner, support self-regulation, and promote autonomy. In reality, instructional design under the context of the Constructivist philosophy includes a concern for the motivational aspects that are not often considered within the traditional approach.

The Design Team at the University of Houston-Clear Lake has created a process to guide their work in consulting with faculty members developing on-line courses for the first time. This ensures a focus on a course design that will provoke intelligent responses to the learning materials, context, and environment (Berge, 1995). Considerations for graphics, media, immersive technology, and effective text must all be embedded within the process to ensure that students will be equipped with the resources and motivational elements they need in order to achieve success. The most important challenge of the Design Team is to support faculty members in developing collaborative assignments, facilitating active on-line communication, and promoting the development of critical thinking and research skills (Pallloff & Pratt, 1999).

The Design Team

Members of the Team

The Design Team at the University of Houston-Clear Lake consists of skilled professionals with expertise in a variety of areas. Accordingly, it was important initially to establish clear roles and responsibilities in order facilitate a systematic development. Otherwise, it is difficult for people to have clear expectations of what is required of fellow team members. The Graphic Designer assists in evaluating content to determine the need for visual information and immersive technology and creates images, interface elements, and animations using a number of graphic, 3D, and multimedia software applications. The Instructional Designer serves as the team leader for the project, performs the needs analysis, task analysis and instructional analysis with the Subject Matter Expert, and reviews and helps to revise course content. The Instructional Programmer evaluates content to determine the need for CGI programming, database integration, and forms; and writes code to integrate programs into Web pages. The Multimedia Specialist assists in evaluating content to determine the need for creation of multimedia and immersive technology and creates video, graphics, animation, audio and other multimedia elements. The Subject Matter Expert identifies the course’s needs, establishes the goals, objectives, instructional events, and readings, writes course content, writes tests and/or quizzes if applicable, develops criteria for student evaluation, reviews and approves all products developed by the design team, and signs off on all completed components. The Web Developer creates the interface, navigation, and theme for project Web sites; evaluates content to determine the need for HTML, CGI programming, database integration, and forms; develops HTML pages for the course Web site; and conducts training sessions for the Subject Matter Expert.

Process Management

The process of creating Web based instruction involves a team of developers from many disciplines. In the development environment, some of the team players may not be able to attend all scheduled meetings for a variety of reasons. The response to this dilemma was to create an Internet-based resource, known as a Project Support Site or PSS. Team members can coordinate and exchange information using this site. The features that are included in the PSS help team members to successfully telecommute while working on a project with a deadline. In order to ensure its effectiveness, team members were asked to verify the features needed to simplify work tasks with the Internet serving as an intermediary. The announcements feature allows team members to receive news and announcements that affect everyone involved. The file exchange allows members to share files, graphics, and documents and is accessible to all project team members. A simple list of email addresses, phone or fax numbers, room numbers, and work hours is listed on the site to help team members maintain contact; password
protection is necessary for this feature. A chat room is also available when other means of communication are not feasible, and each team member also has quick access to the home page for the current project. Calendars and timelines are maintained on the Web site to serve as a reference to deadlines and delivery dates, which helps to keep all interested parties informed of the progress. The maintenance of a PSS for the duration of a project results in an archived source of information that is used to evaluate the process. This captured information serves as a reference system for designing and building future Internet projects. The PSS can be pictured as a common thread that runs through the length of the development process.

The Design Process

The process of developing an effective on-line course is an extensive, lengthy procedure, because it requires a paradigm shift from a traditional methodology. Even the best educators must reevaluate their instruction to ensure its capacity to be integrated into a Web-based format. Considerations for graphics, media, immersive technology, and compelling text must all be part of the process to equip students with all of the resources they will need in order to be successful. Since not all approaches are appropriate for Web-based instruction, some examination of teaching techniques must be incorporated into the development process. This may appear to be an arduous task, initially, but through a systematic procedure, the process is isolated into concise steps concluding with distinct end products. As each step is finished, there is an opportunity for readjustment and change to ensure the best possible outcome at the completion of the process. Within this context the Design Team adopted a modified Dick and Carey (1996) model to ensure that the procedures for developing Web-based classes are unified and systematic. This process incorporates three distinct stages, Pre-Production, Production, and Post-Production.

Pre-Production

During the Pre-Production stage, the design team for the project forms, and an initial meeting is held with the Subject Matter Expert to conduct the course analysis. This helps the team understand some basic information about how the class has been taught in the traditional setting, gain insight into the faculty member's personal strategies, and learn about the student population. From this point, the team splits into two groups. The Instructional Designer continues to work with the Subject Matter Expert as the rest of the design team creates the basic interface and prototypes for the Web pages. The outputs of this stage include a design document, a rapid prototype of a content unit, and a horizontal prototype. The design document outlines the framework of the class, while the horizontal prototype demonstrates the metaphor, navigation, and organization of the Web site. All of these are analyzed through one-to-one conferences and expert reviews before the Subject Matter Expert is asked to sign off on the product.

The design document represents the output from the initial stages of the instructional design process. In consultation with the Subject Matter Expert, the Instructional Designer works through a systematic approach based on the model suggested by Dick and Carey (1996). The process begins with the task and goal analysis, with the purpose of determining the intended outcomes of the course from the instructor's perspective, representing both content specific and affective goals. This provides an overarching perspective of what the class should accomplish. At this point, the Subject Matter Expert attempts to break the main goals into smaller topic areas that can be covered throughout the class. Based on this information, goals and objectives can be established for each individual topic area. Depending on the nature of the class, some faculty members may have very specific goals while others may take a more open-ended approach. At the completion of the instructional analysis, there is some discussion of how students will be assessed, focusing on measures that are appropriate for Internet-based classes, such as rubric grading systems. Once these initial guidelines are conceived, instructional events are established to meet the course goals. While this process first seems to represent a very rational approach to course design, it is much more iterative in practice. Decisions made later in the process often create the need to reexamine earlier conclusions. The purpose of this effort is to produce a design document to articulate the basic structure of the course. This includes outlining the main course goals, the goals and objectives within each smaller topic area, the instructional events, and a plan for the assessment of the learners.

Unlike many instructional design situations, the delivery medium -- the World Wide Web -- has been predetermined for our courses. Rather than looking at whether the Web is the right medium, the task in this situation
involves finding the right blend of Web technologies and print-based activities to achieve the goals of each course. One of the first challenges is to convince the Subject Matter Expert that delivering courses via the Web takes a very different approach from the conventional classroom. It is more involved that just putting pre-existing PowerPoint slides into HTML format. The second challenge is to help the Subject Matter Experts understand capabilities of various Web technologies and to visualize how these technologies can be creatively applied to their course. There are numerous Internet technologies (text, graphics, animation, sound, interactive quizzes, video, chats, bulletin boards, email, newsgroups, video conferencing) that should be considered in putting together a Web-based course in order to ensure the content is delivered in the most appropriate manner for achieving the course goals. The third challenge is to make the development of the course content and Web site as efficient as possible. To address all of these challenges, a rapid-prototyping approach has been adopted for the Pre-Production phase of each of our Web-based course projects.

Rapid-prototyping, which is commonly used in the software development industry, involves experimenting with the design ideas and issues even while the requirements analysis (or content analysis in the case of instructional design) is being conducted. Specifically, through rapid-prototyping the design team can experiment with interface design and the incorporation of a variety of Web based technologies until the right approach for the subject matter of a given course is found. The samples that are generated help the Subject Matter Experts to visualize the capabilities of these tools and to begin seeing advantages and disadvantages of using each technology. Once the design team and the Subject Matter Expert have seen concrete examples of how technologies such as bulletin boards, chat rooms, animations, video, video conferencing, or sound can be used, they are able to think more creatively about how to apply these tools to the course objectives. Rapid-prototyping facilitates formative evaluation to ensure that the chosen techniques actually achieve the desired learning goals and objectives. Through rapid prototyping the design team is able to help Subject Matter Experts understand how Web courses are different from conventional classes. This also enables Subject Matter Experts to choose the appropriate technologies to achieve their course goals.

At the completion of the Pre-Production phase, there are three main outputs. The design document specifies the content to be developed for the course. The rapid prototype provides a framework to guide Web page development. The horizontal prototype of the Web site provides the context for how all of the elements of the course will be unified. These outputs are analyzed through one-to-one conferences and expert reviews before the Subject Matter Expert is asked to sign off on the final products of this stage.

Production

The Production phase incorporates the process of developing the actual content for the Web site. The definition of content at this point is rather loose and may include textual information, graphics, descriptions of activities or assignments, job aides, test and quizzes, and other instructional events. During production, the design team uses a step-wise development process, completing one instructional unit completely before moving on to the next, but the content does not need to be created in the sequence in which it will be used. The Subject Matter Expert with the help of Instructional Designer specifies the content for the site. Information that is not available in the course textbook (if applicable) is emphasized, or additional content is added that will help to better explain the important concepts. As the content is specified, the Subject Matter Expert and the Instructional Designer work with the rest of the team to examine ways to make the content and direct instruction meaningful and engaging to the student. This involves a consideration of options available through the HTML/script coding, the media creation, and the use of immersive technology.

As the textual content, media, and immersive technology are created, they are integrated into the Web site using the template created during Pre-Production. An important part of the process at this level is considering the use of instructional programs that can be integrated into the Web pages using server-side applications or Java coding. Essentially this means that small programs can be run from within the Web pages to perform specific actions. As the Web Developer and the Instructional Programmer examine the content, they may have suggestions for ways to make it more compelling through the use of these programs.

Media creation is the main way that the content of the site is given greater force. Images can be used to demonstrate concepts that are difficult to explain in textual terms and to reinforce ideas expressed in written form. As the content of the site is developed, the Instructional Designer and the Graphic Designer work together to identify areas where images are most appropriate. Generally, images are only used for a sound educational purpose, and the design team does not recommend adding images only for their aesthetic appeal. Other media that...
may be created for the site include video, animation, and audio, depending on what is required to support the content. The Graphic Designer and the Media Specialist review the content and consult with the Subject Matter Expert to make recommendations about what media is helpful to represent some concepts.

The Multimedia Specialist and Graphic Designer provide several different types of media for inclusion in the online courses, including audio, video, animation and interactive segments. Audio and video clips are used to reinforce pertinent information or to provide relevant anecdotes to increase the effectiveness of the content presentation. Interviews with Subject Matter Experts are developed for audio or video to provide relevant information to students, therefore adding a humanizing touch to the Web site (Bonk & Cummings, 1998). These interviews are kept to approximately one minute in duration to minimize download time. Video conferencing between the instructor and students is also possible in order to provide personal feedback to the student and to foster interaction (Bonk & Cummings, 1998). Immersive technologies such as Quick Time VR and Virtual Reality Modeling Language (VRML) pull the user into a simulation of reality on the Web. Shocked Director files can create interactivity to facilitate lessons such as chemistry experiments. The use of Macromedia Flash has been examined as a way to improve download time. Since Flash is a vector-based animation and multimedia tool designed for Web output, the files are small, fast loading, and produce dramatic results. All of these technologies are considered in attempting to increase the effectiveness of the content presented through the Web.

Once all of the components for an instructional unit are integrated into the Web site, it is ready for a series of evaluations. This helps ensure that all the pieces are functioning together and provides an opportunity to judge whether or not it is likely to be effectively used by the students. Formative evaluation involves the collection of data and information during the development of instruction in order to improve effectiveness and efficiency. This determines the weaknesses so that revisions can be made as necessary. Formative evaluation provides feedback that is used for improvement of the products at all stages within the instructional design process (Seels & Glasgow, 1997). During the Production phase, following the Dick and Carey (1996) model, the formative evaluation is divided in two parts, content evaluation and learner evaluation.

In content evaluation, the designers and experts evaluate the content of the instruction. This evaluation is conducted throughout the development process, and the evaluators review the goals, objectives, environment, learner analysis, task analysis and instructional materials. The content is evaluated to determine if the goals and objectives were met and to find inadequacies and flaws. The entire team reviews and makes corrections during the Production stage until the Subject Matter Expert signs off on the product. The learner evaluation involves either one to one evaluation, or small group evaluation. The use of computer programs, immersive technology, graphics, animated sequences, or video make altering the courses at the final stage very expensive and time-consuming (Seels & Glasgow, 1997). To overcome this problem, the learners evaluate the first instructional prototype. In the one to one evaluations, students individually go through the prototype in front of the designer, and the designer takes note of each student's comments. The designer studies the notes and makes the necessary revisions after students review the instruction. In small group evaluation, a group of users will go through the instruction, and the material is presented as it would be in the true learning environment. There is little intervention during the instruction, and a questionnaire is given to the users at the end of instruction.

Before the content unit can actually be released, the faculty member reviews the final product one additional time to make sure that it is an appropriate teaching tool. When the Subject Matter Expert accepts the product, then development moves forward to the next content unit and the process repeats until all content units are complete.

Post-Production

At the beginning of the Post-Production phase, all content units should be completely developed and approved by the Subject Matter Expert. At this point, field-testing is conducted which involves the actual use of the Web site to facilitate the course in a distance setting. The purpose of this field test is to discover areas that need some additional consideration to ensure that the instruction is as effective as possible for the largest number of students over the long term. The students should be asked to provide comments and feedback to help improve the course throughout this semester.

Although training is provided throughout this process, a debriefing session is held at the end of the third semester to answer any questions in order to ensure that the faculty member is ready to maintain the course independently. During these three semesters, all pertinent Web technologies are introduced and demonstrated.
Additionally, basic instruction is provided to help the Subject Matter Expert learn to create and maintain Web pages independently.

Testing and ongoing adaptation testing, which are used to evaluate the merit of a completed Web course begin with simple Likert-type survey questions. The questions examine user perceptions and experiences regarding the various elements of course. The areas of interest that are most important to examine include navigation, graphics or visual appeal, and validity or comprehension of the content. A survey is administered during the field test at the completion of the Web course. The surveys are collected and analyzed for any significant input that impacts the design of the course. If user feedback suggests the need for significant improvement to the site, changes are implemented and noted. During every semester, developers and designers receive new and regular input about each course being offered through the Web. Changes are completed as necessary and the change process begins again to facilitate ongoing data collection and analysis of the Web courses.

When the final product has been delivered with all changes and corrections, and the Subject Matter Expert is ready to maintain the site, the process is complete. The Subject Matter Expert member signs-off on the project, and the full offering of the course begins.

Conclusion

As the number of classes offered over the Internet continues to increase, it is important for educational institutions to develop and maintain effective procedures for course design and development. One way to facilitate this process is to create a division within the university whose sole purpose is to guide, instruct, and assist faculty members as they make this transition. A program such as the one described in this paper ensures through a systematic process that the courses developed for this medium will be effective and produce high quality results.

Interactive Television: The Planning Process

Abstract: Planning is essential to good teaching. When preparing to teach an interactive television (ITV) course, planning is critical and includes additional considerations from the traditional face-to-face course delivery. In this paper, I will share some insights based on my experiences in planning and teaching an ITV course. As we experiment with new ways of providing learning for students, there are serious considerations if we are to maintain standards and integrity.

Introduction

One of the most important roles of a teacher is that of decision maker. Therefore, informed decision making at every stage of the teaching process is the most critical aspect of effective teaching. The key word here is informed. Farr and Brown (1971) observed that “most instructional decisions are made by forfeit; that is, by not recognizing that a decision can be made or by not being aware of possible alternatives. The usual forfeit ‘decision’ involves continuation of a practice whether or not it is the most appropriate procedure for the situation” (p. 341).

There is also strong evidence that teachers tend to teach as they were taught (Nagel & Driscoll, 1992). This is especially problematic when the teaching environment is changed as drastically as when going from face-to-face instruction to interactive television (ITV).

Planning

As with any effective teaching, ITV course delivery requires planning. While there are similarities, planning an ITV course has some special considerations. Teaching a course in the ITV environment that you have taught before is an advantage. However, because of the nature of the ITV environment, planning that begins at least one semester prior to the course delivery is desirable because of the long-term planning issues. Some of the planning considerations include:

- communicating with all other departments, colleges, offices, etc., that would be involved in planning and supporting the course
- learning the capabilities of the medium
- preparing yourself for the experience
- reformatting all visual materials
- getting permission for transmitting visual and audio materials
- rethinking the pedagogy
- planning activities and experiences that could be translated into the interactive television environment
- planning at least one visit to the remote site
- involving equally students in the transmitting classroom and students in a distant classroom

Communicating with support systems
Whereas traditional course delivery involves planning with a variety of support systems, course delivery via interactive television drastically increases the number of people involved in the planning process. Identifying all stakeholders and possible support systems should be one of the first steps in the communication process. First, the infrastructure must be in place and appropriate for the type of course to be delivered. Things we take for granted in the traditional classroom, such as all students being able to hear and be heard, to see and be seen, take significant planning in the ITV environment. Providing library access and materials for students as a remote site require advanced planning with appropriate library personnel. Developing a relationship with the technical support people is necessary to insure good communication.

Capabilities of the medium

The capabilities of the medium determine, to a significant degree, the teaching strategies that can be used. Advanced planning time getting to know the medium will provide a basis for pedagogical and curriculum decisions. Determining exactly what your role will be and the amount of type of technical support you will have will also play into the decisions about the format of the class.

Preparing yourself for the experience

In addition to learning the capabilities of the medium, you need to train yourself to use the equipment. Because you may be expected to serve, at least partially, as your own producer, use the equipment appropriately and with a degree of expertise will eliminate disruption to the learning process. Also, an aspect of ITV teaching is that for at least the students at the remote site, you are a television personality. As we often tell our students, one effective way to prepare yourself as a teacher is to video tape yourself and then critique the video.

Formatting visual materials

Visual materials must be formatted for television. PowerPoint is an effective way of formatting materials. However, the specifics for developing the PowerPoint slides are rather exacting. For example, the color of both background and text have to be compatible for television. Also, the font size must be large enough to allow for ease of reading. Materials that cannot be made into PowerPoint slides have to be redone in some other compatible format.

Permission for transmitting materials

Copyright rules governing transmission of visual and auditory materialsshould be reviewed and appropriate plans developed for either using the materials or substituting. For example, a video that is owned by you or your organization cannot be transmitted without written permission from the producer. This is a rather involved process as getting responses from producers can require persistence and an extended period of time. Another alternative is to have original copies purchased for each site. Again, this can be costly and time consuming.

Rethinking Pedagogy

Planning for teaching an interactive television course involves the process of re-educating the teacher. If sound pedagogical practices are to be maintained, one must thoroughly investigate the medium and its capabilities. When talking with fellow teachers and students, I often hear interactive television courses referred to as the “talking head” and/or “hairy arm” classes. If the customary practice of a teacher is lecture, she or he may approach interactive television as a continuation of this practice. In the interactive television environment, this is translated into a head shot of the teacher talking or the hairy arm of the teacher writing on the document camera or overhead. This is definitely not the stimulating environment we want to provide for our students.

If a teacher has developed an approach to teaching that involves activities, experiences, discussion, and other interactive pedagogical strategies, translating this process into the interactive television environment is a
challenge. Maintaining the integrity of appropriate pedagogical strategies was a primary concern for me when planning to teach an interactive television class.

**Activities and experiences for an interactive television environment**

Meaningful and relevant activities and experiences are an effective way to facilitate learning. However, as Ball (1992) has suggested, activities can be devoid of meaning unless the teacher is capable of providing students with appropriate challenges and helping the learner bring the meaning out of the activity. This challenge is compounded in the interactive television environment. In addition to the usual considerations when designing interactive teaching strategies, the medium must be taken into account. However, there are some interesting ways to design experiences that are enhanced by the medium. For example, providing opportunities for students to discover the differences in perception when one can only see objects, as opposed to being able to handle them, provides for interesting discussion and insight on the part of the participants.

**Remote site visit(s)**

If possible, visit the remote site and transmit the class from that location. Meeting the remote site students face to face changes the relationship dynamics significantly.

**Involving students equally**

Getting to know the students at both the transmission and remote sites is critical. Allowing the time to make sure that students know each other is also important. Because of the familiarity of having students in the face-to-face classroom, a temptation is to focus more on the students at the transmission site. Constantly monitoring yourself to make sure that you are making “eye” contact with the remote site students, including them in the discussion, and asking for feedback from them are all ways in which you can involve students equally. Forming groups or teams whose members consist of students at both the remote and transmission site is also an effective strategy to avoid the “us” and “them” mentality.

Abstract: This paper tries to establish a comparison between the problems IT people are
having, at the end of this century, to evaluate the return on the investment in IT, and the
difficulties faced by those who have been trying to find consistent ways of assessing the
benefits of formal education since the 60's. Our objective was to check if the problems in
assessing investments in the area of education were the same, or similar to those in the IT area.
If that was the case, there would be room for future studies trying to determine if the
Education Economics could, somehow, contribute to the development of better evaluation
tools for investments in IT.

Key-words: information technology, formal education, value assessment

"Invest in education because the cost of preserving our future
is nothing compared to the cost of not having one."
Joe Petterle (1991)

Introduction

Not only academic literature but also computer industry advertising, is full of impact
statements like the one above. However, it's a relief to realize that such statements are not the
sole property of the computer arena. The statement above relates to the educational field,
though it would be well suited to our techie environment if we swapped the word Education
with Information Technology and rephrased the sentence a bit to better suit corporate "ears":
"Invest in IT, because the cost of preserving the future of your enterprise is nothing
compared to it not having one". Perfect!

When we started studying the impact of Information Technology on organizations
(and the subsequent value of IT), we thought it would be interesting to investigate other areas
with similarly intangible benefits. If we were able to identify another area with the same
characteristics and with good, established assessment procedures, we could possibly spare
ourselves a lot of effort and time. We thought of an old Portuguese saying: "When the brains
don't think, the body has to work twice as much". As we didn't want to "work twice as
much", we started looking for studies in other fields of knowledge that could complement or
bring new insights to the way people have been treating the intangibles related to the
investment in IT. It would be quite an achievement if we could shed some light onto IT research pertaining to the value of technology to organizations. The only thing researchers had been able to say so far is that IT really brings a lot of intangible benefits to those who invest on it - benefits which probably far surpass those easily quantifiable.

Curiously, the first areas that came to mind, when we started thinking about the evaluation of intangible benefits - Education, Health, Quality of Life, Tourism, etc. - are all areas related to people, rather than to machines. This only reinforces another idea that has been discussed lately: we have to pay more attention to people and their capabilities, rather than letting them be overshadowed by the glamour of the technology. The value of technology is not inherent to the technology itself, but is directly related to its capacity to make people more efficient and productive, individually or in their teamwork.

This paper tries to establish a comparison between the problems IT people are having, at the end of this century, to evaluate the return on the investment in IT, and the difficulties faced by those who have been trying to find consistent ways of assessing the benefits of formal education since the 60's. Our objective is to check if the problems in assessing investments in the area of education are the same, or similar to those in the IT area. If that is the case, there is room for future studies trying to determine if the Education Economics can, somehow, contribute to the development of better evaluation tools for investments in IT. To quote another popular saying, "we wouldn't need to reinvent the wheel", and our efforts could be focused on "improving other parts of the car".

Coincidences and similarities between the benefits from IT and the benefits from Formal Education

IT and Formal Education are power decentralization and opportunity democratization factors:

In 1963, Schultz (apud CARNOY, 1995a), identified in Education the capacity to change salary structure and payment for work, altering the value relationship between capital and work, favoring work. This could represent a conflict of interests, as the owners of capital could be little interested in having part of their power redistributed among other people.

As IT makes the access and use of information easier to a larger number of people, it also affects the power relations within organizations, requiring special attention to be paid to managing conflicting interests.

Education and IT promise to act as power and income dissipators (which can provide an important social benefit), but this can also be a source of resistance by those who feel to be disadvantaged by it.

IT and Education allow/happen in less hierarchical environments:

Another interesting feature of the educational process and the new activities supported by the use of computers is that, in schools and "information era" organizations, there is no strict hierarchical structure, like the one that predominates in "industrial era" enterprises. Teachers and professors are not usually supervised in their activities. There isn't even a formal contract specifying the results expected from the "processing" of the student by the school. Teachers are assigned responsibility and it is expected that they put their best
efforts into conveying their knowledge to their pupils. The "information era" organizations also tend to be hierarchically less strict than those production-line companies of the "industrial era", assigning more responsibility and expecting, on the other hand, more dedication, creativity and initiative from their employees. SAS's Jan Carlzon once said: "A person without information can't assume responsibility. With information, he can't avoid it" (NAISBITT, 1990).

**IT and Education are important flexibility factors:**

The world is changing faster than ever. Schultz (apud CARNOY, 1995a) wrote in 1975, that one of the benefits of formal education was that it improved the ability to adjust to changes and adopt new forms of doing things. For CARNOY (1996), there has been a major swing in the purpose of education: in the past, the educational process focused on conveying certain skills, necessary for the execution of specific tasks; today, people have to be prepared quickly, and with great flexibility for tasks that are not very clear and which will undoubtedly change more often and more quickly than ever before. Reusable skills should be developed - particularly those skills that facilitate adjusting to change, interacting and problem solving. In the case of education, flexibility seems to mean give people a relatively high level of cognitive knowledge, which makes learning other tasks easier. In the case of IT, organizations expect their investment in technology to make them more able to adapt to the fast and radical changes in their business environment. Such flexibility should contribute to ever smaller production batches and lead times. Ultimately, IT should provide the industry with the main feature, lost since the time of handicraftsmen: exclusive/customized production (only possible by the close and intense interaction with customers). In times of radical change, flexibility is the key to the success, or even the survival, of organizations, it being the product of well educated people, capable of adapting to and generating change, or of the creation of a new technological model, free from the paradigm of serial production in large quantities and focused on satisfying the individual needs of each customer.

**Difficulties involving the investment in IT and Formal Education**

**Depending on the industry, the impact of the investment may vary greatly:**

One major difficulty related to the evaluation of investment in education, as well as in IT, is the fact that the impact of investment is also a function of the environment in which it occurs. CARNOY (1995b) states that the relationship between education and productivity varies significantly from one industry to another.

The intensity of the need for IT also varies widely from sector to sector depending, to some extent, on the level of competitiveness within the particular industry, but also on the productivity gain technology can provide companies with. A good example of this is the banking industry, which is highly dependent on the electronic management of information, and the construction industry, in which the impact of IT is much smaller.

**Difficulty in isolating the benefits directly related to the investment in education or in IT from those caused by other factors:**
Another problem is that, unfortunately, there is no practical way of segregating the benefits caused by formal education from those caused by other factors, such as the influence of the family (schooling level, social status, etc) among others, which are highly interconnected. The differences among people with different schooling profiles cannot be uniquely assigned to their educational experience. This makes it difficult to come to any conclusion about the impact of schooling. SOLMON (1995) argues that, regardless of what happens in the ideal world of research in the social sciences and education, it is impossible to study two identical groups, one exposed to formal education and the other not. For him, attempting to use statistical control in studying the issue is problematic in that one will never be sure one is taking all important factors into account, as many of them may be impossible to measure or even to imagine.

The same kind of difficulty happens when we try separating the influence of IT from that of other factors that are simultaneously acting on organizations. This makes it impossible to assign the majority of benefits related to the investment on IT exclusively to such investments. There is always a reasonable level of subjectivity involved, which allows for different interpretations, depending on the issue one is trying to prove.

Conclusions

Economists must understand the educational process, as well as the new ways of organizing work and the new technologies being introduced. In order to do this, it is necessary to create new, more complex models than those bound by the familiar paradigms of the “industrial era” which have hitherto been used to understand production line processes.

Formal education and the new ways of work organization, made possible by IT, are elaborated processes, which require special attention in their evaluation. Education and the implantation of IT are closely related to changes in attitudes and, as such, are not immediate processes. Ways of thinking as well as values cannot be quickly modified, as a consequence of scenario changes or competitive pressures. Therefore, investment in education and investment in IT are both part of long term strategies. Consequently, any attempt to measure their results should be carried out with a long term vision.

For CARNOY (1995c), the benefits of formal education go far beyond improving an individual’s performance. Higher schooling does not only make people more productive themselves, but also allows them to help others become more productive. Thus, formal education benefits the whole community, contributing to the improvement of health conditions, decreased criminality rates, etc.

SOLMON (1995) notices that there are several beneficiaries of the educational process: the students, the community and the teachers and other workers in the education industry. All of them have to have their interests evaluated.

BENJAMIN (1993) recognizes that, as in the case of education, there are several agents benefiting (or not) from the investment in IT. They also need their interests to be well understood. He suggests that the level of commitment to the success of the investment is contingent on each one of those who have a role in the change process. Their capacity to interfere in the process, their availability, their gains from or resistance to the change should be evaluated. The identification of all stakeholders and their involvement in the change process is crucial to the chances of success of the investment in IT in achieving the expected benefits. The energy required to support the change process comes from the organization's
capacity to satisfy its needs and aspirations. Therefore, it is important that the change process is supported by a sufficient number of people committed to its success.

From what we have discussed above, it is clear that the strategic investment in IT and formal education have several things in common. The reasons for investment can be the same, especially when the focus is on achieving greater flexibility, which is probably why organizations are starting to discuss strategic IT investments, training and education and organizational culture at all. Difficulties with the intangibility of benefits and the time taken (usually long term) also seem to be similar in nature. This makes us wonder if "education economics", which has been around for much longer, couldn't help in the development of "information economics", now.

But CARNOY (1995a) reminds us that things are not going to be that simple, and that we shouldn't get too enthusiastic. He says that, up to now, there is no evidence that increased, more formal education enhances productivity. We only know that there is a strong correlation between more schooling and higher salaries. Researchers like Carnoy only believe that when school increases the student's cognitive knowledge, it makes him/her potentially more productive, as such knowledge is important for him/her to develop the special skills necessary to perform his/her work more efficiently. In other words, although they have been trying to measure the importance of education for almost four decades, by now, they are still conjecturing about the real value of education, and still have a long way to go.

If, despite all research already developed on education economics since the 60's, nobody can yet establish a definitive relationship between schooling and productivity, maybe we should be a little more patient, when we struggle for answers for the evaluation of strategic investment in information technology.

This shouldn't be taken as a reason for discouragement, just that we should be conscious there is still a lot of work ahead of us, before we do have a solid theoretical ground on which to step when looking for conclusive assessments of strategic IT investment. Until then, "mind and body will have to work ceaselessly", regardless of the Brazilian adage!

Abstract: This project examines the impact of technology on the process of higher education and the impact of these advances on both students and faculty. Student demographics and academics qualities from thirty years ago are compared to those of modern students as reported by veteran and new faculty members. The impact of technology on the modern student is discussed, as are technology relevant changes in the university experience for students and faculty. The changes in the accessibility of college classes by nontraditional students due to multimedia and Internet technology is also discussed with respect to the changing nature of distance education, including emergence of teleconference courses, Internet based classes, and other alternatives to the traditional correspondence course.

Introduction

Technology has made many aspects of our lives easier, less worrisome, and much more comfortable. Not all automobiles in 1969 had radios as an option and compact disk players were not even a speculation. Modern conveniences common in 1999 were the stuff of science fiction movies at the end of the 1960's; microwave ovens, home computers, the Internet, and home satellite dish technology were not even very lucid dreams. These conveniences have become near-essentials in lives of many; the institution of higher education is no exception as it has integrated new advances and adapted to the changes these advances have made in the lives of instructor and student alike. Thirty years ago student life was very different for persons engaged in all levels of university education; technology has had a dramatic effect on every aspect of both the graduate and undergraduate experience.

It comes as no surprise that college students now, especially graduate students, rely very heavily on technology in the course of their studies. While this statement may seem obvious, the degree of difference between students, graduate or undergraduate, in 1969 and their counterparts in 1999 is staggering. We expect that the modern student would be computer savvy and accustomed to using information technology in order to produce research projects, complete assignments for class, design and deliver lectures, and to use whatever tools are available for practicum or training in the students specialty concentration. What is not as intuitive is how much the changing face of technology has altered the very nature of what is desirable in a potential doctoral, master’s level, or undergraduate student. Skills, attitudes, and beliefs about their particular fields of endeavor considered preferable by admissions committees seems to have coevolved with society’s technological sophistication. The very face of the student has changed as well; no longer restricted to higher socioeconomic status individuals under the age of 25, many non-traditional students are finding opportunities for study which were simply not present as little as ten years ago. Knowledge of and familiarity with technology unavailable
The University Experience

The process of higher education has changed much in the last 30 years; this is not a revelation of any magnitude, but the impetus of these changes are to a degree differentially attributed by new and veteran faculty. Fourteen veteran faculty members (began instructing at the college level before 1976) and 12 new faculty members (began instructing at the college level after 1994) responded to an E-mail survey about changes in higher education. Veteran and new faculty were asked to describe their observations and opinions with respect to their first one to three years as instructors. Veteran faculty members responded that in their first few years of teaching the primary mode of lecture delivery was classroom instruction. Classes were conducted on campus, during the week, between the hours of 8-5. Night or evening classes were uncommon but when offered they were mostly prerequisites and core classes. For content courses and advanced classes students would have to come to the university/college during normal class hours. Correspondence courses were available but the topics were more limited than today's offerings. Correspondence courses generally required the student to come to campus to take exams. Most veteran faculty agreed that a degree could be completed via nontraditional courses but only if the majority of the work had been completed on campus and only if the courses offered in the evening or by correspondence would satisfy the remaining degree requirements. It should be noted that many universities then required, and many still do require, the last several courses in a student's major field of study to be completed on campus. Student's 20-30 years ago would primarily contact instructors by arriving in person at the instructor's office or by telephone. The majority of students resided on campus and a smaller percentage lived off campus near their university. Students commuting from another town, city, or nearby area was generally rare. The veteran faculty members who responded to the E-mail survey believed that social and policy changes, along with the greater availability of financial aid, had the most pronounced impact on both the student body demographics and on the university experience itself. They noted that advances in technology, specifically the advent of the home computer and the dawn of the age of the Internet, produced changes secondary to those of the changes in society itself.

New faculty agreed that the primary mode of lecture delivery was in the classroom during normal business hours, but many noted that alternatives were available for students who could not attend formal classes. Traditional correspondence courses are still offered, but the faxing or E-mailing of assignments is available as an alternative to the regular post or hand delivery. A wider variety of offerings is present today as opposed to 30 or even 15 years ago. Alternative instruction includes more than just evening/weekend classes and traditional correspondence; Distance Education departments offer Internet-based instruction, televised courses via satellite, courses on video cassette and CD-ROM, and even video-conferencing of courses to several locations at once. The new faculty noted that undergraduate degrees were easily completed by use of alternate means; such as extension campuses, internet courses and distance education. The changes in instruction on the university level are centered on information and computer technology. Veteran faculty reported that the library was the primary source of materials for undergraduate papers. New faculty note that the library is still the source of choice, but an important alternative has surfaced in the last ten years: the Internet. Many students are conducting their literature reviews and searches on the Web; the major professional publication/style manuals now recognize on-line and other web based citations. Specialized search engines and specific on-line information services such as PsychInfo, ERIC, Medline, and dozens of others provide relatively easy and rapid access to specific information. E-mail gives the more industrious student direct access to many sources of information once accessible only by the regular mail. Students now also have access to their professors via E-mail as well; personal visits and phone calls are still the modes of choice, but E-mail communication is rapidly gaining in popularity.

The advent of the computer and its accompanying advances have changed much more than just the dynamics of the higher educational process and the university/college experience, it has changed the demographics of the student itself. Veteran faculty members noted that, in their first three years of teaching, the typical student was Caucasian, upper middle or upper class, unmarried, under the age of 24, and likely to be male. Minority students were rare and female students, while not uncommon, did not make up an even proportion of the student body. New faculty members report that the majority of students are likely to be Caucasian and male, the notion here of a majority may be a misnomer. Most university campuses serve diverse populations, but even this intuitive statement does not accurately describe the population. Examining the
demographics of the modern student body can we see the major interaction between social policy change and the advances in technology. Social policy changes in the form of anti-discrimination laws and equal educational opportunity statutes greatly increased access to higher education for non-majority students. As computer and information systems technology became incorporated in the process of higher education at about the same time as many of these social changes were beginning to take effect a dramatic change in demographic nature of students can be observed, a change most likely due to the interaction between these two forces. An increasing number of non-traditional students began returning to school and their numbers rise with each successive year. Many are returning for advanced degrees to meet the needs of an increasingly competitive marketplace; for others it will be their first exposure to higher education. Some will attend traditional classes but many will take advantage of non-traditional course times and formats; for them these alternative courses may be their only opportunity to pursue a college degree. As the demands of the modern workplace change the engines which support it change as well. Advanced technology is on the forefront of these changes.

The new faculty members surveyed differed in their opinions and observations to a degree. They believed that the personal computer and the Internet were the most influential in establishing changes in the educational experience. The simple availability of these tools has dramatically altered the college experience for professors and students alike. The second most important influence noted by new faculty is the rapid increase in technological sophistication in the workplace; to be productive and competitive a worker must know how to employ and maintain the tools of their trade. Clearly, a place to learn technology competency is during the educational experience in college. While this second observation may seem intuitive, the incorporation of computer and electronic technology into all areas of American life today is extensive, likely more so than would have been projected 30 years ago. Computers are everywhere in modern society. Automobiles, cash registers, gasoline pumps, kitchen appliances, vending machines, and many other seemingly common devices now are fitted with intricate computer cores. Advanced electronics have crept into modern life with equal influence on seeming everyday conveniences. Many specific products common today were not available 30 years ago, many not even conceived as the stuff of science fiction. While the future failed to provide the citizens of 30 years ago with personal jet-packs and colonies on the Moon, it did deliver compact disc players, cable and satellite television, laser surgery, advanced optics, microwave ovens, electric and solar powered automobiles, Fax machines, voice mail, and many other advances now considered to be relatively commonplace. Operating, repairing, building, or designing these devices requires a level of skill and knowledge not available 30 years ago. The modern workplace demands a minimal level of sophistication from each and every employee, regardless of their position. In the same way that a modern architect generates a building design on a computer, a modern cashier must be able to program and operate a computerized cash register. The new faculty members did give credit to the forces of social change, but clearly in their opinions social forces were less influential than technology. It is more than likely that the change is attributable to an interaction between technology and social change, indicating that somewhere in between these relatively specific advances lies the actual agent of progress.

**Technology and The Modern Student**

It seems that the battle cry of faculty across disciplines heard echoing throughout college campuses in the United States is “read the textbook!” Many instructors believe their students could generate higher quality work and achieve substantially better grades if only they would study the course text and the lecture materials. Faculty of all levels of experience generally agree that students demonstrated a higher level of dedication to their studies in the past than is present now. While this argument is not often contested many critical supporting elements are often not given due consideration. The college student of the late 1960’s or the early 1970’s did not have access to the same technology as today’s students. Yesterday’s college student likely had fewer than ten channels of television, no access to a personal computer, no Internet service, no video games, no Fax machines, no E-mail, and certainly no access to courses on videotape, to name a few of the salient differences. Social conditioning was different. The technology which now expedites life simply was not in existence or did not have nearly the same impact. To learn a student needed to read a textbook, attend classes, and use a card catalog-referenced library. Some would argue that this student had more patience and determination; while this judgment is certainly face valid, it is also equally accurate to note that the students of the past simply became accustomed to waiting for the less efficient methods at their disposal to produce the desired results. Papers which had to be typed may have taken several iterations by longhand before a final draft was completed. Mistakes on a typewriter could very easily necessitate the retyping of an entire page or section; this is not a concern with modern word processing software. Completing a ten-page term paper is considerably easier with the assistance
of a personal computer or even a computerized typewriter, not to mention the added assistance of the Internet and on-line reference engines available at the university library. Subjective comparisons of quality between students then and students now are actually more confounded than they may seem on the surface when the differences in available resources and methods are taken into the equation. While both would need a degree of intellect appropriate to their field of study and the expected collection of motivational and supporting variables, the specific skills present in modern students are often technology centered. This provides both the advantage of the availability of the efficient resources of the Internet and of the personal computer and the disadvantage of the dependency on technology to be effective.

Students beginning their university careers in the early 1990's to present have received extensive social conditioning with regard to technology. The impact of this conditioning has been both direct and indirect. Students today grow up in a world of ready convenience; fast food, instant long distance telephone connections, credit cards with instant approval, Automatic Teller Machines, and many other areas that are infiltrated by technology. Stories of the past notwithstanding, modern students have little connection to life without these direct and indirect influences of technology. The vast majority of colleges and universities in the United States offer many of these and other conveniences on campus. Students are conditioned to expect more immediate results from their efforts in all aspects of daily life as compared to their predecessors. This expectancy generalizes well to their studies. Modern students can research a term paper in considerably less time using electronic indices in the university library than was possible using a card catalog. A first draft of a paper can be edited with the assistance of a word processing program, making obsolete the need for pen-and-paper outlines and drafts. The final paper then is printed with the touch of a button, a process much more rapid than typing from a hand written draft using a manual typewriter. Many textbooks now come with content-relevant CD-ROM's or floppy discs. Instructors are beginning to list supplementary sources on their syllabi in the form of web sites devoted to the topic instead of using materials on reserve at the university library. The publishers of many textbooks, in an effort to make their product more marketable to colleges and universities, now offer content-relevant web sites accessible only with a code from the student's textbook. All of these advantages, if they are to be utilized efficiently, demand that the modern student demonstrate specific prerequisite skills to access the information or use the available tools.

A student who cannot use a computer suffers a serious disadvantage in today's university setting. Word processing is more than simply knowing how to type; it requires the applicable knowledge of the software's capabilities and a familiarity with both the general lexicon of the computer age and the specific terminology to navigate the software's various utilities. Students without Internet skills literally have only a fraction of the resources available to them compared to their Internet-savvy colleagues. In many cases the lack of skill in using local area network (LAN) search engines can critically hinder a student; many college and university libraries have eliminated their card catalogs. Knowledge of word processing and the Internet, while a substantial part of the constitution of the desirable skills in a modern student, are not the only important elements. Familiarity with software for designing presentations, for example, is rapidly becoming a requirement for graduate studies in general and for many undergraduate majors as well. The ability to use E-mail for more than simply sending messages is another rapidly developing requirement. Many professional conferences accept on-line submissions, many potential employers require work samples be sent via E-mail; this may require the ability to attach pictures or graphics, convert text from one format to another, import charts and statistical diagrams from specific programs and incorporate them into the final product, and present the effort in a uniform and easily understood manner. Simply understanding the operation of a personal computer does not convey the ability to maximize its capabilities. While speculations of a paperless society by the proponents of computer technology are likely premature, the advantage of the fax-modem is not to be underestimated. Graduate and undergraduate students alike who can compose and send by fax a document without leaving their terminals possess a great advantage. Many professors allow the E-mailing and/or faxing of reports and other assignments as an increasing number of students commute to their college or university from some distance away. These skills and others allow a modern student to maximize the educational experience by utilizing available resources efficiently; students without these skills suffer a distinct disadvantage, a disadvantage that will only become more detrimental as institutions of higher learning embrace advances in technology.

Most institutions now have programs in place to meet this need. Most colleges and universities now offer a course that essentially serves as an introduction to the university itself. In such courses the student is introduced to the university's resources and receives basic instruction on their use, including the use of computer based facilities. Many universities offer clinics and other forms of instruction designed to introduce the new student to word processing, Internet and E-mail utilization, availability of services and alternate course formats, and training on discipline specific software packages. Almost every modern university now offers computer labs
and facilities staffed with personnel trained to assist students in the use of these facilities and to troubleshoot specific problems encountered in either the learning process or the application of computers and software to the student’s course requirements. Many faculty members have begun requiring Internet assignments from their students as a method of ensuring that the student has at least a basic level of knowledge of how to navigate the Internet and of the operation of Internet browser software. As class presentations in both graduate and undergraduate courses of study become more and more dependent on multimedia applications, many instructors are coordinating with university departments which offer instruction in presentation software to ensure that their students have every opportunity to acquire the skills necessary to generate high quality work. A quick search of the Internet will reveal a large number of course syllabi and lecture notes or supplemental materials posted by faculty for their students and other visitors. Such postings serve as motivation for students to use the Internet for their academic careers. As students become used to acquiring information from the Internet, they will likely begin to perform searches for information related to their studies or other aspects of their future careers.

How important is the Internet and the personal computer to current students? A survey was presented to 68 students in an upper division psychology class in a mid-sized university in Louisiana. These students indicated that they believed persons with current Internet and computer skills will have a distinct advantage in the job market. On a scale of 1-10 where 10=very important and 1=not at all important, the mean response of these students to the importance of Internet and computer skills to future employment success was 7.04; 62% (44 of 68) rated this item’s importance as 7 or higher. These students also indicated that computer and Internet skills will be a requirement in the future for college students. Their mean response to the question of how likely such skills were to be a requirement in the future was 6.92; 56% (38 of 68) rated the likelihood as 7 or higher. When asked how important technology would be with respect to their future careers the mean response was 6.3 on a scale of 1-10, 48% (33 of 68) rated the importance of computer technology to their future careers as 7 or higher. Of the students in this informal survey, 70% (498 of 68) reported that they owned or had access to a computer in their primary residence. 72% (49 of 68) reported that they had access to the Internet at their place of residence. 81% (55 of 68) reported that they were familiar with the basic operation of a home computer. 66% (45 of 68) reported that they used a computer for writing class assignments at home or at school. 48% (33 of 68) reported that they believe textbooks will be entirely replaced by CD-ROM’s in the future.

Technology’s impact is profound in the life of the traditional student, but many nontraditional students may very well owe their academic existence to computer technology. Every state in the U.S. now has at least one university or college that offers some form of distance education apart from the traditional correspondence course. The new wave of distance education is the teleconference course. Instructors in one setting, possibly hundreds or thousands of miles away, are connected in real time to students in a classroom via satellite audio/visual technology. The potential for such instruction is staggering; students unable to commute to a traditional or night/evening class now have access to university instruction. Internet based classes are developing almost as rapidly as remote conferencing; a quick search of the Internet will reveal many offerings for web-based courses, many with online exams and assignments. The Internet class is the natural evolution of the correspondence course of old; where correspondence courses could reach anyone with a mailbox and a free day to come in and take an exam. The Internet now serves as an extension campus in everyone’s living room. Many universities allow remote access to their libraries’ facilities via the Internet. On-line, peer reviewed journals have begun to appear in many fields, offering the modern nontraditional student access to current research and theory without having to make a trip to the university’s library. The importance of these developments to the nontraditional student cannot be overemphasized; single parents, shift workers, military service members, persons unable to commute to a traditional university, and many others now have opportunities simply unavailable before the advent of computer and satellite technology.

Technology and the Modern Faculty Member

Technology has not simply impacted the lives of students; the advent of the computer and the Internet has had a profound impact on faculty members across disciplines in higher education. The same advances that have impacted the modern student have also influenced the instructional style and careers of modern faculty. Professors and graduate teaching assistants now have ready access to multimedia aids and information which was previously either difficult to acquire or simply unavailable. Once again the Internet and the personal computer appear as primary agents of this change. Faculty members can communicate with colleagues via E-mail much more easily and cost-effectively than by telephone or even by fax. Lesson plans and exams can be devised using word processing software with the same efficiency as that experienced by a student writing a term
Paper. Presentation software and modern multimedia equipment have added a new element to classroom lectures. Teaching is not the sole area of influence for the computer in academia, however; computer technology has quickly established itself as indispensable in all areas of research. Professors and graduate assistants now have the potential to be considerably more productive with the aid of computers and specialized software. Statistics packages such as SPSS have literally reduced the time involved in data analysis to a fraction of that which was required to compute the figures by hand. Speed is not the only advantage of such programs; the accuracy of a computer greatly reduces the chance of human error. Many potentially valuable statistical procedures and research methods previously considered prohibitively time consuming and cumbersome to be of any utility are now in regular use due to the availability of computers and specialized software. The Meta-Analysis, for example, is an invaluable tool for outcome research in almost every applied discipline. Advanced software packages for this specific procedure have reduced the time necessary for a Meta-Analysis to a fraction of the original time required, normally many months (and in some cases, years). These advances have also allowed research-oriented faculty to essentially engage in a form of academic multitasking. The potential productivity for faculty and graduate students involved in active research is much greater now due to current technological aids, but the same prerequisites are in force for the faculty as for the students; before a computer or a software package is any utility, the professional must first know how to use it efficiently.

Conclusion

The university experience for both the graduate and undergraduate student is dramatically different now than it was 30 or even 15 years ago. While many of the same qualities are desirable in modern students as were generally present in students of the early 1970's, modern students are required to have a level of knowledge about computers and advanced technology not present in their predecessors. Modern students are technology dependent, but this is a statement that simply reflects the current state of our society. The Internet, while relatively young, has become an ingrained part of American life both on and off campus. The computer has rapidly grown from an expensive curiosity to a basic household appliance and educational tool. The modern student must be computer savvy in order to maximize the university experience and it appears that the modern student is aware of this fact. Academic life is rapidly moving forward to maximize computer and multimedia technology and the effects of this movement can already be seen in almost every institution of higher learning in the country. In comparison to thirty years ago, much has changed with respect to the college experience. Traditional student bodies are much more gender-balanced than before, campus populations are more diverse, possibly to the point of making the term "majority" a misnomer. Even within the Caucasian-male student body greater diversity exists now as opposed to thirty years ago. No longer is a college education restricted to the upper strata of American society or to a specific geographic location. Modern students have the opportunity to access more information with greater speed and efficiency. Faculty members have useful new tools available to design not only traditional courses of instruction but to take advantage of a nontraditional body of students formerly restricted from higher education due to various constraints in their lives. Internet based instruction, teleconference classes, courses on videotape, and other products of the multimedia/computer fusion have extended access to college courses beyond the campus grounds. Faculty members have seen a number of direct benefits from computer and software advances as well; research productivity and teaching efficiency have dramatically increased and likely have not yet reached their apex. As for the future, it is likely that once computer skills have become a requirement for college attendance or a faculty position we can expect to see an increase in the requirements for the successful completion of a class or for a professor's tenure. As a group becomes more productive the requirements always increase to match productivity. While this is merely speculation, it will be interesting to examine the state of theory in academia 30 years into the new millennium. Technology has dramatically impacted research, but the theoretical engine which drives academic pursuits has not been as affected; while colleagues can teleconference and discuss postulations and principles, no computer or software currently available will be able to directly influence the development and delineation of academic theory in any discipline.
Higher Level Thinking Skills and Individual Differences: Bridging Gaps with Technology

Barbara Moore
College of Education
The University of South Florida
Tampa, Florida - United States
bmoore@typhoon.coedu.usf.edu

Abstract: Pre-service and in-service teachers are expected to address individual differences in students. However, the nature of differences and the needs of individuals can slow or, at times, completely stop learning for the rest of the classroom. Teachers are also encouraged to teach higher level thinking skills, although standardized tests are often composed primarily of lower levels of questioning. By taking advantage of new technologies as they become available and combining them with old methods that are effective, teachers can accommodate individual learning differences and help develop higher thinking skills. Steps for designing effective instruction while integrating new technology are described.

Introduction

Two common instructional quandaries appear to be separate questions, but are interdependent: how best to address individual differences in students and how to correctly allocate student classroom time. Time schedules are established according to course objectives, which determine the content that is to be taught, which influences the level of required student thinking skills. Addressing individual differences, especially differences in cognitive ability, can destroy a classroom time schedule. Pre-service and in-service teachers can learn new ways to accommodate individual learning differences and effectively schedule student time through integration of appropriate technologies as they become available.

In a perfect world, instruction would always address individual differences in students. Eisner (1999) notes that ideal instruction enhances diversity. In other words, the higher quality of education, the greater the difference in student outcomes. Each student would experience challenge and would learn at the optimum rate for his ability. Individual talents would be expanded and individual interests stimulated. Differences would be addressed in formats that nurture positive outcomes for each student. In reality, the nature of those individual differences can slow or, at times, completely stop classroom learning.

The ideal is not always reality based nor is it easily attained. Teachers are encouraged to address individual differences and, at the same time, teach higher level thinking skills. If thinking and learning tasks are categorized according to the questioning levels of Bloom’s taxonomy (Bloom, Engelhart, Furst, Hill, & Krathwohl, 1956), those higher level thinking skills would be analysis, synthesis, and evaluation. In ideal learning conditions, creativity is stimulated as students develop and produce community centered projects. In the process, they use those higher level thinking skills. Student work is assessed by examination of portfolios that include many facets of the individual’s work. In reality, project-based instruction takes a great deal of class time, precious time that teachers need for teaching and re-teaching the basics so that their students score well on required tests. This occurs because currently predominant assessments of teacher effectiveness and school quality are based on student achievement on standardized tests. Those tests primarily assess content acquisition at lower questioning levels: knowledge, comprehension, and application, according to Bloom’s taxonomy. Accordingly, in order to satisfy that portion of teacher, school, or program evaluation that is based on student achievement scores, a great deal of classroom time must be spent on instruction and practice of the basics.

Teachers can become stressed because they are trying to address individual differences while stimulating higher level thinking skills within limited classroom time. Unless they learn new ways to plan, teachers are in a difficult situation! Pre-service and in-service teachers need skills that will allow them to make accommodations for physical, emotional, and behavioral disabilities while addressing differences in learning styles and cognitive ability. They also need new planning techniques for allocating classroom
time so that higher level thinking and learning takes place without displacing time needed to prepare for tests that assess lower level thinking skills.

Specifics

Individual differences can cause serious problems in the classroom. A typical classroom includes students with a wide range of learning styles and cognitive abilities. Inclusionary laws that require the least restrictive environment have placed students with physical, emotional, and cognitive disabilities into most classrooms. In addition, many traditional classrooms contain students with undiagnosed or unclassified but evident emotional or behavioral disorders. Teachers often give direct instruction suited to the majority in the middle of the cognitive ability range, a process that ignores the needs of those at the high and low ends. For example, if direct instruction of a concept is presented to 30 students for fifteen minutes of class time, at the end of the fifteen minutes there would be several different levels of comprehension among the students. There might be ten students who understood the concept within the first five minutes. They are now completely bored because they had to spend ten extra minutes hearing the same information presented in several ways. After five minutes these students were ready to add new information. On the other hand, five different students still don’t understand. They were paying attention and trying to comprehend, but they still have little grasp of the concept. They need more time and other presentation methods. For these five students it is difficult, if not pointless, to continue the same activity. Fifteen students are now restless and may begin to disrupt the learning of the rest of the class. Least visible outcomes are one or more students who simply sit, but don’t learn. The other, more visible outcome can be cessation of learning by all in the classroom due to disruption by one whose needs are not being met in positive ways.

Teachers need the means to allow each student, whatever his level and ability, to work at his optimum growth rate. They need tools that will allow their students to acquire all levels of information and thinking skills. While teachers and technology can be excellent means of student learning, student interaction with teachers or with technology is not as important as student interaction with the instruction itself. Teachers need tools that allow each student to interact as directly as possible with his instruction.

Solutions

The key to teacher survival lies in having the ability to integrate the new with the old. New technologies can complement old methods that have proven effective. New teaching tools allow technology to assist with the time-consuming lower-level tasks of instruction: individualized instruction of content at knowledge, comprehension, and application levels. The use of computer-based or web-based K-12 learning resources for acquisition and/or drill and practice of content at lower cognitive levels can free up teacher and student time for projects that encourage higher level thinking skills. These resources can also address individual differences efficiently by allowing each student to interact with content at his optimum rate.

An example of a web-based learning resource is The Digital Bridge. The prototype unit of The Digital Bridge can be found at http://typhoon.coedu.usf.edu/~bmoore/wits2.htm. The instructional tools at this web site include objectives, essential terms and their definitions, tutorials of several types, links to related information, flashcards, and quizzes. The site, which allows self-paced acquisition of knowledge, comprehension, and application levels of content, is designed to address individual differences in learning style and ability. Students can use the Digital Bridge as a learning resource individually or in pairs to acquire and practice one small segment of content at a time. The prototype unit covers an introduction to the concept of motion. The Digital Bridge is appropriate for enhancement of traditional instruction, but can also be useful for students in alternative educational settings. By taking advantage of new technologies as they become available, teachers can shift lower level learning tasks to the student. Teachers can spend more class time coaching students as they work in teams on community based projects, which, in turn, stimulate higher thinking skills.

Teachers are instructional designers. Not all teachers are designers of effective instruction. Successful instructional techniques, though they may differ in format, often include similar features. Geiger (1995) pointed out that effective instruction usually includes the following:

112
1. The student must be capable of the task.
2. The student must be relevantly active in the learning process.
3. The student must have incentive to interact.
4. The curricular materials must be flexible (individualizable).
5. Each task should result in an identifiable product (not necessarily teacher-defined, but having met certain criteria) for two reasons:
   a) The student and teacher both know that the task is completed.
   b) The product acts as a natural reinforcer for the student.
6. The student must come to feel satisfaction about the learning over time.

**Designing Effective Instruction**

Processes that occur in effective instruction must be carefully planned with constant anticipation of possible consequences and monitoring of actual consequences. Following an instructional sequence, the various outcomes must be analyzed and processes revised when necessary. Haphazard planning may result in a classroom filled with students industriously on task, but poor outcomes when student portfolios and/or standardized test scores are analyzed. The following steps for designing instruction incorporate success features and offer guidance for correct allocation of classroom time:

6. Identify teaching goals and objectives.
7. Identify required student assessment(s) and the relative importance of each.
8. Identify resources, keeping objectives and assessments in mind.
9. Allocate student time according to student assessments.
10. Sort and match possible student activities to objectives.
11. Monitor student progress according to assessment.
12. Evaluate and revise.

The steps are each explained briefly below.

13. **Identify Teaching Goals and Objectives.**
   - These items are available through department heads or supervisors. There should be complementary district and state level documents.

14. **Identify Required Student Assessment(S) and the Relative Importance of Each.**
   - There may be district, state, or national documentation of student progress in the form of:
     - achievement tests: standardized, benchmark, or teacher designed.
     - portfolios containing samples of work, evidence of product or performance, etc.
     - combination of test and portfolio.
   - Identify the relative importance of each instrument. If it is a required instrument and is used as documentation of student benchmark progress or standardized achievement, or for teacher or school evaluation by any public entity, such as the school district, or state or national government, that instrument has extreme importance in designing instruction. Examine old tests and samples of grading rubrics for portfolios and take them into account when planning student activities.

15. **Identify Resources Keeping Objectives and Assessments in Mind.**

   What activities are available to students both in and out of the classroom?
   What related activities are available in the Media Center?
   What activities have worked for successful teachers?
   What technology is in the classroom?
   What can be borrowed or signed up for?
Is there a computer lab?
What's the Technology Plan?

16. **Allocate Student Time According to Student Assessments.**

Class time should be allocated in proportion to student assessment(s). If half of student assessment consists of product or performance evidence contained in portfolios and half comes from standardized test scores, it is reasonable to schedule half of student time on portfolio activities and half on test preparation.

17. **Sort and Match Possible Student Activities to Objectives.**

**Test preparation and portfolio activities should coordinate.** If lab reports, research, and writing assignments are to be included in their portfolios, students should have basic knowledge and comprehension of terminology before starting the portfolio project. Constructivist learning research suggests that, given an assignment, a student will construct his needed body of knowledge, including vocabulary that would be covered on tests. While incidental learning that takes place during constructivist activities may be preferable to rote memorization, the practical issue of class time demands that student time and attention be spent on acquisition of basic facts. Unless students and parents can be relied upon to see that basic facts are acquired outside of class time, it becomes necessary to schedule class time for the acquisition of content.

**Students must be engaged.** Students can acquire lower level concepts (knowledge, comprehension, and application) using technology. With several learning resources or tools covering the same topic, each student can acquire necessary content at his own best pace. Technology automatically adjusts to the pace of the student.

- **Identify the product for the student.** The product, whether part of a portfolio or retention of certain body of knowledge, should be clearly identified to the student. If technology tools are used, they should identify small, achievable goals for the student and keep him aware of his progress.

- **Build product value for the student.** Student learning choices are made for individual reasons at any given moment. Teachers can become familiar with students' values through observation of student choices.

- **Learning should be relevant.** Portfolio and testing products should be related to students' lives. They will then become aware of the relationship of the topic to their own environment.

**Build from student Knowledge Base.** Use automated tools such as quizzes to assess student knowledge.

**Expand the Knowledge Base.** Let student move through acquisition of new information at his own best pace, in his optimum learning format. Technology with varied learning tools give students options that include text, graphics, and interaction.

**Reach for community-based problem solving.** The student becomes aware that his learning affects his community and, therefore, his own environment.

**Encourage higher level thinking skills through constructivist learning sessions.** Once the language and basic concepts are acquired to a degree that satisfies assessment, allow the student to reach into higher level thinking skills as his time allows. Each student will reach this point at a different time.
18. Monitor Student Progress According to Assessment.

Preliminary automated testing can monitor status of lower level content acquisition. Portfolio progress should be monitored often.

19. Evaluate the Activities Used and The Task Time Allotment.

Are they producing desired outcomes (assessments)? If not, other activities should be considered and/or time allotment adjusted accordingly.

What Happens?

Using technology-based learning resources such as The Digital Bridge, each student can work at his own pace to acquire the vocabulary and application skills needed to plan and carry out lab experiments or community based projects. When the student knows his goals, is given the means to achieve them, and can monitor his own progress as he proceeds, he can assume responsibility for his learning.

Using on-line learning resources, students who learn quickly, completing required quizzes over assigned units ahead of the rest of the class, can move on to automated tasks that encourage higher level thinking skills. For example, The Digital Bridge prototype unit on Motion contains links to web-based lab activities that allow the student to manipulate variables via the computer, observe consequences, and make predictions about other possibilities.

After students have acquired basic information via self-paced web or computer-based instruction, they can then join other students to work on projects or actual lab experiments. Each student will be at a slightly different place in acquisition of vocabulary and basic concepts. The differences are not important, since each has acquired, at his optimum rate, as much as he is able. The alternative of group-presented direct instruction would have resulted in holding back fast learners and losing slow learners.

Should teachers worry about abandoning the direct teaching of thinking skills? Bereiter (1999) says "Forget about teaching people to think. Teach people things that are worth learning. Focus on goals and problems that really matter. Create an environment in which quality counts but where people feel safe in taking chances to achieve it. Then the thinking will take care of itself." (Bereiter, 1999, ch. 10, p. 37)

Conclusion

As technology becomes available, K-12 classroom processes are changing. Trips to the media center for research projects are being replaced by Internet research. Constructivist learning activities are replacing learning based on behaviorist and cognitive learning theories. The teacher role is shifting from dispenser of knowledge to learning coach. Student assessment is shifting from standardized tests to portfolios based on a variety of student products. But we're not there yet. None of the shifts are complete. There is wide variation in the status of procedural changes between classrooms, between schools, and between school districts. As the changes take place, neither the technology nor the theories that evolve from research can have any positive effect unless they are passed on to the people at the front line, classroom teachers.

Teacher training must address issues that are relevant to practicing teachers. Individual learning differences and correct classroom time allotment are important concerns for every educator and student. By helping teachers identify and combine effective old methods with appropriate new technologies, the gap between reality and the ideal can narrow if not disappear entirely.

Abstract: As computer technology getting more and more advanced, educators have accepted the assumption that computer has a potential to renovate education and is necessary to enhance effective teaching and learning. However, computer is a tool and the value of this tool in education does not depend solely on its qualities (Maddux, Johnson, and Willis, 1997). It is its users, teachers and students, who make the difference. Teachers' creative use of available computing tools makes the teaching and learning more meaningful. Life long and self-paced learning is the key to the effectiveness of implementation. This paper is to review pre- and in-service teachers' computing literacy training in the past decades, discuss the current trends of computing education for teachers, and explore another perspective of implementation in pre- and in-service teachers' education.

Introduction

The growth and acceptance of computer technology in education have become undeniable, and computer application is believed having an important instructional role to play in the classrooms (Lockard, Abrams, and Many, 1997). Implementing technology in education is no longer the question of "should we or not" but "we must." Since the first computer was born in 1946, computer assisted instruction has experienced mainframe plus terminals stage, individual Apple or PC computer stage, and present network plus multimedia stage. As computer technology advances rapidly, educators have accepted the assumption that computers have a potential to renovate education and is necessary to enhance effective teaching and learning. However, computer is a tool and the value of this tool in education does not depend solely on its qualities (Maddux, Johnson, and Willis, 1997).

Computer literacy training

Computer-assisted instruction in education started in the early 60s and increased in the 70s. Since 1980s, more and more computers have entered schools, computer-assisted instruction has become a booming topic, and computer literacy is becoming a sensational buzzword in education. The assumption is that as far as teachers become computer literate, they will automatically use computers in the classroom and the potential of the computer technology in education will be unquestionably achieved. Therefore, computer literacy training for teachers is increasingly recognized. However, it is always a controversy topic. Started with programming centered approach, the teacher training has experienced with other
different approaches such as computing-curriculum focused, problem solving emphasized, and productivity tools anchored approaches. Each approach has had its proponents and defenders, and all have their critics. The common thread through the criticism has been that these approaches treat the computer as the subject matter, not the implementation.

Programming centered approach was dominated in teachers' computer literacy training in the early and middle of 1980s when microcomputers entered the schools in the late 1970s. Teachers attended the training mostly on BASIC (Beginners All-purpose Symbolic Instruction Code) language, few on PASCAL or COBOL languages. Teachers learned to write programs to tell computer what he or she wanted to do. Computer literacy therefore became a synonym of programming. Computers were then used for programming instruction instead of being implemented in curriculum-related instruction. The results of this approach turned out that a few teachers, mostly from math or science area, knew how to write and interpret a computer program to communicate with computers and became capable of designing simple drill and practice courseware. On the other hand, many educators just developed technophobia for themselves because of the training (LoCkard and Abrams and Many, 1997). Programming centered training seems to turn more teachers away from using computer technology than have teachers becoming computer literate to innovate their teaching.

Gradually, the computer literacy training was shifted to computing-curriculum focused approach. The literacy definition was broadened to become units or classes at different levels. With this approach, teachers received the training first on basic computer operating skills, such as how to boot up a computer and format disks. These were considered as "survival skills" that enable teachers to work effectively on a computer. Then the training was on the computer awareness. It was believed that the knowledge of computers would help teachers better understand what a computer can do and cannot do. Therefore, teachers were required to master the survival skills and become knowledgeable of the uses or misuses of computers before moving to the next level. The next level was application. Computing-curriculum was implemented across the existing curriculum or as new courses at various grade levels. Teachers at all levels and in all different disciplines were supposed to become "computer teachers," teaching computing unit for that grade. They learned to use word processors, spreadsheets, and database-management packages. It emphasized on the packages, which were available in each institution and could assist teachers to accomplish certain desired tasks. Programming was included in this approach; however, it was more considered as a skill to enhance students' ability to function as a problem solver. Logo programming language was taught in schools for the younger children and Pascal or Cobol for older students. This approach is no doubt helpful for some teachers to work at computers; however, one study of 125 Stanford professors in the middle of 1980s showed that 80% of them used computers to prepare lectures, handouts, and exams. About one quarter of them required students to write paper or analyze a database at computers. Examining the uses of computers in the classroom, it was found that only 13 out of 125 professors had actually blended the computer into their classroom (Cuban, 2000).

By the end of 1980s, developing problem solving ability became a universally accepted objective. The problem solving emphasized approach joined the computing literacy training. It tended to seek a new way to stimulate the use of computers in classrooms. However, few software packages were designed specifically for problem solving in depth. Although LOGO firmly dedicated to the mathematics problem solving, it was frequently taught as a change of pace, as a way to create pretty patterns, and as something separated from problem-solving. A survey conducted in 1989 among 660 faculty members in humanities and sciences found that 80% of the faculty members used computers to prepare handouts, 72% to design exams, and 62% to prepare lectures. In the classroom, only 10% actually used subject-related software (Cuban, 2000). The causes might be the time, the time to locate or develop problem-solving emphasized software and the time to conduct problem solving activities at computers. Problem solving approach turned out very time consuming and at the expenses of something else. Unless a teacher is firmly convinced of the value of the problem solving activity, comfortable and skillful in presenting it, he or she is unlikely to adopt it in the classroom voluntarily. Therefore, problem solving emphasized approach usually had a sensational start and ended as a product of miscarriage.

When computer literacy training turned against programming approach, found the computer-curriculum model difficult to implement, and proved problem solving was not realistic, productivity tools anchored approach merged in. In the early 1990s, there was a trend of looking at the computer as a tool and believing its effectiveness depends on the person's skills of using this tool. Followed was a teacher preparation program renovation, in which almost every teacher preparation program in the United States included either required or elective education technology courses to satisfy NCATE review. Computing
literacy training for teachers was therefore transited to the focus of productivity tools and applications one after another. The common sequences of the training were basic operating skills, word processor, spreadsheets, database, E-mail, and finally multimedia and WWW. The courses tended to provide teachers with the knowledge and skills of using these productive tools. Yet, a faculty survey in 1994 found even worse results of using technology in the classroom. 59% of 750 professors who taught undergraduates said that they never used a computer in the classroom; 10% of them used the computers occasionally and only 8% said that they used computers often. Since 1994, even much evidence of frequent use of E-mail and Internet among faculty and students occurs, less than 10% of the Stanford faculty frequently use these new technologies increasingly. Low-tech teaching exists in high-tech schools (Cuban, 2000).

Current computing education for teachers

Computing education for teachers nowadays is facing the challenge of how to integrate appropriate technologies and strategies for maximum learning. Since 1980s, computers have flooded into schools. Compared with the academic year of 1983-1984, the ratio of students to computers in the school has changed from 125:1 to 12:1 in 1995. A research has found that never a case in the history of American education has so much money been spent with so little thought given to implementation and so little demanded in return (Lockard, Abrams, and Many, 1997). NCATE has set the integrating computer technology in education as one of its criteria for the review of teacher education programs; however, what had been expected to happen did not occur. The implementation is still in struggling, like one jumping on the buses but having no clear destination.

The arguments of computing education for teachers are focused on the question that whether it should be technology course(s) driven or technology/curriculum combination driven in teacher education programs. The former is in favor of keeping or creating computing technology courses in the teacher education program. These technology classes provide pre-service or in-service teachers with different level of computing skills and strategies. It is believed that as far as teachers master these skills and strategies, they will automatically implement technology in their classrooms. The latter prefers to embed computing skill into all courses in the teacher education program, having computing skills and strategies integrated into each specific class. It is believed that pre-service teachers or in-service teachers who have enrolled in teacher education programs will gain the computing skills and strategies bit by bit and eventually be able to use the technology in their classrooms.

Most teacher education programs with technology courses-driven are more likely to have one or two required courses dedicated to the computing education. The courses usually cover productivity tools, e-mail and Internet skills, and multimedia productions. Curriculum/technology combination-driven program requires each curricular content course to integrate one or two computing skills and has course assignments reflect these skills. Should those technology courses be considered as required components in a teacher education program or be eliminated but have each curricular content course covers one or two technological skills? To be or not to be, that is still the question.

Rapid changes in technology pose another challenge for computing education for teachers in the current. Oblinger (2000) believes that these changes are due to four major technologies that will have an impact on global education in the 21st century. The four major technologies are processing power, digitization, networks, and storage. The rapid growth in microprocessor performance doubles every 18 months. It is predicted that the clock rates will move ahead and exceed one GHz or billions of instructions per second within the next decade. Digitization makes more work shifted from physical to virtual, and more new value-added services become possible by re-shuffling pre-existing information in new forms. Increasingly developed network makes it possible to transmit close to 1.2 gigabits of information over a network with current capabilities. That is roughly to transmit 85 books or 39,000 pages of text per second. Data storage has been expended so dramatically that it allows the text of 375 average-sized novels to be stored in a single square inch of disk surface. It is estimated that a high-density CD will have the capacity to store six billion bytes of information, equivalent roughly to one million pages of text.

Because of these rapid changes, technology will become an accepted tool for almost everyone and everything. The virtual will displace the physical for many tasks. The cost of technology is going down, and the access to the technology is becoming increasingly easier. Ideally, the lower costs and improved ease-of-use will allow teachers to use computers more often and implement technology in instruction and learning more effectively. However, few of us need reminders of the rapid pace in the technology industry. It is not difficult to realize that a computer may become out-of-date almost as soon as it is purchased, and
the technology training a teacher receives is no longer applicable almost as soon as he or she goes back to teaching in the classroom. Upgrading software and hardware is taking schools and teachers enormous time, energy, and money to catch up with the current. Should we or can we take a breath to think about how to make the implementation more meaningful or keep catching up exhaustedly with increasingly advanced technology? It is the question looking for an answer.

**Another perspective of implementation**

Computer is a tool. The actual value of the tool does not solely depend on its quality of advances. Creative use of the tool can make the difference. Common tools, such as Microsoft office and ClarisWorks, have more potentials to help teachers and students build up their dreams. Word processor has more powerful uses than paper writing; spreadsheet is not limited in compiling grade sheets; database can definitely go beyond the student records keeping; and PowerPoint is not only a presentation tool for teachers at all. The authors believe that unless teachers and students use the tool creatively, the implementation can become meaningful. The approaches of integration and applicable strategies of implementation can only be constructed with teachers' curiosity and enthusiasm of using the common tools, and the implementation can only be meaningful when these common tools are aligned with curricular contents.

Facing the rapid changes of computing technology, life long and self-paced learning is a key to the effectiveness of implementation. Obtaining technology training once or twice or having one or two technology classes is not enough. No single teacher education program will be able to provide schools with a fully and permanent qualified professionals. Few of us can anticipate what technology will be available a few months or years from today.

Therefore, implementing technology in teacher education program needs to emphasize the creative use of common tools, such as productivity tools (word processing, spreadsheet, database, and presentation tools), Internet and WWW resources, and multimedia applications. Since these common tools are available in the majority of schools and classrooms, let us have them integrated into disciplinary curriculum and make them be meaningful in teaching and learning. Technology courses will help teachers to master the use of these tools. Alignment of these tools with curricular disciplines will enhance the technology implementation in teacher education program. Meanwhile, teacher education program should encourage pre-service and in-service teachers to work collaboratively and to be initiative to explore new technologies whenever they become available. The commitment of being a life long learner is critical for a teacher to upgrade his or her implementation skills and improve the effectiveness of teaching and learning.

Abstract: This paper will review the traditional instructional media and technologies offered in teacher training programs in the past and in some of the programs today, primarily presentation media and technologies, such as audio/video systems, overhead, slide, filmstrip, and opaque projections, and multimedia kits. New technologies in digital information storage, access and retrieval, delivery, presentation, and electronic communications as related to instruction will be examined, discussed, and compared to the traditional instructional media and technologies. Approaches to integrating new technologies into teacher training curricula and programs will also be discussed.

Introduction

Lozano (1997) depicts a vivid picture of a classroom, where traditional media and instructional technology is used, "... the cumbersome and noisy opaque projector, of armloads of slide carrousels, tape players, and handouts resting on purple-stained fingers for trying to mimeograph that elusive image, only to arrive at a new classroom in which the security, on at all times, shone just over the projection screen." Lozano is not exaggerating. This is still the picture in some classrooms or instructional environment today. Some instructors are still using such instructional technologies like films, slides, analog video and audio, overhead projectors, and so on (Lozano, 1997). Not surprisingly, some educational technology programs for pre-service and in-service teachers still have these traditional instructional technologies on their curriculum list.

Instructional media and technologies vary widely in forms and uses. According to Teague, et al. (1994) and Heinich, et al. (1999), traditional instructional media and technology involves overhead transparencies, opaque projections, multimedia kits, 35mm filmstrips, photographic slides, motion picture films, audio recordings, video recordings, display media (chalkboard, pegboards, bulletin boards, posters, etc.), and object media (objects, models, mock-ups). Overhead transparency is displayed via overhead projector. It has been one of the most commonly used tools for presentations in the classroom. Opaque projector is used to present information in a similar way an overhead projector does, but it does not project transparencies. Instead, it presents images of printed materials or real objects. The advantages of using overhead transparency and opaque projection are that one can point to or block out part of what is being shown. On a transparency, one can also add drawings or marks while displaying information. With multimedia kits, one can display several types of media at the same time, such as books, drawings, maps, video recordings, etc. With 35mm filmstrips, one can present still or animated images with a filmstrip projector. A filmstrip can normally hold 25 to 60 frames of images. Photographic slides are made from film slides, but processed by being mounted in 2x2" frames so that images can be displayed via slide projectors. Motion picture films are more vivid when they are presented in the classroom. However, the presentation
requires a 16mm film projector. Traditional audio and video recordings use magnetic tapes to record audio or video information. An audiostreamer/recorder/player is needed to record and playback audio content. For video, a video camera is required for shooting videos and a videocassette recorder/player and a monitor are needed for playing back the video. Today, most classrooms are equipped with a TV set and VHS VCR for video display. To edit these analog audio or video is a very tedious and time-consuming job, and additionally, professionals and professional equipment are needed for creating high-quality video materials. Display media usually refers to those non-projected visuals, which have been used in instruction for a long time, such as the chalkboard and multipurpose board.

Typically the instructional media and technologies used in schools reflect the curricula of our pre-service and in-service teacher training programs. Teacher training programs determine, to some extent, the diffusion and effective use of new technologies in schools because the trained teachers use the technologies that they were trained with back in their schools. In this sense, the technology that schools will use in the future rely much on the curricula we provide in the teacher training programs today. By examining curricula and textbook contents in some teacher training programs in instructional technology or educational technology, the above mentioned traditional media and technologies are still being taught as major instructional technologies. "Audio Visual Materials," "Print & Non-print Materials," "Television," "Film," etc. are frequently seen in teacher training curricula. Looking at schools, it is not difficult to find that teachers are still depending heavily on the traditional media and technologies listed above.

According to Villamil-Casanova and Molina (1997), we are now living in an information age. In this information age, computer-based multimedia technology has become a major tool for communicators and an effective catalyst for change in all disciplines. Not only has computer technology led to changes in our living environment, but it has also generated changes in our learning environment. Increasingly advanced computer and communication technologies are having an enormous impact on the ways in which educational materials are created, stored, acquired, and delivered to the learners (Barker, 1998). At this juncture, it is the time to create curricular materials to train a new generation of multimedia-assisted communicators (Villamil-Casanova & Molina, 1997). Several "change agents" identified by Barker (1999) are bringing about changes in many academic institutions, and they have served as a catalyst in the change of instructional media and technology. These "change agents" are ease of educational material creation, ease of information storage, ease of access to and retrieval of information, ease of fast and global information sharing, ease of electronic communication, and ease of information presentation and display.

### Ease of Educational Material Creation

Traditionally, a variety of appropriate facilities, equipment, techniques, and materials are required to create desired educational materials. Transparencies have to be made and overhead projectors have to be used in order to present information to a larger audience such as in a classroom. Rolls of films have to be consumed in order to create filmstrips. No doubt, special techniques are required to shoot the filmstrips and have them developed before they can be projected with a filmstrip projector. Photographic slides have to be framed in order to be projected on a slide projector. To make photographic slides, one has to use cameras to shoot the images, and techniques to operate the camera, develop the film, and mount the slides are required. To create bulletin boards, letter-cutting device and coloring tools are needed. To create drawings, charts, graphs, posters and the like, various tools and techniques are required. In order to produce high quality sound or video materials, much more sophisticated facilities, equipment, and materials are required, and well-trained professionals are needed, which makes educational material creation very expensive and difficult.

Today, however, all the above-mentioned educational materials can be created with a single tool--computer, though some peripherals and extra compatible equipment are required depending on necessity. Software packages, such as Microsoft Office and ClarisWorks can be used easily to create charts, graphics, and drawings. Electronic bulletin boards can be created with computer and put onto the network or Internet. Digital camera or scanner can be used to capture digital images. Then using computer, we can create slide shows. Computer sound card and compatible software, such as Sound Forge or Wave Studio (for PC), or Sound Edit (for Macintosh) can be used to produce digital sound or music materials. For video material creation, analog video can be digitized using video capture boards, such as Targa 2000, AV Master, Video Blaster, MiroVideo DC30 Plus, etc. The captured digital video can also be edited with such non-linear video editing software as Avid Xpress, Media 100, Final Cut Pro (Macintosh only), Premiere, Speed Razor, Trinity,
just to name a few. More recently, a standardized digital video interface called FireWire interface (IEEE 1394) provides direct connection between a computer and a digital video camera, such as Canon GL-1, which has made digital video creation and editing much easier and time-saving than before.

Ease of Information Storage

Computing technology has made information storage much easier than ever before. Without computer, documents are stored primarily in printed materials. Books, magazines, newspapers are the major media for delivering stored information. Information in other formats, such as sound and video, is stored in audiocassette tapes and videotapes. To save documents, students have to either write them down in a notebook or type them out with a typewriter, or make photocopies. For audio and video, students have to have audiocassette recorder/player to store information on audiocassette tapes and VCRs to store video information. With a computer, however, one can digitize information and save it to a single storage device—the hard drive, or on a floppy disc, removable drive, or optical device with simple button clicks. Furthermore, digitized information can also be saved onto networked servers. This technology brought about the success of information sharing on the Internet. To say it is easier on storing information, not only because of saving data by simply selecting Save function from the menu bar on the, but also due to the ease of making corrections of the stored information. For traditional printed media, it is almost impossible for the writer or reader to make any changes to the original material without repeating the entire creation procedures. While in the process of writing or typing, making changes is no less a hassle practice than that on printed media, let alone making changes in the recorded audio or video information. But information stored in a computer, regardless of its format, can be modified at any time, except when the file is created read-only or burned on to a CD-ROM.

Easy of Access to and Retrieval of Information

The primary way of accessing information before this computer era was to go to a library, search the card catalog, and check out whatever was needed. The real labor was not going to the library itself and check out materials, but the tedious job of going through all the card catalog to find where the information is. The same is true with finding audio and video materials. Whereas with today's networked computers or online computers, one can easily log into a library’s database to search for information regardless of the format. For some people, they can do it even without going out of their office or home. Today's Internet, especially the World Wide Web, has become almost an open library, providing information in all formats, text, graphics, images, animations, audio, and video. Many classroom teachers begin to use networked computers to access information for their students during class time. Moreover, teacher-created web pages are on the rise. These teachers put their teaching materials onto the network and/or their own web pages to allow students to access course syllabi, instructions, assignments, test materials, and the results of evaluations directly from computers at school or home. Location is no longer a boundary for accessing information. At home, one can use dialup feature to get onto the Internet through a modem. On campus, students are provided with Internet access from either computer labs or dorms. Even when traveling, one can search information on the Internet by using laptop computers that have Internet access capability. Card catalog system, though simple and inexpensive, but slow and time consuming, has given its position to the fast computer-based automated cataloging system in almost all the libraries in the United States.

Ease of Fast and Global Information Sharing

Because of the ease of creating digital media and material and the ease of storing, accessing, and retrieving information, information is now shared unprecedentedly faster and around the global. Traditionally, information is shared through local public media, such as newspaper, magazine, radio, television and even books. All these take certain time, material, and manpower for creation and then are delivered to the readers or viewers through complicated distribution channels. Educational materials are shared in the same manner. The disadvantages of traditional information sharing is the time delay between
the transformation of information into certain format, such as printed books or magazines, and the
information receiver; the duplication of information resource, material, and manpower; and the high cost of
distribution. A book on science would take normally over a year before it could reach its readers. A piece of
information resource has to be duplicated into numerous copies in order to meet multiple users' demands.
Large quantity of materials is consumed for distributing one single information resource when copies of the
resource are duplicated, such as book copies or video copies. Meanwhile, matching manpower has to be
involved in the duplication and distribution of the duplicated copies. However, information technology has
changed fundamentally how information is shared.

Today's information sharing is moving toward on-line formality. Information is stored digitally and
put into either local network for local sharing or onto the Internet for global sharing. To share information
on-line, there is only minimum information resource duplication since the resource, once on-line, can be
accessed without time and place restriction (unless the resource is purposely controlled in that way). Since
resource duplication is minimized, materials and manpower required for the resource duplication is reduced
to the minimum, too. Books, magazines, newspapers, audio and video materials have all been witnessed on
the Web today. For example, a book can be saved as PDF (portable document format) file and put onto the
Web. With Acrobat Reader software, one can either read it or print it out easily, or download it to the local
drive and read or print it later on. Only one resource and one distribution channel, the Web, needs to be used,
and it can be accessed twenty-four hours a day, seven days a week. Sharing multimedia information on the
Web has become a trend, challenging the superiority of CD-ROM, one of the major media devices for
multimedia distribution today.

Sharing information on-line is also changing the way we teach in schools, where computers are in
use and wired to the Internet. The traditional one classroom with one TV/VCR environment is being
replaced with one-computer or multiple computers plus Internet environment. Teachers therefore can share
global information with students in their classrooms. They can create their own web pages easily with web
authoring tools such as Learning Space, TopClass, Quest Net Plus, and the like, and have their web resources
shared not only with their own students, but with other students and colleagues in the world.

Ease of Electronic Communication

Electronic communication has been in use for decades, but never before has it been so popular and
easy to use as today, due to the availability of computers and the Internet. E-mail, used by millions of
people, has become a daily activity for most of us. In recent years, voice mail, video email, and desktop
video conferencing have gained popularity. Microsoft's Net Meeting is being used by millions of people
around the world for on-line video communication. PC-to-PC calls, particularly PC-to-Phone calls such as
MediaRing Talk and DialPad, are attaining prevalence. Without exception, the ease of electronic
communication is affecting classroom instruction greatly. Distance education is the area where a revolution
has been witnessed. "Correspondence course" and educational TV are no longer representing distance
education. Instead, in its place arise communications technologies. E-mail and webboard are used to offer
on-line courses. World Wide Web is employed to offer web-based courses. Two-way interactive video
network, which involves computers, compressed video technology, telephone lines, and television
technology, is taking the lead in distance education to deliver live courses over a great distance. A recent
study found that 58% of two-year and 62% of four-year public colleges offer such kind of distance education
courses (Hodgson, 1999). Furthermore, virtual universities (Barker, 1999), which hold no campuses, have
been set up to offer complete degree courses on-line.

Ease of Information Presentation and Display

Traditionally, in the classroom, information is displayed by using chalkboards, multipurpose boards,
pegboards, bulletin boards, or flip charts (Heinich, 1999). They are teachers' basic instructional tools.
Though simple to use, instructors have to manually write things on and erase them off every time when they
use chalkboards or multipurpose boards. Writing and erasing on these boards in the classroom consume
plenty of valuable instruction time. To project instructional materials in the classroom, overhead projectors,
slide projectors, and the like have to be used. To display video information, TVs and VCRs have to be available.

Information technology has brought tremendous impact on classroom presentation and display today. Computers can be used to create teaching notes for classroom presentations. PowerPoint has been a favor of teachers and students for classroom presentations. With PowerPoint, presentations can be made and modified shortly before the actual presentation. The advantage of using this software for presentation also lies in its ability to incorporate images, graphics, charts, animations, even sound and video. Presentations can be saved digitally and reused at any time later on. No more tedious and labored work on preparing presentations with traditional presentation tools! No more chalk dust or the labor of writing and erasing on boards because all these jobs can be done on a computer! Another advantage of using digitized presentation is that if the presentation is saved on the network server the instructor can pull up the files and make presentations with computers in other classrooms or at other locations as long as these computers are on the same network. Or the digitized presentations can be put onto the Web and displayed with web browsers.

Of course, a projector is needed if the computer presentation is to be projected. A LCD projector such as Infocus, Proxima, and 3M will do the job. Since images, graphics, charts, animations, sound, and video are all digitized and/or incorporated into computer software, LCD projector can project them without involving other equipment. A LCD projector is relatively expensive at this time, but it will be commonplace as we move into the new millenium since the cost is falling.

Image display has taken dramatic change from the traditional instructional technology to today's advanced computer technology. Filmstrip technology has already become an antique. Slide projectors and overhead projectors are being replaced with digital projectors. Opaque projectors have given their positions to visual presenters like Elmo (also called document camera). Scanner is now used to digitize film-based images. Digital camera eliminates film by digitizing images on a chip, like Kodak DC series or Sony's Mavica, which captures images directly to a floppy disk. Using software like Photoshop, the digitized image can be edited and incorporated into various kinds of applications for display, which are almost impossible for traditional printouts.

Traditional video display has been relying on TV and VCR. Analog video creation is expensive and complicated. Editing analog video is more expensive and complicated. It requires high-end facilities, very expensive equipment, and well-trained professionals to complete the job. Laser disc has been accompanying TV and VCR in the display for some years. The size of the laser disc is huge, and it can only hold about 30 minutes of video on one side. However, today's video creation and editing is no longer as it was in analog video, thanks to the digital technology. Digital video, as mentioned earlier, can be captured using digital video camera and transferred to computer easily by using standardized interface. Non-linear digital video editing has completely changed video editing system. After the video clip is digitized, all needed for editing is the computer and compatible software. Video clips can be cut and expended to the specific frame. Video effects can be superimposed with almost unlimited layers. Sound can be added and edited with simple clicks, drags, and drops. Tools for shooting video footage are turning into digital, too. New DV video cameras or camcorders can capture video in digital format directly on the videotape. The cost for a DV video camera has dropped drastically. Couple of years ago, a high quality DV video camera would cost between $10,000 and $20,000. Today, a Canon GL1, with the same high quality, is only around $2,000. This DV video camera has a LCD color-viewing window, and it can serve as a viewing monitor for editing. This new digital video technology makes video capturing and editing at an affordable level, even for home entertainment.

While video turns digital, presenting video on the Web is challenging for new technologies. Video files are usually very large, making it much difficult to be played back on the Web. Nevertheless, new technology has made it possible with relatively lesser problems. To solve the playback problem on the Web, video compression is used. The technology is also called streaming video. The three major web video players on today's market are Apple's QuickTime, Microsoft's Window Media Player, and RealNetwork's RealPlayer.

Curriculum Issue

Giving money to schools or purchasing new technology for schools is a way to insure that schools get the new technology, but it is not an effective way for integrating technology into instruction. Over the past decade, school districts have spent billions of dollars on classroom technology, yet the classroom has changed little (Yao, et al., 1999). One of the major problems that schools are encountering is the lack of...
trained teachers who know how to use and diffuse the new technology. To solve this problem and help schools use new technologies, especially the new instructional media and technologies, we need to shift the training focus into the renovation of the curriculum for pre-service and in-service teacher education programs. Graduates from a teacher training program should be the leader in using and diffusing new technology in schools, but they can not take up this responsibility if they are not trained with new technology while they are in the teacher training program.

Experience tells us that appropriate curriculum change can make a big difference. Curricula designed for technology should follow the current technology trend. Courses designed for technology should follow a sequence, which introduce technology in an adaptive and logical manner and introduce current technology that are appropriate for schools. Some teacher training programs have only introductory courses on computer literacy, which focus on basic computer applications, such as word processor, spreadsheets, database, and so on, but do not have introductory course on instructional media and technology. Some may have courses on instructional technology, but those courses still hang on to the traditional technologies. This problem needs to be addressed. In addition to introductory courses on computer applications, a course, which introduces current instructional technology, should be arranged for new students in the program. Also introductory courses on instructional design, human computer interaction, and learning theories should be offered. Based on these courses, other courses offering digital audio and video, web design, multimedia production, and courses of such nature should follow. This kind of design for teacher training program can help ensure that students trained in this program will have the knowledge and techniques on using and diffusing the current instructional technology.

Conclusion

It is apparent that computer-based instructional media and technology has far more greater advantages over traditional media and instructional technology in almost all the aspects: Educational material creation, information storage, information access and retrieval, information delivery, and information presentation. Moreover, the industry is switching from the traditional technology towards the new digital media and technology. As digital media and technology advance in the new millennium, some of the traditional instructional media and technologies will remain in use, most of them will give way to the digital world. It is the time when we can say a farewell to the traditional media and technology as we walk into the new millennium.

Abstract: This paper reports on the design, development, and application of a Checklist intended to assist educators in recognizing strengths and weaknesses in their technology-based programs at their institutions. The Checklist sampled public and private schools to validate the existence and impact of the Technology Facade. Initial findings indicate that schools have masked the effective use of computers labs and classroom computers behind the auspices of teacher activities, student participation, and parental involvement. The study and suggests possible courses of action to address deficiencies in the use of technology, the construction of the necessary infrastructure, and the design of a viable instructional strategy.

Introduction

The Technology Facade...have you seen it? Has anyone mentioned it to you? Do you know what it is? Although a precise definition may elude us at the outset, as dedicated educators, we probably know it when we see it. Consider these scenarios....

"A state-of-the-art computer lab is filled with Macintosh or Windows personal computers. They sport the latest processor, the fastest CDROM player, the largest memory capacity, and the most sophisticated multimedia sound system. But students are not permitted in the lab after school and no one can use the machines unless the computer teacher is present."

"A school district handbook contains a Technology section lauding the expensive inventory of hardware and software recently purchased and installed courtesy of the local PTA. After nearly two years of bake sales, candy drives, and magazine campaigns, we have the most up to date computer systems available. But not a single teacher, much less any member of the staff, has been. Students know more about how to operate these tools than their teachers."

And, finally... "A technology coordinator briefs visiting dignitaries on the benefits of computers to our school. No one asks the teachers. And, of course, the technology coordinator does not have the educational vocabulary much less the classroom experience to communicate with teachers who are being pushed to integrate technology into their curriculum."

Do any – or all – of these scenarios sound familiar? If so, welcome to the Technology Facade. Much like a guided tour through the back lot of a famous movie studio, with its false fronts and hollowed out sets, the Technology Facade presents a false sense of activity and substance with respect to the uses of technology in the school. Shiny computer labs, ill-prepared and overworked technology coordinators, and last minute budget re-adjustments run counter to a technology-based curriculum that deserves to be grounded in proven pedagogy, a viable support infrastructure, and sound fiscal propriety.

For many schools (and many more students), this is the reality of technology in the classroom. This article will help you recognize the Technology Facade in your district, your school, and most importantly, in your classroom whether that be as a teacher, student, or concerned parent. The Facade can only be overcome by a steadfast refusal to be taken in by what appears on the surface. It takes a willingness to displace the facade with a robust structure to bring about real change in the classroom of the 21st century.
Defining The Technology Facade

The Technology Facade is best described as “the use of technology in a school without benefit of a necessary infrastructure to support its application as a viable instructional strategy.” Key elements of this definition provide some common understanding about terminology: technology, infrastructure, and instructional strategy.” The Technology Facade occurs when we fail to understand that the educational imperative of technology involves the integration of computers and software with learning strategies, developmental principles, and pedagogical ideals to solve real-world educational problems. The Technology Facade occurs when we fail to understand that technology is an on-going process that demands the time, attention, and dedication of many competent people; a significant and consistent level of financial investment; and, a commitment of resources that will necessarily be diverted from other critical school-wide obligations. And, finally, the Technology Facade occurs when we fail to equip our teachers with the necessary skills to successfully prepare, present, and evaluate instructional lessons using technology.

The Study

The Technology Facade Checklist (Tomei, 1999) was developed for application to schools and school districts. A selective sample of public and private schools was chosen to validate the Checklist and to test for the existence and impact of the Technology Facade on a variety of institutions representing a range of student populations, ethnic diversity, teacher preparation and in-service programs, financial support capability, and instructional focus. In conjunction with the Technology Facade definition, the 20 item Checklist includes questions categorized as Use of Technology, the Necessary Infrastructure, and a Viable Instructional Strategy.

Use of Technology. Questions pertaining to the Use of Technology focuses on access to computer facilities, incorporation of technology-based competencies in classroom lessons, status of hardware and software, use of computer facilities for classroom instruction, and the ratio of students to computers (in both classrooms and computer labs). They include:

1. Are the computer labs in your school used by classroom teachers or is the computer teacher the only educator who dispenses technology-related instruction? This item uncovers the practical, daily applications of technology by all teachers within the school, not only the computer teacher.
2. Are computer facilities locked or are they available to teachers and students during recess, study halls, lunch, and before and after school or when there are no classes scheduled? This item determines whether computer facilities are for “show” or provide a workplace suitable for teacher and student advancement in technology.
3. Are teachers expected to include specific learning objectives related to technology-based competencies in the Lesson Plans? Teachers should incorporate specific learning objectives dealing with technology in their lesson plans; most states already require technology-based competency standards.
4. Does the software found on computers reflect current classroom curriculum? Or, is the computer software outdated, seldom reflecting what student are doing in the classroom?
5. Do classroom teachers use computers for grades, lesson preparation, out of classroom assignments, and professional self-development? Many teachers are forced into using technology by principal, peers, or parents. This item examines four particular uses that evidence commitment on the part of teachers to model and demonstrate technology in the classroom.
6. Are major computer facilities located in the school’s Library, classrooms only, or a majority of regular classrooms? Most schools are moving away from the computer lab as the single focal point for classroom technology. This item awards extra points for those schools who are integrating technology in the classroom.

Necessary Infrastructure. Items regarding the Necessary Infrastructure include related issues of teacher training, preparation, and incentives; strategic technology planning and funding; professional staffing of technology facilities; and, replacement policies for the school’s technology. They include:
7. What is the extent of technology training received by teachers? Research has found that many of our teachers have received no training or initial training only in technology. Others receive in-service training on technology or are provided training classes upon demand. The very best are offered formal programs in instructional technology programs.

8. Who is participating on formal committees, teams and boards pertaining to the use and development of technology in the school? Schools tearing down the Technology Facade include teachers, administrators, parents, alumni, community leaders, and even students on their committees for technology budget preparation, curriculum technology, technology planning, and hardware and software acquisition.

9. Are technology funds provided by PTA magazine drives and bake sales and end-of-year fallout monies or is it included in the General Operating Budget as a specific, recurring line item? A critical measure of the Technology Facade is whether technology is given equal weight with other school programs and projects or funded with leftover monies at the end of the academic year.

10. For teachers who develop technology-based instructional materials, do they receive compensatory time, monetary compensation, or other specific remuneration? If not, perhaps the school has recognized excellence via school newsletters, bulletins, and school board reports. Regardless, the Technology Facade is greatly affected by teacher attitudes. If the school sees no merit in instructional technology – and evidences that value with tangible rewards – teachers will ignore the rhetoric to the detriment of the technology program.

11. Is there a Technology Plan for the school and is it revised on a regularly scheduled basis? A viable Technology Plan is critical to meeting the long-range goals of the school.

12. Does the school's Technology Plan contain the following: vision/mission statement; demographics; procedures for purchasing, maintenance, facilities, and security; curriculum impact; a plan for the use of technology for lifelong learning, special needs learners, and exceptional learners; and, an evaluation plan? Many plans are in "name only." A viable Technology Plan includes most, if not all, of the items mentioned in this Checklist question.

13. Does your school provide a computer teacher, computer technician, and/or a technology coordinator? Most schools in the grasp of the Technology Facade place all of these responsibilities in the hands of a single individual – sometimes even a teacher with a full or part time load.

14. Are the majority of computers in the school less than two years old, CDROM-capable, connected to the Internet? Some schools will declare their commitment to technology and still employ outdated systems incapable of running today's educational software packages and unable to access the wealth of materials on the World Wide Web.

Viable Instructional Strategy. Analysis of a Viable Instructional Strategy is supported by questions related to scope and sequencing of technology-based skills/competencies; use of lesson planning for technology-based learning objectives; incorporation of teacher vs. professional materials; and, student assessment of learning opportunities with regards to technology. They include:

15. For technology-based lessons, has the school developed a "scope and sequence" to include technological competencies for all students, by grade and subject area? "Scope and sequence" is a tool used by educators to design a curriculum with explicit learning objectives (scope) delivered in a precise arrangement (sequence).

16. Is there evidence of behavioral learning objectives that include the components of behavior (action to be performed), condition (tools to be used in the instruction), and criteria (assessment standards) in these lesson plans? A teacher's lesson plans should include specific learning objectives (based on a preference for the behavioral, cognitive, or humanistic teaching style) when using technology-based resources.

17. When using technology-based lessons in the classroom, do teacher prepare their own Handouts, study guides, and workbooks to guide the lesson presentation? An over-reliance on "off the shelf" instructional materials is one indication that teachers are not truly committed to learning how to use instructional technology. They should be designing some of their own materials to ensure the instruction is addressing the learning styles of their own students.

18. When classroom teachers wish to use technology resources to present a lesson, are the computer labs available for scheduling without significant delays or are they always filled with students who are "required" to receive a certain amount of lab time each week? The Technology Facade manifests
itself by computer labs occupied by students who are there only because “every student gets two hours of computers every week” whether they are addressing technology competencies or not.

19. Do students in the computer classroom/laboratory describe their experience as play time or preparing them for self-learning and future vocations? Students know when their computer time is productive. The Technology Facade Checklist actively solicits their input.

The Technology Facade Rating. The final item on the Checklist (Item 20) rates the School and compares their Composite Score against the following Standard, see [Table 1].

<table>
<thead>
<tr>
<th>Total Possible Point: 200</th>

</tbody>
</table>

Table 1. Technology Facade Rating

Findings

See [Table 2] below. The primary component which seems to detract most from the successful implementation of technology is, not surprisingly, the Necessary Infrastructure. On average, the sampled schools lost 57.6% (58.8 out of 102) of their possible points in this category. On the positive side, the Use of Technology scored highest with 62.4% (39.3 out of 63) of the possible points. A Viable Instructional Strategy found middle ground with 59.4% (20.8 out of 35).

Table 2. Technology Facade Checklist Results

It is interesting to note that several questions contributed to overall low scores more than others. For example, few schools provided any incentives (Item 10) for teachers who went the extra mile to prepare technology-based materials for their classroom. Items 3, 15, and 16 contributed to an overall poor showing with regard to lesson planning and learning objectives – a trend that should demonstrate the need for school administrators to begin working more closely with their teachers with regards to curriculum redesign to integrate technology into classroom instruction.
Conclusions

In the final analysis, most schools sampled merited a solid C Rating with an average Composite Score of 118.9 points. Only one school warranted an A Rating and several received the F ranking. An interesting note: many schools had an intuition, before applying the Checklist, that their institutions would fare much better than they actually did. Several administrators were terribly disappointed in the final results; however, none questioned the validity of the checklist, the appropriateness of the points awarded, or the areas of emphasis for the purpose of assessing technology-based school programs.

The Technology Facade is all too real. Does it exist in your school? The Checklist can help you recognize problems with your school’s instructional technology program. Share the results with your administrators -- along with your volunteer statement to help tear down the Technology Facade and replace it with a viable program. Good luck.

Technology Planning and Technology Integration: A Case Study

Dr. Linda Espey
Heartland Area Education Agency 11 and Drake University
Iowa, USA
lespey@aea11.k12.ia.us

Abstract: The purpose of this study was to consider how the development of a school district technology plan facilitates meaningful use of technology in the classroom. One school district’s experiences were the focus of the case study, from the formation of a technology planning committee to the implementation of an expanded use of technology in upper-elementary classrooms. Components of the research include document analysis of a district technology plan, interviews with technology plan committee members, fieldwork observations and interviews with teachers. The study demonstrated that effective technology planning can lead a district through establishment of a technology infrastructure, including a district-wide network, Internet access to all classrooms, and high quality staff development. Findings suggest that teachers need curriculum integration support, beyond what is often provided in the technology plan, in order to take full advantage of available technology.

School reform continues to be a focal point in education today, as it was in 1983 with the publication of the A Nation at Risk report (National Commission on Excellence, 1983). School improvement planning and technology integration are two areas that emerge from the reform agenda in K-12 education today (Mehlinger, 1995; President’s Committee of Advisors on Science & Technology, 1997). Technology integration is offered as one of the cornerstones of the school reform effort (Collins, 1991; David, 1991; Kelly, 1990, Pearlman, 1989). However, Mehlinger makes the point that “we have scarcely begun to understand the role technology will play in schools of the future. ...Technology is not merely another reform idea, like site-based management or ungraded elementary schools; it will force a reconsideration of the very nature of schooling itself” (Mehlinger, 1995, p. 8). Schools are investing large sums of money into hardware and software, with the expectation that teachers will use instructional technology to improve student learning (Hope, 1995; Means & Olson, 1994; Office of Technology Assessment, 1995). Research shows that technology use in classroom instruction is increasing, however, meaningful integration into the curriculum remains the exception rather than the norm (Dryli & Kinnaman, 1994; O’Neil, 1995).

Researchers have identified many barriers to the use of instructional technology (Marcinkiewicz, 1994; OTA, 1995; Smith & O’Day, 1990), including lack of access to suitable hardware, poor quality software, inadequate staff development, lack of technical assistance, and teacher resistance to changing instruction. Planning guides for technology advise school districts to address these issues in their strategic plans and administrative practices (Dryli & Kinnaman, 1994; Kimball, 1996; Kimball & Sibley, 1997). However, it is difficult to sort out the factors related to the planning process from the implementation factors involving changes in instruction and learning.

The state of Iowa made efforts to help school districts make advances in use of technology through state funding initiated in 1996 (Iowa code, §295, 1996). A requirement of the funding was the development of a multi-year technology plan. The purpose of this case study was to examine whether development of the required technology plan facilitates meaningful use of technology in the classroom. The study began with the selection of one Iowa school district, Boone Community School District (Boone CSD), based on its strong technology plan document. The district's planning process of 1996/97 was examined retrospectively. The study then followed the implementation of a planned technology integration project at the upper-elementary classroom level. Each classroom, grades 3-5, received a second computer at the beginning of the 1998/99 school year, explicitly for student use. Classrooms doubled their access to technology by having available two multimedia, Internet-capable computers and the means to display the computer image on a classroom television. For teachers not yet using technology with students, this new addition to the classroom sent the message that technology should be integrated into the teaching and learning process.
Review of Literature

The President’s Committee of Advisors on Science and Technology (PCAST, 1997) recently published the Report to the President on the Use of Technology to Strengthen K-12 Education. In the report, the promise of technology’s role in school transformation is expressed.

While a number of different approaches have been suggested for the improvement of K-12 education in the United States, one common element of many such plans has been the more extensive and more effective utilization of computer networking and other technologies in support of a broad program of systemic and curricular reform. Particular attention should be given to the potential role of technology in achieving the goals of current educational reform efforts through the use of new pedagogic methods focusing on the development of higher-order reasoning and problem-solving skills. (p. 6-7)

While Kimmel and Deek (1995) agree that technology can play a key role in the school reform effort, they warn that educational technology should not be considered a “panacea for educational reform” (p. 327). They stress that curriculum, in the hands of good teachers, should drive the use of technology. They identify active student involvement and integration of technology as two educational practices growing out of the school reform movement. Collins’ (1991) survey of the literature on the role of computer technology in school reform agrees, but he adds that classroom use of technology may help to reduce the didactic style of teacher-led instruction and allow a more constructivist practice in teaching and learning (p. 36).

Although gains have been seen, the full impact of instructional technology has only been seen in a small portion of classrooms (Becker, 1994). This is due in part to administrative and organization factors at the district-level. To help with these district-level decisions, a number of guides to the technology planning process have been developed (Anderson, 1995; Kimball & Sibley, 1997; NCRTEC, 1996). In a study of technology planning in California schools, Kimball (1996) identified components of strong technology plans by reviewing available educational research and planning guides. He then confirmed the findings by surveying technology practitioners in California. This process yielded nine essential components for a strong technology plan (Kimball, 1996, p. 74). These components are (1) broad-based support in the planning process, (2) comprehensive needs assessment, (3) vision based on the school district’s overall vision, (4) goals based on the vision, (5) action plans for achieving the goals, with timelines, responsibilities, and budget, (6) plan for evaluation of progress, (7) multi-year planning, (8) elaboration on the curriculum integration of technology, and (9) planning for staff development. In Kimball’s examination of the plans required by California legislation, he found that only 47% of the districts submitted plans, and these were of “questionable quality and indeed, ... for the most part inadequate” (Kimball, 1996, p. 83-84). Dyrli and Kinnaman (1994) also found technology plans to be inadequate. The focus of many technology plans has been on hardware acquisition, resembling a shopping list of the latest fads, without apparent thought to integration into teaching and learning.

To remedy this situation, most planning guides recommend that the technology planning committee begin by identifying the district’s vision for learning, then determine how technology can support that vision. Only then is the committee ready to begin the process of needs assessment, goal setting, and action planning.

To better understand these issues, two research questions were addressed. (1) How did Boone Community School District develop their technology plan? (2) How did the district’s technology planning process impact the integration of computer technology into the teaching and learning process? Descriptive, qualitative case study was selected as the primary research method for the examination of the efforts of technology integration in one school district. Components of the research included document analysis of a district technology plan, interviews of people involved in the technology plan preparation, fieldwork observations and interviews with teachers.

Findings

The Iowa School Improvement Technology Act (Iowa code, §295, 1996) required school districts to submit a board-approved technology plan to their regional Area Education Agency (AEA) by June 1, 1997. Boone Community School District began to develop their plan in September 1996. The development process was detailed during interviews with seven members of Boone’s Technology Committee and through review of the completed Educational Technology Plan (Boone CSD, 1997).

Important components of the technology planning process that emerged from interviews include "Committee Membership and Organization," "Committee Scope of Responsibility," "Knowledge-building," and "Decision-making and Writing Process." These components are illustrated in Figure I.
The formation of the Educational Technology Planning Committee was a first step in the development of the plan. Members were selected by the assistant superintendent to represent the elementary buildings, middle school, and high school. Community members and support staff were also selected. All of the district media specialists served on the committee. The committee met monthly throughout the school year under the leadership of the assistant superintendent and district media specialist. Members felt the Technology Committee represented the district well, although having twenty members made the process difficult at times.

After initial work trying to write a vision statement as a whole committee, the need for subcommittees or work groups was recognized. A vision subcommittee was formed, as well as other subcommittees to investigate hardware, software and curriculum, personnel, staff development, and staff competencies. The subcommittees met as needed to discuss options and develop recommendations to the larger committee. Subcommittees were credited with allowing leadership to emerge. One member commented,

We had members of the committee who were very effective. When we divided up into subcommittees different people took leadership roles and really got their subcommittees going.

The district's superintendent did not directly participate on the Technology Committee but a committee member commented, “He met with our committee maybe the first meeting and said his main concern was to get more technology, especially computer technology, into the hands of the kids.” The superintendent was also instrumental in authorizing the Technology Committee to allocate the budget available through state technology funds and other sources.

Committee members and district administrators recognized their scope of responsibility to include hardware, software, technology support personnel, staff development, and networking. Several members mentioned that the superintendent, when asked to make a decision related to technology, would suggest that the person “take it to the technology committee and see what they want to do.” Looking back over the past years since the plan was written and approved by the board, one committee member expressed, “I think that our committee really worked hard that first year, but I think it has been rewarding because our plan does actually guide what we’re going to do.”

Committee members spoke about areas of knowledge they needed to develop in order to complete the technology plan. They needed to learn about effective planning processes, the existing situation in their schools, and the range of possibilities with instructional technology. They gained this knowledge through research, participation in an AEA Technology Planning Institute, and by conducting needs assessments.
The Technology Plan was written over a period of one school year. The process required the committee to make many decisions related to vision, goals, and priorities for action. They divided into subcommittees for some of their tasks, but they came together to vote on priorities at the end of the year. The plan was completed and presented to the school board in May, 1997. It was approved and implementation of the plan began immediately. Unlike many of the school districts in Iowa, Boone CSD did not limit itself to one year of planning. The Technology Committee continued meeting monthly during the 1997/98 school year and the 1998/99 school year, adding written updates yearly. The committee adjusted their planning by adding students to the committee and by establishing different subcommittees as needs arise. The Technology Committee’s decisions continue to drive the development of technology resources within their district.

The connection between the technology plan and the resulting use of technology at the upper-elementary level in Boone CSD was examined by document analysis of the plan using Kimball’s (1996) components of a strong plan and through interviews with committee members, administrators, and classroom teachers. Two areas of impact emerged from the data: “Communication of the Vision for Technology” and “Funded Projects Impacting Classroom Integration.” A third area of discussion related to “Potential Impact,” which includes planning decisions that have not yet been resolved by the district. See Figure 2, Technology Plan’s Impact on Integration, for a diagram of the concepts that emerged relative to this research question.

The Educational Technology Plan (Boone CSD, 1997) included a strong statement of the committee’s vision of the role of technology. The following statement communicates that vision clearly:

Integrated technology is an essential element of both active learning and schools as learning communities. It is the use of a computer as a tool in the classroom, where students and teachers have immediate access when needed to pursue a specific line of inquiry, build meaning, or interact locally or globally, through the use the Internet/World Wide Web. (BCSD, 1997, p. 8)

Student use of technology is stressed, rather than instructional management uses. Technology is referred to as a tool to support the existing curriculum, rather than a subject area. The plan’s stated goals include one related to improvement of student performance in the areas of reading, writing, speaking, listening, mathematics, reasoning, studying, and technological literacy. Another goal addresses the creation of “learning environments which make use of technology for problem solving, critical thinking, creating and designing” (Boone CSD,
The learning environments are to be provided early in the student’s schooling and include quality facilities with flexible access and appropriate personnel to support their use.

When comparing the plan’s stated vision of the role of technology with the teachers’ views, we see many of the same elements. Teachers most often described the role of technology at the elementary level to be a tool to support the curriculum in areas such as writing, communicating, and research. A fifth-grade teacher expressed her belief:

I hope that students are seeing the technology as a tool to help them with research, like when we use the various CD-ROMs. With word processing, they see that it is a tool for them to communicate their finished published product. They should be getting to the point where they work fairly independently. They’re using it as a tool to get to some of those other kinds of things like research and publishing.

It is unclear whether the committee’s vision about the role of technology helped influence the teachers’ visions. It could be the case that the committee represented the teachers well and that the resulting vision reflected the teachers’ beliefs. In any case, the plan helped to reinforce the idea that technology is a tool to support the curriculum, to enrich students’ learning, and to prepare students for the technological future.

A notable way that the technology plan impacted the integration of technology in the upper-elementary classrooms was through the recommendation of project funding in the areas of networking, hardware, and technical support. Resources provided in the plan allowed more student access to technology. However, as issues moved closer to curriculum and pedagogy, the committee seemed to have more difficulty identifying options and solutions.

The technology planning process had a significant and positive impact on student use of technology in the upper-elementary classrooms. This was achieved through the committee’s communication of a vision of technology-enhanced learning and through funding of technology projects such as Internet, email, computer presentation capability, and two multimedia computers in each classroom. The difficulties seem to reside in areas that are outside the Technology Committee’s scope of responsibility, namely the curriculum and pedagogy at the upper-elementary level. The existing district committee structure provides a means to address those issues, but the funding does not follow the responsibility. Again, this is an area for continued collaboration and planning.

**Conclusion**

The qualitative case study showed that Boone CSD was successful in writing an effective technology plan to lead their district through establishment of a technology infrastructure, including a district-wide network, Internet access to all classrooms, and high quality staff development. A strong technology committee evolved whose members built expertise, made difficult decisions about complex issues, developed a plan, and managed the change process over three school years. Leadership relative to instructional use of technology emerged from the administrators, support staff, and teachers throughout the district. Teachers, students and principals were eager to establish greater integration of technology into the formal curriculum of the school district.

The technology plan helped to communicate a shared vision about the potential impact of technology on student learning and preparation for their future. The vision was multi-faceted, including technology as a tool to support the existing curriculum and creation of a powerful learning environment where students can use technology as a way to solve problems. However, there is more to making these changes than providing access to classroom computers, display capabilities, and an Internet connection. Use of technology to support learning or to solve authentic problems does not come from exposure to technology alone. Teachers need to develop expertise in curriculum, technology, and effective teaching strategies in order to make the vision attainable. Boone CSD’s committee structure appeared to make this difficult because the technology expertise had been isolated from those making curriculum decisions.

This research showed that the technology plan and planning process provided the means to integrate technology, but more work remains to be done before teaching and learning change significantly. As the issues move away from infrastructure and closer to curriculum and pedagogy, the decisions move away from the technology leaders and the Technology Committee. It became increasingly apparent to the researcher and the district’s educators that curriculum leadership needed to join with technology leadership in order to take the district to the next step in this process. The results reveal the district has progressed in terms of technology integration, but the results must be seen in the context of looking at only one small part of a longer journey of school improvement.

Effective Curricular Software Selection for K–12 Educators

James Marshall
San Diego State University

Marguerite Hillman
Hillman Consulting

Increases in the availability of technology, the range of content software, and curriculum via the Internet have placed countless options in the hands of teachers. Similarly, increasing accountability has placed added pressure on teachers to meet stated objectives and ensure student performance. How can teachers optimize available technologies and related content to support classroom efforts? Effective decisions are based on clear understanding of the challenge or challenges to be addressed, selection of software based on the identified challenge, dedicated classroom usage, and evaluation and implementation modification as required. The 4DIEM Model supports teachers as they engage in selection of technology-based content.

The last five years have increased the amount of technology available to classroom teachers. Personal computers, networked classrooms, and the Internet—in addition to televisions, VCR's, Videodisc players, video cameras, digital cameras—all provide opportunities to extend classroom resources and present informational and educational materials to students. Between 50–89% of school library media centers in the United States have Internet access; 30–79% have access via computer labs.

With hardware and an access infrastructure increasingly in place, attention moves from the technology itself to the content provided via the technology. Educators are faced with finding technology-based content that:

- is correlated to district and state standards;
- makes full use of the features and advantages of technology;
- is easily integrated into the classroom;
- provides meaningful feedback;
- and is pedagogically sound, rich, and motivational.

Our experience working with three different software vendors and schools in each of the 50 United States has provided valuable insight as we seek to provide at least a partial solution to these technology-based problems. While attention has been given to specific guidelines for review of a specific software program, less attention has been dedicated to the larger issue of matching educational software to specific needs. Our intent is to encourage simple planning and assessment, followed by evaluation, to increase the effectiveness of any type of software technology purchased and implemented in the classroom. By pre-defining needs and selecting technology interventions matched to those needs, educators can optimize their available resources and the content provided to their students.

According to Dale Mann of Teachers College, Columbia University, "The school is the last unreformed institution from the 18th century that we are about to trundle, unreformed, into the 21st. Agriculture, medicine, commerce, transportation, and communications have all transformed" (Mann, 1999). We encourage you to play a part in the transformation of education.

Content Software and Internet Resources
Diverse pedagogical approaches provide the underpinnings of most effective educational software and Internet activities. Software and Internet-based experiences can be routinely placed into one or more of the following categories with which educators should be familiar as they evaluate content options.
Tutorial
Tutorials present a new concept. They often employ text, illustrations, description, or simulations to teach a specific task, skill, or application. Most productivity software packages include a tutorial to teach the user how to use the application. Many educational software programs provide step-by-step instructions describing how to perform an objective and include examples of problems and solutions.

Drill and Practice
Drill and Practice software targets the reinforcement of skills, most often by shaping user behaviors. Mavis Beacon Typing Tutor and Math Blaster are examples of this type of software.

Simulation
Simulations put the user in the middle of the action, often creating an environment which the user manipulates with varied results. Problem solving is key to most simulations, and activities typically reinforce the discovery process through primarily constructivist learning environments. Oregon Trail and SIM City are examples of an educational simulation.

Productivity (Tools)
This type of software supports the user in accomplishing specific tasks. It seeks to relieve the user of routine tasks, allowing concentration on the content being developed. Word processors, spreadsheets, and databases are all examples of productivity tools.

Informational (Tools)
Information software is just that, information rather than instruction. It provides data for the user to access and examine. Microsoft's Encarta CD-ROM encyclopedia and Dictionary.com (www.dictionary.com) are examples of informational software.

Software Needs Assessment
Regardless of the type of software, the chance effective learning will occur is at risk when the content and approach does not match the specific need of the learner. For example, providing students with drill and practice software on the multiplication tables will likely provide benefit. However, if multiplication tables are not currently the focus of classroom instruction, and therefore not supported and reinforced through other experiences, learning is not optimized. This can be likened to what we refer to as the Sesame Street effect: children may indeed learn basic skills from Sesame Street, but the impact is greatly increased when parents reinforce the skills presented in the television program, and further still when what is presented in the program and reinforced by the parent is a current classroom topic.

Understanding the specific need, or learning objective(s), to be addressed is critical to making effective decisions regarding content and technology. In fact, a clear understanding of the need may prove that technology is not the best approach or medium for meeting the need. Predicated on this assumption, Table 1 details a process which emphasizes front-end assessment and follow-up evaluation.

We call this the 4DIEM method of software selection and use, with each letter of the acronym supporting a specific step in the process. The overall intent is to first identify and then remain focused on the specific objective(s) you seek to target with the software. The following pages provide further detail for each component of the 4DIEM model.

The 4DIEM Model

DESCRIBE the objective
It is critical to have a clearly defined set of finite instructional objectives before you begin a software search. Many software vendors promise to boost basic skills or enhance critical thinking, but beware of these generalized promises: You have to be able to evaluate the success of the software in your classroom, which means that you have to know what you want it to accomplish. Make a list of the specific objectives that you want to target and keep it close by throughout this process. Ask yourself if the identified objectives are appropriate for your students and whether or not attainment of the objectives can be measured.
DETERMINE the type of software

After identifying the learning objectives that you will target, you must determine if appropriate software exists. Additionally, from a budgetary position, you will want to consider what software your school already owns.

If technology-based instruction is appropriate for the identified objective, consider what type of software would best meet the identified objective(s) and the needs of your students. Do you need it to teach the steps of a rule? Do you need it to provide lots of practice? Is it teaching a real-world skill that needs simulated application? Is the software you need a tutorial, a drill and practice, a simulation? Or should it provide content knowledge or be a productivity tool?

Think about how you will use integrate the software into your classroom. You will want to ensure students receive instruction to develop their initial understanding of a particular skill. Some drill software just helps children become fluent at a skill; in these cases, teachers should use another method to help students learn the underlying concept.

DECIDE on several appropriate software titles

Here is where you will likely be influenced by the budget available. You may be looking for a CD-ROM or two for use with your class or you may be involved in a district-wide technology adoption. It really makes little difference; if you have clearly defined your need, you will be able to review the appropriate software and determine if there is a match.

If you have a small allocation, you will most likely turn to over-the-counter software. Go to catalogs of respected providers. If you are involved in a significant technology adoption, you'll likely be reviewing and considering comprehensive curriculum software products. For example, the integrated learning systems provided by Jostens Learning, Lightspan, CCC, Davidson, or Kaplan.

Tables 2, 3, and 4 detail some educator-reviewed resources that include both over-the-counter and Internet content. Additionally, there are many excellent software review services: see SuperKids Educational Software Review (http://www.superkids.com/aweb/pages/reviews/alpha2.shtml) and the Children's Software Revue (http://www.childrenssoftware.com/). In addition, the Children's Software Review links page (http://www.childrenssoftware.com/links.html) provides many other resources where reviews are shared and software is discussed.

TEST DRIVE the software

If you are in the market for a new car and you heard in an advertisement that the new Ford Focus made driving 100% safer, would you walk into a dealership and purchase the car sight unseen? Unfortunately, educators have been known to spend ten-times the amount of that car on technology-based curriculum without allowing the driver and passengers (read: teacher and students) to take it for a test drive.

Most important, next to identification of your targeted objective(s), is reviewing the software and ensuring it will meet your needs. Many software programs are purchased only to collect dust due to the omission of this step. Routinely question the marketing claims made by the vendors—after all, they are trying to sell the software. Personally review the program to see if it is easy-to-use and matches your identified objectives. Ask for evidence of effectiveness in classrooms similar to your own. Then, select a few students and have them work through the program. Solicit their experiences; have them reflect on what they learned.

Note that many software review checklists and guidelines have been published over the years. Use these resources to ensure adequate and comprehensive review. For a rich resource of evaluation guidelines, checklists, and heuristics, see http://school.discovery.com/schrockguide/eval.html.

INTEGRATE the software into lesson plans

In a survey done by Global Strategy Group, Inc. only 37% of polled educators consistently integrate instructional software into their curriculum. Do not assume simply because you have targeted objectives that the software will immediately integrate into your classroom curriculum. Technology is a relative newcomer to the classroom and must be introduced, welcomed, observed, respected, and called-on to become an integral member of the class. Textbooks have a century of historical precedent on their place in the classroom—technology needs some hand holding as we figure out how best to integrate it. EdWeek
recommends that teachers "make sure the technology has features and functions that fit your curriculum. If a software publisher hasn't worked out how to integrate its product with the subject, you must do it—or cast it aside" (Trotter, 1998).

**EVALUATE its effectiveness regularly**

Our experience has shown that once a software program is selected—be it an over-the-counter drill and practice math program or a school-wide integrated learning system—scant resources are dedicated to evaluating the effectiveness of the program. We encourage you to question your decisions and seek opportunities to prove effectiveness. This certainly does not need to be a full-scale evaluation; make use of existing assessment materials or develop specific tools. Quick checks, quizzes, and tests can be used to evaluate tutorials, informational products, and drill and practice software; consider portfolio projects and other authentic assessments to evaluate simulations and productivity tools. It should be noted that many teachers have found clever ways to use the technology itself to evaluate student learning. Regardless of the approach, seek to understand the effect technology is having on student learning in your classroom and identify ways you can continuously improve your practices.

**MODIFY use as needed**

Based upon the results of your evaluation, repeatedly modify your classroom use to meet the changing needs of individual students and classes. Continue to use evaluation to diagnose and assess student needs and match appropriate technology-based content.

**Summary**

When selecting technology-delivered content, educators must identify specific goals and objectives which the software will support. Rather than having learning be incidental, we encourage teachers to target specific learning objectives and seek out software to meet those objectives. Follow selection with effective classroom usage, evaluation, and modification of your implementation plan. Using the 4DIEM model to guide this process will help ensure attention to front-end assessment, thus enhancing the effectiveness of your technology-based content.

Concept Mapping in the Classroom with Inspiration Software

F. Thomas Scappaticci
Education Department
King’s College
U.S.A.

Abstract

Concept mapping is a technique that allows one to understand the relationships of ideas by creating a visual map of the connections among these ideas. It is a structured process that is focused on a topic or construct of interests. It involves input from one or more participants that produce an interpretable pictorial map or representation of the ideas produced. The pictorial view or concept map as it is called not only displays a visual product, but it also shows how the ideas or concepts depicted are interrelated. (Trochim 1999) When used with students, it allows them to see the connections between knowledge they already possess and how this knowledge connects to new knowledge. It can also be utilized to organize a myriad of ideas in a logical kind of structure. Another advantage for educators using this process is that it is the type of visual language process that encourages students to operate at all six levels of Bloom’s Taxonomy of the Cognitive Domain. (Bloom 1956) (Gaines, Shaw, 1999) (Novak and Gowin 1984) Concept mapping is a useful and very powerful visual-thinking tool that transforms information into knowledge. Concept mapping is very helpful for the organization of information and development of higher level thinking skills, thus deepening knowledge and facilitating clarity of thought. (Concept Mapping Companion 1998)

Concept mapping lends itself to a variety of interesting applications and products of unique design, therefore for the purposes of this paper, a broad definition of the procedure referred to, as concept mapping will be utilized. Concept mapping will include virtually any graphic production that is constructed specifically to represent knowledge.
Concept maps illustrate the shape of the structure, the relative importance of the information and ideas, and the way that the information relates to other ideas. Concept maps can be used to summarize information from different research sources, to think through complex problems by viewing the overall structure of the subject, as a quick way to review, and to associate ideas and make connections that would be otherwise too unrelated to be linked. (Mind Tools, 1995). Another strong advantage of using concept maps is that once a student has developed a concept map, the organization and details of the map will tend to be remembered for a much longer period of time than is usually the case when trying to remember the material in text form.

Concept maps have a very wide application. They can be used in many fields to facilitate a visual representation of knowledge structures (Concept Maps 1999) but, in the field of education, it probably began with Ausubel's learning theory treatment of advanced organizers and meaningful learning which holds that in order for meaningful learning to take place, students must relate new knowledge to relevant topics that they already know, that teaching strategy in and of itself does not necessarily result in meaningful learning (Ausubel 1963).

Ausable's work prompted Novak (1977) at Cornell University to develop an extensive system of concept maps, which have been applied in the evaluation of students' learning in the school system in a variety of ways. (Lambiotte, Dansereau, Cross and Reynolds, 1989) His primary purpose was to provide a framework in which learners, rather than teachers, could be the cause of learning. Novak's vision of concept mapping was to provide a locus for student-teacher interaction that would empower students to take the responsibility for their own knowledge. He believed that teachers who were freed of the responsibility of causing learning could concentrate on the achievement of shared meaning. Novak concluded that meaningful learning involved the assimilation of new concepts and propositions into existing cognitive structures. (Concept Mapping Companion 1998)

However, one drawback of developing concept maps in the past has been that they had to be hand-drawn. Today we have software that is capable of generating concept maps more easily and efficiently. There are a number of software programs and tools that are very useful in producing computer generated concept maps. Some of them are, Axon Idea Processor, by Chan Bok, Cmap 2.0 for Macintosh, Decision Explorer (formally called COPE) by
While Inspiration software will be the focus of this paper, it is not the intention of this paper to evaluate or compare the various software to Inspiration software or any other software. That would beyond the scope of this paper. The purpose of this paper is point out how effectively the Inspiration software can be utilized to promote the use concept mapping in the classroom.

Inspiration Software (1999) is a software package that is specifically designed to facilitate the construction and use of concept maps. It is a powerful visual-thinking tool that helps clarify and organize ideas and information. The research supports visual learning strategy as one of the best ways to teach thinking skills. Visual learning techniques help students to think clearly, and to process, organize and prioritize new information. Visual learning techniques help students clarify thinking. Students can readily see and understand how ideas are connected and how the ideas are grouped and organized. Visual learning also reinforces understanding, since students recreate in their own words, albeit graphically. As a result they tend to assume and appreciate ownership of their own ideas. Additionally, as diagrams are updated in class students gain insights into how new knowledge is integrated and how misconceptions of knowledge are identified.

The purpose of this paper is to give an overview of the Inspiration software program and relate it to the construction of the powerful visual learning tool, the concept map without elaborating on specific techniques, which can be viewed in the Inspiration Manual.

The Basic Functions of Inspiration That Can Facilitate the Construction of Concept Maps

A. Diagramming: Helps you to quickly record ideas and map out concepts.
B. Rapid fire: Makes it easy to get your ideas down as fast as you can think of them. Inspiration can automatically
C. Move A Symbol: A symbol can be moved at any time and when it is moved, Inspiration automatically adjusts the link.

D. Adding Unconnected Ideas: Sometimes you may have an idea but are not sure how to fit them into the diagram. The program allows you to add the idea anywhere in the diagram and adjust it later.

E. Changing Symbol Shapes: Inspiration has a variety of built-in symbol shapes that can be assigned to the diagram at any time and changed with relative ease at anytime.

F. Drawing a Link: Symbols are connected with links automatically, but unconnected links can be connected manually at any time and the program will make the link precise.

G. Adding Text to A Link: When additional information needs to be added to a connection, as is the case in many concept maps, Inspiration does it easily.

H. Scrolling and Magnification: Inspiration lets you move the diagram around within the window or zoom in and out on the diagram.

I. Formatting Symbol Text: Text font, style and font styles can be set for the entire diagram, or selectively.

J. Printing to Fit: The print to fit option reduces the diagram so it will fit on one page or the number of pages specified.

K. Switching Between Diagram and Outline Views: You have the option of working either in the Diagram view for visual diagrams or the Outline view for your text.

L. Importing and Installing Graphics: Color or black and white graphics created in other applications can be imported into you Inspiration diagram or installed in the Inspiration User Symbol menu.

A thorough grounding in the techniques of concept mapping and the Inspiration software program will provide all the foundation necessary for utilizing concept mapping successfully in the classroom.

148
Proving Competence: Integrative Assessment and Web-based Portfolio System in a Dynamic Curriculum

Douwe Wielenga
Amsterdam Faculty of Education
d.k.wielenga@efa.nl

Abstract: Since 1997 Amsterdam Faculty of Education (EFA) has been officially recognized as a center for experimental teacher education. We describe the development of an assessment system and a web-based portfolio system to help students take responsibility for their learning and their proving competence at three consecutive integrative assessments. In this paper the new concept of curriculum for educating professional teachers is discussed. A new concept can only be successful in implementation if the assessment system is correspondingly altered. We also briefly describe a web-based portfolio system that supports students in building proof of competence. A more elaborate description of that system is given in the documentation of the poster session "EFA’s Digital Portfolio System".

Introduction

The Amsterdam Faculty of Education (EFA) provides for about 4000 students. Most of them study to become teacher on the elementary or the secondary level. In 1997 the Dutch minister of Education reacted to a rather provocative report of one of his advisory committees on the future of education in the Netherlands, and the way teachers should be prepared for this. After a competition between several institutes for Teacher Education, EFA got the ministerial appointment to transform into an ‘Experimental Teacher Education Program’. The basic transformation concepts are set in a constructivistic view on learning. The corresponding processes of change in the institution and in the members of Faculty should mirror the intended processes of change that should occur in students on their way to professional competence.

The advisory committee report speaks about CARE for the present situation and COURAGE to envisage what is needed for the next century. In the next decade society will have gone into the information age, whilst education seems to be organized in the ways of the industrial age. The experimental Teacher Education is one of the courage-projects. It will be an experiment, so we don’t know where exactly we will end up. That’s why we call our endeavor ‘expedition’ rather than ‘experiment’. This expedition is based on a few important ideas:

Capable of managing change

Teacher Education should adequately prepare students for their profession in a largely unknown future. We cannot predict what that future will be like. However, what we do know is that in the decades to come there will be an increasing demand for professionals who are capable of managing change and who can give form and shape to education in the information society – not only because teachers must be able to react quickly to changing circumstances in their teaching, but also because learning paths, in part due to rapid developments in information and communications technology, are becoming increasingly individualized.

Responsible

The program should offer students an environment in which they are indeed given the opportunity to shape their own learning processes. For this, students need to be given responsibility and they need to accept it - responsibility not only for the way in which they acquire the (constantly changing) competencies they will need in professional practice, but also for the way in which they demonstrate to the outside world that they have indeed acquired these competencies.

Freedom

In this environment, students have a considerable degree of freedom in filling in the details of their own learning processes. Our program operates in a context in which the requirements for newly qualified teachers are stipulated by law. This means that, although students should be given the opportunity to create their own learning paths toward becoming adequately qualified, we wish students to demonstrate to us, through integrative moments of assessment at three points in the program, that they have acquired the competencies they need to be admitted to the next phase.
This view runs directly counter to the view that, under the direction of the institution offering the program, the road to becoming a competent and qualified teacher consists of parts of a curriculum that have been determined in advance, and that evidence of competence is synonymous with the successful completion of those parts of the curriculum.

The central concept: Meaningful Learning

Authentic Learning in Professional Education

At as early a stage as possible, the program should create an environment for students which mirrors professional practices. Learning during the program must be linked as far as possible to useful and responsible work resembling work in the profession for which one is being trained. In professional practice, teachers have to carry out relatively complex tasks that fit in with the objectives of the school. To be able to do this useful work well, they must be able to use 'two kinds of learning'. They should not only be able to acquire on their own initiative the knowledge and skills they need to do their job well (learning of the first kind), but they should also be able to continue to learn from the experience gained and to experiment systematically with actions leading to improvement or change (learning of the second kind).

![Figure 1: congruence between work and education](image)

Both kinds of learning are important in the concept of 'lifelong learning'. Both are 'guided' by the competencies, which the competent and qualified teacher must have. The program should offer environments in which students can (and indeed should) put these two kinds of learning into practice connected to authentic practical work, in order to acquire the skills required for the profession.

Each learning process the student goes through in that environment, consists of the phases of orientation, planning, execution and evaluation, and is guided by the competencies derived from the professional profile. For students this means that in their orientation with respect to the learning and working process they take the competencies they need to acquire as their point of departure. In doing so, they are aware of the fact that at a later stage, during the assessment, they will have to demonstrate that they have actually acquired the required competencies. On the basis of that orientation, they formulate concrete learning goals and activities (plans), subsequently work on useful products in a learning environment created by the program (execution), and, finally, they evaluate the degree to which those activities have contributed to the realization of their learning goals and the acquisition of competencies.

The assessment of a teacher’s work is – if all is well – based on the degree to which the teacher’s work has been useful in aiding the achievement of the school’s objectives, and on the teacher’s ability to make improvements and to manage change. This assessment is therefore not based on disconnected knowledge and skills. Since the program is intended to mirror professional practice, it includes at three points in time an integrative assessment. During these assessments, students must show that they are qualified to take the next step: first to be admitted to the main phase, then to enter the assistant teacher phase, and, finally, they need to show that they are competent and qualified to start a professional career. The student’s admission to each phase depends on the outcome of these integrative moments of assessment, which are in that sense decisive and final. During these integrative moments of assessment, students demonstrate individually to a small committee (consisting of people from within the institution and from outside) that they have reached a level of development...
which is at least that required. They also show how their growth in acquiring competencies has progressed so far. As proof of their growth, students must compile a 'showcase' from their portfolio containing results of their work and studies, including judgements made by others. In principle, students are thus made responsible for proving their own level of competence, measured against externally specified criteria. This is also in accordance with the procedures followed in professional organizations and professional practice.

Program facilities in relation to learning processes

The program environment consists of a number of facilities which students use in taking responsibility for achieving their processes of learning and gathering evidence of competence. Below, we demonstrate in general the role and function played in the learning and/or working processes which students work through by existing facilities and facilities yet to be developed. In the next section, this is worked out for each phase separately. Although reality is always more complex and ambiguous than schemes and pictures may suggest, a simple graphic representation is given in this figure of the relation between learning and/or working processes and program facilities.

![Diagram of program facilities in relation to learning processes](image)

Figure 2: program facilities in relation to learning processes

**Orientation**

At fixed points during the program, students orient themselves with respect to the competencies they still need to acquire or improve. In this, 'metawork', in the person of the mentor and peer students, plays a supervisory, coaching role. Students and their mentor will use facilities such as the competence descriptions and (the results of) the integrative moments of assessment.

**Planning**

On the basis of this orientation, students translate the selected competencies into concrete learning goals they want to achieve in a learning practice and they determine which sources in the fields of knowledge, skills and information are required for this. In this phase, students enter into a learning contract and a work contract. In metawork, the mentor and peer students helps students in formulating learning goals.

**Execution**

In this phase, students work and learn within the frameworks agreed upon in the contract. The learning practice relates the learning process to the work to be carried out in the profession, sources support learning of the first kind, and learning of the second kind takes place by reflecting within metawork on one’s own learning and working processes.

**Evaluation**

In this phase, students consider their growth in acquiring competencies ('internal thermometer') and work on building up part of the evidence for the integrative moments of assessment ('external thermometer'). For both aspects, the portfolio is the main tool. In this, metawork fulfils a coaching, advising function.
Program facilities in detail

Orientation: The role of competency descriptions and moments of integrative assessment

If students are to take responsibility in orienting themselves with respect to the competencies they need to acquire during the program or a particular phase of the program, a clear description must be given of the competencies they can acquire demonstrably during the program. Competence descriptions are necessary both in relation to the ‘internal thermometer’ (self-assessment) and in relation to the ‘external thermometer’ (assessment by others), and they will therefore need to be described in two ways:

1. For the internal thermometer: description in terms of long-term objectives, including functions such as becoming aware of the competence requirements, monitoring of growth and justification of choices made by students within the program facilities.
2. For the external thermometer: implementation of the above-mentioned long-term objectives in criteria to be used during the three integrative moments of assessment for admission to the following phase of the program. Presently, we assume there will be three integrative moments of assessment during the fulltime program (competent for main phase, for Assistant Teacher phase, and qualified to start a career in the teaching profession).

The integrative moments of assessment during the program are based upon the competence descriptions; for this to be possible, for each competence, criteria must have been formulated which students have to meet before they can consider themselves ‘competent to undertake the main phase’, ‘competent to undertake the assistant teacher phase’ or ‘a competent and qualified teacher’. During the moment of assessment, students must demonstrate individually to a small committee (consisting of people both from within the institution and outside it) that they have developed at least to the required level and they must also show the committee how their growth process proceeded (‘lines of development’). Students are also required to show that for a few competencies they exceed the minimum requirements.

The integrative assessments are being developed in a two-dimensional space (see figure 3). The parameters determine how much freedom a student will have in designing his or her own convincing way of proving competence, and which role the show-case from the portfolio plays in that proof. The sequence of three assessments will follow the positions indicated by the skew arrow.

In collecting the evidence, students make use of their portfolio to draw up a ‘show-case’, a kind of current curriculum vitae. They do that by making a selection of their own learning and working results, which they have compiled in their portfolio with the aim of complying with the criteria for competencies. In addition, the committee can employ a number of standardized tools to assess students’ competencies.

![Figure 3: dimensions of moments of integrated assessment](image)

A prerequisite for the proper functioning of the integrative moment of assessment as an external thermometer is that the institution has established clearly formulated criteria for the competencies in such a way that students still have enough freedom to formulate their learning goals themselves.
Planning: The role of contracts

In the planning phase, students have to formulate their own learning goals and the activities they plan to undertake, based on an orientation on the competencies they have to acquire. Students' learning goals must be related to the competency descriptions. Students should formulate their goals in such a way that they are related to the work they are going to do in the context of the learning practice. In doing so, students must also take into account that during the integrative moments of assessment they must be able to demonstrate the competencies they have acquired.

After students have oriented themselves, they enter into a contract with the educator responsible for the learning practice and with the commissioner. In the contract with the commissioner, the commissioner specifies the requirements the product or service must meet. In the contract with the educator, the student determines the competencies he or she is going to work on and — more specifically — which concrete (and short-term) learning goals they want to achieve and the resources (knowledge, skills and information) they feel are necessary for this purpose. Students also specify in the contract with the educator how they propose to show (or be tested) that they have indeed worked on these competencies and that they have achieved their learning goals.

In principle, the mastery of resources (knowledge and skills) are not tested as separate units. However, students may include in the contract with the educator that, given the way in which they wish to organize their evidence, certain knowledge should not be tested on the basis of the product delivered, but directly. In order to help students on their way, descriptions of certain learning goals may be given. Subsequently, students, in consultation with their mentors, must themselves locate these descriptions in their line of development toward competencies and place them in the context of the learning practice. In addition to the learning goals provided, students may also formulate personal learning goals or choose to work with learning goals from learning practices carried out earlier.

Execution: Learning practices and the role of resources and metawork

Students work in learning practices. These practices are learning environments within which students are personally responsible for carrying out tasks that are useful to themselves and to others. In learning practices, students deliver products or services, preferably commissioned by institutions or people who will make use of the result and who therefore have an interest in the delivery of a useful product. In the contract the student enters into during the planning phase, the responsibilities of those involved in the learning practice are described. The educator in charge of the learning practice will supervise students to help them achieve the agreed learning goals.

Resources refer to the knowledge, skills and information students feel they need in order to be able to do the work in the learning practice well. In the course of their development, students assume a greater measure of personal responsibility for determining the resources involved. Resources are therefore as far as possible offered independently of educator, place and time. In the offering, students' various learning styles are taken into account (varying from lectures to consulting experts to searching libraries and internet to instructions on CD-ROM). ICT plays an important part in making the resources more flexible. In principle, resources are demand-driven. In Year 1, this is only true to a certain extent, because students then still need to acquire basic subject knowledge and skills, which will allow them to ask for new resources.

The metawork element has two functions for students, both of which fall under 'learning of the second kind':
- It provides a tool to help students acquire the metacognitive skills they need to prove during the integrative moments of assessment. For this, use is explicitly made of students' activities and experiences during learning practices;
- It offers students supervision and/or coaching in formulating learning goals and choosing learning practices and preparing for the presentation of the proof of their competence to official bodies (both internal and external) during the integrative moments of assessment. This function provides important support during the phases of orientation, planning and evaluation.

In metawork, the link is made between the learning goals students formulate and the competencies they have to achieve. Metawork pays explicit attention to the course of students' development toward becoming competent and qualified teachers.

Evaluation: The role of the portfolio

Students keep a record of their learning processes in a digital web-based portfolio system that is currently being implemented. The portfolio system is a multi-functional evaluation tool used within the context of metawork. In principle, the portfolio has three functions:
• It is a tool to help students become aware of the competencies involved in the teaching profession: helping them evaluate their own process of development and keep a record of it;
• It is a tool to help students keep a record of their personal curriculum: students record which learning practices they have worked on, which learning goals they had intended to achieve, which products the work resulted in and the assessments they received from commissioners, teachers and/or fellow students;
• It is a tool to help students compile a showcase or curriculum vitae of material they have collected to provide evidence to the assessment committee.

![Figure 4: portfolio system](image)

The portfolio therefore has three roles: an educational tool for the development of metacognitive skills, a navigational and recording tool for the personal curriculum, and tool to build convincing proof of competence for the three integrative moments of assessment during the program.

The portfolio plays the role of a 'student tracking system' in a dynamic curriculum.

EFA has chosen to have a digital portfolio in the form of an individual home site for each student. There were a number of reasons leading to this decision:
- A digital portfolio makes it possible to order a great deal of material clearly and compactly.
- Through hyperlinks students can easily show the relationship between different parts of the portfolio and so demonstrate the coherence between different elements in the program.
- Experience from other institutes also indicates that many students find it motivating to present themselves on their own web-site.
- In this way the portfolio contributes to the necessary development of future teachers' ICT skills. With the latest software it is becoming progressively easier to make a web-site and also within reach of students who are not computer experts.
- Through placing the portfolio on the intranet or internet it can become a means of communication between turers and students and among students themselves.
- Finally, students can continue to develop their portfolio after finishing their studies and can present themselves to future employers on their own homepage. In this way the portfolio becomes an instrument in 'life-long learning'.

During the paper session at SITE the results of the development of the Integrated Assessments will be shown. A more elaborate description of that system is given in the documentation of the poster session "EFA's Digital Portfolio System". That poster session will show the actual system.
Distance education is described by McLsaac & Gunawardena (in Jonassen Handbook of research for educational communications and technology, 1996) as instruction offered through many media, from correspondence study to video broadcast, in settings synchronous and asynchronous. This year’s research presentations focus on teaching and learning facilitated by the Internet, almost to the exclusion of other settings and media. Only one (W.E. Wessel, “Technology in the Classroom”) of the accepted studies addresses studio-based distance education; the Web presides over the rest.

Readers will not be disappointed by the substantial variety of studies within the general subject of Internet planning and delivery, however. The twenty-five studies presented here deal with teacher education, course design and platform selection, program research and evaluation, and learning or communication techniques for students and instructors. Many of the studies address distance education as a medium for delivering programs, as opposed to single courses, particularly within teacher education and certification. A rich representation of international and multinational programs reflects the truly global potential of education facilitated by technology.

Strategies for teaching & learning

Critical thinking, communication among students, and collaborative learning models comprise the subject of six papers. Loving discusses Nursing Education as a model of critical thinking strategies in an “instructional strategies in nursing” course. Miltiadou & McLsaac present “Problems and practical solutions of web-based courses” related to interaction, motivation, and organization in the faculty development process. “Evaluating new ICT-based models for teacher training” presents Lysne and Tvedte’s discussion of collaborative techniques for including external and campus-based students within a single teacher education course. Casual learning and the learning outcomes of chance, virtual encounters are addressed in Contreras, Llamas, Favela, & Vizcaño, “Improving collaborative learning by supporting casual encounters...” while Tarouco & Rodrigo describe tools and techniques for automating decision-making and summarizing in “Group learning through Internet.” The “Challenges of using CSCL in open distributed learning” include the faculty member’s journey from teacher to learning facilitator in the Nilsen & Instefjord study.

Design and delivery platforms

Pioneering distance education offerings relied on text-based media like e-mail, Usenet news, and MUD universes. Recent multi-media and graphical environments, as well as course-management programs, extend and improve both the possibilities and appearance of Internet classes; hence, six studies explore the choices available in design and delivery platforms. Novice distance educators are helped along the path to “The convergence of power and user-friendliness” in Lan’s stud; Hamza, Alhalabi, & Marcovitz describe more sophisticated applications supporting shared and virtual laboratory experiences in “Remote labs!” Serrano, Santiago, & Medina trace their institution’s search for a platform suitable for “Online interactive learning” for a variety of liberal arts courses. Marsh, Price, & McFaddin present “An overview of online educational delivery applications” a review of a dozen prominent platforms for instruction with particular attention to their utility for the new distance educator.

Tarouco & Rodrigo evaluate a Sun-based Remote Procedure Protocol for forming, categorizing, and distilling “Group learning through Internet.” Abramson, Cohen, Ellis & Pratt, in “Teaching and learning in an anytime/anyplace classroom,” explore other uses of bulletin-board applications. Course design can also be re-conceptualized through intellectual tools, as Gomes & Bastos Gottgroy describe in “DEP WEB: A concept mapping based on web distance education process.”

Research and evaluation

Selection of media will be followed by evaluation of media and the standardization of research protocols for investigating learning through new distance education technologies. Four studies address the complex of issues arising from program evaluation and research in distance education.
Identifying the elements of a successful distance education experience must surely occupy a preeminent place among the evaluator’s priorities. “Qualitative factors that affect learning in a web-based university course” are explored by Sujo de Montes & Gonzales, who investigate the ways learners feel about themselves during the process of participating in an online course. The learner, reacting with the teacher, is the subject of Offir and Lev, “Content analysis as a tool for evaluating the effectiveness of distance learning systems.” “Creating an instrument for a new course delivery mechanism” is described by Izat, McKinzie, Mize, & McCallie, in a report on the design and validation of a class and instructor evaluation instrument for Web courses. Tarouco & Hack apply Kirkpatrick’s (1998) training evaluation model to investigate a suite of “New tools for assessment in distance education.”

**Teacher education**

Teacher education forms a large part of most college’s offerings, and the need to reach out to all teachers and, particularly, to extend alternative certification to non-traditional and teaching students is critical. Distance education reaches further into the network of public schools as those schools become connected and equipped, and the possibilities of collaboration among pre-service and serving teachers promises to change both distance and campus-based programs. nine studies present model programs and techniques related specifically to P-12 teacher education.

“Trickle-down technology” describes a professional development model that Parker has applied to transferring technical expertise from college faculty member to pre-service teacher education student and thence to teachers in service. Active learning and interactivity occupy the forefront of Lysne’s “Evaluating new ICT-based models for teacher training.” Kissock presents a core pre-service “WWW based comparative education course” as a model for undergraduate courses in many disciplines. Blending the styles and experiences of on-campus and off-campus teacher education students provides a “Shifting focus from teaching to learning” in Haugen, Ask, Breatseth, Engelsen, Lysne, & Tvedte’s study of using distance education to integrate training and practice in a pre-service program.

Programs, rather than simply individual classes, occupy several investigations. Hirtle & McGrew-Zoubi explore “New horizons in distance education: Re-mapping the pedagogical terrain” in a four-course certification sequence for uncertified teachers. Teachers working in a master’s degree program participate in “Three community building strategies and their impacts in an online course,” which are analyzed by Egbert, Chao, & Ngeow. Wessel argues for comprehensive change to accommodate “Teacher education: Implications for teacher education.”

Two studies focus on the relationship of course management to specific topics. Ask & Haugen present an online course on designing online courses in “Introducing ODL in teacher education: An online course on how to create online learning environments” for a European college consortium. Naudé describes a South African project to train and make available Computer Studies teachers in an underserved environment.

**Global perspectives**

The twenty-five studies, and their far-flung authors, contained in the Distance Education section remind the reader of the global reach that these technologies give to programs. Henrichsen presents “Distance education insights from eight case studies in TESOL teacher preparation” in a system designed to reach ESL teachers worldwide.

Naudé’s computer studies teacher preparation meets a need for an entire nation, and Ask & Haugen describe a teacher education instructional platform designed to facilitate international collaboration. Informal interaction is worthy of study in every distance education setting; consider how remarkable it becomes in Contreras, Llamas, Favela, & Vizcafno collaboration among Massachusetts Institute of Technology, the Pontificia Universidad Católica de Chile, and the Centro de Investigación Científica y de Educación Superior de Ensenada: a collaboration that is international and intercontinental.

Though no reader of this section likely needs persuading, the studies contained here will convince the skeptic, inform the searcher, and further enlighten the professional concerning powerful tool for learning and teaching, collaboration and communication, understanding and creation that Distance Education continues to become.
Role Modeling Critical Thinking in an Online Course for Nurse Educators

Gary L. Loving
College of Nursing
The University of Oklahoma Health Sciences Center
United States
Gary-loving@ouhsc.edu

Abstract: In this paper, the author describes the use of critical thinking strategies in an online master's level course entitled, "Instructional Strategies in Nursing". The course is a required specialty course for graduate students in the nursing education track. These students are preparing for careers as nurse educators. The course combines online learning activities with periodic synchronous classroom sessions. Tools used to role model critical thinking strategies include online threaded bulletin board discussion, online reflective journals, and practice questions with automated feedback. The course employs WebCT as an online course template.

Introduction

Nurse educators have traditionally delivered classroom instruction using a didactic model. Nurse educators combine this didactic classroom instruction with structured clinical learning experiences to prepare nurses for practice. In an age of accelerating knowledge obsolescence, nurse educators must examine strategies to assist their students in learning critical thinking skills. Nurses who are able to transform knowledge and who are able to apply this transformed knowledge to a variety of contexts will be well prepared for nursing practice in the new millennium.

To prepare nurses who are capable of critical and reflective thought requires graduate nursing education programs that prepare nurse educators to role model critical thinking abilities. While delivering the course, the author role models the use of critical thinking learning strategies for student nurse educators.

Critical Thinking Models

Learning to critically think is a developmental process requiring practice and feedback. Having a common language to discuss critical thinking facilitates meaningful dialogue about one's critical thinking practice in any discipline. One popular model that provides such a language is Paul's (1995) Universal Features of Thinking. Universal features of thinking include the elements of reasoning and intellectual standards.

While critical thinking is a complex construct with many definitions, one simple way to define critical thinking is thinking about one's thinking with a goal of improving that thinking (Paul, 1995). In order to think about one's thinking, one must have some way to break apart thinking in order to analyze that thinking. The elements of reasoning provide a system for breaking apart one's thinking. The reasoning elements include purpose, issues/problems, information, concepts and theories, inference, assumptions, point of view, and implications. One can question one's own thinking or the thinking of others using these elements. For example, "What are the primary issues that I must consider before deciding?" or "What assumptions am I making if I take this position?"

Additionally, if one is to assess one's own thinking or that of others, one must have some criteria by which to assess that thinking. Paul's intellectual standards provide the criteria for assessment of thinking. These standards include clarity and precision, accuracy, depth, breadth, significance, relevance, and logic. One can formulate questions using these standards. For example, to assess depth of thinking one can ask, "Am I considering all of the complexities of this issue when I formulate my decision?" Or, to assess breadth one might ask, "Are there other relevant perspectives that I haven't considered?"
The instructor can use the elements of reasoning and intellectual standards to design instruction that facilitates critical thinking. Questions are the fuel that drives critical thinking. By formulating questions using the universal features of thinking the instructor can promote students' practice at thinking critically about key course concepts. With repeated practice and feedback, hopefully the student will develop the ability to ask him/herself the critical thinking questions that the instructor has repeatedly asked. That is, the student learns to assess his/her own thinking as a matter of habit.

There are many stimulus materials about which the teacher can ask instructional critical thinking questions. Examples include written case studies, videos, and readings. Perhaps the most powerful materials, however, come from the students' own experiences in practice. Reflection on practice is an element that Kataoka-Yahiro and Saylor (1994) add to Paul's model to describe clinical nursing judgment.

**Online Tools to Practice Critical Thinking**

The web-based tools used to practice critical thinking strategies in this online course include: threaded bulletin board discussion, reflective journals of educational practicum experiences and the student/teacher dialogue associated with these journals, and interactive practice questions with automated feedback. Each of these online experiences is structured using instructional design principles associated with the universal features of thinking.

The author uses threaded bulletin board discussion extensively in the course. Threaded bulletin board discussion is a tool that I have described as technologically simple, yet pedagogically complex. One doesn't need much technical expertise to design this instructional activity. Yet, one must be able to ask appropriate stimulus questions to facilitate students' thinking about key course ideas. One must also be able to keep the discussion going and focused.

The teacher establishes a timeframe for the discussion. For example, "We will discuss roles of clinical instructors during the week of April 2". The teacher also includes threaded discussion participation in the course's grading structure. Unfortunately, students often need this extrinsic motivation initially. Students have reported, however, that after having become engaged in the online discussion the bulletin board proved to be one of the most useful learning activities in the course.

The instructor posts the original discussion questions to the electronic bulletin board for all to see. Students post their responses. The teacher and other students post their responses to the students' responses. And the discussion builds. Positive feedback to the students for their initial postings is of particular importance. Students report that they are initially reluctant to post their ideas on the board for all to see.

The instructor's responses to student articles posted on the bulletin board may take the form of additional probing questions using the universal features of thinking. For example, "You have addressed a very important point. I wonder what the issue looks like from the perspective of a new nursing student." Or, the instructor may periodically summarize key points included in the discussion. It may also be necessary to include key points that have not been covered by the discussion. The teacher's facilitating the online discussion provides the students with an ongoing example of how discussions are facilitated and how questions are designed to facilitate students' thinking.

Class discussions can be organized by forum. Using the forum feature of WebCT, the teacher can create private fora as a means of dividing a large class into smaller, more manageable discussion groups. Or the teacher can divide the discussions by subject fora. With large classes it is necessary for the teacher to devise a system whereby he/she does not have to respond to each student posting. Examples of such a system include the following. The instructor can randomly select students' articles for review and response. Or, the teacher may designate and orient selected students to leadership roles in discussion groups.

It is important that the teacher advise the students of parameters for the teacher's involvement. That is, the teacher should inform the students specifically how often they will check and respond to bulletin board discussion. For example, "I will check the discussion daily in the late afternoon", or "I don't access the course on the weekends." Such information provides the students with the security of knowing the instructor is a part of the learning community.

In an online, asynchronous discussion students who are otherwise reticent to spontaneously share their experiences in a classroom are able to carefully formulate thoughtful responses that can be posted online. By carefully formulating contributions to online learning activities, students are able to consistently
practice their writing skills. Faculty can then provide consistent, documented feedback to students on their writing and thinking skills.

Another tool that provides students with consistent feedback on their written work is the online journal. The instructional strategies course includes a practicum component in which students practice their teaching skills in a nursing education setting. Students then submit a journal via WebCT private e-mail. In their journals students describe and analyze practicum experiences, describe students' reactions to teaching strategies they employed, and compare their teaching experiences with theoretical and practical literature. The instructor writes the feedback directly on the students' electronic journals and then returns the feedback via electronic mail. While the bulletin board discussion is a forum for establishing discussion among all the class members, the journal creates an instructional dialogue between the teacher and the individual student. Both tools, however, are capable of producing a rich dialogue between and among the students and teacher.

With WebCT there is also the capability of programming automated feedback to students for practice questions. These self-test questions are multiple-choice items that the teacher creates and attaches to a particular unit of content. Students may independently view and answer the questions. With each answer chosen, feedback appears. This feedback provides rationale for why the answer is right or wrong. The feedback can also provide the student with the thinking process involved in arriving at that answer. Such a method is analogous to the teacher thinking aloud to role model thinking in real time.

**Evaluation and Discussion**

Online course evaluations collected during the first two semesters of this course reflect extremely positive student responses to the online critical thinking activities used in the course. Many of the questions contained in the online course evaluation are based on the American Council on Education (ACE) (1996) guidelines. Samples of questions from the final course evaluation and the associated mean response scores for those questions are included in Table 1. These means are based on 14 student respondents during the fall, 1998 and spring, 1999 semesters. Responses were on a five point scale as follows: (1) Strongly agree; (2) Agree; (3) Neutral; (4) Disagree; (5) Strongly Disagree.

**Table 1: Mean Responses for Selected Course Evaluation Questions in an On-Line Course for Nurse Educators**

The author's demonstrations of critical thinking teaching strategies provide a model for student nurse educators who will practice these strategies with their students. The developing nurse educators can use case studies, dialogue, reflection on experience, and critical thinking questions to design instruction that will provide their students with practice at these valuable thinking abilities.

While many of these same critical thinking strategies can be used in a traditional classroom, there are advantages to online critical thinking learning activities. Asynchronous, online learning activities allow
working graduate students to complete the activities at times convenient for them. Online practice questions can be structured with automated feedback for student responses. Once developed, the automated feedback can save the instructor time. Additionally, experience with online instruction will prepare these student nurse educators for using technology in their own nursing education careers.

Abstract: The purpose of this paper is to review problems encountered in web-based courses delivered at three different educational institutions. Implications are discussed based on distance education theories of interaction. Interaction is a vital issue to the design of online courses. Further inquiry that sheds light on online students' motivational characteristics and organizational skills is vital in order to empower educators to design instructionally sound courses and students to benefit from them. Results would also aid academic administrators to predict student success with the ultimate possible purpose of lowering attrition rates.

Introduction

Historically, distance education has been defined as the delivery of instruction in which time and geographic location separate students and teachers (McIsaac & Gunawardena, 1996; Moore, 1988). Distance education courses have been an alternative for students in remote areas, or with difficult time schedules, job demands, or family responsibilities, unable to participate in traditional classroom instruction. The lack of face-to-face meetings between teachers and students in a shared classroom has led to the development of systems of delivering instruction in modalities often very different from those used in traditional teaching. Over the years different delivery systems have evolved along with the development of communication technology. In the late 1800s, traditional mail played the role of the first delivery system in correspondence studies. During the next one hundred years, radio, television, and computer multimedia were used to deliver instruction. The development of advanced technologies in the last decade has had an important impact on education. As a result, computer networks and the Internet are becoming the leading way to reach online learners and proving to be a global communication system (Harasim, 1996).

The present trend and market demand for education is indeed toward online education. This trend is highlighted in the "The Condition of Education" report published by the National Center for Education Statistics (NCES, 1999). According to this report, in 1995 thirty-three percent of higher education institutions offered distance education courses and another twenty-five percent indicated plans to begin courses within three years. Furthermore, Peterson's (1999) Distance Learning Guide provides information about two thousand degree and certificate programs available from nearly 900 institutions. This number can be compared to 762 institutions in 1997 and 93 institutions in 1993. Many educational institutions offer a wide variety of online courses and provide the opportunity for students to enroll in certain online courses as part of a degree. Other institutions offer complete undergraduate and graduate degrees through online distance education. Finally, the Kellogg Commission on the Future of State and Land-Grand Universities (1999) recently published a report entitled "Returning to Our Roots: A Learning Society." Members of the commission included presidents of state institutions that have invested heavily in technology in recent years through statewide distance education programs. According to the report, online technology needed for universal access to education is available today.
The Three Educational Institutions

Three institutions in the metropolitan Phoenix area offer Internet courses in a wide disciplinary spectrum. The first institution is a community college that offers traditional as well as distance learning courses. The "school without walls" is one of the leading institutions in the race for online distance education and offers more than 200 courses on the World Wide Web. Online students use the FirstClass conferencing system for fulfilling course requirements and promoting interaction in the virtual environment. The Distance Learning department provides technical support to students on a twenty-four hour, seven days a week basis. Attrition rates in online courses range between twenty and forty percent at this institution.

The second institution is the second largest traditional community college in the United States. The Center for Teaching and Learning department offers about 110 Internet courses, but provides very little technical support to students who face hardware or software problems. Attrition rates in online courses were up to seventy percent at this institution.

The third institution is an urban university that offers about seventy online courses. Students use the CourseInfo conferencing system for synchronous and asynchronous interaction and to fulfill course requirements. The Distance Learning Technology department provides some technical support to students by phone or email. Attrition rates at this institution range between forty and fifty percent.

While the three institutions possess extensive hardware and software resources, attrition rates are very high. Attrition rates in distance education courses tend to be forty to fifty percent higher than the ones in traditional face-to-face classrooms (Dille & Mezack, 1991; Parker, 1994). Distance education requires students to monitor and regulate their own learning because of the geographic separation between students and instructors. One of the main factors that influence attrition rates is the concept of interaction.

Distance Education and Interaction

The use of communications technology is still a recent development in education and many online students (as well as instructors) encounter various difficulties and feel frustrated with using such technologies. Examples include students who are technologically illiterate and therefore are not able to interact with their classmates or the instructor, download instructional material from the class web site, or submit online assignments and participate in discussions.

Interaction in an online environment is one of the most important factors that influence the success or failure of a program. Keegan (1988) views interaction as a key to effective learning and information exchange, and Moore (1989) considers interaction as "vitally important" in the design of distance education (p. 6). Furthermore, Kearsley (1995) points out that a high level of interaction positively influences the effectiveness of any distance learning course.

There are four types of online interaction identified in the literature. Moore (1989) identified learner-content, learner-instructor, and learner-learner interaction. Hillman, Willis, and Gunawardena (1994) identified a fourth type of interaction, namely learner-interface interaction.

Moore (1989) defines learner-content interaction as the intellectual interaction between the learner and the topic of study. According to Moore, learner-content interaction is an important concept of online environments because it changes learners' behavior toward an educational goal. The importance of this type of interaction is also depicted by Moore and Kearsley (1996) in the statement: "it is not too difficult to present information over a distance, but getting people to participate and making learning active at a distance is much harder" (p. 133).

The second type of interaction in online environments occurs between learners and instructors or team of subject-experts who prepared the course material. In this type of interaction, instructors are responsible for stimulating and continuously maintaining learners' interest in the topic, motivating students to learn, assessing students' progress, and finally providing support and encouragement to them (Moore, 1989).

The third type of interaction occurs among the learners of an online environment with or without the real-time presence of instructors. This type of interaction represents the communication between one learner with another learner, or with a group of learners, and takes place either synchronously, via "live" discussion chats, or asynchronously, via the exchange of electronic email or posting of messages in bulletin boards.

Hillman et al. (1994) define learner-interface interaction as "a process of manipulating tools to accomplish a task" (p. 34). Learners must understand not only the procedures for working with the interface, but also the reasons why these procedures obtain results. This fourth type of interaction links the other three types of interaction together.
Learners must be able to use online technologies in order to interact and communicate with instructors, peers, and the course content. The absence of interaction can inhibit student success and may even force online students to drop out of online courses.

Enhancements of the four types of interaction in an online environment are the lessons learned from our experiences with the three educational institutions.

Lessons Learned

Based on our experiences with the three educational institutions, we classified the findings in two categories. The first category pertains to technological aspects of online education, while the second category includes instructional design and course development principles for online courses. Both categories target lowering the high attrition rates encountered in online courses.

Technological Aspects of Online Education

Students enrolled in web-based courses are often required to use technology for the daily procedures of the course. Such procedures include (a) email interaction with peers and instructors, (b) using a web browser to access class material, (c) searching for journal articles using the Internet, online databases, and the institution's libraries, (d) submitting assignments online, and (e) participating in weekly discussions. These are examples of the four online types of interaction identified before. Moore (1989) suggests that online students need to interact with the instructor, the course content, and their peers. The only way for any interaction to take place is for students to use CMC systems. Interaction is vital to distance educators because if one type of interaction is missing, or it is not well thought and planned, then online courses might not be effective and successful. For example, if there is no interaction between learners and the topic being studied (because of unspecified or unclear instructions, assignment questions, or discussion topics), then learners will not obtain the desired learning outcomes. Moreover, if learners cannot communicate with instructors in order for the latter to answer any questions or clarify unclearness in any aspect of the course, then learners may not perform as expected. In the same context, if learners do not communicate with each other to provide support to each other and discuss intellectual topics in synchronous and asynchronous modes, then instructors’ expectations will not be met nor students will master the content. In addition, if both learners and instructors have difficulties using the hardware and software necessary for interaction, then all their efforts will be consumed with how to figure out how to communicate with each other and little effort will be spent on the actual class content. All four types of interaction need to be present in a distance education course in order for the course to be successful. Research in this area would help educators define the set of skills needed to enhance interaction and satisfaction among distance education students.

Enhancing social presence in an online community should also be one of the first priorities of instructors and course designers. In order to do so, instructors should require online students to participate in asynchronous discussions about various topics of the course. Instructors should also provide immediate feedback to students’ questions and assignments in order to help students feel that they are not alone in the class and that if they face a problem they have somebody to turn to.

In order to ensure easy access to course information, the course Internet address (URL) as well as the URL for the distance learning department homepage should be printed out in the published schedule of classes. Also, when students register for a course, they should provide updated personal information such as their current email address, telephone number, and postal address. This will ensure that students receive a registration packet with vital information.

Students who lack computer skills face major frustration and may drop the course because they cannot deal with technology. One way to prevent students from dropping out is to organize, possibly during an orientation week, a one-day technology meeting, during which students are taught how to use an email system, the Internet, and the conferencing system used in the course. Furthermore students should also be taught on how to submit online assignments. During the technical orientation meeting, students could create and post on the Internet their personal web page that includes a photograph and a short biography. This is a great way for classmates and instructor to put a face to the name. The meeting would be also useful for students to get to know each other and the instructor of the course.

In case students are not able to visit campus during the technology orientation meeting, the educational institution should provide technical support assistance via email or a toll free number. Online tutorials detailing the
daily procedures of a course as well as describing how to use technology should also be developed. Institutions that created such a department and offer technical support twenty-four hours a day, seven days a week have lowered attrition rates that were due to technology problems. Some may argue that creating such a department will require a huge budget the university might not be willing to pay. However, funds for such a department might be available from the increased amount of students. Alternatively, institutions might charge students a small technology fee in order to overcome the cost barrier.

Providing a teaching assistant (TA) for instructors who teach web-based courses is another solution to help students stay enrolled in the course and succeed. The TA could be responsible for providing technical support to online students. Twenty students per TA is a reasonable number of students for such a task. One drawback to this solution is that the TA will not be available to provide immediate feedback twenty-four hours a day, seven days a week. Still, some technical assistance it is better than nothing.

In case none of the above is possible, course instructors should consider teaching students how to use technology during the first few weeks of the course. This might take away from the course content, but in the long run it will pay off. Students are less likely to drop the course and more likely to enjoy the content, and instructors will not be frustrated every time they receive a phone call or an email message from students who require help with technology.

Instructors should identify students who lack the ability to use online technologies in an online course and should provide early feedback. Students' perceptions of their skills with using technology can be measured using a self-efficacy questionnaire administered by the instructor at the beginning of an online course (Miltiadou, in press). The questionnaire can be posted on the Internet and students' answers could be collected either by email or using a database application. After analyzing results, instructors could warn students of their lack of skills with using technology and advise them accordingly. The provision of early feedback and remediation could result in students staying in the course. This may translate to a decrease in the high attrition rates evidenced in some online courses.

Instructional Design and Course Development Principles for Online Courses

The abundance of web-based courses that exist today does not guarantee that these courses are all instructionally sound. There are a number of design and development issues and principles that course developers need to consider in order to design high quality courses.

First, course developers need to answer some very basic questions such as (a) is the course content appropriate to be taught on the web? (Porter, 1997) (b) who is the target audience? (c) what are the course goals and objectives? (d) how will objectives be assessed? (e) what are the limitations of technology? Instructors who simply post lectures and assignments on the web are supplementing their course, but this would not usually constitute an instructionally sound course. Course developers should refer to instructional design models, procedures, and techniques and follow the necessary steps in order to ensure high quality courses (i.e. Dick & Carey, 1990; Gagne, Briggs, & Wager, 1992; Smith & Ragan, 1999). Several other good sources for advice regarding instructional design principles for distance learning include Eastmond and Ziegahn (1995), Hirumi and Bermudez (1996), Ritchie and Hoffman (1997), and Savoye (1999). Additionally Hannafin and his colleagues have developed guidelines for designing open-ended learning environments, which might form part of the distance learning course (Hannafin, Hall, Land, & Hill, 1994; Hannafin & Land, 1997).

In addition, instructional designers could follow Keller's (1987) Attention, Relevance, Confidence, and Satisfaction (ARCS) model in order to develop an intrinsically interesting course which would enhance students' motivation. Keller's (1987) ARCS model would be used to develop courses that would capture students' attention, enhance content relevance with their prior knowledge and experiences, built students' confidence, and enhance their satisfaction with instruction and content material.

Instructional designers should also make an effort to enhance the relevance of course contents with students' educational backgrounds and experiences. Incorporating case studies that approximate real life situations and match students' interests would increase students' learning goal orientation because it would capture students' attention and motivate them to learn. Instructors should not substitute the learning experience with easy assignments because students might lose interest (Locke, 1996; Locke & Latham, 1990). As a result, students' learning goal orientation might decrease, and it is learning goals that are responsible for students' mastery of the subject being taught.

Instructional designers should create well-planned and structured online courses, including syllabi that are clear and concise. Students should know exactly what is expected of them and the precise steps they need to follow
to accomplish the objectives of the course. Instructors thus would help students control their own pace for finishing assignments, posting messages to various discussion questions, and reading the required material. Johnston (1997), for instance, recommends developing an hyperlinked syllabus, providing students access to many other types of resources.

Course developers also need to either design their own interface, or use a web-course template provided by the distance learning department at their institution. Web page design is not a simple step and should not be taken lightly. The interface should be user-friendly, allowing for sufficient white space and consistent placement of text and images on each web page. A dark font size on white background should be used because often students print out web pages to be able to read the material easily. An appropriate font style and size, universal for both PC and Macintosh computers, is required for students to be able to read without difficulty. Colors should be subtle and should complement the content. Navigation should include a site map for easy access of all web pages by the students.

At the end of the design and development phases, course developers should post all necessary information on the class web page before the beginning of the semester. Such information should include the weekly schedule of readings, assignments, and discussion topics.

The issue of online exams is another major one in online courses. Often instructors feel that they do not have control over such examinations. One way to solve the problem is to have educational institutions collaborate on testing. For example, collaborating universities could provide the classroom and the exam proctors for students living in that area. Another idea is to have students submit essay-type questions, case studies, or research papers, on which it would be difficult for them to cheat.

A final instructional design consideration is the value of conducting formative evaluation and revision on the distance learning course and materials, as specified in most instructional design models. Porter (1997) in her chapter on determining whether courses are appropriate for distance delivery includes a useful checklist for evaluating distance learning courses. Another example of criteria to be considered in evaluating distance courses in schools is presented by Hawkes (1996).

Conclusion

Inquiry that sheds light on online students' motivational characteristics and organizational skills is vital in order to empower educators to design instructionally sound courses and students to benefit from them. Such research studies would aid academic administrators predict student success with the ultimate possible purpose of lowering attrition rates.

Abstract: This paper shows how we have developed new models for integration of internal and external students into the same type of courses, and made a dual mode learning environment with common courses for on-campus and external students. Based on feedback from students, we present our experiences about how these models work. In our work we focus on changing the student from being a passive listener to an active learner. We present a tool to implement interactivity in the course material presented on Internet.

Introduction

Over the past eight years we have through our R&D work been experimenting with different models for teaching ICT skills to teachers. The courses have gradually evolved from traditional lectures in the classroom, to Open and Distance Learning (ODL) courses. We have developed, implemented, tested and evaluated different models where the physical location of the student is of less importance compared to methods of presentation. We very much work towards a situation where we can call a student a student, and not focus on whether he or she is actually an internal or an external student. The focus is on what methods to use in working with the content. This means in practice that internal and distance students are participating in the same courses and working with the same material. They take part in the same electronic conferences, and participate in the same discussions. An important goal of this work is to make models for teaching which is the same for both internal and external students. By developing these new models we also try to find new ways of teaching on campus, making the internal students more responsible for their own learning, where the teachers are tutors or guides in the learning process. In our work we have used different tools to make an interactive learning environment where students take an active part.

Our work is based on cooperation with different institutions in Norway and Europe through various projects. For three years we participated in the European JITOL (Just In Time Open Learning) project, which is a European project for developing courses in an ODL environment. Towards the end of the JITOL project work continued in a similar Norwegian project NITOL (Norway-net with IT for Open Learning). Through this project four institutions have worked together to make a common course pool. The last and most comprehensive project we participate in is the Norwegian Network University (NVU). This is a joint project with seven Norwegian Universities and higher education institutions, making a common course pool for Open and Distance Learning in higher education in Norway.

Organization of the Courses

In our courses we provide the majority of learning material through Internet. In this material we include references to books and URLs, integrate video shots to illustrate actions and so on. On Internet we
present exercises and assignments as a part of the course. Internet is also used as a forum for discussion and exchange of views and experiences according to the learning material and assignments. This is building an electronic learning environment where both learning material and student work are presented and discussed.

The contact with the students is also done electronically. Student assistants and teachers are made available for net based interaction and guidance, and tools like IRC are used to create cooperating groups.

This is done both for external students and for internal students that attend the course in a more «traditional» way. All the content of the course is presented on Internet and internal students have to read and work with this material in order to prepare for the classes. The teaching in the classroom is no longer dominated by lectures from the teacher where students are passive listeners, but guidance related to the material and assignments in the course. This guidance and these discussions are also made through electronic conferences, and IRC, in order to include the external student in the discussions. Since external students take the same courses as internal students without showing up on campus, the teaching is becoming an «extra service» for the internal student, and not an absolutely necessary part of the course. Internet is gradually becoming the arena for teaching and guiding, and the problem based learning method is becoming rather dominating.

Another important factor is to make interactivity in the course material in order to force the students to take an active part in the course. In some of our courses we «open» the material, and the students can add information to the content, ask questions, show examples and present personal experience directly in the material, not in a separate newsgroup. This is done by letting the student make annotations to the material. This is making the curriculum a «living» learning environment, and not a static material that is made once and for all by the teacher. To make such an interactive material, we use a tool called WebOrama. The WebOrama is a tool in the SHARP project (http://www.softlab.ntua.gr/sharp/).

WebOrama is a system where video clips, sounds and texts are integrated and played or showed as sequences. The way we use WebOrama is to start a video sequence and on certain predefined points, annotations are shown or started as other video sequences, sounds or texts. Annotations are used to give additional explanations to a video clip, text, sound and so on. In this way we organize the video sequence as a hyperstructure, not as a linear sequence. Annotations can both be shown automatically, or as a consequence of user interactivity. These annotations are usually programmed by the author of the sequence, the teacher, but an important point is that new annotations also can be made by students. These new annotations will be integrated in the sequence in the same way as annotations made by the teacher. In this way we can make the course material increase by student activity and participation in the course.

A video clip in WebOrama is shown in e.g. AVI-format, ASF-format or as a GIF-animation. The buttons below the picture can be used to add different types of annotations:

![WebOrama with a video clip and buttons for definition of annotations.](image)

Figure 1: WebOrama with a video clip and buttons for definition of annotations.
To a video clip we can typically have a list of annotations. The user can click on these annotations to start another video clip, a sound file or a text. These annotations are defining the hyperstructure in the WebOrama sequences:

![List of annotations in WebOrama](image)

The main structure is the video clip. When the video clip is shown, the time is the trigger to show the annotations. Annotations can be made to the main video sequence, but also to other annotations. This is building a hyperstructure with no limits according to levels of annotations in the sequence.

The WebOrama is one example of tools we use to increase interactivity in the course material. By using this tool, we enable the students to be active in the learning process, and to participate in developing the content of the course by making annotations. Annotations made by students are available to all other participants.

Annotations made directly to the course material, and in the material itself, will make a strong connection between the original material and the problems, questions, answers or comments to the content. The separation of the content and the place to interact with fellow students and the teacher seems to be a factor that disadvantages the use of newsgroups in this kind of interaction.

WebOrama is not implemented as a groupware, but on some points it is similar to how groupware works. In WebOrama the students and the teacher work on the same document, and all changes and additions that are done are published to all other participants. The main difference between WebOrama and «traditional» groupware is that in WebOrama the students do not work simultaneously on the same document. This prevents the student from real-time teamwork, but this system helps the students to cooperate and to work on the same content. The WebOrama system provides a simple and efficient way of publishing changes and new content in the work.

From Teaching to Learning

Maybe the most important factor and goal in our work is to change the students’ attitude from being passive listeners to active learners. This has important and rather dramatic consequences both for the teacher and the student. In our courses the teacher is no longer an oracle. He is more of a guide. The teacher is no longer the most important person in the learning process because of what he teaches in the classroom, but rather because of the learning environment he makes to stimulate the students’ learning.

For the students one consequence of their new role is to a much greater extent to take responsibility for their own learning and education. Much of the work in the courses requires student activity to solve different tasks. The amount of time used for teaching the students is reduced, and replaced with more time for the students to learn through their own work.

The three most important factors in our courses are engagement, work and guidance. Because of the integration of internal and external students in the same learning group, much of the traditional teaching has to be replaced by individual work, and work in groups of students. The course material on Internet shall not be a complete description of everything the students have to learn and to know for an exam, but rather be a trigger to the work of the students themselves. Students are guided to overcome difficulties in this part of the course. Input to students is very often based on the work done by the student, so the engagement and participation in the course plays an increasing role in how far into the curriculum the students are able to work.

Without work and engagement the students are not likely to learn. Teaching cannot replace the work done by the student. With traditional teaching to groups of low student engagement, no one but the teacher is likely to learn anything!
Findings

Through our work where we have organised the courses according to new models for teaching, we have systematically collected information about how these new models work. These data are organized in a database, and can be used to draw some conclusions about how the models function and give ideas about how they can be improved.

Even though we treat the internal and external student almost the same way, we notice some differences between traditional, internal students that work together on campus, and external students who very often are working alone and therefore have to use only electronic tools to interact with other students and the teacher.

Expectations

The majority of internal students still have expectations of getting traditional lectures as the dominating teaching method when they join a course. The content of the course is to be learned through lectures and a predefined curriculum. The attitude is still very often based on behaviouristic learning theory, and the belief that «someone can teach someone something», and that this is the best way of learning. This may be an effect of our examination system, where facts and information are asked to be recalled or reproduced. But does this actually test what is learned, and are the students in this system only motivated for using methods that make high scores in an exam? Do they really learn out of their own needs?

The traditional «delivery» of facts and science material in the classroom, or over Internet should not be confused with learning. This material should be considered as information until the students have treated it and gained some kind of knowledge. This is similar to databases. A database only stores data, and these data have to be interpreted to become information. In our courses we focus on constructivistic learning theories and do not only base the course on delivery of information to students. Our students have to work throughout the entire courses to gain their own knowledge and understanding of the content.

In the beginning our students can be a little confused, and have some problems to get started with the work. Many students need some time to adjust to the new way of working, when the courses very much are based on activity from the student in relation to the teacher as a guide, not as a lecturer. But the feedback from the students shows that after adjusting to this way of working, they find these models to be an efficient way of working and learning. They actually need some time to shift focus from listening to working.

In our courses we focus on using Internet as an interactive working arena. Internet must not be used as an excuse for presenting linear text, but as a tool to increase student activity. If knowledge is gained through work, Internet must be more than a delivery system for information. It has to be a place for working.

Results and Final Scores

The results and scores on final exams and compulsory work are the easiest factors to test and to compare with results from other courses. Over the past years we have seen that increased emphasis of active students, problem-based working methods, makes better scores on the final exam. The exam is still the same, but the results are better. This means that even though the courses do not focus as much as before on lecturing, teaching and a predefined curriculum, our experience is that the students learn more and better.

The feedback from many students reflects an attitude that they learn the curriculum out of their own needs, not with the exam as the only goal. The student finds the curriculum of the courses important to learn, and we find that this new way of working has adjusted the courses to the students’ need of knowledge and skills. The methods and the content fit together.

According to how males and females score in the courses, no major differences can be spotted in the results.

In our courses we treat internal and external students the same way. The courses are actually taught over Internet, and the use of lecturing and guidance in the classroom can be considered as an extra service» for the students that show up on campus. In this way we can say we still have some differences in teaching
internal and external students. If we look at differences in scores between these two groups of students, we can see that external students score equally or even better than internal students, both on final exams and on compulsory work. There can be many explanations to this, but we believe that when external students have to rely on the Internet based course, this inspires them to work more. And when they do not meet in the classroom, it is more obvious that the only way to learn is through their own work. We also find that many external students are older than the internal students, and therefore are more experienced learners, even though their experience may not directly be related to the content.

Transformation of a Physical Classroom to an Electronic Learning Environment

One important challenge in ODL courses is to create an electronic learning environment. How do we integrate external students into a common environment where they interact with each other and the teacher, and how are internal and external students organized into one group through electronic tools? As we often see in different courses, the interaction in a physical classroom cannot directly be transformed to an electronic learning environment. For instance the participation in electronic conferences can be limited. Feedback from many students tells us that they do not always want to ask questions in an open environment like a news conference. To help this interaction we have closed the conference for participants outside the course. Direct interaction with teacher and other students through e-mail, is more popular, because it is a closed interaction between two or a limited number of persons.

Another factor that seems to disadvantage the news groups and also to some extent the e-mail as a tool for interaction between students, is that these tools often function as a separate and not integrated system in the curriculum. The distance between the content and the arena to ask questions, make references, interact with others and so on, may in many situations be too big. The integration of curriculum and student activity, like the one in the WebOrama system, can help to overcome some of the problems related to interaction with the course material.

One of the major challenges in ODL courses, is to integrate and use electronic tools that allow and motivate the students to interact.

According to feedback from the students, we find that the search for information on Internet is efficient. Searching on Internet is a well established method for getting information, and is easy to integrate as a tool in the curriculum. In practice this means that the teacher as a resource of information can be replaced by these tools.

Groupware must also be evaluated as tools in electronic learning environments. The importance of these tools will depend on need for synchronism in student work. Our experience is that these tools function as a meeting point for chatting and for making appointments. Cooperating students often work individually, and at defined points present framework for discussion. Usually they do not work simultaneously on the same document.

Practical Aspects

Many students attend ODL courses for practical reasons. Because of work, family, physical location and so on, they are prevented from showing up on campus, and the only realistic alternative to get an education is to attend ODL courses. This is actually an important argument for making ODL courses in Norway. They are needed for practical reasons to implement lifelong learning. An important finding is that the organisation of the study as ODL courses from the students’ point of view do not reflect negatively on the outcome of the courses.

Based on the given feedback and results in the courses, we see that the combination of education, work, family and so on forces the external student to be efficient. They do not have time to surf on Internet unless it is related to their work. This is a factor that we also believe has an impact on the score and results of external students. The efficiency can help them to focus on the important items and to work with them, and not sort of flounder around. This is something we see more of among internal students.
Conclusions

Our experiences are based on developing and producing courses to provide ICT skills and ICT knowledge to teachers. We use ICT to create an electronic learning environment for learning ICT. An important goal is also to implement our experiences in other topics and subjects within teacher training. The use of new models for learning and the emphasis on using ICT should not only be related to teaching ICT.

The models developed for teaching ICT skills can be used to change parts of the teaching in other topics. At least 50% of what the lecturers are teaching verbally can be presented as hyper structured interactive lessons on Internet. Instead of talking to a passive audience, the lecturers can use their time as advisors and mentors for the students. And the students should use their time working, not just listening! The teachers in teacher training must change the way they work.

To change the methods used in initial teacher training in Norway is a great job. By using methods based on ICT tools, we can rationalize the time spent on theoretical subjects, and increase the time spent on interaction with students.
Improving Collaborative Learning by Supporting Casual Encounters in Distance Learning

Abstract: Casual encounters, in a learning environment, are very useful in reinforcing previous knowledge and acquiring new knowledge. Such encounters are very common in traditional learning environments and can be used successfully in social environments, in which students can discover and construct knowledge through a process of dialogue, negotiation or sharing. In the context of these casual encounters we developed a system that informs the user who accesses a web site of the presence of other participants and the messages they have exchanged with each other in order to interact with other people reading course-related documents within the site at the same time. The system will be used in a distance education class in collaboration between the Massachusetts Institute of Technology (MIT), the Pontificia Universidad Católica de Chile (PUC), and the Centro de Investigación Científica y de Educación Superior de Ensenada (CICESE).

Introduction

In the last few years, we have seen an increment in online courses, video-conferencing courses, and courses that combine both technologies, offered by different universities, in which students from all over the world can receive, participate and collaborate with other students in different cities or countries.

However, most of the casual encounters and social interactions that occur in a traditional learning environment, in which students are taking coursework on a university campus, are lost in these distance education environments. In these casual encounters in which the conversation topic, duration

---

3 Third author
and number of participants are not defined, a rich information exchange occurs between students and professors (Kraut, 1990). Some of the characteristics of these encounters are the following (Isaacs, 1997):

- Brevity: The duration of the interaction may be seconds, a couple of minutes, or 15 minutes, at the most.
- Informality: Conversations do not include formal greetings or leave-takings.
- Spontaneity: Interactions is what may be called opportunistic, not planned, although it can be planned by either party.
- Intermittence: The purposes of interpersonal interactions are seldom achieved in one interchange, so that such conversations occur over intermittent episodes (Whittaker, 1994), with participants on average interacting with each other 2.5 times per day.

Casual encounters, in a learning environment, are very useful in reinforcing previous knowledge or in acquiring new knowledge. Most researchers believe that knowledge can be acquired successfully in social environments, in which students can discover and construct knowledge through a process of dialogue, negotiation or sharing (Boekaerts, 1998), for example, when students are waiting to take an exam and are together in the room where the exam will be held (perhaps some of them have never even met before), they begin to talk with each other about doubts, and possible questions, commenting on ideas and exchanging information. In some cases, with this communication, students can understand concepts that were not completely clear to them previously and, as a result, improve their performance in the exam.

In the case of distributed collaborative learning, due to the distance and the distribution of students, casual encounters are very rare, and students cannot interact with each other as if they were in the same campus, and in general their only recourse is to attend formal meetings in order to talk about the class meetings with a definite topic and at a particular time, and they cannot talk freely about other class topics.

In the next section we discuss a distance learning course that was given through video-conference between CICESE (Centro de Investigación Científica y Educación de Ensenada) and MIT (Massachusetts Institute of Technology). In section 3 we introduce brief descriptions of systems that support casual encounters in distributed environments. In section 4 we discuss the implementation of a system that supports casual encounters in a web-based environment and will be used in the distributed software engineering class and, finally, we present our conclusions and future work in the development of new courses and systems that can take advantage of the characteristics of the system implemented.

A Distance Learning Course in Distributed Software Engineering

The main objective of this course was for students to experience the software development process in a company with a project from a real client. The client was interviewed by the students to present the project that he wanted to develop and then professors assigned the roles that students would play in the software development company.

In this course we had a group of 14 students, four at CICESE (Centro de Investigación Científica y Educación de Ensenada) and ten at MIT (Massachusetts Institute of Technology). The course was taught through video-conference, with two classes per week, one theory class and a lab. Each class lasted two hours. Theoretical classes were given in alternate weeks at each site.

The Software Engineering class created a web site to publish all the documents generated during the course. It also had an e-mail list with all the participants, used to exchange information between all members of the group. We stored all the e-mail messages sent through this list in a web site.
It was possible for all members of the group to check all the information and tasks assigned to them.

All the students in this class were assigned a role as if they were part of a software development company (i.e., analyst, designer, programmer, etc.). To assign the roles all the students were asked to select two main roles they wanted to play in the class. The professor considered the selections made by the students, and the skills that each student had to best accomplish the work assigned to each role.

The short informal conversations that normally take place in the halls, which allow participants to exchange valuable information, in this case, took place through chats, via e-mail and ICQ messages. Between professors and students, such conversations took place through e-mail and video-conference but were less frequent.

The course attempted to promote interaction through group division by geographically distributing all the roles. That is, the group in each location was subdivided with two members at MIT and one at CICESE for each of the subgroups. Each group had a leader in charge of its organization and coordination. Based on this course and because of a need to find further support for casual encounters we revised several systems so that they could be utilized to improve students performance in distance learning classes.

**Systems that support casual encounters**

Several computer based systems have been developed to support casual interaction, but they have been used only in office environments. Some of these are the following: Piazza (Isaacs, 1996), whose approach is to use networked computers to provide opportunities to encounter others through tasks and activities accomplished on-line; Cruiser (Fish, 1989), which provides innovative mechanisms for initiating connections between users to encourage frequent, informal, and unplanned communication among a large but selected group of members of a distributed community; Ubique (http://www.ubique.com), a system that provides virtual places that allows users to see graphical representations of others browsing the same web page at the same time and to open up a text or audio chat with them, and which also offers mechanisms for navigation through Web pages together; Telenotes (Whittaker 1997), is a system designed to support lightweight interactions through conversational tracking, rapid connection, the ability to leave a message, context management, and shared real time objects. However, some of these systems require the use of special software or hardware and require, also, that people come together at a specified online "place in the network to see others (Isaacs, 1996). This approach is acceptable within a homogeneous environment where all users are using the same client-server. Only one of these systems provides mechanisms for casual encounters in web sites. With this in mind we developed a system to motivate learning produced by the interaction among people visiting the same web site. In the next section we discuss the structure and implications of this system.

**The INCA system**

In the context of these casual encounters we developed a system that informs the user who accesses a web site of the presence of other participants and the messages they have exchanged with each other in order to interact with other people reading course-related documents within the site at the same time. The goal of INCA is to motivate learning, produced by the interaction among people interested in similar topics. The interaction takes place when the user realizes that another person is reading the same or a related document and decides to initiate a chat or a video-conference session with him.

The main requirements to be provided by INCA were:
1. Support for informal interaction.
2. Recreate a traditional library system, in which one can meet with other people reading the same book or document.
3. Provision of audio and video resources to permit users to communicate with each other.
4. Navigation within the site that would be as natural as possible. As if there wasn’t no other system, just the web browser.

The INCA system uses several servers (Web Server, Awareness Server and Collaboration Server) which delivers the different Web Pages and announces new users that connect to the web site. The server takes the real name, nickname and e-mail address from the users registration information on the main page of the site. When a user logs into the system, the web server sends the registration information to the awareness server and requests information about other users already connected and announces the new user to other users connected, then it sends to the new user all stored information about other users. Each time a user logs off the system by loading a page that is not in the site, all other users connected are notified and their user’s menu is refreshed. In fig 1, we can see a typical scenario for a user connection and the interaction between the different components of the system that lead to a casual interaction through the INCA system in a web site.

![Diagram of INCA system](image_url)

Fig. 1 A typical scenario for a user connection

In fig. 2 we can see the INCA system architecture for an interaction request and interaction acceptance for two users.
In fig. 3 we can see the site in which the INCA system was installed to test its functionality and we can also see an interaction between 2 users using the chat. A user connected to the system can navigate normally through the web site, by clicking on a small button attached to a frame on the left side of the web browser, the user also has the option of seeing pictures of other users who are connected, by pressing a button, that opens a small window showing all the users nicknames and allows one to select a user. Once a user is selected, a window pops up showing the user information and containing three buttons that permit starting a chat conversation, establishing a video-conference or cancellation. The system presently accepts all video connections, but it will be changed so that, as in the chat request, the user may accept or reject the connection.

While users interact with each other, they have the option of synchronizing their web browsers to navigate on the web site. Then the chat or video-conferencing subsystems can be used to exchange comments about the information they are browsing. To stop interacting a user can simply close the chat or video-conferencing window or press the finish button.

In fig. 4 we can see an interaction between two users with the video-conference subsystem.
The INCA system will be used in the next edition of the distributed software engineering class in collaboration between the Massachusetts Institute of Technology (MIT), Pontificia Universidad Católica de Chile (PUC), and Centro de Investigación Científica y Educación Superior de Ensenada (CICESE).

Conclusions

In this paper we discussed the importance of casual encounters in a distributed learning environment since they allow a rich information exchange between students. We presented some systems that have been used only in office environments that support this type of encounters and only one of them permits the use of web-based environments. We also presented a system that permits casual encounters in web-based distance classes and informs the user of other people connected at the same time and allows them to establish an interaction among two or more users.

We think that the development of this system to support our distance learning courses will allow students to better understand the course material and as a result improve their performance in the classes because they can consult other students or professors about their doubts or solve problems in groups.

Abstract: Internet is being intensively used for distance education. Normal services like email, chat and videoconference are not enough to fully support for properly handle interactions without extensive non-automated work. To support group work related to learning activities it is necessary develop applications to handle participants contributions and consolidate contributions providing summaries of the discussion. At the same time it must be integrated with group decision support tools to help students to build results from what was discussed. This paper presents a learning environment developed to support through Internet for distance education.

1. Introduction

Computer-mediated distance learning (CMDL) is an uncommonly bright star on the horizon of higher education innovation. According to a recent study by CCA and Associates, 30 percent of colleges and universities have at least one distance learning program in place and an additional 28 percent are planning such programs. (Tucker 1998)

As Internet use in distance education grows exponential nowadays, services used at the beginning was only the ones having strong relation with ancient forms of distance education. Distance education started using post services and even those days, many courses use in wide scale Post Office distribution of printed material. Other mass communication media, as television and radio or recorded tapes with video or audio where also very usual. Some Internet services started to be used in replacement or complementing this kind of services technologies used are shown in table 1.

Table 1: Distance education services

Internet utilization adds more possibilities, for news forms of interaction like is shown in figure 1.
The use of the Internet for distance education derived some advantages but one of the main is the support for human-to-human interaction that is as essential activity in learning. But long experience on using showed a need of a better level of automation on handling of group contribution. Huge number of contributions are some times just relegated to a historical register kept in log files. So the group activity may give opportunity for student to present contributions that some times are relegated to forgetfulness.

To support more good use of contributions derived from group work, related to learning activities, it is necessary the development of applications to handle participants contributions in such a way to provide support for group decision and utilization of contributions that came up during group activity. Collaboration strategies are requested to improve the information quality provided to support decisions. In distance education it shows up as an educational innovation.

For all the bells and whistles of groupware (Bannon 1992), e-mail continues to be the most widely used groupware component. So one can count on all the automated work provided by email or news service servers to receive, store or/and properly forward the messages. But no matter if only email or news service is used for group communication, as well as other forms of interaction, like chat combined with videoconference or with other multimedia environment (as The Palace or Virtual Reality based environments), the results from group activity are huge amounts of text derived of participants contribution. When it comes to the consolidation phase of the work, usually it is needed a lot of non-automated task to extract main ideas from the many ones presented almost randomly during the discussion. It is also needed a voting system to support group decision about the consolidated results from discussion (ordering, reordering, selecting, discarding etc).

This work describes strategies and tools designed to accomplish automatic ideas grouping (with focus on common themes) for organization of contributions resulted from steps in a group decision. A set of tools was designed and developed for to support distance education cooperative work.

2. Group tool

The work start on the supposition that group activity results on a log file containing interchanged texts (synchronous or asynchronously) during a group debate. These inputs are submitted set of routines that group ideas automatically. The system uses a WWW based interface and log files derived from the group interchange of ideas. The actual results were built from existing previous works at UFRGS.

First considered work to give a start to present project was a tool denominated "Issue Analyzer" that provides natural language recognition. It also contains an algorithm for calculation of similarity between contributions of participants from a group discussion. This prototype was implemented on Sun stations and the software used RPC (Remote Procedure Protocol) for intercommunication between a server and client applications. It provided the grouping of similar ideas generated in the phase of brainstorming and organized them according with definitions of the group.

Another previously developed work, named Eurekha, showed the importance of information retrieval techniques, to support textual information organization. It pointed the usefulness of this kind of support in an
environment with information overload like Internet. This solution uses methods for grouping textual objects. Objects are organized automatically in similar objects groups, facilitating their location, manipulation and analysis.

Both systems are directed to natural language (in written form) processing. In natural language processing, one of the more important aspects is the formal language representation. In this work it was used Discourse Representation Theory. This kind of system faces big challenges: linguistic aspects of natural language representation and handling of problems like ambiguity, references to names, pronouns, etc. So another aspect present in this solution was the grammatical classification of sentences.

The present work aimed a result in terms of group decision support system tool that is able to handle natural language input.

2.1. Proposed Model

The designed system used existing results derived from previous works, referred above. It starts with an Module I that handle log files (derived from chat sessions using software like CuSeeMe, The Palace and similar ones). Files are split up in smaller units (files with only one sentence or contribution). Those smaller units are submitted to a routine that performs similarity calculation. This module, process each sentence resulting in properly labeled version according with a Syntactic Derivation Tree (ADS). Stop words are removed from sentences because they do not add significance. It is possible to customize the system adding or removing stop words to the dictionaries. Figure 2 shows types of stop words (adverbs, pronouns, cardinals, prepositions etc)

![Editing stop words](image)

Module II (previous work named Eurekha) handle sentences grouping them in cluster according similarity. In this step pre-processing of natural language is done. It is considered that the documents have already been corrected with the use of an orthographic checker (task also performed by the module I). Besides, it is interesting that the texts have suffered some normalization of terms. However, these procedures are not conditionings. Figure 3 show an example of results using Eurekha.
It is important to play with similarity coefficient to get better results. If one chooses a very high coefficient of similarity will result on high number of cluster with few sentences. If one choose a very low coefficient of similarity will result on few cluster but full of non related sentences. To handle files with student contributions we find out that 15% is a good number for the desired coefficient of similarity.

Other modules, built during present development of the project (Module III to V) handle the resulting cluster of sentences, identify the most frequent/relevant words that will be used to compose a set that represents each cluster. Module III performs this task.

The module IV index words and links them to original sentences for further information retrieval. So one can wants to know which sentences provided the most words resulting as representative for clusters (and of course who created that contributions).

Each group of words became an alternative in a voting process. The voting results in a hierarchy of representative ideas by the group. Module V implements this voting process. An HTML page with the results of this stage of the discussion is presented to the participants of the group to subsidize one more discussion round.

2.2 Results

A prototype version of the system is running. It provides all the functions described above:

- clustering of sentences
- generation of consolidated idea for each cluster
- integration with a voting system to allow participant to weight and vote consolidated ideas

The results of this process can be used as starting of a new step of the group work where new discussions will use the results of previous consolidated work. This cycle can be repeated as many times as desired.

The tool will be used not only to support building conclusions from consolidated sentences but as it also...
keeps the original sentences and their originators, it is possible to derive conclusion about productivity of each participant. Not only the amount of contributions can be counted but it is also possible to identify contributions that originated consolidated clusters selected by participants as more relevant and representative of the discussion conclusions. So it is possible to identify those students whose contributions are more significant, being more often included in the clusters more accepted by the group.

3. Conclusion

Tools described in this work where designed to support group activity in distance learning because it is believed that cooperation and collaboration are key components in distance education. Natural language processing was needed to handle contributions of group activity resulting in clustering of sentences and summarizing cluster to came up with representative ideas of each cluster that are submitted to a voting process and resulting ordered representative sentences are the essence of the group activity. These results may be partial being used as input for a new cycle of discussions.

Abstract: The role of the teacher is changing. The teacher is to be the one who organizes the entire learning environment. Real-time educational groupware systems allow geographically separated learners to work together in a shared virtual workspace at the same time. There has been a move from teaching to learning. As a compulsory part of the MEd in Pedagogical Information Science at the University of Bergen and Stord/Haugesund College in the Spring term of 1999, the students participated in a distributed group activity. In this paper we present some of our findings—both challenges and decisive elements, based on our participation in this open, distributed and collaborative learning environment.

Introduction

Recent research draws attention to a change in the role of the teacher. The teacher is no longer an information-transmitter who transfers his own knowledge into the minds of the pupils. The new teacher role is instead defined more like an information organizer and adapter. The teacher is to be the one who organizes the entire learning environment. The expansion of the Internet and computers as a means of communication, have since the late 1980s opened for widespread research on different models of distributed collaborative learning. The introduction of recent technology, in particular computer-supported tools in education, has during the last 40 years gone through a number of paradigm shifts (Koschman, 1996). Tapscot (1997) describes these shifts as a change from broadcast to interactive learning. Thus, there has been a move from teaching to learning, where the roles of the actors on the learning arena have become more equal. The emerging area of theory, which several researchers are concerned with, is referred to as Computer Supported Collaborative Learning (CSCL).

Our Theoretical Framework of Computer Supported Collaborative Learning

The development within research on learning through collaboration has experienced a shift from focusing on the individual in the group (1970-80) to studying the entire group as a whole (Koschman, 1996). Research on CSCL (Koschman, 1996) focuses on instruction as practice rather than lecturing. Focus is on the process rather than on the result. Theories are based on observed situations, and the tendency is that CSCL is based on a descriptive method, as opposed to a more experimental form of work. In addition, attention is on understanding the process from the participants’ point of view. It is important to focus on the single factors, and try to understand the role of these factors in the process of collaboration, so-called process oriented focus. This, however, demands brand new tools for analysis and modeling of collaboration (Dillenbourg et al., 1996).
ICT-based collaborative learning has emerged from several theories of learning: Social Constructivism, focusing on the development of the individual, based on social interaction (Bauersfeld, 1995). Soviet's Sosio-Cultural theories, focusing on the cultural environment for understanding the actions of the individual. Furthermore it is claimed that learning rises on two different levels, first, at the inter-psychological level, and second, on the intra-psychological level (Wertsch, 1985). Situated/distributed cognition, emphasizing on the concrete situations and environments where learning takes place (Lave & Wenger, 1991). In addition, this theoretical framework contains a mutual understanding of language, culture, and other aspects of the social relations (Scott, Cole & Engel, 1992).

The process of learning in such an environment is based on collaborative learning. Collaborative learning can be defined in several ways. Bruffee (1993, p. 3) describes collaborative learning as "a reculturative process that helps students become members of knowledge communities whose common property is different from the common property of the knowledge communities they already belong to". Roschelle and Behrend (1995, p. 70), on the other hand, define collaborative learning as "the mutual engagement of participants in a co-ordinated effort to solve [a] problem together".

In designing new information- and communication technology mediated forms of open distributed learning (ODL) environments, the expression collaborative telelearning (Wasson, 1998) is commonly used. Rather than explaining the expression distance only to aspects of time and space, as we know it from traditional ODL, we want the mediation of learning activities to be supported by i.e. multimedia shared workspaces. CSCL and collaborative telelearning use means that emphasize ICT as mediating tools in collaborative situations. Such a tool should contain mechanisms for supporting synchronization, exchange and sharing of information and documents. Access to tools and services should be as transparent as possible to avoid obstacles in the learning process. A distributed collaborative learning environment is a place that is being constructed by the participating students through individual and collaborative work. The role of the designer will be to support the students in the process of creating this environment in such a manner that the computer system becomes an integrated part of the student activity.

Our Experience

As a compulsory part of the study in Pedagogical Information Science at the University of Bergen and Stord/Haugesund College during the Spring term of 1999, the students participated in a distributed group activity. The activity, which was part of the DoCTA (1999) project, was to provide experience on distributed collaboration and use of online groupware systems. The University of Bergen, Nord-Trøndelag College, Stord/Haugesund College and Telenor Research & Development participated in the project. In practice this meant that students in each group came from different geographical places and technical environments.

The entire group collaboration process was to be mediated by information- and communication technology. The work was done on the presumption that each group member had access to his or her own computer. The groups were to collaborate through the network by means of a groupware program called TeamWave Workplace (1999). This program offers the participants a joint workspace. The workspace is defined as a room. One great advantage in Team Wave is that it is based on the place metaphor with its persistence, and not on a
meeting metaphor like many other groupware systems. The participants may create their own rooms, and navigate between the different rooms by using the doorways provided in the room. In each room there are a number of available tools. By means of these tools the group members can collaborate, show and exchange files and URLs, have common databases, address books and calendars, may write and draw on the same screen etc. In a room of TeamWave, participants can see who else is logged in and what room they are in. They can also observe each other’s cursors and observe each other create, delete or move objects in the room.

The task of the students in this assignment was to create a room in TeamWave Workplace, which enables learning of a specific subject. The work process of the group was made up by several stages. After the group had installed and made the program work on their computers, a rehearsal stage started. In this session the students were led through a number of assignments where the underlying goal was to provide experience in using the tool and practicing interaction with the rest of the group, and simultaneously getting to know their fellow students. The main part of the activity was the design activity. The group was to design a room in TeamWave where students can learn a specific topic with theory, procedure, process etc. Throughout the collaboration, focus was directed towards the actual collaboration process within the design group. The main interest of the activity was on how students made their decisions and how they were carried out, rather than on the final contents of the learning room that was designed.

Challenges

It is a great challenge to create successful collaborative situations in a classroom. When participants in addition seek to transfer this workflow to an ICT based environment in order to build what is referred to as CSCL, the task becomes even more complex. In such a situation the composition and orchestrating of the entire working environment will, according to Salomon (1992), be more important than the design of the technology. In a computer supported collaborative learning environment Salomon (1992) identifies two effects connected to the learning design. He chooses to distinguish between effect with CSCL; changes that take place while one is engaged in intellectual partnership with peers or with a computer tool, and effect of CSCL; more lasting changes that take place as a consequence of the intellectual partnership. This is the lasting cognitive result, defined as being more general than the previous. Seen from a perspective of learning the natural choice will be to emphasize and increase the effect of CSCL. Thus one may train for independent thinking for use in unforeseen circumstances where technology is unavailable. However, taking Vygotskys (1978) thoughts of zone of proximal development into consideration, and his theories of how social interaction creates cognitive changes, one should also consider the effect with factor.

By concentrating on the totality of the learning situation, focus will also be on the environment surrounding the pupils, the actual work process and the technical profit. Due to the fact that the student primarily manages the process of working on a PC, learning becomes more a process of active construction of knowledge than simple acquisition of facts. In order to strengthen and maintain effective CSCL, motivation and engagement from the participants are important. This is what Salomon (1992) describes as mindful engagement. Although the students are sincerely engaged this does not always lead to effective and adequate collaboration. To increase the quality of the collaborative process Salomon (1992) sketches a
need for genuine and necessary context or genuine interdependence between the participants. The decisive factors that this expression consists of are the need for sharing necessary information, division of labor between the participants and joint thinking, thinking in explicit terms that can be considered, adjusted and prepared by the other members. However the computer itself cannot create these effects. The development of knowledge demands a motivated engagement in a social process of acquiring opinions. This stresses that the environment is designed as a well-combined entity.

Salomon ascertains that group collaboration cannot fully function if the process consists solemnly of division of labor and individual work. He therefore stresses the fact that participants require engagement and a joint platform to base the tasks upon. In order to build this common point of departure the participants will need to share information. The fact that information is only presented in written form can clearly be seen as a weak point, considering that tone of voice and gestures disappear. It is difficult to know how much to write either by e-mail or chat modus. Being capable of producing a clear and concise message by means of only few words is a clear strength in the use of written text on the computer screen. The groupware programs which are used today for educational purposes enable students to work together, regardless of time and geography, in a common virtual room. For the present, however, the systems are not as good as face-to-face learning situations.

The success of a method of collaboration depends, as mentioned above, on the engagement of all involved parties. In an opening phase it will thus be important that the design allows and the teacher manages to motivate and activate the students. Throughout the process the role as an evaluator will also become more and more relevant. Thus it can be claimed that all these different roles are necessary for creating successful and efficient collaborative learning. In order to maintain activity and engagement among the pupils, attention is drawn to other decisive factors in addition to the evaluator function. In an early stage of the development of distributed learning using ICT, the use of e-mail has been important, especially in computer mediated communication. Internet students have sent e-mail to their supervisors and fellow students, and received response and comments on the contents of their message. Seen from a behaviourist learning perspective this form of communication may have been satisfactory.

The last few years, studies have been performed on different net based forms of collaborative work. In these studies (Koschman, 1996; Dillenbourg et al., 1995) a more socio-cultural learning paradigm is chosen as point of departure. There is emphasis of the context, environment and culture surrounding the learner. In addition there is also a tendency to increase focus on the activity of the individual as a framework for learning. Both constructivists and those who support activity-theory try to create healthy learning environments by placing the activity in the center of attention. One has focused on creating a social network around the participating students. Although students are placed at separate computers in different geographical areas, it is important to provide the students with the feeling of not being alone. This leads up to the conclusion that use of e-mail communication only, is not satisfactory. Based on this theoretical framework, Goldman (1992) has studied student behavior and divided them into three categories used as a starting point for further analysis: social-, task- and conceptual interactions. In a distributed learning environment the participants should build up a shared understanding and knowledge within these fields. Have the participants the same understanding of the social context? How are the connections between the participators? How is the work task interpreted and solved? How does a particular activity or piece of knowledge fit into the existing pattern of knowledge? In order to work efficiently and create an environment that encourages collaborative learning, the groupware program should contain functions providing the participants with such knowledge. In addition to these elements Gutwin et al. (1995) introduces what they refer to as workspace awareness. This expression embraces up-to-the-minute knowledge about the group members and the shared workspace. This expression is presented for two reasons. First, it will reduce the distance and differences in the level of knowledge between the collaborating members and enable them to act more naturally and efficiently, and second, it makes the students more capable of engaging in practices where collaborative learning may arise.

Among students in a traditional collaborative environment there are several mechanisms, which creates learning environments:

- Students frequently tempt to model their skill and knowledge to their fellow students
Learning arises through identification and finding solutions to distinctions between crossing ideas and theories

- Peer teaching, where one student instructs and assists another where needed
- Construction of new, shared hypotheses

How can we transfer these mechanisms to a distributed ICT-mediated learning environment? The most important reason why these methods work as a means of learning in a face-to-face situation is that they enable students to take notice of and observe each other, and see with their own eyes how fellow students work. They can study each other's methods in order to copy or correct them later. In a traditional collaborative situation these factors are taken for granted. This may explain why this part so far has experienced weak support in existing GroupWare programs. Based on Gutwin et al.'s (1995) argumentation we see that it is necessary to work out knowledge about fellow students in the work field. From a visual point of view, enabling the students to observe each other's cursors and movements performed by fellow students in the workspace solves this. The use of workspace awareness as a starting point also makes it possible to make use of artifacts as conversing objects. This is done when the object is visible for all parties.

There are advantages with the function presented above, but you will eventually encounter the question of where to draw the line. How many details should be revealed? Will I always know everything about everybody? Could observations of what fellow students do, and incoming messages hamper and confuse my own work? Gutwin et al. (1995) propose to define two stages: task stage and work space stage. If several people are working simultaneously in the same room, it is often a great advantage to be able to observe who the other persons are. At the same time you may want to work alone without being interrupted in the task stage. How can you as a participant manage this? One of the main aspects presented by Gutwin et al. (1995) is that students should be able to peek over each others shoulder to observe what they are doing. But, as mentioned above, you may wish to work undisturbed. It is important that the program used also supports this choice, unless you plan to perform such operations in other environments. Especially when it comes to awareness concepts, but also when talking about genuine interdependence, we should be aware of the fact that the net-generation will develop a whole new attitude to virtual rooms and worlds compared to what adults ever will. This is why it may not be necessary to write or show everything about everybody, but rather leave to the students to find out on their own.

The written word, on the other hand, brings out images and metaphors that draws its material from the readers imagination and experiences. When we read a novel we provide the colors, sounds and movements ourselves. I believe the same form of personal supply is needed in order to understand what being digital means to ones own life (Negroponte, 1995, p. 13).

Crucial Elements Noticed

It is almost impossible to achieve full effect of CSCL without total engagement from the participants. Within several of our groups there were signs of lacking motivation among the participants. Salomon (1992) argues that we are dependent on seeing the totality of the learning session, “the curriculum, the activities that students engage in, students’ perceptions of the learning goals in the classroom, their social interactions, the (p. 63). We agree that the totality of the learning situation plays a decisive role on the educational profit of the CSCL-activity. It is easier to create engagement if the task is significant. When working with learning activities in the classroom we quite often experience receiving feedback on whether the activity is good or meaningful. Usually the teacher is present and visits the group every now and then, or may be called upon to comment on the work. In a number of other educational situations one also experiences being corrected and followed up by a teacher. This can be found in professional working life as i.e. the method of

1 Translated from the Norwegian edition.
cognitive apprenticeship (Brown et al., 1989). In connection with the expression awareness, together with response and facilitation from teachers and others, the students experienced a lack of feedback on their work. How can we see who has been in the room and observed our work? -When were they there and how did they appreciate our work? This could be compared to the inspiration of being peeked over the shoulder in the classroom, it does, however, assume that you know who it is and what their reactions are.

To what extent the students know each other, is also an important factor that will influence the process of collaboration. In the activity referred to in this paper, the students did not know each other. This was reflected in the method used in solving the task. The method was influenced by the fact that everybody did something, and then we discussed what we had done. The discussion was influenced by the fact that the participants did not know each other, and it takes time to get to know each other. Perhaps we were too insecure? It probably takes far more time than we had at hand to establish the necessary contact. This caused difficulties in creating an honest engagement among the participants.

Seen from our experience, genuine interdependence is important, perhaps even more important than workspace awareness. Knowing people’s strengths and weak points, in addition to their being engaged, becomes important elements in the process. Nevertheless we do not neglect what an influential role workspace awareness serves in strengthening the engagement and the division of information that Salomon points out. Motivation and engagement regarding the work performed in such CSCL-environments will be connected to the concrete piece of work that is given. In addition, it is therefore significant that the participants experience a feeling of actually performing something of importance in order to achieve a proper result. Otherwise the actual activity will have to be inspiring enough to make the participants wish to finish the task. Based on these experiences we find it necessary to point out that the significance and functionality of a program is strongly dependent on the type of work and the task a group has been assigned with.

In the use of CSCL and telelearning it is important to look for methods for contextualizing a subject, creating more vivid descriptions and closer relations to common practice. Although the software used in our design activity has proven to contain certain weak points, we consider ICT and groupware programs like i.e. Team Wave Workplace to be a useful aid and tool for achieving this goal. The advantage of this usage is that it involves the user in constructing his or her own learning environment. In this way Tapscotts (1997) wish for a shift in the learning situation from broadcast to interactive learning is getting closer to reality.

Abstract: The authors of this paper propose an Internet facility that will authentically provide laboratory experiments remotely. Such a facility is brought to the doors of the distance learner to help provide learning that is comparable to that offered for conventional students. This paper describes the development of a prototype remote laboratory system including software, hardware, procedures, and instructional systems. This includes surveys of existing alternatives (mainly software simulation environments), a description of the prototype remote lab environment developed by the authors, and a discussion of development issues, such as the reasons behind JAVA and RMI as the system's development tools over other popular alternatives.

Introduction

Distance learning (DL) has become a powerful educational tool to reach students at times and places that are not strictly dictated by the educational institution. New technology has made it possible to overcome many of the obstacles of distance in the educational process. Electronic mail, chat rooms, and live interactive video conferencing, for example, help to bring together the people involved in the educational process. The World Wide Web has made available many of the resources that used to be reserved for use on an educational campus (Alhalabi, Hamza, & Sudeep, 1998; Harasim, Hiltz, Teles, & Turoff, 1995; Turoff, 1994).

The success of DL, however, has been problematic for courses that require extensive use of laboratory facilities. In such courses, learning processes (i.e., problem solving and exploration) via laboratory experiments are indispensable. Thus, the distance learner has experienced a void, as no amount of theoretical explanation can be a quality surrogate for real laboratory experimentation. The challenge is to find ways to overcome the obstacle of distance and allow all students to fully participate in laboratory experiments.

In a study that investigated currently available Internet-based educational modalities (Alhalabi, Hamza, & Sudeep, 1998), the authors surveyed a large number of online courses, distance education and virtual universities, and electronic online universities that are involved and actively taking part in DL programs. None of the researched universities and publications discussed or investigated the idea or the concept of real labs via the Internet. Instead, they used primarily simulation software; i.e. virtual labs. Virtual labs, by design, place limitations on students’ and teachers’ abilities to experiment in real lab environments (Alhalabi, Hamza, & Sudeep, 1998; Hsu, Oge, Hamza, Alhalabi, 1999).

In contrast to the simulated laboratories, this paper provides a conceptual proposal for the implementation of an unrestricted environment where authentic laboratory experiments can take place via the Internet through remote access. Students have unrestricted freedom to apply any inputs and acquire resulting outputs as though they attend the experiment in person. Such a method can liberate students from physically attending the laboratory, and hence, engineering or science experiments can take place through distance learning facilitation software.
Thus, the authors of this paper, propose an Internet facility that will authentically provide laboratory experiments remotely. Such a facility is brought to the doors of the distance learner to help provide learning that is comparable to that offered for conventional students. This paper describes the development of a prototype remote laboratory system including software, hardware, procedures, and instructional systems. This includes a description of the prototype remote lab environment developed by the authors and a discussion of development issues, such as the reasons behind JAVA and RMI as the system's development tools over other popular alternatives.

Distributed Interface and Protocols

Java Language

Java was chosen for several reasons for the implementation of remote labs. Java allows for programs that can be embedded in Internet web pages. Currently many applications, which are written in a wide variety of languages, including C++, C, and Pascal, have fairly low level facilities like protocol handlers. As remote laboratories rely on the Internet, Java was chosen due to its Internet readiness (Ince & Freeman, 1997).

Java is a machine-independent language, which creates programs that run on a wide variety of computers using a range of operating systems. Since students will log on from a variety of computers to attend the labs, it is more efficient to choose Java, which inherently solves the problem of portability (Planagan, 1998).

Java programs do not execute directly on the computer and hence will not interfere with the operating system or user data. Instead, they run on the Java virtual machine, solving the problems of security and unauthorized access.

Java is a language well suited for interactive web applications. Most of the applications which are built in other languages, such as CGI and HTML, give the impression of being interactive. But in reality they usually move through a series of text and visual images following pointers to other sections of text and visual images.

Java language offers the feature of multithreading. This means that there are multiple concurrent executions of code, providing a high-level implementation of concurrent processing. This allows many students to work on the same laboratory setup simultaneously (Geary & McCleallan, 1998).

Java is an Object Oriented programming language. It offers facilities to define and manipulate objects, which are self-contained entities that have states and accept messages. Therefore, Java programs can be easily modified, as reusability of code is possible (Cornell & Horstmann, 1997).

Distributed Interface Protocols

Since the virtual online laboratory will be a distributed environment, the implementation had to be in CGI, JDBC, Sockets, IDL, or RMI methodologies. RMI was chosen to build the distributed computing environment, written purely in Java. Other distributed computing environments are compared to RMI below.

The Common Gateway Interface (CGI) is a standard interface that allows web developers to execute programs on an HTTP server. This is a very crude form of client-server computing whereby an HTTP client invokes a program running on the server (usually passing it some data), and the program sends some results back to the client for display on a browser. CGI programs operate in a stateless mode, which means that there is no persistent connection maintained between the client and the server programs. Each time the CGI program gets invoked its runtime environment (memory and system variables) also gets re-established. The program being executed sends the information back to the client and the process shuts down. These recurring starts and shutdowns generate an extra overhead in the server's load and cause delay in the performance. In contrast to CGI, RMI operates in a persistent mode. In other words the network session between the client and the remote objects remains active until the client or the server closes the connection. RMI's garbage collection process automatically closes the TCP stream when the remote object is no longer referenced.
Because of its persistence, RMI is far more effective than CGI in cases where the client is running within the Java virtual machine. The extra overhead is eliminated and the performance is improved.

In some environments, JDBC calls are managed directly by the clients (Reese, 1997). A few JDBC drivers require direct interaction with native database drivers such as the Microsoft ODBC, Oracle SQL Net, etc. The security contained within most commercial browsers prohibits the execution of native code by the Java applets (Cornell & Horstmann, 1997). Other JDBC drivers remove the native calls by introducing an application server. The application server operates as a form of middleware, performing all database interactions and session management on the server. When JDBC calls are incorporated in large-scale applications, such as maintaining student records, it is extremely difficult to maintain the up-to-date database drivers on every client. Also, if either the database engines or the middleware were replaced by another product, every client application that accessed it would require modifications. The JDBC client is responsible for managing the database session and processing the Information. This might cause the network to be burdened with additional traffic as the client repeatedly communicates with the database. In contrast, RMI allows partitioning of data access and workload from the client by encapsulating the JDBC code within a remote object. This approach eliminates added maintenance of the client-side drivers. This also reduces the network utilization by placing the RMI server physically closer to the Database server on the network. In this case a single server was used both as a database and for RMI.

The actual exchange of information between the client and server is performed through the TCP sockets. Architecturally the RMI process operates in a very similar way to those written with Socket objects. Both support persistent network connections between the client and the server (Horton, 1997). In RMI information between the client and server objects is performed through object serialization. However in Sockets one must create the program logic to marshal and unmarshal the objects that are serialized. The RMI is a higher level architecture than sockets. Although the two perform similar functions, the RMI allows you to concentrate on value-added program logic and not network or object transports.

The IDL or Interface Definition Language (Baker, 1997) is a standard defined by the Object Management Group for defining object interfaces. This is intended to establish the object’s interface definition regardless of the programming language and environment within which it is implemented. The IDL operates in a model that is similar to the RMI, making use of stubs and skeletons to marshal parameters between objects. RMI is useful in brokering object requests when the objects are written purely in Java.

Although there are many alternatives for building distributed applications like ours, RMI shows its strength in several areas. Since we will be writing the code in Java it is completely portable. It also facilitates application partitioning as the communication takes place across virtual machines. The JDBC package was used as an interface for executing SQL statement (Reese, 1997). We implemented it in this way because: it helps large-scale applications like ours to be written to the JDBC interface without worrying much about which database will be deployed with the application; it keeps the main application insulated from vendor specific issues, so the application can run equally well on Oracle or Microsoft-Access (see Figure 1); the JDBC is built on drivers based on other databases API’s, and they are very closely and deliberately mapped to the ODBC counterparts, sharing conceptual components like Driver Manager, Connection, Result Set etc.
System Hardware and Software Model

Hardware Model

For a prototype, we have built a remote laboratory for experimentation with electronic circuits. The 6B Series product family from Analog Devices was used to build the required hardware as it provides a direct interface between the host computer and a variety of analog input, analog output and digital I/O applications. The hardware consists of analog input and output modules and the 6B50 digital I/O board. The following input modules were used in the circuit: the 6B12 Module accepts millivolt inputs from 150mV to 500mV, voltage inputs from 1V to 50V and process current inputs, returning data in engineering units; the 6B21 Module is an analog output module that provides digitally controlled, isolated current loop output to a resolution of 12 bits with an output range from either 0 to 20mA or 4 to 20mA.

System Software Model

The JDBC-ODBC bridge is included in the JDK 1.1 which enables Java applications to access data through drivers written in the ODBC standard. The driver bridge is very useful for accessing data in data sources for which no pure JDBC driver exists (see Figure 1). Through RMI a student can access any other Java object running on a separate virtual machine where the serial communication and the database accesses are performed. The Java applets, on which the students are working, invoke methods contained in remote objects, which issue the calls for serial communication and database access.

The RMI architecture shows the student (client) process and the remote object (a particular experiment) running on separate virtual machines. These two are logically linked to each other through the registry. The Java virtual laboratory application executes as a server process on Virtual Machine A. This application (the remote object), identifies itself with the RMI registry, which is another Java application whose role is to maintain active references to remote objects. A stub is a proxy for the remote object implementing its public interface. When a student object references a remote object, it does so by referencing its stub. A skeleton is
the stub's counterpart running on the remote server. Similar to the stub, it provides the mechanism for accepting students' requests, forwarding them to the remote object and sending results back to the students. Through the registry the remote objects offer their services to the students. When the student working on Virtual Machine B wishes to invoke a method contained within the remote object, he/she first communicates with the stub. The stub passes the information to the object reference, which requests the service from the registry. The registry passes the request to the remote object through the skeleton. The student talks to the remote object by accessing the RMI registry on the host where it resides, through a TCP socket connection (i.e., the Internet). Once the registry accepts the student's requests, it delivers a reference in the form of a stub back to the client.

The student now invokes a method contained within the remote object's stub. This invocation may involve exchange of additional objects as parameters to and return values from the function call. Making both the server and the student's applet code serializable makes this communication possible.

At the server end, the parameters, such as the results of the experiment performed and the grade of the student in an experiment, are forwarded to the remote object through a skeleton object. The skeleton dispatches these parameters to the remote object and invokes the appropriate methods. When this function is completed the return value is sent back through the skeleton and the stub objects and is received by the student as shown in Figure 1. The remote object and the student lie at the same level of communication i.e. any request by the student can be answered only by the remote object and vice versa. The same is true for the stub-skeleton and the RMI registry object reference. The Security Manager in RMI (Horton, 1997) also makes sure that the appropriate measures are implemented to make sure that the application is well behaved and does not violate the laboratory rules. With the help of the security manager the students will be prevented from accessing restricted information, such as grades, on the server machine.

Implementation Details

Once the student goes to the URL (http://jupiter.cse.fau.edu/directory.html) the ClientApplet gets loaded (Geary & McCleallan, 1998). The browser now halts and the RMI procedures associated with the browser start by establishing a one to one connection with the Virtual Laboratory server.

When the applet runs, it automatically connects to the remote objects because the start method of the applet contains the remote objects' IP address and the remote object registry name. Once the connection has been established, RMI will get the Remote Object Proxy into the users' machine, and this proxy has the reference of the remote object. RMI has server-side skeleton and client-side stub. Once the student invokes any methods the stub interacts with the skeleton and retrieves the required remote object (see Figure 1).

The student can invoke all the methods of the server (remote objects) from the client program with the use of the stub. The server contains the skeleton of the remote objects (stubs and skeletons are generated by the RMIC compiler provided in the JDK kit). The skeleton knows the location of the remote objects in the memory of the server. When the client invokes the method, the stub sends the message to the skeleton; the skeleton calls the remote object; the remote object does the work requested by the client and replies to the server skeleton. The skeleton then replies to the client stub and the stub sends the message back to the client.

Following is an example of student registration into the virtual laboratory. To register, the student types in his/her login name and password and clicks on the register button, invoking the Register() function in the applet, which gaps the login name and password. The OpenDirectory() function will return the thread number for that student (Horton, 1997). Using this thread number the remote object's method is called with the login name and password as parameters. This calls another method for database connection using the JDBC predefined command for SQL query, which checks if any other login name in the database matches the one the user has entered. If it does, a message is sent to the ClientApplet code which asks the user to try another login name. If no duplicate login exists the login name and password are inserted into the database and a positive message will be sent to ClientApplet code which informs the user that registration has been successful. At the end, PerformLogin() calls the CloseDirectory() function that closes the connection between the client and the remote object (Horton, 1997; Bishop, 1998).

The registered student enters his login name and password and clicks on the Login button invoking PerformLogin() in the applet. The OpenDirectory() function will return the thread number for this particular client. Using this thread number the remote object methods are called and the login name and password are
passed as parameters. This method calls another method for database connection using JDBC predefined command for SQL query. This method checks if the student's login is present in the database. After the check is made, it asks the student to perform Experiment Number 1, if not already performed, or to click on the Get Grade button to see his/her grade in the lab. Finally, PerformLogin() calls the CloseDirectory() function, which closes the connection between the client and the remote object.

If the student has not performed the experiment the student selects Experiment Number 1 from the choice menu and clicks on the Get Experiment button. This will build a new panel, which consists of the new experiment. The Get Experiment button will be enabled only if the student has not performed the experiment. Once the experiment number 1 panel is built the student enters three different values for the current. The student can now click on the Run button, which invokes PerformHardware() in the client applet. This function grabs the current values entered by the student in three different strings. OpenDirectory() will return the thread number for that particular client. The data, which the student has entered needs to be passed to the hardware connected to the serial port of the server. Since the Java Virtual Machine cannot interact with the serial port of the server directly or the operating system, the Win32Port class is developed. The values, which the student enters, are passed as parameters in the function calls to the Win32Port class. The output results are received by the function provided by the Win32Port class methods and these are then passed on to the students as outputs of the experiments. Finally, PerformHardware(), calls CloseDirectory() which will close the connection between the client and the remote object.

After the student has submitted the data to the hardware and gets back the results, the Submit For Grade button is enabled, which will invoke the performSubmission() function in the client applet. This function grabs the values of the currents, entered by the student and the voltage values and calls another method for database connection using JDBC predefined command for SQL query. This will insert all the values along with the student's name in the database. A positive message will be sent to ClientApplet code informing the user that the values have been successfully submitted. Finally, performSubmission() calls CloseDirectory(), which closes the connection between the client and the remote object.

The Hard Part: Java Native Interface (Serial Port Communication)

The last part of completing the package was to write a native interface in Java that talks to the Serial Ports. This consists of Java code (a class) that accesses data through native methods, which are typically particular to a vendor library. Like the bridge driver this class is convenient when a C data access library already exists, but it isn't always very portable.

The Win32Port class implements the access to the computer's communication ports through the Win32 API. The native methods are contained in the JWINPORT DLL, and the Win32Port class is the Java interface to them. The DLL is built using the JNI, which comes with Sun's JDK 1.1.

The standard drivers for serial ports in Windows 95/NT are limited to the ports COM1 through COM4. The compiled DLL adopts this limitation and provides space to handle the four ports. However, the multi-port interface card with a Windows driver makes additional ports visible for the operating system like the standard ports. In this case the DLL has to be recompiled for the number of ports needed.

The port number is passed to each of the methods as parameter rather than having it as a field of the Win32Port class. This is because to access an object field from the C code, a symbolic look up must be made. The port number parameter on the other hand gets passed as a plain integer and works faster.

Conclusion

The authors are successfully progressing through the design and the implementation of the Virtual Lab process over the Internet. Unlike time-shift instruction (experiencing instruction following the live lesson, i.e., videotape, or a software simulation), real labs or real-time instruction (experiencing instruction at some point during the live lesson or experiment) provides students the ability to receive instructions without the teacher's direct presence. Students in Real Lab environments have the freedom to analyze their experiments at a distance. By no means is the student thinking limited but instead his or her complex thinking processes...
(basic thinking, creative thinking, critical thinking) are stirred at a distance without any technical limitation of any kind. A student is still able to conduct an experiment, collect needed information, categorize the information, synthesize the information, and create his or her own conclusions based on data collected, from input and output, without physically attending a lab.

Abstract: A group of professional leaders are in the process of developing an active and continuous virtual learning space based on the Educational Objectives which promote the technological advances in all the academic community of the Inter American University of Puerto Rico, Bayamón Campus. After evaluating different technical tools and choosing "Learning Space" as the platform, the Professors at the Bayamón Campus have developed the OIL (Online Interactive Learning) Project. The members of the team include a coordinator, a group of professors, a technical team composed of students, administrative personnel and the technical advise of a specialist in curricular design. This group has developed several online courses. Their duty was to begin the first stage, which was to create eleven online courses in Spanish, which include the areas of Biology, Chemistry, Marketing, Spanish, English, Accounting, History and Computer Science. The second stage of the project consists of testing these courses, and the creation of new courses by other professors. A permanent structure called Faculty Support Center was created to support this stage of the project including future development of other courses by other faculty. The implementation and third stage will start on January 2000.

Introduction

The Inter American University is the largest private university in Puerto Rico with 11 campuses throughout the island and a total of 42,000 students. The development of the online course project, called Online Interactive Learning (OIL), responds to the institutional long-term educational objectives identified as Vision 2012. These educational objectives present the Inter American University as a vanguard institution: a leader in information technology. The OIL project also responds to the educational objectives of the Bayamón Campus, which promotes a technological culture through the development of innovative projects within the university community.

The development of this virtual learning space required the creation of the Faculty Support Center (FSC) and the training of technical personnel, faculty and several students. This Center is composed by a technician and students majoring in computer sciences who provide technical support and assistance to the faculty in the
development of the online courses. The mission of this center is to develop and promote innovative educational projects that can transform the teacher-learning process according to the new educational vision of the Bayamón Campus. The goals and objectives of the Center are to train professors in new technologies related to the teacher-learning setting and to stimulate interdisciplinary teamwork. In August 1999 the Faculty Support Center was established to offer technical support and advise to professors in the production of online courses.

To fulfill the expected outcomes, the OIL project was divided into stages. The first stage consisted of the training of faculty members; the second was the creation of the course in the LearningSpace platform. The third stage is the course validation by groups of students and finally, the last stage will be the implementation of the courses in a semester through the Internet.

Materials and Methods

The human resources used were professors, administrators, technicians and computer science students. The project was done exclusively with our campus personnel. In June 1999, the twelve participating professors received training from a specialist in curricular design. At the same time they were developing the educational materials to be used in the online courses. The Director of Computer and Telecommunication Center trained six computer science students, who are completing their degree, in the use of Lotus Notes, LearningSpace and Publisher. A faculty member was the director of the project. LearningSpace was the platform chosen for the creation of the online courses. This tool permits the use of technology in teaching and learning and can also be combined with traditional face to face training. LearningSpace enables the instructor to teach the course content in 3 different ways. These are: synchronous training that permits online training sessions in which the instructors and the learners work together through the Intranet or Internet; asynchronous training which enables learners to work at their convenience and it also allows them to collaborate with others students in the course; and a self-paced training that allows students to work alone when they are ready. Other applications used were: Word, Power Point and electronic mail.

Results

The first group of professors created eleven online courses in 7 different disciplines (Tab. 1).

**Table 2**: Schedule for the creation of the Online Courses in the Bayamón Campus of the Inter American University.

**Conclusions**

The creation of the virtual learning space integrates the knowledge and the talent of a group of computer science students, professors from diverse disciplines and technical personnel. This project promotes collaborative work and increases the productivity in the different academic areas.

For all the individuals that were involved in the OIL Project, it constitutes a doubly enriching learning experience. It offers the faculty members a challenging experience that requires them to surpass the traditional educational methods and visions. In addition, it offers the faculty the opportunity to reflect on the teaching-learning process.

However, the planning and implementation of this project has allowed us to become aware of the following problems: some faculty members are resistant to the use of new technology in this process, and there is a need to create new regulations to facilitate and establish the project administratively and academically. In conclusion, this project has been the biggest challenge we have faced in the past months, and it has become an enriching experience, which has promoted massive changes.

An Overview of Online Educational Delivery Applications

George E. Marsh II  
Barrie Jo Price  
Anna C. McFadden  
College of Education  
The University of Alabama  
United States  
gemarsh@bamaed.ua.edu

Abstract: This paper is a report on the types of online delivery applications used in institutions of higher education to develop and implement web-based courses. Many institutions of higher education (IHE) are grappling with ways to implement and manage online instruction by using local personnel and resources, purchasing some components of management, or outsourcing distance education entirely. While each institution will make decisions that meets its unique needs, it is important to know about the range of possibilities available to university administrators today. The major problems confronting IHE's are twofold: (1) the lack of technical skill among faculty members to convert their courses into online formats, and (2) the need to support and manage distance education. This paper provides an overview of the most popular online educational delivery applications.

Introduction

Web-based instruction (WBI) is a comprehensive set of instructional materials available through a browser over the Internet, an intranet, or extranet. WBI can provide content in hypertext, audio, video files, and other multimedia formats, and include such resources as chat, threaded discussion, e-mail, and hyperlinks. Many institutions of higher education (IHE) choose expensive distance education options rather than WBI, although WBI is much less expensive and equally effective. Most educators adopt technology with the following progression:

- **Phase 1:** An instructor achieves some level of basic computer literacy.
- **Phase 2:** The instructor uses computers for personal productivity.
- **Phase 3:** Venturing into instruction, the instructor uses technology to enhance lecture presentation.
- **Phase 4:** E-mail is used more widely to interact with colleagues and students, along with Internet searches.
- **Phase 5:** The instructor decides to re-purpose a course as an imitation of the conventional class requiring live, real-time interaction.

The typical faculty member re-purposes an existing course only after first experimenting with technology in the traditional classroom.
technology in the college classroom is used almost exclusively to augment the classroom lecture. The first instructional application attempted by a professor is usually a PowerPoint presentation, a progression that is almost routine.

Synchronous and Asynchronous Delivery Systems

Synchronous Delivery. The technologies used in synchronous delivery include two-way interactive video telecourses, one-way video with two-way audio, audioconferencing, and audiographic conferencing, and may include electronic white boards, radio, television, IIITS, closed-circuit, satellite. Not only are the production systems more complex and expensive, but the number of potential students is limited by the real-time requirement for class attendance. In effect, this is a variation of traditional classroom instruction rather than a replacement. In most respects, the classroom structure and routines are similar to a conventional classroom, with the instructor treating persons at remote sites as if they are members of a large class in a lecture hall. In fact, other than using presentation graphics, instructors do not act much differently than in a conventional classroom. Students on-site or at a remote site are expected to listen, take notes, and answer questions.

Asynchronous Delivery. In the asynchronous method of distance education, the instructor and students are not required to have real-time contact on a regular basis. It is not time and location dependent. In some cases students are mailed videotapes or CD-ROMs, when the content could be put on the web, and this drives up costs due to production and post-production costs, personnel to handle the mailing of products, and other expenses. However, the WBI course that avoids videotape and CD-ROM development enables students access to any remote resource at the students' convenience, or on demand. There is no need to have full-motion video for an entire class, especially if computer software and learning activities are designed for students to preclude the need for lecture. Asynchronous WBI is much less expensive and equally effective as the more expensive synchronous models and traditional classroom instruction.

To determine a break-even point an administrator can calculate development costs and plot the projected income necessary to recover costs (i.e., cost - the sum of fixed and variable expenses, and price (per unit/enrollment). A general formula for calculating break-even

<table>
<thead>
<tr>
<th>Fixed Costs</th>
<th>Revenue to Break-Even</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - (Variable cost per unit/Selling Price per unit)</td>
<td>= Revenue to Break-Even</td>
</tr>
</tbody>
</table>

IHEs often do not account for many fixed items in a budget on a daily or hourly basis, such as office equipment, utilities, office space, and so forth. Variable costs are often easier to track because they may be hourly wages paid to specialists, contracting for online delivery, new software or equipment for production, and so forth. Factors that contribute to variable costs can be identified in this table (rented and/or owned):

Some costs, particularly for faculty time, can be considered a redistribution rather than additional costs. Changing a faculty member's role temporarily to develop courses for WBI may raise costs for the short-term, because of the need for someone else to teach certain existing
courses in the faculty member's absence, but these costs can be recovered in the long-term as the income per professor increases.

If development costs for a web-based course are less than a synchronous course, and if student outcomes are essentially the same, the IHE administrator needs to consider developing web-based courses and avoid more expensive synchronous endeavors. However, the one factor that can drive up such expenses are online delivery systems for WBI. Some IHE's provide their own management systems with varying degrees of comprehensiveness. Examples of efforts by institutions without significant commercial vendor support include the University of Virginia, Iowa State University, Florida State University, and Penn State University.

Commercial Comprehensive Delivery Applications

The following commercial vendors are in alphabetical order, either by name of the product or service or by the name of the company, whichever is most prominent in the literature. Some of the vendors provide aids to develop courses, others offer various tools for synchronous courses, and some offer comprehensive services including management for the IHE. Costs are not discussed because it is almost impossible to determine due to the menu of services and different costs associated with scalability and number of users. Furthermore, there is no intention to evaluate these products or to suggest that one product is better than another, a determination best made by potential clients. Finally, some products were excluded from consideration because they are specifically designed for corporate training or do not appear to have the necessary components to circumvent the greatest obstacle, namely the inability of instructors to create web content.

Blackboard. (http://www.blackboard.com/) Blackboard Inc. provides Blackboard, "CourseInfo" and "Campus" for hosting their own courses for individual courses, multiple course sites, and academic intranets, respectively. Blackboard allows instructors to point and click to incorporate learning materials from word processing, audio and video, and presentation files. At the high end, with "Campus," the services include a comprehensive management system and the software becomes a campus portal for all distance courses and a variety of related services: business and strategic planning, content conversion and course migration, instructional design, systems integration and project management, application integration, training and education, web hosting, and maintenance and support.

Collegis. (http://www.collegis.com/) Services can range from implementing web-based courses into the curriculum through support services to incorporating campus-wide "Administrative Technology Services" such as new student, finance, to providing comprehensive Network Infrastructure Services such as planning and developing technology migration strategies. Collegis advertises its product by stating that personnel will be assigned to the campus to work with faculty in the development of course content and other aspects of development, delivery, and maintenance of a distance education system.
Complete On-Line Teaching System or COLTS. (http://www.corgisoft.com/public/colts/index.html) COLTS uses form-based tools to create classroom homepages. An instructor can input text or paste from word processing then convert the text to HTML code. The instructor can create or edit seminars, quizzes, and exams through a library structure. Also included is a "Student Journal Module" to allow an instructor and student to work together on a document.

Convene. (http://www.convene.com/) Convene develops partnerships with IHE's and provides a six-week training program for instructors. Convene also offers a host server and network, technical support, and other services.

Creator. (http://www.melbourneit.com.au/creator) Universities, schools and corporate trainers can use "Creator" to create online learning environments with interactive elements including video/audio-conferencing, newsgroups and chat sessions.

eCollege (http://www.ecollege.com/student/index.html) eCollege is a recent project created by Real Audio/Real Video to offer partnerships with IHE's to build online courses. In the Premium program the IHE receives course development, instructional design, student orientation, virtual campus development, hardware and software as a complete "turn-key solution" for distance education. The eCollege page is prominent on the IHE home page and serves as the portal for distance education connection.

e-Education. (http://www.e-education.com/software.html) Instructors can use a set of tools to create courses or in the full service plan. An IHE may simply provide course content in an electronic format and e-education will create a course. In the "self-service option" the instructor creates the course content. Course elements include a course builder, announcements, roster, TestMaker, and forum administration.

Embanet. (http://www.embanet.com/) Courses can be created with an online wizard, including tests and other features. The company claims that courses can be operational in two months if instructors develop the content, or in a matter of days if the company makes the course. The best known courses of Embanet are those operated through the UCLA extension service.

MadDuck Technologies (http://www.madduck.com/) This company provides three major products: Web Course in a Box, Web Campus in a Box, and Web CourseBuilder ToolBox. "Web Course in a Box" provides for development of a syllabus, calendar and/or scheduler, announcements, personal web pages, forums, lessons, tests, a whiteboard, and chat. The "Campus" tool supports building lists of instructors, students, announcements, active courses, inactive and archived courses and home pages for instructors and students. The "Faculty" tool supports home page, forum development, and campus lists of courses.
SocratEase. (http://www.SocratEase.com/school.htm) Primarily for corporate training but also used by universities, SocratEase incorporates a course management, testing and test tracking, built-in e-mail communication for discussion and questions, and a course authoring tool.

WBT Systems. (http://www.west.ie/) The company provides "TopClass," which is a comprehensive system including course development, quizzes, discussion, and other features of web-based courses. Sections from one course can be imported into other courses. "TopClass Assistants" enables Microsoft Office 97 documents to be converted automatically into courses. "TopClass Creator" instructors "authorized by TopClass Server" have access to web tools for assembling complete courses from any "web-compatible" content. Other tools can render presentations or documents into courses.

WebCT (http://www.webct.com) Tools include a conferencing system, chat, student progress tracking, group project organization, student self-evaluation, grade maintenance and distribution, access control, navigation tools, auto-marked quizzes, electronic mail, automatic index generation, course calendar, student homepages, course content searches and much more.

Evaluation of Online Delivery Applications

Comparisons or evaluations may be found at ZDNet (http://cma.zdnet.com/) and The British Columbia Standing Committee (http://www.ctt.bc.ca/landonline/choices.html) conducts its own evaluations and also includes links to reviews online. Comparisons are difficult because of the differences in features and the variety of services available. Products can be evaluated in terms of technical aspects, support, training, cost, and many other features that can be of variable importance to different IHE's. For institutions that outsource everything, only cost and services are important. For those interested in providing a mechanism for inexperienced instructors to develop course content, the nature of the development tools and continued support or management features may be more important. Some programs emphasize tests and test management, which may be unimportant to some and critical for others. In general, the following areas are used in developing evaluation criteria:

• Circumvention of HTML to develop course material
• Password and username security
• Desktop based file management
• Flexibility for instructors to revise and manage course content
• Test banks (development, randomization, timed, scoring, reporting, feedback options, etc.)
• Feedback on tutorial questions
• Progress tracking for instructor and student
• Electronic Mail
• Bulletin board
• Chat facility  
• Logged chat  
• Application sharing  
• Asynchronous sharing  
• Synchronous sharing  
• File exchange  
• Newsgroups  
• Whiteboard  
• Virtual space  
• Videoconferencing  
• E-commerce (registration, fee payments, enrollment, and so forth)  
• Technical issues (numerous and often unique to each site)

Conclusion

As many IHE's consider the need to develop distance education because of student demand and competition, outsourcing or contracting with a private vendor is an option many consider. As indicated in this article, there are several options. Whether or not an IHE develops its own system or contracts for the services, the more difficult issues are resistance by segments of the faculty to distance education, faculty intellectual property fights, workload, training and technical support, faculty support, and job security. These are important concerns for any administrator or faculty. The WWW threatens to widen the gap between rich and poor, between North and South, and perhaps between IHE's that thrive and those that go out of business. While the paper does not permit room for comparative data, anyone requesting information from the authors will receive information promptly.

Overview of Session

The explosion of the World Wide Web has changed the way we live, work, shop and learn. Increasingly, colleges and universities are offering graduate and undergraduate courses that are delivered fully or partially over the Internet. One category of computer-based tools that is increasingly being used as a classroom in cyberspace is the forum or electronic bulletin board. An interactive forum presents a unique opportunity for everyone with a web browser and permission to access the site to be part of on-going dialogues on a variety of pertinent topics.

At the School of Computer and Information Sciences at Nova Southeastern University, we conduct fully online and partially online classes using a variety of electronic technologies in the learning process. These include e-mail (for group and private messages), the Electronic Student Electronic Teacher (for uploading, downloading, and responding to homework assignments), and a custom-modified Allaire Forum that serves as an anytime/anyplace forum. Essentially, electronic tools are programs whose uses need to be mastered. Functionally, the uses of the three tools named above have very short learning curves for people who are computer and reading literate. Devising procedures for best practices to meet cognitive and emotional needs of remote learners is a much greater challenge.

This session will focus on the forum as the meeting place of the class in cyberspace. Since it is asynchronous, it does not matter where a participant happens to be or what time it is in any given place. The people on the panel are all experienced educators with many years of face-to-face teaching that preceded the distance learning experience.

We will begin with a short demonstration of different forums (pending Y2K availability) so that the audience clearly understands the subject under discussion. The precise content of the panel and greater group discussion will target the interests of the audience. Discussion will focus on, but not be limited to, questions to which answers have been prepared in advance by members of the panel. Again, the objective of this session is to share best practices taking into account the wants and needs of faculty and students. We have determined to limit discussion to post-secondary learning environments and, whenever possible, to focus attention upon professional development for teachers.

Questions for Discussion

What aspects of the physical classroom should be carried over into the forum?

What do you do to prepare your forum for optimal learning before the first day of classes?

How do you organize and maintain your forum to accommodate a range of learning styles?

What are students expected to do in the specific contexts?

What constitutes acceptable participation?

How do you use the forum to reduce isolation for the remote learners?

How is in-depth discussion stimulated?
How do you use the forums to promote the ancient concept of a liberal education?

How do you use the forum to meet learning needs in an era of rapid change?

What are the rules of participation that you provide to students?

How do you deal with improper postings?

How much teacher-intervention is optimal?

How do you move away from the hub-spokes model of teacher-student participation?

What are the demands on the teacher in terms of preparation and mentoring?

How does your institution accommodate these demands?

Wearing the graduate student hat, compare the cyberclassroom to the physical one.

Wearing the graduate student hat, compare your peer relationships with traditional ones.

Wearing the graduate student hat, describe your level of frustration/satisfaction with the distance program.

Wearing the graduate student hat, what advice would you have for newcomers to the program?

Members of the Panel

Moderator: Trudy Abramson, Professor of Computing Technology in Education (CTE) at NSU/SCIS teaches partially online doctoral courses and mentors dissertations.

Member: Maxine Cohen, Associate Professor, CTE and Information Systems, NSU/SCIS teaches online master and partially online doctoral courses and mentors dissertations.

Member: Tim Ellis, Assistant Professor, CTE, NSU/SCIS teaches online masters and partially online doctoral courses. Tim is one of our recent graduates and has used the forums extensively as a graduate student. His dissertation focused on distant learning at the community college level.

Member: Cordelia Twomey, Associate Professor and Program Coordinator of the Masters degree in educational technology, NJCU, teaches on-campus and on-line teacher education courses and adjuncts in the CTE doctoral program at NSU/SCIS.

Member: Mitchell Pratt is lead trainer for the Alpine School District, UT and teaches in an online program for Connected University of Pepperdine University. Mitch recently completed his dissertation through the CTE program at NSU/SCIS.
DEP WEB: A concept mapping based on web distance education process

Abstract: This paper relates the development of a concept mapping based on web distance education process, pointing out the concepts and relations that integrates teaching-learning process, so this can be used to understand the technology and terminology used in the context of computer and distance education, and conduct, for example, the construction of virtual courses, the specification of methodologies, educational tools and etc.

Introduction:

Nowadays, the most important school challenges are related with how to use different media and technologies, as well as, lead and guide students for all the variety of informations available in our lives.

Internet appearance and invasion, without knowing why and how computers can be used in an efficient manner, almost imposed the beginning of learning process by this way. As result, not prepared teachers and other professional, involved in this process, became resistant and threatened by the ignorance of the potential of this tool (Mercado, L, 1998;1996) (Lollini, 1985). As a matter of fact, we realize that this resistance is not only by the use of computers, but of technology, in general. Some people do not know, however, technology is not going to "renovate" teaching-learning process in an effective one. It depends on its use. Let's see, for example, the invasion of a pencil (it is a technology), it is used for both writing something very important and kill somebody (Souza, R., 1999). It happens with technique aspects of technology like TV, radio, computer and etc: depending on how it is used, it can revolutionize or perpetuate existing learning structures.

Minimized the faze of resistance, we began searching knowledge of computer science as an educational tool. In practice, some schools are using this technology, in their context, without appropriated knowledge of its features, deficiencies and virtues. Professionals form different areas began to lead and interfere in education, for example, developing educational software and on line courses, without the guarantee of its quality in terms of education. On the other hand, education professionals are tied up with this technology, in a certain way, away from their usual tools and its necessary some time to know, evaluate, develop methods and use it in an efficient manner, as a complementary instrument of formal teaching, as an instrument of distance education.

Distance Education

Many discussions are concerned with distance education. Among other facts, it is attempting to search another ways of learning. Certainly, the evolution of technology is a very important element in its process of maturing. From alternative it is considered, in many cases, as a kind of regular teaching (Leite, L, 1999).

In attempting to become part of the context in distance education, many courses have transposed the local teaching model to the environment provided by the Internet. The local teaching model has its advantages, since this model provide the social development of its students, but from the moment that teachers
do not know educational ways to your students reach the objectives proposed for their education, this is an inefficient model. The use of Internet, for example, we realize that when a course is published as a distance teaching course it can not be, simply, composed of *home pages* referring transpositions of local courses classes. In fact, it would be a pure and simple transposition of a bad education model, according to education history. In an environment like this, students are, in a basic way, seen as contents receivers, which task is to assimilate and reproduce, but almost never discuss, analyze, reflect. According to this model, from what propose does the technology contribute in this case?

Searching some ways to give solutions referring the use of different technologies, in special, the computer, we conclude that technology ally to many interpretations of their use, in a local teaching or distance education, reinforce the need of two actions (Gomes, A, 1999): a) an education systematization, in a general way, as a "gear" for process of knowledge generator, that allow professionals reconsider educational processes existent and the opportunity to consider about school social function and b) a model conception that glimpse the understanding in the knowledge generation and in the elements involved manipulations. By the way we ca not use the tools provided by the appearance of new technologies, in special the use of computer, if we do not discuss models that can be computed.

**The Conceptual Model**

We believe that becoming the knowledge silted up, by now, available in education and computer science, as well as the relations of its basic principles need to be discussed for the real teaching-learning process. The objective of this paper is generate a mapping referring the systematization of distance education process so it can be discussed, evaluated and used for professionals interested in providing teachers an efficient tool, as among of training, tools constructions, softwares, virtual environments and many others, pointing fails and feasible solutions to teaching-learning process, enlarging knowledge about distance education and the use of technologies, providing conclusions about the model mapped or it can be used to create new teaching models.

The development of this model is based on constructivist approach from meaningful learning proposed by Ausubel (Ausubel, D, 1978) and concept mapping principles which was first developed by J. D. Novak (Novak, J., 1977) to map the concepts and the relations among education, distance education and other concepts related to them to establish more understanding, questioning the actual educational paradigm. Which learning theory does exist? What are the methods and teaching techniques and how are they related in teaching process? What are society role in education? What is teaching and how do it interfere in the teaching-learning process execution? What are the objectives of education? Do these objectives interfere in the way the process is executed? What is distance education? What are the principles of distance education? These are some of the questions that have been mapping, see figure 1. But we bear in mind the most important result of this mapping, beyond the others quoted above, is not the model obtained, but mainly the mapping process, in other words the appreciation and experience that can be obtained searching articulation, organization and criticisms evaluation of the model during its development, answering and/or pointing questions as shown along this paper.
Expecting Results

The systematization, the model construction process and the resulting model, as a final product of this research will have large contributions for teachers, computer professionals, educators and anyone interested in propitiate an effective environment of meaningful teaching-learning process.

We are certain, however, that the most important result is not only the conceptual model, but mainly the concept modeling, the experience obtained, discussed and presented by this process.

Abstract:
Web-based courses are becoming more common. Although several studies have been conducted to research the effectiveness of those courses, few investigations have focused on the human aspect of an online course. This paper proposes that for an online learner, the way she or he feels during the course itself is as important as the course content. In addition, the professor's abilities to lead an online course are crucial for the success or failure of the course.

Introduction
Technology in the Communications Age impacts learning and education by providing numerous sources of information and communication. The new electronic technologies present teachers, administrators, and policymakers with both unprecedented opportunities and unprecedented challenges. The Communications Age promises the delivery of information and education "anywhere, anytime." Technology is changing the landscape of education and creating a new set of possibilities for attending college.

Due to the diversity of today's learners, it is necessary to offer many diverse forms of education (Office of Technology Assessment, 1993). In support to this, Secretary of Education Riley (1997) stated, "Technologies also are important for providing opportunities in higher education at a time when college is becoming more crucial... making courses available at convenient locations; reducing time constraints for course-taking; making educational opportunities more affordable; and increasing the institutions' access to new audiences."

Owston (1997), in an analysis of teaching and learning on the World Wide Web (WWW), concluded that a promising case exists for the Web in three vital areas: access, improved learning, and cost effectiveness. Institutions of higher education will need to understand how to utilize these new media while maintaining instructional quality and meeting an increasing demand for continuous professional development of the knowledge workforce.

Many factors, including tradition, funding, credit units, semester schedules, and other academic structures, constrain institutions to geographic boundaries and on-campus classes. However, as Olcott (1999) points out, "preserving historical traditions and embracing new innovations can occur together."

The rate of Internet use is constantly increasing. In 1994, three million people were connected to the Internet. By the end of 1997, more than 100 million people were using the Internet, and its traffic has been doubling every 100 days (U.S. Department of Commerce, 1998). Distance learning programs that use communication technology, especially the Internet, have been growing. These programs cater to students who share the following characteristics: (1) they have families and jobs, (2) they come to school after work and before going home, (3) a large number of them already have a college degree, (4) they are returning to school for retraining, to learn new skills, or to obtain an additional degree or certification for professional achievement, and (5) they...
have high expectations for products, goods, and services, and many of their expectations have been created in technology-mediated environments (Fulkerth, 1998).

**Purpose**

Traditionally, studies have focused on the quantitative effectiveness of distance education as compared with a face-to-face setting (Miller, McKenna, and Ramsey, 1993; Souder, 1993, to mention some). However, an important aspect of the learning process is sometimes left out: the perspectives of the distance education students. The purpose of this paper is to report the perceptions of inservice teachers participating in a web-based university course.

Additionally, the researchers wanted to analyze and study the pedagogical soundness of distance education courses that model constructivist learning theory and that are available to learners at times and places convenient to them. Online teaching is a relatively new development, but recent research has shown it to have as much rigor and educational merit as is found in face-to-face courses (Sujo de Montes, 1999). Frank Odasz states, “the promise of online teaching is both the teacher and learner can be anywhere, participating at any time, through any type of microcomputer with modem. If online instruction can demonstrate economies of delivery of distance learning, it opens the door to ongoing learning for all potential learners” (Odasz, 1994). Christopher Dede (1996) says that technology can help transform schools but only if it is used to support new models of teaching and learning. Interactive distance learning (distributed learning) is a use of technology which supports constructivist pedagogy and school reform. It provides opportunities for faculty and students to communicate in and out of the classroom, become members of learning communities, utilize information from voice, text, graphic and television-video sources, develop technology competencies, and construct and apply knowledge.

**Theoretical Framework**

Constructivism and adult learning theories framed the present study. Constructivism views the learner as an active living being who internally creates interpretations of the world based upon his or her experiences and interactions with the environment, which are socially and culturally mediated (Cunningham, 1992; Fosnot 1996; Perkins, 1992). Constructivism also endorses the idea of the teacher as a facilitator, a senior partner whose function is to help the learner develop the skills to construct and reconstruct plans to respond to everyday life’s diverse demands and opportunities (Cunningham, 1992; Duffy & Jonassen, 1992).

The word “constructivist” is defined as both a theory of learning and a strategy for education which involves having students work on complex projects, often in groups, and synthesize information to construct their own understanding of a content area. In this model, students learn technology skills and concepts in the context of using them to solve a real-world problem; for example, they might create a product they can use in their classroom. These projects follow from a theory of learning that suggests that subject matter becomes meaningful, and therefore understandable, when it is used in context-rich activities (Fosnot, 1996). The courses will be designed to emphasize the students’ own responsibility for learning, for figuring out their own methods of solving problems, and for assessing their own work. Teachers who learn in this way will be better able to provide such environments for their own students.

On the other hand, adult learning theories emphasize the importance of participation, choice, experience, critical reflection, and critical thinking (Froman, 1994). Andragogy, the art and science of helping adults to learn, first pioneered by Malcolm Knowles in 1968, is a conceptual framework useful in organizing the way we look at learning with adults. Andragogy is based on humanistic assumptions about the adult as a learner, characterized by an independent self-concept, a depth and breadth of prior life experiences that can be used in learning, internal motivation, and the acquisition of new skills learned by an individual who is actively engaged in the learning process. Knowles’ (1980) theory of andragogy is an attempt to differentiate the way adults learn from the way children learn. Andragogy assumes that learners learn what they need to know, moving towards autonomous self-direction and drawing from the rich resources of their prior experiences. In other words, adults
learn more efficiently by doing or experiencing. Unless what is learned can be applied to actual work of life situations, the learning will not be as effective or long lasting.

**Methods and Data Sources**

Different methods from the qualitative paradigm were used to collect data. These methods included (1) an open-ended questionnaire (The Middle and End of the Semester Course Analysis), (2) electronic journals, and (3) in-depth interviews. They will be briefly discussed below.

**Middle and End of the Semester Course Analysis**

This email delivered, open-ended questionnaire was administered at the times indicated in its title. It asked the students' perceptions about their own technology learning and the ability to integrate it into their daily practice. The survey also asked the students' opinion about how beneficial their mentoring relationship with the course professor was. Two other questions addressed how students felt about the class and about using technology. The responses to the questionnaire were sent to the researcher and were treated as confidential data.

**Electronic Journals**

Online journals were kept by the participants and sent weekly to the instructor and the researcher. In these journals, students discussed their accomplishments and/or problems with the assignments. Journals were also a channel through which the participants vented their frustrations with technology, with timing of the projects, and with group work. However, they were also an avenue to keep the communication open between the students and the course professor, providing a sense of participating in a class, even when there were no walls and times that delimited such a class.

**In-Depth Interviews**

Four participants were asked to participate in a series of three interviews, each of which lasted approximately 90 minutes. Following Guba and Lincoln (1989), the researcher selected a purposeful sample. Interview participants included an elementary teacher, two high school teachers (one first-year teacher and one veteran teacher), and a technology coordinator. Each of the interviews were conducted utilizing a chat room. The times and dates were selected by the participants, and ranged from 6:30 a.m. on a Sunday morning, to 5:00 p.m. on a weekday. Transcripts of the interviews were obtained from the software environment that was utilized to deliver the course. In other words, the researcher did not need to transcribe the interviews because they were automatically recorded as they happened. The content was retrieved and the files were immediately erased to avoid any confidentiality issues.

**Results and Conclusions**

Content analysis and analysis of emerging themes were used to analyze the data collected from the open-ended questionnaire and the electronic journals. Analyses of emerging themes were used to examine data collected in the in-depth interviews. The data collected from each source will be briefly discussed below.

**Middle and End of the Semester Course Analysis**

The emerging themes from this open-ended questionnaire were grouped into four categories: (1) class perceptions, (2) technology, (3) self, and (4) professor. In the class perception category, the major theme that emerged was group work. As might be expected, some responses complained about groups that did not work
well together. However, most of the responses were positive about how supportive it was to create the class projects in a group environment.

In the technology category, the salient theme was the improvement of technical skills. Responses abounded about how useful this class was to sharpen the participants' technical skills. The researched class was almost considered as "in-time professional development" since it allowed participant teachers to apply their newly acquired skills to extend their own classroom activities that already utilized technology, and/or plan and try new activities.

The third category, self, was an interesting one. Although the most mentioned topic was "problem solving," the theme "frustration" was very much mentioned. Frustration usually came from having technical difficulties with the software and/or hardware, as well as with having server problems.

The main themes of the fourth category, professor, expressed the importance of the role that the course professor plays in the success or failure of an online course. The two main themes, "professor support," and "professor as a mentor," discussed the participants' positive feelings of knowing that there is somebody "at the other end of the line" who gives them feedback and encourages them in their learning endeavor. At the same time, the class participants perceived having a good mentoring relationship with the course professor. Undoubtedly, the professor's efforts to have constant communication with the participants through the journals and separate email messages contributed to the development a good mentoring relationship.

Electronic Journals

This data source provided a greatest insight into the students' perceptions. Journals were also analyzed using content analysis and analysis of emerging themes. The themes that emerged from the journals were divided into three categories: (1) class, (2) problems, and (3) feelings.

In the first category, the main theme was again "group work" which was mentioned in almost every journal entry. For groups whose members lived geographically apart, they discussed their adventures on trying to synchronize and meet in one of the chat rooms to discuss the assignments. For groups whose members lived in the same location, their journals discussed how important it was for them to meet face-to-face and receive support from each other. As discussed above, journal entries on this theme also discussed their frustrations when groups did not click together and completing an assignment was a monumental task.

In the second category, problems, two themes emerged and were mentioned in the journals the same number of times: technical problems and self-organization. The "technical problems" theme was already discussed in the section where the open-ended questionnaire results were presented. The other theme, "self-organization," discussed the problems that the class participants experienced to meet their job and family commitments and simultaneously keeping up with the pace of the class. For some of the participants, the convenience of taking a class at any time at home turned into an inconvenience. For them, constant interruptions from their families made working at home a stressful and difficult situation. For others, being able to take a class from a higher education institution without having to travel was a blessing.

Finally, in the last category, feelings, two themes that emerged and were mentioned nearly the same number of times were "frustration" and "reflection." "Frustration" was already discussed above. In the "reflection" theme, participants wrote about their ideas and thoughts on how to improve their daily practice based on what they were learning through experience and self-monitoring of improvements while participating in the investigated class. As Froman (1994) noted, reflection is the result of climates that support open communication, beneficial debate, and critical evaluation of untried assumptions and values. The online class was a conducive environment for thoughtful participation and personal growth.

Many other themes emerged from each category, but only the major ones were discussed. By doing a content analysis, the researchers discovered that the number of times the different themes in the class category were mentioned tallied almost the same number of times the themes in the feelings category were discussed. This is
an important result because it suggests that for an online student, meeting the class requirements, deadlines, and completing the class projects are as important as they way s/he feels during the learning experience.

In-Depth Interviews

This data source did not provide a major insight into the way a student feels while taking an online course. However, it revealed that students come to class with a set of ideas and assumptions that situate them more or less in the constructivist paradigm or in the traditional paradigm. Of the four interviewees, three were situated in the constructivist paradigm and the fourth was more in the traditional paradigm. This result needs to be further analyzed and looked for connections between online students’ teaching paradigms and the degree of technology proficiency and risk-taking ability that students exhibited during the class.

In summary, qualitative data provided an excellent avenue for gaining an insiders’ view of the learning experience from the students’ perspective. An important result of this research was to understand that for a distance education learner, the way she or he felt during the course itself was as important as the course content and assignments. In addition, it is important to recognize that the professor’s abilities to lead a web-based course are crucial for the success or failure of the course. Of utmost importance is the class atmosphere that the course professor creates through the degree of communication that s/he maintains with the students.

Educational Importance of the Study

After several years of investigating the effectiveness of distance learning, researchers need to focus on the human aspect of such interactions. Even when the Internet has become ubiquitous, more research is necessary to understand what happens after the web-based course participants get efficient hardware and a good Internet connection. Although the results of this study are not conclusive, they provide an insight into the complex interactions that occur in a web-based distance education course.

Content Analysis as a Tool for Evaluating the Effectiveness of Distance Learning Systems

B. Offir and Y. Lev
School of Education, Bar-Ilan University, Israel
email: veliksd@mail.biu.ac.il

Abstract: Knowledge is a necessary condition for any kind of progress in our society, and the teacher is an important factor in transferring knowledge. Distance learning enables the transfer of knowledge from one place to another. There are different methods of operating DL (videoconference, internet, satellite), each with its advantages and disadvantages. DL is accepted as an innovation in the field of education and instruction. However, any change in education is only as effective as the ability of the teachers to successfully accommodate the change. This study evaluates the level and quality of the teacher-learner interaction and included three phases: a) Defining the circumstances and situations where the research can be performed; b) Constructing research tools and proving their reliability and validity; c) Operating the research - collecting information on the teacher-learner interaction. During the past three years our research team worked on the first two phases of the research.

Introduction

The challenges facing schools today are in the realm of teaching development so that with the assistance of teachers, the learners will be able to deal more effectively with the problems posed by the world in which they live by becoming independent learners and mastering basic skills. Each individual learner needs a unique set of circumstances in order to learn to the best of his ability. The fulfillment of the learner’s potential is one of the better methods of enabling learners to cope with social demands. The contribution of the teacher to the process of learning is very significant. The teacher-learner interaction is an important condition for any kind of learning and for acquiring knowledge. The personal relation between the teacher and the learner is crucial for developing the learner’s ability, curiosity and level of thinking. However, in many countries there is lack of good teachers, and a lack of financial resources for coping with educational needs. In widely scattered placed it is difficult to have good teachers, compared to main cities. This has increased the need for using distance learning. Distance learning (DL) is a teaching method in which the teacher and the learners are separated from each other by place and/or time. It enables the transfer of knowledge from one place to another (Holmberg 1986) and the rapid development of computers and electronics has contributed to the increase in the effectiveness of DL (Dede 1990, Feasly 1983, Pain 1989). The interaction between a teacher and a learner, or among the teachers themselves, can be performed with the aid of computers, videoconference, radio, satellite, internet, fax, telephone, television or in mailing some learning materials. Each communications technology has its advantages and disadvantages. We should learn the characteristics of the different communications technologies and media and how they have been used in distance education. All communication technologies are accepted by teachers as being an innovation in the field of education and instruction. When they are introduced into the classroom, the teacher must make some changes in his instructional and teaching methods so as to accommodate the communication technology’s efficiency in the instructional process. However, any institutional curriculum or instructional change is only as effective as the ability of the teaching staff to accommodate the change successfully.

The effectiveness of any staff development policy can only be considered in the light of how the teachers themselves respond to such a policy. The understanding of teachers’ behaviors and attitudes is a prerequisite for the initiation of any kind of reform in teaching and instructional methods. The connection between change and personality variables is well known in society in general and in education in particular. When society feels that a fundamental change is necessary it calls upon innovative leaders to initiate the necessary changes. This is also true for education (Duke 1987). DL is a fairly new instructional aid and only those teachers whose personalities feel comfortable with novel and innovative teaching methods will react...
positively to DL and make a firm decision to use DL in the classroom. Research aimed at evaluating the
teacher-learner interaction should be operated under circumstances where the teacher reacts naturally and does
not feel frightened. Only in such an isolated situation will the data on the different interactions and their effects
be accurate. The first phase of this research is to define such isolated circumstances. Different communications
technologies are used in our project: a) Two-way videoconferencing (via cable, ISDN, 384K). This allows the
learners and the instructor to interact face to face and is the closest match to traditional classroom instruction.
b) Computer conferencing which allows the learners and instructors to interact via a computer network. They
can send messages to each other (by electronic mail) as well as transfer data files. c) Two-way
videoconferencing (one way via satellite with the learner responding via email). The learner can see the lecturer
on the computer screen and can ask questions by email or by microphone. DL can alleviate the teacher’s task of
transferring information, so that he/she are free to deal with the learner as an individual and the teacher
becomes more of an educator and less of a source of information. In our research various variables were
collected, defined, isolated and analyzed by a variety of research tools, including observations, interviews and
questionnaire. The lessons were also recorded on a video tape. The information collected helped us define the
duty of the teacher in the process of teaching, which communications media are best for a given course and how
the media should be combined for maximal effectiveness.

The Study
Teacher personality and innovation in education

The aim of the first phase of this research was to examine the connection between the teacher’s
willingness to adopt innovations and the personality trait of risk-taking. The research sample was made up of
80 fully qualified teachers (Offir & Katz 1990). Two questionnaires were specially designed for use in this
study: 1. Risk-taking questionnaire; 2. Attitude towards innovation (computer) in education questionnaire. The
subjects were divided into three levels of risk-taking according to their responses to the risk-taking
questionnaire. Analysis of variance (ANOVA) was then performed for risk-taking by attitude to innovation
variables (F=17.21; DF=2; p<0.000). This test indicated significant differences between groups with different
risk-taking levels. A post-hoc Scheffe test, designed to examine the significance of inter-group differences
emanating from the significant ANOVA main effects was then performed. The results of the Scheffes test
indicate that high-level risk-takers have a significantly more positive attitude to computers than medium-level
risk-takers who have a significantly more positive attitude to innovation than low-level risk-takers. The risk-
taking trait is apparently necessary for adopting a new and innovative instructional and teaching method and
augurs well for the successful accommodation of novelty in the classroom situation. On the other hand, low-
level risk-taking seems to indicate traditionalism in the teachers’ perceptions of teaching and instruction, and
as such, impairs the low-level risk-taker’s ability to come to terms with novel classroom methods. These results
confirm the findings of Katz (1984), that certain personality traits are required for successful adjustment in
novel situations. When the use of a new method in the classroom situation is universally perceived to be totally
successful, all teachers will agree to accommodate it in all their instructional activities. However, if the
innovation is perceived to be only 50% successful in the classroom the low-level risk-takers will agree to
incorporate it in only 20% of their teaching activities. Medium-level risk-takers will use the new method in
50% of their instruction and high-level risk-takers will agree to use it in 80% of their teaching activities.
Therefore, only those teachers who feel comfortable with novel and innovative teaching methods will react
positively to DL and will make a firm decision to use DL in the classroom and if a school wants to succeed in
operating DL, the personalities of the teachers must be taken into consideration. A history of failure in
operating DL can contribute to the teacher’s negative attitude towards it. After a period of accommodation,
during which DL can be shown to be a useful teaching and instructional instrument, DL can be introduced into
the classroom of medium and low-level risk-takers who will be more inclined to accept DL as a new but not
threatening teaching method. On the basis of these results it was concluded that evaluating the teacher-learner
interaction in DL should be performed under natural circumstances where there is no proven failure in
operating DL or where the personality of the teacher influences him or her to relate positively to innovation.
Under such circumstances the teacher-learner interactions can be evaluated, since interference by other factors
will be minimal. The conclusions from the first phase of the research helped us choose the conditions for constructing the research aid for evaluating teacher-learner interactions.

Aid for evaluating teacher-learner interactions

Biggs (1982), presents a model of three P's, according to which learning is divided into three phases: presage, process and product. The first phase, "presage", includes the learner's abilities and information on the method and structure of program learning. The second phase is related to the "process" of learning and emphasizes different elements in the interaction between learners, subject matter, method of learning and teacher contribution. The third phase, "product", is related to the learner's achievement.

defines the importance of the teacher-learner interaction and its contribution to the process of analyzing the content of a message during a lesson. The interactivity of a lesson is an active process enabling the learner to adapt the lesson to his or her level and ability (Weller 1988). Interaction is a dominant and important factor in teaching. The interaction can lead the learner to take an active part in the learning process and encourages him to make decisions and analyze the knowledge transferred. Analysis of the interaction can help in drawing conclusions on the efficiency of the lesson (Hueyching & Reeve 1992, Jones & Vesilind 1992, Flanders 1970, Mcloughlin & Oliver 1995, Murry & Zuzovsky 1994, Hogelucht 1996, Brophy & Good 1969, Ruberg et al. 1996). Based on the information obtained, Henri (1992) developed an analytical model that can be used by educators for a better understanding of the learning process. This analytical model was developed to emphasize five dimensions of the learning process exteriorized in the message: participation, interaction, social, cognitive and metacognitive dimensions. Henri's content analysis model provides information on the participants as learners, and on their ways of dealing with a given topic. Thus informed, the educator can fulfill his main role of offering support to the individual and the collective learning process. Henri, in his article "Computer conferencing and content analysis" (1992), expressed his conclusion "We do not yet possess a body of knowledge concerning the pedagogical characteristics of the content of computer conferences, the scenarios of how the learning occurs, or the elements which give rise to learning. Only when we have a better understanding of computer-mediated learning will we be in a position to say that we are making the best use of the computer conferencing and content analysis - using its full potential. We believe that this understanding can come only from a finer-grained content analysis." Henri's analytical model has been evaluated. It was found that real and very accurate information about most of the "categories" can be supplied by this model. However, when dealing with the "interactivity" category, the results collected by different judges was not significant. The judges did not recognize the same "interactivity" categories. The same conclusion was reached by Oliver and Macloughlin (1996). Based on these results, Oliver and Macloughlin suggested some changes in Henri's analytical model. They recognized five different kinds of interactions: social, procedural, expository, explanatory and cognitive.

We have used Oliver and Macloughlin's model for analyzing the different kinds of "interactions" in distance learning and in traditional teaching. It was found that the interactions most commonly used in distance learning are the procedural and expository interactions, whereas the most commonly used interactions in traditional teaching are the cognition, social and explanatory interactions (Offir & Lev 1999). In our research, 50 hours of lessons were fully video taped, where twenty five hours recorded traditional teaching and 25 hours recorded distance learning. The traditional and the distance learning lessons were given by the same lecturers (n=5). Each lecturer was video taped for five hours and the video cassettes were analyzed and evaluated. The results of the video analysis led us to the following three conclusions: 1. There is no clear agreement between the analyzers as to the definition of each "interaction", since there is no list of behaviors which can help classify the different interactions; 2. The concept of "cognitive interactions" is not clear, since the other interactions (explanatory and expository) can sometimes be "cognitive interactions"; 3. The different interactions are not defined operationally. The results of our evaluation led us to make some changes in Oliver and McLoughlin's analytical model.

In the process of constructing our model for analyzing the content of a distance learning lesson (M.A.C.L.), the five interactions were divided into two categories: interactions which supply an encouraging environment for studying (social and procedural interactions) and content-related interactions (explanatory, expository and cognitive interactions). Interactions that support learning (social and procedural) do not deal with the subject matter, nor with the content. The purpose of the social interaction is to create a personal
connection between the teacher and the learner and to afford a relaxed environment, emotional support and encouragement for the learner, when necessary. The purpose of the procedural interaction is to deal with administrative problems arising during the lesson. These two interactions have the same goal, of helping create a supportive atmosphere for the learner.

Cookson and Chang (1995) make a distinction between a “positive emotional interaction” and a “negative emotional interaction”. A positive emotional interaction is concerned with encouragement, decreasing tension and creating an informal atmosphere. With a negative emotional interaction the teachers behave formally and do not help and are not involved in the student’s work, correct and react negatively towards the student, prevent help, etc. Our model divided the “social interaction” into two parts, negative and positive. Cookson and Chang (1995) helped us define the “procedural interaction”. In our model the procedural interaction included administrative behaviors related to the students.

It was found that an element of “cognition interaction” is contained within the “explanatory” and “expository” interactions. Since these three interactions are cognitive in nature, the cognitive processes to be analyzed and how they can be recognized should be clearly defined. Furthermore, a clear distinction should be made between these three interactions. We are interested in analyzing “the way the student learns”. Henri (1992) used the taxonomy developed by Ennis (1986). This taxonomy contains twelve different abilities. Henri reduced them to five abilities. This taxonomy can help define cognition skills.

The destination among the “explanatory”, “expository” and “cognition” interactions can be based on Henri recognized different analysis levels in the cognitive domain. He mentioned the processing level: “surface processing” and “in-depth processing”. Schmeck (1983) defined in-depth processing. Entwise and Waterston (1988) also made a distinction between “surface processing” and “in-depth processing”, which enabled us to define the three content-related interactions: “explanatory” and “expository” interactions related to “surface processing” and “cognitive interaction” related to “in-depth processing”. Based on approach, the different interactions can be defined as: 1. Expository interaction: Teacher or learner present knowledge or ability; 2. Explanatory interaction: Teacher uses learner’s reaction for explaining information; 3. Cognitive interaction: Behavior which presents ability for drawing conclusions, analyzing and decision making, learner applies information to new circumstances.

The literature and the information obtained by our researches directed us in developing our matrix for evaluating “interactions” during the process of operating “distance learning” lessons.

The researcher divided the interactions into messages. A message can be a single word or a complete sentence. The sentence can consist of a unit of meaning, for example, when the teacher says “your reaction is very exciting and interesting, but how does it complete your idea?” This sentence is a single message but has two units of meaning. The first is a “social interaction” and the second is a “cognitive interaction”. We evaluated our analytical model for collecting messages during distance learning lessons. Eight judges observed the same video cassettes of two hours of recorded lessons. Their content analysis was directed by the existing content analysis matrix. The results are presented in table 2. The reliability of the matrix was proven in two stages: 1. Video cassette of a DL lesson was given to three judges. They divided the lesson into conversation units; 2. Six judges used the matrix for analyzing the lesson’s content.
## Findings

## Conclusion

The teacher-learner interaction was found to be an important factor in evaluating the learning process. Five different interactions were defined: social, procedural, expository, explanatory and cognitive. The collected research data led us to construct a matrix for evaluating the teacher-learner interaction. The reliability of our matrix was proved by six judges to have a significant correlation (at the 0.01 level) between these six judges. The information collected by our matrix can help in understanding the role of distance learning. It helps in drawing conclusions on the advantages and disadvantages of different kinds of technologies. During the past twenty years our research has directed us towards developing a model for decision making: where, when and how to use different means for achieving defined aims (Katz & Offir 1990, Offir 1988, 1990a,b,c). We were led to the conclusion that measuring the “interaction” should be performed under natural circumstances, where the teacher feels free to behave naturally. Any stressful atmosphere will affect the teacher-learner interaction. Our research has tried to define the most suitable circumstances for measuring these interactions.

Schools that plan to introduce DL into the classroom should do so only with teachers who are classified as high level risk-takers, or after DL has been shown to be a useful teaching instrument. The teacher will then be more inclined to accept DL as a new, non-threatening teaching method. This study directed us towards finding a method for combining different means to achieve the aim of education: content analysis of distance learning can supply information which will help in the decision making process in the DL field. An effective tool for analyzing the content of a lesson can help define the role of distance learning and the role of the teacher in the process of learning. Distance learning can be effective in transferring knowledge when there is no other method for reaching this information.

Abstract: Research was performed during the 1998 and 1999 calendar years that had as its purpose the development and validation of a course/instructor evaluation instrument specifically for use with graduate and undergraduate courses delivered online via the World Wide Web. The primary goal of the study was to develop an instrument that would collect valid perception data from students at West Texas A&M University concerning technology of delivery, course content, and instructor related aspects of courseware delivered via the Internet. To this end an instrument was developed using the input of two panels of university faculty, administrators, and staff, and repeated pilot studies to collect data on the validity and reliability of the instrument. Feedback received from the expert panels, short and long-term pilot studies, and analysis of the collected data provide preliminary evidence to support the validity and reliability of this Internet delivered course-specific evaluation instrument.

Introduction

As the increased use of instructional technology in teaching becomes ever more necessary in higher education, the use of computer technologies to deliver course content to students constitutes the new frontier. Because the possession of a university degree in the latter part of the twentieth century has become more and more essential to career success, access to a university education for all that desire it has become a priority for universities large and small. One method of providing such access to students who have not previously had the opportunity to attend a university is to deliver course work to the student through the use
of newly available Internet based technologies. The delivery of courses in post-secondary education via technological means, while not new, has gained greater impetus through the expanded use of Internet technologies that center on the World Wide Web. Through the use of the World Wide Web, undergraduate and graduate courses can be delivered without any limits as to the geographical location of the student. Johnstone (1997) has found that students who elect to take courses via technological means have an expectation of convenience and ease of access. This desire on the part of traditional and non-traditional students for higher education delivered to them on their own schedule has driven the strong growth in both institutions of higher education offering such electronically delivered courseware, and the range of courses offered. Twigg (1994) finds that non-traditional students in particular define their role as a participant in higher education differently than their younger counterparts. Older students tend to view themselves as discriminating consumers of an educational product. Because of this view these students do not view themselves as limited to what professors and administrators of higher education think they need.

In addition to the differing perceptions and expectations of students for on-line delivered courseware, the medium of delivery also plays a role in shaping how students' perceive their experience as a student in this new type of learning experience. While several authors (Tait 1993; Dringus 1995; Cresswell & Hobson 1996; Johnstone 1997; and Magalhaes & Schiel 1997) have addressed the need for high quality evaluation of courses delivered at a distance, there is currently a dearth of research studies published that offer validated evaluation survey instruments specifically written for World Wide Web delivered courseware. It is the above listed differences in perceptions by potential consumers of distance delivered courseware that makes valid evaluation of student perceptions and experiences in these courses essential to university administration and faculty.

This study took place during 1998-1999 academic years at West Texas A&M University in Canyon, Texas. West Texas A&M University is a member of Texas A&M University System that serves the panhandle region of Texas. This region of the state of Texas has an approximate population of 700,000, with the university having an approximate enrollment of 6,800 students. In the fall semester of 1997, West Texas A&M University implemented four courses for online delivery through the World Wide Web with a total enrollment of approximately 125 students. Currently (fall semester 1999) 33 different courses are offered with a total enrollment of approximately 660 students in initial enrollment. West Texas A&M University currently plans to make available 25% of its course offerings via World Wide Web delivery by the year 2003.

Of the many challenges faced by universities and instructors who develop and offer online courseware, course evaluation may be among the most difficult challenges to address. In this study, a new instrument was developed to collect course evaluation data for courses that are delivered online through the World Wide Web. The first phase of the development process involved the associate Dean of Information Technology, research specialists, and faculty who have designed and facilitated online courseware. The new instrument developed as a result of this process was designed to collect data concerning student perceptions of course content, instruction, and delivery. The second phase of the project involved analysis of the data gathered from participants in the study to determine internal reliability and the benefits and limitations of using the Internet to conduct online course evaluations.

During the first three semesters that courses were offered online at West Texas A&M University, no course evaluation instruments were distributed for the collection of student perceptions as to course and instructor. The university had used (and still uses) a Course/Instructor Evaluation Questionnaire (CEIQ) instrument which was an adaptation of the Aleamoni Course/Instructor Evaluation Questionnaire (Aleamoni 1978). This instrument had been used to gather student perceptions as to course and instructor for some ten years prior to the offering of online courses at WTAMU, but had not yet been applied to online courses due to the early stage of development and implementation of this new instructional medium.

Much research has been written on the validity and reliability of using standard survey questionnaires to assess student perceptions of instruction and course content quality (Costin, Greenough, & Menges 1971; Centra 1973; Cashin 1988, 1990, 1995; Abrami, D'Apollonia, & Cohen 1990). However there is very much less literature that deals specifically with either the development or validation of online course-specific student evaluation instruments. The research team began their investigation with an Internet search for
instruments currently used to evaluate online courseware. This search conducted in January 1999 found less than 5 such instruments that were accessible. The majority of the instruments located and evaluated were structured using the familiar Likert type questions that sought to quantify student perceptions of perceived course and instructor quality. A similar search conducted in late November 1999, found a much larger number of such evaluative instruments available for study, although their quality ranged from comprehensive to perfunctory. Due to the lack of existing instrumentation available for adaptation at the beginning of the study, it was determined that the development of a new instrument would be necessary.

This newly developed instrument must be valid and reliable, and the data collected through the use of this instrument should be able provide data that will be valuable for formative and summative evaluation of courseware. It is essential that instructors whose online teaching effectiveness is being evaluated through such an instrument have confidence in the fact that the instrument being used to evaluate their teaching can actually gather data that is validly measuring their level of success with students in this new teaching medium. If instruments used in the evaluation of online delivered courses have previously been validated only for use in the traditional classroom, confidence can be diminished in the feedback generated by those evaluations by online faculty.

Method

As World Wide Web courses became more widely implemented and include the participation of more faculty members at West Texas A&M University, concerns were raised by the faculty teaching online courses as to whether the evaluation of courses delivered via the World Wide Web would be comparable to the evaluation of courses delivered in the more traditional manner. Due to the dearth of World Wide Web course delivery evaluation instrumentation in the literature, the need for a delivery method specific course and instructor evaluation instrument became clear to both those who administrate and those who taught online courses at West Texas A&M University. The first goal in developing such an instrument was to provide for a comprehensive validation strategy through which the validity of the instrument could be quantified procedurally and later statistically.

This study was pursued in two main phases. In the first phase, a panel of web courseware development faculty, administrators, and staff were gathered at West Texas A&M University in the fall semester of 1998 for the purpose of developing a course evaluation instrument. The expert panel assembled consisted of LeAnn McKinzie, Associate Dean for Information Technology, James Izat, assistant professor of instructional technology and research, Charles Mize, program head of instructional technology, and Trey McCallie, instructional technology graduate student and WTOnline university network programmer. This panel met to decide on the initial form of the instrument and questioning domains to be used in gathering data. Three main questioning domains were chosen; they included questions designed to elicit perceptions as to delivery technology, course content, and instructor. The questions in the delivery technology domain sought information from students as to how they perceived the role of the Internet-based technologies used to deliver online courseware in their overall course experience. The course content domain questions were written to collect data on students' perception of the quality, structure and value of the course content as they experienced it through the online course presentation. Lastly, the instructor evaluation domain sought to determine how students viewed the contributions, expertise, and responsiveness of the instructor. Incorporated into the first draft were instructor and course content questions that were reflective of the five main questioning domains of the CIEQ (Aleamoni, 1978) instrument used to evaluate classroom-based courses (course value, method of instruction, instructor attributes, course material, and student interest). The second phase of the study began with the completion of the first draft of the online courseware evaluation instrument. This instrument was distributed among several instructors of courses that were offered through World Wide Web delivery for comment. These comments were evaluated and, when appropriate, incorporated into the instrument. The draft instrument was then distributed to a class of graduate students at West Texas A&M University. The students participating in this pilot study were asked to complete the survey instrument and check for proper wording, phrasing, and time of completion.

This second draft of the instrument was then rewritten as a World Wide Web based point and click form and posted on the university server which hosts online courseware. Instructors of online courses were requested to encourage their students to participate in the study by evaluating the courses in which they
were currently enrolled using this instrument. Additionally, all students currently enrolled in World Wide Web based courses were notified by email of the existence of the instrument and were asked to use the instrument to evaluate the course or courses they were currently taking. A point and click World Wide Web address was included in the email sent to all students enrolled in online courses to enable the students to easy locate the web site where the instrument was posted.

Data gathered from the spring 1999 semester field study was used to refine and further focus the instrument used for distribution to summer online courses. Similarly data gathered from two summer session distributions was used to further refine the instrument distributed in the fall semester of 1999. Data collected in each of the three field trials of the instrument have been analyzed to characterize the perceptions of study participants of their online course experiences. Also gathered data was used to discover the strengths and weaknesses of the online evaluation instrument, and the use of the Internet to evaluate student course perceptions. At the time of the writing of this paper data has been gathered from the fourth distribution of the instrument. The accumulated data will be used to perform a factor analysis of the questions used to quantify the validity of the instrument.

Findings

The process through which the instrument was developed progressed through two expert panels (research and development, and online teaching faculty), and both a small and a large-scale pilot study. When the data from the first three distributions (Spring, Summer I, and Summer II semesters of 1999) of the instrument were analyzed to determine a reliability coefficient for the questions used to gather data from the three questioning domains, a standardized item alpha coefficient of .7784 was obtained.

Data collected through the summer semester included 204 usable responses reflecting a total response rate of approximately 30% of students who were requested to participate in the study. At the writing of this article approximately 185 further responses have been gathered from students enrolled in fall semester 1999 courses, a response rate of approximately 35%. Of those students responding, approximately 28% were male, and 72% were female. Students responding to the survey were from a range of ages, including 38% from 23-30 years of age, 27% from 31-40 years of age, and 18% from 41-50 years of age. The remaining 17% of respondents were either under the age of 22 (14%) or over the age of 50 (3%). This result is affected by the fact that West Texas A&M University has a strong population of non-traditional students, and that graduate courses were predominant (graduate 64%, undergraduate 34% in respondents) in the online offerings of the university in the early stages of its development. The majority (53%) of students responding to the survey instrument reported having taken no online courses previous to the course they were evaluating, while an additional 31% of respondents reported having taken either one or two classes previously. Respondents to the study reported confidence in their mastery of course material taught as is evidenced by the fact that 71% reported that they expected a grade of "A", while 27% expected a "B." Only 2.5% reported an expectation of a grade less than "B." When respondents were asked how long they spent completing the survey, 96% of respondents reported that it took 15 minutes or less, while 74% reported taking 10 minutes or less.

Although text boxes were provided for respondents to comment upon the instrument itself, there were no comments or suggestions submitted. Similarly there were no comments added by respondents concerning questions that should be added or deleted. Respondents did, however, use the text boxes provided to comment on their instructor and/or their course.

Conclusions

Many lessons were learned by those researchers who worked together on this project during the 1998-1999 study period. Chief among these lessons is the finding that the traditional method of inviting participation in a study that is facilitated through technological means (i.e. the submission of a world wide web point and click form after notification by email) has not resulted in the rate of return desired by the researchers. While this low rate of return is not as significant an issue during the pilot testing phase of a validation study as it would be when the instrument, the researchers has hoped for a higher rate of return overall. In the
A traditional classroom setting achieving a high rate of return on such an evaluative instrument is relatively straightforward, collecting such data through the internet has the potential to be somewhat more challenging. The maximization of student participation in online course evaluation will depend upon the implementation of new technologically enhanced methods developed and used to compel students to participate in an online-based course evaluation regardless of type. The use of such methods will allow the return rate of online course evaluations to approach or even exceed the return rate of evaluative instruments administered in the classroom.

A second lesson learned was that in any process which has as its goal the development of an instrument for the purpose of evaluating instruction there is a need for involvement of all effected groups in the development process. Those researchers who wish to develop such an online course specific evaluative instrument would be well served to involve the faculty, both those teaching on-line and those not, in the development process. Those faculty members who are teaching online will most probably be doing so without great experience in using Internet and World Wide Web technologies and media, and will view some trepidation evaluative methods that will affect their overall teaching effectiveness ratings.

Abstract: This paper describes a strategy for improving the quality of distance education assessment providing a set of complementary tools to help on formative evaluation. Regular forms to assess learning are analyzed and Kirkpatrick's model for evaluation is described as well as a set of tools to provide capability to assess according this model. The set of complementary tools includes consensus, tracking, voting and self-evaluation.

1. Introduction

Learning assessment became a challenge to those working with distance education. In its definition of learning assessment, Bloom, Hastings and Madaus (Mendes 1998), proposed that the evaluation process should includes a great variety of evidences that go beyond the traditional final examination pencil and paper based. In a face-to-face context, professors use more than just formal mechanisms to evaluate students. Body language, participation, quality of questions proposed by students are good indicators of learning. In distance education what normally occurs it is the use of formal mechanisms only. It occurs not only because of the lack of accessible mechanisms that can assist instructors on this task, but also, because many professors prefer to work with more traditional methods of evaluation.

However, thanks to evolution of networks and computers and especially the Internet, mechanisms, that can fill this gap started to show up. Tools became available, to keep track of students activities and interactions with learning environment, with colleagues and with the professor. These kind of information present new opportunities for monitoring the way students learn and for learning assessment.

The use of the Internet for distance education assessment offers many advantages:

- Reduction of the distribution costs;
- The corrections and updates are simpler, therefore they are carried through in an only site, being immediately spread to all students;
- Several techniques for evaluation are possible using multimedia for the between professor and students and between students;
- The Internet facilitates collaborative writing;
- The student has more easiness in sending feedback allowing formative and evaluation

A research conducted by Dirks [Dirks] with instructors of distance learning MBA programs presented some questions like: Considering all the time you spend on this course (100%), how much of that time do you think you spend on student assessment (writing tests, grading, giving feedback, and reporting scores)?

Answers indicated that the newer teachers, 2-9 years teaching, spent over half their time on assessment (56%), those with 10-19 years experience spent less time on assessment (46%), and the career instructors, 20+ years teaching, spent the least amount of time doing assessment (35%). The primary reasons given for having assessments include providing feedback, giving grades, and motivation. The four types of assessment most commonly mentioned are: case studies, exams, papers, and projects. All of them requires extensive time to grade and are very difficult to get automated help to do the evaluation.

Other researches point also that what is often used for assessment in distance education are the
following:

- individual works developed individually and sent by regular mail or by email
- assessment based on contributions for group discussions
- tests (automatically handled by computer program)
- term papers (analysed by professor or assistants)
- oral or written tests conducted in the presence of the instructor (some times through videoconference)
  or with a remote assistant.

Learning theories state that group learning has significant relevance and must be supported also in distance education. Participation in group activities, cooperation and collaboration must be supported and graded. But there are a lack of good tools to help evaluate the participation of the distance education student in group activities.

Slowly, thanks to evolution of networks and computers and especially the Internet, mechanisms, that can fill this gap started to show up. Tools became available, to keep track of students activities and interactions with learning environment, with colleagues and with the professor as indicated in figure 1.

These kind of information present new opportunities for monitoring the way students learn and for learning assessment.

As stated by Tucker (Tucker 1998) the CMDL (Computer Mediated Distance Learning) classroom is routinely a far more scrutable educational environment than the physical classroom. The virtual classroom's electronic data storage, retrieval and exchange system (i.e., the text of student and faculty transactions, communication logs, file structures and information presentation algorithms that exist on the file server's hard disk drives) represent concentrated, structured and highly accessible artifacts of the learning transactions. These artifacts can be retrieved, analyzed and reported via highly economical, automatic processes operating in the background of the communications system.

This work presents a proposed solution for assessment on distance education mediated by Internet using innovative approaches based on Kirkpatrick model for evaluate training problems and will describe how they where implemented.

2. Assessment models and tools

There are today some systems, available in the market, that provide detailed information on the evolution of the student working at distance mediated by Internet. Examples of this kind of system include, CyberQ, WebCT and AulaNet. Statistics of usage and regular approaches for testing like multiple choice quiz and term papers are usually possible in these kind of systems.

Donald Kirkpatrick developed a model of evaluation, used in training programs. It recommends a
division of the evaluation process in four levels (Kirkpatrick 1998):

- **Level 1: Reaction** - level measures how those who participate in the program react to it. It may be called a measure of student satisfaction.
- **Level 2: Learning** - can be defined as the extent to which participants change attitudes, improve knowledge, and/or increase skill as a result of attending the program.
- **Level 3: Behavior** - can be defined as the extent to which change in behavior has occurred because the participant attended the training program.
- **Level 4: Results** - can be defined as the final results that occurred because the participants attended the program.

Mendoza is other researcher that it is also relevant to investigate student context to find out which aspects of course contents he/she is in the know (Mendoza 1999). So an aspect to be also considered is the lack of suitable tools to asses their current level of knowledge and skills. Mendoza recommends utilization of techniques, other that conventional ones, to collect data and suggest formative evaluation as well as summative evaluation. To achieve formative evaluation is important to make easy for the students not only inform their opinions and feelings about how course is going on but see this contributions being handled and considered.

To help in all these tasks and also support evaluation as proposed in Kirkpatrick model one should have a tool that would help organize polling and receive data in a suitable form to allow counting and summarizing results. To do this, it was designed a system aimed to support flexible and dynamically built of enquete for polling. The system has a WWW interface that allows designing of different kinds of multiple choice questions. Basic data informed are question and alternatives. Depending on type of desired measure the system ask for:

a) Feedback for each alternative
b) Indication of correct answer
c) Nothing more, just counting incidence of selections on each alternative

Option a is used for questions inserted in the learning path to ask for active response. Option b is used for testing and give grades. Option c is used for polling purposed. This system was designed to complement regular tools used to assess distance education students. The following mechanisms have been selected to assist in the evaluation process in this framework:

- **Tool of consensus**: based in the Delphi technique, allows on time creation of enquete proposing instigating questions, as well as the collection and tabulation of responses. The tool has the capability to keep track of each student's level of contribution to the discussion as well as enquete responses.
- **Tracking tool**: the register of learning activities (accessed page with dates and time) is important because it allows the professor to monitor the progress of students trough the course. The collected information will show that type of access the student has made (visited units, tools used, etc), as well as the time spent on it.
- **Voting tool**: aimed to provide conditions for a fast feedback for the instructor on specific subjects.
- **Self-evaluation tool**: allows the dynamic building of enquetes for self-evaluation by professor and by students.

It is important to stand out that this proposed work is not an alternative approach to assessment rather it is a complementary one and is supposed that may be used together. Each on of this tools are supposed to be used to help evaluate at more than one level in Kirkpatrick model.

To implement the tracking tool, a generic interface was designed to intermediate all the interaction of the student with the server. Interactions are processed in real time (for authentication purposes) and periodically in batch to generate records in a student data-base.

To implement the voting, consensus and self-evaluating tools a set of CGI programs where developed to allow dynamically create pages with questions and propositions (HTML forms) that are presented to students and collect their answers (Tarouco 1997).

**Conclusions**

It is our believe that formative evaluation plays an important role to get distance students motivated because
they feel a sense of not being lost in space. Just the opposite, they feel that being closely monitored and having their opinions being asked often is more like having a personal tutor that pays attention on way they do and what they say. This kind of attention provided by the system helps to minimize solitude that sometimes is referred as main desisting factor from students.

Trickle Down Technology: A Distance Education Approach to Professional Development

Dr. Angie Parker
Gonzaga University
Educational Technology
United States
aparker@soe.gonzaga.edu

Abstract: Technology is definitely a part of our world but all too often that world does not include the K-12 classroom. Technology seems to stop short because of lack of teacher training, lack of well developed lesson ideas, and the fact that universities are not offering courses that model the use of technology in the content areas. The Trickle Down Technology (TDT) Project offered a three-pronged solution: a collaboration between college faculty in education, current K-12 teachers, and pre-service teachers. While college faculty grew more comfortable with technology, they began to integrate computers into their classes, while helping K-12 teachers do the same. Concurrently, faculty modeled technology application as a part of the curriculum and helped their students develop lesson plans for K-12 classrooms. The teachers then implemented these lesson and provided online feedback to the preservice teachers.

Introduction

Educational technologies have been traced historically to the advent of movable type in the fifteenth century, to illustrations in seventeenth-century books, and to slate chalkboards in eighteenth-century classrooms (Jonassen, Peck and Wilson, 1999). Educational technologies in the twentieth century include the first lantern slide projectors, radio, motion pictures, and most recently the personal computer. As each media emerged, educators realized the importance of professional training and the development of new teaching strategies that would transform the technology into a partner in the learning process rather than a substitute for the teacher.

The Trickle Down Technology (TDT) Project, funded through a grant from AT & T, offered the impetus needed to change the way both K-12 and university educators capitalize on technology in the classroom. The project had three key components: the modeling of technology in the university classroom, online technology workshops, and finally interactive communication among inservice and preservice teachers. Each of these components of the project will be discussed in this article.

Modeling Technology in the University Classroom
All too often, the only technology training offered to education majors is a single course on instructional media. In that class, students are offered directives on how to load software, access the Internet, and change the bulb in the overhead projector. To add to the problem, university faculty seldom model technology in their classes due to the time needed to prepare a lecture that integrates the new media.

In the TDT Project, three professors were paid a stipend to integrate technology into their daily teaching. They were also assigned a graduate student who was available to create PowerPoint materials, conduct Internet searches, and assist with the technology during the class. As the instructors became more proficient with the technology, the graduate student was phased out, thus motivating the instructors to become self-sufficient with the technology.

As the project began, instructors were tentative about using technology to convey the message of their lectures. However, within a few weeks, PowerPoint presentations became the norm and a "technology team" approach among the instructors was initiated. Through email, the sharing of ideas and techniques was suddenly a daily occurrence.

Modeling of technology integration as only one of the tasks assigned to the university instructors. The nine faculty were encouraged to participate in bi-monthly chats to discuss their success and concerns as the media became more pervasive in their classrooms. The online chats provided written evidence of the steep learning curve involved in re-thinking the way universities teach. Through the chats, it became evident that software and hardware were only a part of a much larger picture. Instructors were changing their thinking to embrace technology as a partner in the learning process. The faculty found that students could now actively share their new knowledge, rather than memorizing facts from lectures, textbooks, and computer software. One instructor commented, "The classroom computer is simply a tool, but if we think about technology as a learning tool that students learn with, not from, then the nature of student learning and that of instruction must change".

Online Chats among University Professors

Twice per month, the nine professors met online in a recorded chatroom to discuss the integration of technology into their classes. The chats offered a place for these nine, novice computer users to discuss the utilization of the computer to illustrate a point, to enhance a lecture, to provide a hands-on approach, or to problem-
solve with their students. Although the chat occasionally included discussion of technical difficulties, this was generally discouraged in lieu of topics that focused on synthesis of technology with content.

The first chat of each month had a pre-defined agenda such as, “Using the Internet in the University Classroom”. Professors were given the agenda several days prior to the chat as well as websites on the topic. They were asked to share personal experiences that related to the topic and comments on the readings.

The second chat of the month, was a open forum where any topic related to the TDT Project could be discussed. The three universities rotated the responsibility for hosting these open forums. If a topic in the forum required prior preparation, the university that was presenting the topic was asked to email the material to the other two colleges several days prior to the chat. Although the chats were scheduled for 30 minutes, most chats lasted well from 45-50 minutes. One chat, “The Time Consuming Nature of Technology”, lasted well over 60 minutes and resulted in nearly 35 email messages during the week that followed.

Role of the University Student

The TDT Project not only changed the role of the instructors but also had a profound influence on the students. Students were assigned the task of developing two lesson plans per month that combined some facet of technology with the content area they were studying. The first lessons were low tech with little more than stale material combined with a word processor or the Internet. As the students “lived” the use of technology in their university classes, they began to see that integrating new media meant more than “updating the same old lesson”.

By the end of the third month of the project, low-tech lesson plans were transformed into technology-rich ideas that focused on learning with technology. Students moved away from lesson that “taught technology” to lessons that utilized the classroom computer for simulations, research foundations, experimentation, and open-ended, student directed projects. Examples of these lesson plans are available online.

Each month nearly fifty lesson plans were carefully reviewed by the nine faculty for both content and use of technology. One lesson was selected each month for implementation in a classroom in each of the three states, Washington, Nebraska and Wisconsin. Teachers were given three weeks to institute the technology-rich plan and to provide online feedback to the student who developed the lesson. While the chat was dedicated to the student who authored the lesson and feedback from three teachers who executed it, other teachers, education students, and
professors were invited to join. In this way, the preservice teachers received a wide variety of feedback on their lesson ideas including a regional focus and the education requirements for the individual states.

Teachers were asked to respond to the following questions:

* What did your students like about the lesson?
* What would you change if the lesson were to be implemented again?
* How did the lesson fit with your curriculum content?
* What advice would you give the student author of this lesson?
* Explain any problems you encountered during the actual implementation of this lesson?
* What auxiliary learning did you see taking place during this lesson?

The chat was logged and available online to anyone participating in the project. The student author was given a printed copy for future review. Making the chat logs available online allowed the education students the opportunity to learn strategies for developing successful lessons that combine technology with content. The website recorded nearly 50 hits after each online lesson review.

**Technology Training for Teachers**

Most universities across the United States offer from one to five credits in Instructional Technology. This limited focus is insufficient to prepare teachers to succeed in classrooms that are wired for Internet, linked for internal communication, and programmed with attendance and assessment capabilities. Teachers are unprepared to utilize teaching strategies in combination with technology and content. The TDT Project attempted to rectify a portion of this void through a series of online professional development workshops. Each workshop focused on technology topics that were addressed in the lesson plans and one or more of the following: word processing, spreadsheet, database, PowerPoint, Hyperstudio or the Internet. Not only did the workshops provide a simple and quick way for teachers to develop personal skills with the software, the hands-on activities also outlined numerous techniques for synthesizing the software with current curriculum. The teachers (also university students and professors) could access the online lessons any time, twenty-four hours per day, seven days per week. Each lesson was designed to take no
more than twenty minutes to complete so teachers could easily review the lesson during a short break or before or after school without taking an excessive amount of time away from their preparation or other instructional tasks.

Three Regions and the TDT Project

In addition to the enhancement of technology in the delivery of content, the TDT Project was instituted to identify regional educational perspectives including the influence of ethnic diversity and rural vs. urban diversity on technology in school systems throughout the United States. Only though this mix could the integration of technology in today's schools truly be studied. The diversity of the schools chosen provided the student teachers as well as the professors an insight into educational systems across the U.S. and the opportunity to chat with teachers who teach in distinct educational regions.

Although all schools fall under the jurisdiction of the United States Department of Education in Washington D.C., the manner in which that education is dispersed can vary from state to state depending numerous factors including: monies allocated to education, the number of students, and the geographic and ethnic diversity of the state. The number of computers per classroom, for example, varies widely from state to state and region to region. In the TDT Project the number of computers varied from one computer per classroom to fifteen. Some of the schools had a vast library of software while others had only the software purchased personally by the teacher. Some schools had parental support for the advancement of technology, especially the Internet, while others still feared the use of technology in the classroom. All of these factors added to the enriched knowledge gained not only by the student teachers at the three universities, but also the professors who must prepare students to teach in all geographic and ethnic regions of the United States and the world.

Summary

Throughout history, media and numerous technologies for learning have influenced the delivery of education. Most recently, for example, the computer has invaded instructional settings and has provided the possibility for improving the learning process. For that improvement to take place, the teacher must be provided with the methodologies and strategies for successfully combining technology with content. Students must be given the opportunity to learn with technology, not from technology and finally, universities must model the development
of technology-rich activities and lessons in all content areas. The TDT Project provided funding and support to accomplish these goals.

Abstract: New information technology introduces new challenges for the teachers - and also for the teacher training system. To make the new teachers really understand what the new learning environment is all about, they should be exposed to the new methods during their own training process. Therefore our revised teacher training programme includes netbased learning material, thus demonstrating the dual mode system, where both off and on campus studies are integrated. The close relation between training and practice is focused as well as PBL and CSCL methods. Students should also have an introduction to how netbased learning material is constructed, the pedagogy of open learning, and be given an overview of services and tools available on the net. All of these fields are subject to rapid development, and have to be revised continuously.

Changing role of the teacher
Traditional teacher education

Teacher education varies between different countries and cultures. A general goal, however, seems to be that the students in a teacher training situation are supposed to acquire sufficient subject and pedagogical knowledge to conduct the learning process of their future pupils. The teacher’s role in primary school is often a mixture of a sage on the stage, an entertainer and a social worker. At secondary - and higher - levels, the subject content is more focused, and the goal is often to transfer as much of the teacher’s knowledge as possible to the pupils. The tradition is to tell them, ask them to read books and keep them on their toes by requiring exercises done and giving test. The role of the pupils is traditionally that of recipients and accumulators of knowledge and skills.

Training of new teachers is done by much the same methods, only at a different level. Experienced professors and senior teachers are striving to transfer their own knowledge, experiences and skills to new generations of teachers. The teacher training is in itself a conservative process, keeping up traditions that 'have always worked.' New research and findings have led to new trends and methods, but the system of knowledge transfer persists. Now the time may have come for a real change, perhaps a new paradigm.

The new role for the teacher

The introduction of new technology does not imply that the teacher may leave his duties to the computer. Instead of being the sage on the stage, however, he is rather expected to guide his pupils to acquire know-
ledge from a variety of sources - many of them available through Internet. For new teachers to manage this role they should themselves have experience from these kinds of learning environments.

Technology & challenges

Learning environments based on new technology impose new challenges on the teachers - and on the teacher training system. Advanced and broadband networks, PCs being able to present sound and graphics, animations and video as well as texts and simulations, call for new skills and approaches by the teachers. To an even higher degree this also goes for teacher educators. The technology is there, but how does the academic staff, may be in their fifties, manage the new challenges? Is it easiest to continue the traditional way? We have tried out some ways to change the system.

Dual Mode Learning Environment

Over the past eight years we have developed courses that gradually have evolved from traditional lectures in the classroom, to Open and Distance Learning (ODL) courses. We have developed, implemented, tested and evaluated different models where the physical location of the student is of less importance with respect to how the content shall be presented and taught. Work has been directed towards a situation where a student is a student, no matter whether he or she is actually an internal or an external student. The focus is on what methods to use in working with the content. This means in practice that internal and distant students are participating in the same courses and working with the same material. An important goal for this work is to make models for teaching which is the same for both on-campus and external students, a dual mode learning environment where internal and external students interact and work together. By introducing this model new ways of teaching on-campus have also been found, with the clear intention of making internal students more responsible for their own learning, where the teachers are tutors or guides in the learning process. Different tools have been tried to make an interactive learning environment a place where the students take part.

Internet

Most of learning material, exercises and assignments, are distributed through Internet. In this material are included references to books and URLs, integrated video shots to illustrate actions etc. The Internet is also used as a forum for discussion, exchange of views and experiences with the learning material and assignments. This is building an electronic learning environment where both learning material and student work are presented and discussed.

The contact with the students is also kept electronically. Student assistants and teachers are available for net based interaction and guidance, and tools like IRC are used to create co-operating groups. This is done both for external and internal students. Teaching in the classroom is no longer dominated by the teacher with students as passive listeners. The Internet is gradually becoming an arena for teaching and guiding, where problem based learning methods are dominant.

Student activity

By including interactivity in the course material students are forced to be active and to take part in the course. In some courses the material is "opened" to the students, encouraging them to add information to the content, ask questions, show examples and present personal experience directly in the material, not in a separate newsgroup. This is done by letting the student make annotations to the material. This is making the curriculum a "living" and dynamic learning environment, and not a static material made once and for all by the teacher. To make this evolving material, a tool called WebOrama is developed as part of the SHARP project (http://www.softlab.ntua.gr/sharp/). Annotations made by students are available to all participants.
The attitude among internal students is still often based on behaviouristic learning theory and the belief that the best way of learning is to be taught by a teacher. The traditional delivery of facts and scientific material in the classroom, or over the Internet, should not be thought of as learning. Such lessons should be considered as information. The students have to interact with the material to acquire knowledge. Focussing on constructivistic learning theories and not on delivery of information the teachers invite the students to work on the entire course to construct their own knowledge.

During the first stages the students may be slightly confused, and have problems to get started. Many students need some time to adjust to this new way of working, with courses mainly based on student activity and the teacher as a guide. But the feedback from the students shows that after adjusting to this way of studying, they find it to be an efficient way of working and learning.

In our courses we focus on using the Internet as an interactive working arena. Internet must not be used as an excuse for presenting linear text, but as a tool to increase student activity. If knowledge is gained through work, Internet must be more than a delivery system for information. It has to be a place for work and active learning.

Focus on Practice

One of the main dilemmas in teacher education, and in other kinds of professional education as well, is and has for a long time been, finding the correct balance between theory and practice. There is a tradition for discussing these problems among students, teachers and philosophers of pedagogy. The counterparts in this discussion are on those who will place the learning situation on the university or college campus, and on the other side, those who will make practice the main arena for teacher education. In Norway it may be that until now the first group has won this discussion. Teacher education is and has for years been a theoretical and academic kind of education - with some practice added. There has been a gap between theory and practice. Even though educators have spent a lot of efforts to bridge theory and practice, there still seems to be a fear that increased focus on practice will reduce the academic quality of the education, and thereby reduce status for teaching as a profession. This is often described as the “fear of tyranny of experience” (Kvernbekk, 95, Weniger, 90), trying to avoid a teacher education where “practice is enough, and one doesn’t need theory”. It is difficult to understand this fear. A practice-based teacher education could as well be based a theory. By placing the theoretical reflection in the context of practice, the reflection will obtain a new dimension.

In general there are two main perspectives on the theory-practice relation. The first is to consider practice as an application of theory. This is usually how the students understand theory, as some kind of recipe for their own teaching. Among others Donald Schøn is distinctly critical to this way of thinking. He characterizes this as “Technological Rationality”, a way of thinking based on the view that a scientist should develop general principals that the practitioner should follow. Schøn points out that this creates a totally wrong image of what practical competence is. He is concerned with the distance that exists between a discipline’s technical rationality and the experienced practitioner’s reflection in action and the research based reflection on action (Schøn, 86). The Swedish language researcher, Ingela Josefson, points out that the main question should be: “How can we secure that practice impress the theory-lessons” and not “How can we secure that theory lessons impress the students practice.”(Josefson, 91) This is a constructivist point of view. Theory should also be something, that students construct by themselves, not always something served to them as general, established knowledge. A new practice-based approach to teacher education is suggested based on the didactic concepts of Problem Based Learning, within the framework of Computer Supported Collaborative Learning.

A platform of knowledge- and learning theories for PBL-based CSCL

Problem Based Learning (PBL) is derived from the older ”case-study method” and is introduced as a fundamental pedagogical method, a model and concept initially applied in different fields of health education. One of the founders of the PBL term, Howard Barrows, points out 3 main goals for PBL:
• Students should achieve knowledge they can use in their professional work
• Students should be responsible for their own learning
• Students should develop skills for problem-solving

One common demand of a PBL environment is that the learning activity should reflect well known scientific thinking and methods. The working model is called "the 7 steps" (Pettersen, 97), with references back to John Dewey's ideal-model for problem solving (Dewey, 33). According to Timothy Koschmann the acronym CSCL has been established as a designation of an emerging paradigm within the ICT-area. Very briefly Koschman characterizes the CSCL-paradigm as a paradigm with focus on...

... the use of technology as a mediational tool within collaborative methods of instruction (Koschman, 96, p2).

According to Koschmann previous paradigms approach learning and instruction as psychological matters (Computer assisted instruction (CAI), Intelligent Tutoring Systems (ITS), and Logo as Latin). CSCL is built on the research traditions of disciplines that are devoted to understanding language, culture and other aspects of social settings, like anthropology, sociology, linguistics and communication science. The foundation of this learning theory is within the tradition of the Soviet socio-cultural theories and Vygotskys Theory of cultural historical psychology with references to the movement of social constructivism. On the other hand the paradigm combine insights from the Vygotskian school with insights from American pragmatism, represented by Dewey and Mead, and the contemporary work of sociologists and anthropologists like Rogoff and Lave and theories of situated learning and situated cognition.

PBL and CSCL may be placed on a common platform of learning theories supported by three pillars:

• The learning psychology pillar: social constructivism
• The learning theory pillar: situated learning
• The knowledge-sociology pillar: critical pedagogy and project-organized learning

These pillars are tied together within the epistemological framework of Wittgenstein, Polanyi and Schen with focus on the relationship between tacit and focal knowledge.

Why CSCL and PBL?

Timothy Koschmann et. al. sketch up a theory-based (not technology-driven) approach for design of CSCL-tools, applied within the framework of Problem-Based Learning and the context of medical education. They call this approach Computer-Supported Problem-Based Learning (Koschmann, 96, p.83). The main argument for introducing this approach to medical education is the complexity of the domain, handling ill-structured problems in ill-structured domains. The characteristics of ill-structured problems are, according to Barrows and Feltovich, primarily the dynamic character of this kind of problems. Problems unfold over time and change as new information is obtained. Secondly there are several ways of solving a problem and collecting information, relevant for the solution. Finally, there will be no "one and only" solution to this kind of problems, and decisions have to be taken in the absence of definite knowledge (Barrows and Feltovich, 1987). Koschmann et.al. point out the special challenge that education related to ill-structured domains represents:

For example, because of the problem of multiclassifiability and the irregular patterns of features across cases of the same type, classification of cases cannot be done in any simple regular manner. Further, teaching conceptual knowledge in the abstract will not prepare the student for the concepts' variations and combinations with other concepts that practice will demand. Finally, each problem that challenges performance is unique with respect to the definitive parameters that it lacks and the possibilities for their definition. (Koschman et. al, 1996, p.87)

The PBL-approach has been spread widely within health education both as a method and as a didactic basis for educational institutions within the field. The same has not happened within teacher education, in spite of the fact that constructivism as philosophy in general has deep roots in the pedagogical environment within teacher education. Somehow it may be said that the teacher educator preaches constructivism where the health care educator practices constructivism. Is there a difference between these kinds of education that
could explain the different ways of implementing a problem based concept or is this just a matter of traditions? There is no simple answers to this question. Most likely the answer is that there is a combination of causes. The main reason for the differences seems to be related to how problems emerge within the education. In education of health personnel it is relevant to define problems as cases and look for the treatment of the defined cases. This is a very concrete starting point which for example fits well to the 7 steps process prescribed for Problem Based Learning.

In teacher education there will be an extra didactic meta-layer and therefore less focus on ‘finding solutions’, but rather point out directions for making a suitable learning environment. This will be on a more abstract level than proposing concrete treatment of a patient. A consequence is that the problem defining process in teacher education in many cases has to be more complex.

Another problem is that the traditional organization of the main practice field, primary and secondary schools, give little support to a didactic based on constructivism. It could be considered as a paradox to use a constructivist approach in educating teachers for a non-constructivist practice. On the other hand, it could well be the only way to turn practice towards constructivism by starting education of new teachers in a different way.

Preparing teachers for open and flexible learning
Introducing ODL in Teacher Education

To introduce this new concept in teacher training, the most natural way should be to train them by teaching them ODL through ICT based ODL. Learning by doing has always been a sound principle. In this case there may be an alternative approach to expose them to a basic course on ‘Learning-to-learn through ICT’, where the first, introductory part is presented in a traditional way, either as a face-to-face course in a lab or as a printed text. After one or two sessions of this kind, the rest of the course is delivered on-line, by ICT. This way they should be able to compare the two methods and also have to learn to make good use of other on-line courses.

Pedagogy in Open Learning, PiOL

The other alternative is to offer a course on how to construct ICT based ODL material by attending an Internet course that demonstrates the content. The course provides a basic understanding for newcomers in the field of course ware development, and will hopefully also demonstrate new ideas for the more experienced developers. This on-line course on Pedagogy in Open Learning has been offered to national and international audiences since 1996. Every term it has undergone some revisions and has gradually evolved into the form it has now. A major objective is to provide guidelines for the development, implementation and running of open and flexible, net-based learning environments. These guidelines are based on experiences from user trials and evaluation of several national and European projects, as well as on theoretical discussions.

Resources on the network

Net-based studies are based on a multitude of tools and resources. Some of the central, on-line ‘assistants’ are mentioned below.

A distinction is made between educational pages and supporting pages. An important goal is to stimulate communication between students, between students and tutors, and between students and teachers. Information about the assignments, extra help and answers to the questions are available on the web-site through the lessons, the discussion groups, the IT recipe book, the Topic Search", the Oracle-service and the Note Book. The web pages are divided into public and non-public pages, where non-public pages are protected by password.
IT recipes book (cooking book), Topic Search, Oracle-Service and Note Book

The *IT recipes (cooking book)* is a tool for students that need extra help when it comes to topics like using a browser, making homepages etc. The IT-cookbook offers an introduction to the chosen theme on a basic level and provides the students with a number of different topics, known to be difficult to previous participants of the course (How to make their own homepages etc.). Each topic consists of explanations, directions, video and animations to show the students how to practice it themselves. In addition to the lessons and animations/videos, the IT-cookbook also offers an encyclopaedia, explaining over 4000 words within computer terminology.

**Topic Search, Oracle-Service and Note Books**

The *Topic Search* is formed as a text-search where the students can search through the lessons of their course (both new and previous editions) for an explanation of a word or phrase. The search then gives the opportunity to go through the lessons and find the context in which the word or phrase appears, or an explanation to the word/phrase. The results appear as links to the various lessons that match the search.

Through the *Oracle-Service*, the student can get the answer to his/her question concerning the course, within a short period of time. The answer is given through e-mail. The oracle-service shows the status of the tutors, who are online/offline or occupied, at all times. The panel of the oracle-service consists of the course providers and several assistants.

With less and less hours where the students actually see each other, it is important to create a feeling of community, and each student contribute by making own personal *note book* during the start-up phase of the course. In these personal *Note Books* (available to all the students), they write about their own experiences during the course. By this the feeling comes that the course site belongs to every participant and grows with each individual contribution. It becomes a true *evolving knowledge base*. Through the personal note books, the participants have a unique possibility to inspire each other and give each other feedback during the course.

Abstract

This paper presents a case study of an online block of four courses leading to certification of secondary teachers who are presently teaching in middle and secondary schools on an emergency certificate. The courses were taken by sixteen post-baccalaureate students over fall semester 1998 and spring semester 1999. The primary goal of this project was to answer the question, can distance education courses actually be aligned to pedagogical practices which serve the needs of a rapidly-evolving, technology-assisted, information-driven society? Data was gathered from students and professors, as well as ExCET test (state licensure exam) results. The outcomes of the case study supported the belief that online courses could be interactive and problem-solving in nature, making use of the student's teaching placement. Consideration of current issues in teacher preparation and that access to a laboratory for real time assignments supported the success of the students in their work environment and on their required exam for certification.

Perspective

In a time when modern culture is linked by telecommunications technologies in ways never before possible, people transmit and process information, conduct business, collaborate in research, and engage in social and political discourse in dramatic new ways (Kapor, 1998, Wriston, 1996). Jobs are being redefined, and the age-old restrictions of time and space are imposing fewer limitations than ever before in economic/social/political arenas. Education, typically a bastion of cultural values, has been slow to adapt to the radically changing cultural landscape that characterizes this Age of Information. Education, stifled by bureaucratic norms, historical values, and linked to the political and economic destinies of its constituents, struggles for a cost-effective way to enter the efficient development of a technological infrastructure to effectively serve the needs of a changing clientele. The intensity of effort required to implement such development monopolizes professional energies that need to be put into understanding the pedagogical implications of technological development in order to guarantee its effectiveness (Traub, 1997).

Unfortunately, this lack of focus on the pedagogical implications of technology, resulting perhaps from a lack of human resources for exploring this problem or society's faith in scientific progress may have detrimental results. Institutions implement new technologies under the assumption that "if we bring the technology, they will come," or more specifically, "if we bring the technology, they will learn." Such blind faith may actually diminish the effectiveness of educational technologies and transform the profound and dynamic tools they offer into the static appendages of outmoded pedagogy.

Higher education has been particularly challenged to apply technological tools to meet the needs of its faculty and students. Economically speaking, the introduction and implementation of new technologies within a higher education compels institutions that are perpetually concerned with finances and funding to maximize the efficiency and effectiveness of such implementation. From a pedagogical perspective, higher education institutions are acutely aware that they need to meet the diverse needs of student populations whose characteristics are continually transforming beyond those of the traditional student (Dalziel, 1997).

Contemporary students need alternative times to attend classes because many of them work as they attend school; indeed, they often need to access information "just in time," in order to meet the demands of their jobs, and they need to accelerate beyond traditional course units of time and content. As a solution to these diverse needs, distance education is heralded as an excellent vehicle to help such students
move across the challenging terrain of higher education towards their uniquely individual destinations. Unfortunately for these students, distance education classes may often rely on pedagogical techniques and traditions that are not consistent with the changing needs of society. Traditional courses are put on-line in a traditional pedagogical manner, with didactic lectures, quizzes and paper assignments. Yet today's highly interactive society demands that its citizens think critically, problem-solve, and see outside traditional paradigmatic structures (Cox, 1997, Frazier, 1997, and Boetcher, 1997). Thus, effective educators must prepare students in a manner consistent with the needs and demands of their society. Distance education in particular needs to provide the types and extent of interactivity consistent with the new global society. But the question is: Can distance education courses actually be aligned to pedagogical practices which serve the needs of a rapidly-evolving, technology-assisted, information-driven society?

Purpose of the Study

The purpose of this study is to analyze a case study that examines a block of secondary teacher education methods courses taught at a mid-size state university using a web-based distance education approach for sixteen post-baccalaureate students who were teaching in grades 7-12 on emergency certification during the 1998-99 school year. The primary component of this project was to evaluate the development of an on-line learning environment that replicated some of the primary needs of the information-driven society in the context of the courses. Strategies implemented to support this goal were:

- Professor created problem-posing curriculum that required students to take the information they were learning in their methods courses, synthesize it, and apply it within the context of their own school or classroom.
- Professor created public cyber spaces for students to publish their work and to react to the work of their peers.
- Professor created public cyber spaces for students to debate, solve problems, and dialogue about current issues and concepts associated with the courses and their work.
- Professor modeling of meaningfully integrated technology in order to support a problem-posing curriculum.
- Students learning of requisite technological skills for engaging in class activities.
- Student reflection about their learning through journals, conversations, and electronic portfolios.

Methodology

Informants for this study include sixteen post-baccalaureate university students teaching on emergency certification, two professors, and the scores of the sixteen post-baccalaureate university students on the ExCET (state licensure exams) test. Data sources for this project include:

- Syllabi for the four courses in the distance education methods block
- Students' electronic papers, projects, field notes, response logs, and forum responses posted 30 classes meetings that were held over the course of two semesters, (36 weeks).
- Sixteen student-created web pages.
- Instructors' field notes from throughout the semester.
- One 60-minute professors' taped debriefing following the course.
- Sixteen end-of-course evaluations by students.
- Sixteen student EXCET scores.

Analysis

The course syllabi were analyzed for evidence of pedagogical practices that support the needs of a rapidly evolving, technology-assisted, information-driven society? The students' electronically posted papers, projects, field notes, response logs, and forum responses were analyzed qualitatively looking for evidence of theory to practice connections reflective of the changing pedagogy. The instructors' field notes
were analyzed qualitatively for evidence of professor reflection about their own theory-to-practice alignment with the changing needs of an information-driven, technologically-assisted society in the design and implementation of these courses. Sixteen end-of-course evaluations were examined for student satisfaction in meeting their learning needs according to the traditional university evaluation rubric.

Findings

Formative evaluations made at the close of Fall 1998 indicated student, instructor, and supervisor satisfaction with the methods' block. Students report a high correlation between material studied and its relevance to their classroom practice. Students, professors and supervisors also addressed areas of concern and recommendations for improvement.

The professors for the methods-on-line class published web pages to deliver information about the structure and content of the course, but the threaded message boards became the forum for students to interact with the class community, professors and other students in the class. Threaded message boards served multiple instructional purposes in the Spring 1999 component of the block. They provided a mechanism for the professors and students to:

- deliver information about the structure and content of lessons,
- post expository assignments discussing the application of theory to classroom practice,
- report primary data collected,
- post lesson plans and construct instructional strategies,
- summarize and reflect upon assigned readings from texts and journals,
- evaluate textbooks & class assignments,
- participate in book club discussions,
- present persuasive arguments on educational issues,
- analyze educational issues and current events, and
- simulate classroom practices through role play.

In a typical lesson, a professor posted:

- information about the dates and times the assignments were due for any particular class meeting,
- questions which guided student inquiry into the lesson,
- introductory information about the topic and supporting links to sites on the web, which provided a basis for linking student prior knowledge to the topic to be studied, and
- threaded message boards for students to respond to the readings, discuss their responses with each other, or post other instructional activities products.

Student Interactions with Web-Based Lessons

Learning Community Discussion via Threaded Message Board

While professors created web pages for each "class meeting" and primarily presented the structure and the content of the lesson on these web pages, they used the "forums," or threaded message boards, to reply to immediate questions about the lessons and to give feedback to student responses to the lessons. Students were also required to respond to their colleagues original postings and responses made by other class members. For example in SED 560, Advanced Techniques and Methods of Instruction, the lesson for class meeting three was designed to help students focus on their educational philosophy as they studied a range of learning theories and instructional models. After reading, students were asked in an open forum to explain the rationale and theory that supported their educational decisions and practices. As a first step toward the development of their educational philosophies, students simply summarized the four basic learning theories being studied: Behaviorism, Gestalt theory, Field theory, and Cognitive theory. The responding professor and members of the class were able to provide immediate feedback to the student by affirming the accuracy of what had been written. They extended the definition of cognitive theory, thus extending the content of the lesson and changing the structure of the original presentation of the material.
In addition to delivering responses related to information about the lesson, threaded message boards provided a forum for posting expository assignments which helped make explicit the application of theory to classroom practice. One student, Lee Ann, illustrated how she used a behavioristic instructional strategy in her Spanish classroom. Then she made explicit how the instructional task was related to the theoretical definition of behaviorism. The forums provided a public space for her to articulate her understanding of the four basic learning theories. She used the threaded message boards to give her a public forum to reflect on her classroom practice and connect an element of that practice back to the theories she was studying. This posting of expository assignments encouraged a dialogue between students in the class and the rest of the learning community about the connection of the learning theory to classroom practice, giving them time and space to explore the connections.

**Posting Primary Data**

Providing a mechanism for delivering information about the structure and content of lessons and a public space for posting expository assignments led to making a more explicit connection between the educational theory and classroom practice. The threaded message boards provided a space for publishing primary data collected about the use of technology in the schools in which these post-baccalaureate students taught. For one assignment, students inquired into how technology was being used to support teaching and learning in their schools. They collected data and interviewed colleagues to find out about how they thought it helped and/or hindered the teaching and learning process.

Through the use of threaded message boards to disseminate primary data collected by the students, they had an opportunity to have their work read and responded to, and to read and respond to their classmates. This helped increase an awareness of the vast disparity among the schools and districts surveyed regarding the use of technology in teaching and learning and it helped increase students' awareness about the possibilities and limitations of technology within education as perceived by educators. The public forum gave an opportunity for rapid publishing, reading, and response by professional colleagues, thus increasing the magnitude of their primary research.

**Posting Lesson Plans and Textbook Evaluations**

As part of the methods block of courses, students were required to write lesson plans that were supported by the learning theory they were studying and included the instructional strategies which exemplified this theory. The threaded message boards provided a public forum to publish lesson plans. The open nature of this forum allowed students to give and receive feedback on each other’s lesson plans, to test them against the theories or constructs they studied, and helped them to be accountable to a more extensive audience than just the instructor.

Students learned to evaluate instructional materials and had the opportunity to read, reflect and respond to each other’s evaluations. Once again, the public nature of the forums increased awareness of each others’ responses. Students reflected on the fact that textbooks have enormous influence on students; the amount of classroom time students spend reading textbooks; and the rights and responsibilities teachers have to evaluate text materials for their own classrooms, school, district, state, or national curriculum committees. Through the public nature of their posted evaluations, students realized the variety of opinions and perceptions that were held by textbook evaluators, and began to realize how this diversity of opinion could impact the larger economic and social issues surrounding textbook evaluation and purchasing. Students reported in the post-course debriefing, that they felt an increase in responsibility about textbook choice and reported feeling like they had an entry point into the process of textbook evaluation and purchase. They reported an increase in confidence after reading each other’s evaluations. The evaluation task was not just limited to their perspective, but expanded to include the perspectives of the diverse group of peers who evaluated and posted to this forum.

**Book Club Discussions**

As part of the teaching and learning process, students read and discussed current education books
online through interactive forums. The discussions were held "book club" style with 2 or 3 students facilitating the discussion for each book club meeting. These students posted open-ended questions and class members responded on the forum and posed questions of their own. Discussions consisted of anything that the readings prompted the readers to think about - issues, concerns, questions, and comments.

The books were challenging, and controversial. They were chosen to challenge traditional view points and to encourage students to think, debate, and push the frontiers of teaching. The books were *Grading in the Post-Process Classroom: From Theory to Practice* (Hourigan et al, 1997) and *Life in Schools: An Introduction to Critical Pedagogy in the Foundations of Education* (McClaren, 1998). With the open parameters of this assignment, the student control of the discussion, and a public forum in which to discuss these issues, students increased their postings to the forums and the length of their responses. Student discussion leaders for the first book club meeting, posted questions to encourage processing the text. Students responded to the leaders pulling in many personal and professional experiences to passionately argue their points about assessment.

Students' responses addressed the issues the discussion leaders raised and greatly expanded those issues with anecdotes and illustrations from their own professional and personal experience. The open, public nature of the forum, as well as the assignment, opened boundaries of traditional teacher-directed assignments, allowing students to discuss be books and pertinent issues in a manner consistent with literary discussion in a real world context. The discussion, mediated by the technology, opened the way for everyone to speak and to be heard. Students commented in the post-course debriefing that, in regular classrooms, they could sit silently and just listen, not having to form or offer an opinion, but, in these public forums, there was no place to hide. They had to consider the issues in the context of the multiple perspectives people used as they responded, and, moreover, they had to form an opinion and be able to justify their stance. The students credited this requisite participation with a great deal of their growth in this course.

**Analysis of Current Issues**

Current events that affected the educational community and society at large were used to encourage students to analyze the issues using the theories, concepts, and strategies that guide educators as they make critical decisions. Immediately after the shootings at Columbine High School, in Littleton, Colorado, an assignment was posted as a part of the SED 590 Advanced Methods of Classroom Management course that pressed the students for their interpretation of what had happened. The students were to use the context of the material they were reading and working with related to conduct disorder, emotional problems, and physiological problems. They were asked to describe what they believed to be an appropriate effort or approach to the issue of school violence.

The students' responses to the forum were thoughtful and thought provoking. Again, the very public nature of the forum, coupled with the fact that peers would be reading and responding to their ideas caused students to answer with care, knowing that they would have to defend their stance to their peers.

**Simulation**

Lastly, threaded message boards were used for the purpose of role-play and/or simulation. One simulation assignment presented a scenario from an Assessment, Review, Dismissal (ARD) Meeting (staffing of special education students). The online students were asked to prepare a contingency contract based upon their particular teaching situation and the age level of their students. The online students were to create the main character in the parameters of the students who they worked with in their teaching assignment. The contingency contract was posted to a forum where the other students could read each person's approach to dealing with the simulated student.

Through this public forum, students could freely examine each other's responses to the problem posed for this simulation. They reported that this not only provided a benchmark for their own thinking but greatly expanded their opportunities to examine multiple solutions for the problem. Once again, done in a traditional classroom assignment, the opportunities for peer feedback might not be as significant. And, once again, there could be no silent observers. Everyone had to offer a solution and had to hold their own solutions up to the scrutiny of their peers.
ExCET Test Scores

Teacher certificates are given to those individuals who meet the required course of study and successfully perform on one licensure examination related to the content area the teacher will be certified in and one related to pedagogy. Fifteen of the sixteen online class members passed both exams on their first attempt, a 94% pass rate which exceeded the face to face class statistics for other sections of the methods block of courses.

Recommendations

- Educators must situate learning in the context of problems that require students to take the information they are learning in their courses and synthesize it and apply it within a real world context.
- Educators must facilitate virtual communities of learners who work in small, collaborative groups to achieve a common goal.
- Educators must create public cyber-spaces for students to debate, solve problems, and dialogue about current issues and concepts associated with their courses and their work environment.
- Educators must model the meaningfully integrated technology in order to support a problem-posing curriculum.
- Students should learn technological skills in the context of engaging in class activities.
- Student should have opportunities to reflect about their learning through authentic means such as journals, conversations, and electronic portfolios.

Abstract: This paper describes three instructional strategies designed to support community building in an on-line graduate teacher education course. The impacts of these strategies are also discussed briefly.

Two common problems noted in the literature on distance education include a sense of isolation on the learners' part and insufficient support for learning. Many researchers (see, for example, Dede 1997; Zhang 1998) propose that the development of learning communities helps to provide interaction and support for distance learners, thereby breaking down these barriers to learning. Moore (1997) notes that a "good quality distance education program not only delivers high quality presentation of information but also provides a high quality personal experience for every individual student to interact with that information..." (p.6). This paper describes three instructional strategies designed to support such personal experiences in an on-line graduate teacher education course. The impacts of these strategies, which support such experiences by encouraging the development of a learning community, are also discussed briefly.

The course described is L530: Computer-assisted language learning, an elective in the Master's program in Language Education at a large midwestern university. Participants in this methods course are pre-service and in-service teachers of second or foreign languages. The Web-based course is offered three times per year and runs concurrently with the on-site version once per year. More about the development of the course can be found in Egbert & Chao (in press).

Strategy 1: MOO Field Trips

MOO field trips are one of the central activities in the course. Participants are introduced to text-based virtual environments on the Internet through metaphoric on-line "field trips" on their computers. Since MOOing requires synchronous interaction (all participants must be on line at the same time), the complication of scheduling is unavoidable. Different time zones often require that the class meet late at night or on a weekend for the MOO field trip. Other preparation includes contacting the field trip sites to ask for permission for a group visit and providing sufficient information to help participants prepare for it. Despite these potential complications, participants find this experience rewarding.
Description of the Activity

In a unit where the focus is on classroom atmosphere, we take participants to two MOOs: SchMOOze University, a MOO designed specifically for learners of English as a foreign or second language, and TAPPED IN, designed for teacher professional development.

The SchMOOze U visit is the first opportunity for the distance participants to meet and interact synchronously; the trip is not only a new learning experience but also a rare opportunity to socialize for the on-line class. Typically, an itinerary for the trip indicates that in the first trip participants will be introduced to ways of helping their learners function in this environment. Participants explore this environment in small groups with the instructor providing necessary support. During this time, participants realize the difficulties involved in text-based MOO navigation. They also see possibilities as well as problems in interacting with people outside of the class in this environment. Participants realize that they must develop ways of supporting learners and of dealing with safety concerns. A follow-up discussion is conducted asynchronously on the class electronic discussion forum after the first trip. The purpose is for participants to talk about their experiences and insights from the perspective of a new learner. Participants also discuss potential activity designs using this virtual environment.

On the second trip, to TAPPED IN, the group is introduced to a different kind of MOO setup by an outside expert from the host site. The expert helps with some of the participants' concerns and questions. The group tries out some of the activity designs that they came up with after the first field trip. The discussion in the MOO is in-depth and related to teaching and learning in the MOO environment. Another follow-up discussion is conducted in the class discussion forum for participants to compare and contrast their experiences in the two MOOs and to discuss their insights from the perspective of educators. The student facilitators and the instructor then conclude the activity with a summary of the discussion.

Impacts

We observe two kinds of impacts of this MOO field trip activity: (1) it encourages collective reflection and (2) it fosters a sense of community within the on-line group.

Encouragement of Collective Reflection

Reflection is an important daily activity that a successful teacher must do in order to learn from her experiences, successes and mistakes in everyday practice (Schon 1987). During the MOO field trip, the participants experience how it feels to lack control, what kind of help is useful, and how they can manage the flow of conversation to become active and independent participants. Since the experience is full of new opportunities and ideas, participants are eager to share their thoughts after the trip. We see participants reflect on the issues in the roles of both learner and teacher. Examples of the kinds of questions upon which participants reflect are presented in Table 1.

Fostering a Sense of Community Within the On-line Group

The second important impact that MOO field trips have is facilitating a sense of community. In this Web-based distance education class, participants use the asynchronous conferencing tool for most of the discussions. Although conferencing requires daily participation, the interaction is very different from that in the MOOs. In the conference, responses are delayed and little emotion is usually expressed. The result is a serious, business-like, no-fuss academic discussion. The MOO field trip is just the opposite. The participants’ initial excitement is obvious by the way they and the instructors greet each other and interact light-heartedly. For example, on one occasion the instructor noticed that one participant from Kuwait suddenly became quiet for a long time during the MOO visit. Once the group knew that this person had a headache, everybody started asking the reason and asking her to take care and not to worry about having to leave early. During the MOO trips, the group finally has the chance to pay real attention to each person, giving sincere care, voicing concerns, and developing friendships. After the trip, even the asynchronous discussion becomes more personal.

Our observations have convinced us of the power of synchronous interaction in fostering a sense of community in on-line classrooms. Following the suggestion of previous student groups, we have moved the MOO visits to an earlier part of the course so that a sense of community can be developed from the beginning of the semester.

It is important to note this activity would not have worked as well if developing a sense of community were all we wanted from it. MOO field trips are meaningful to our participants because they match perfectly with our goal of encouraging our participants (who are language teachers) to use technologies selectively and reflectively. When the excitement of on-line socializing dies down, we need to show that there is a deep meaning in this experience.

Strategy 2: Integrating Experts

Johnson (1997) and others support the integration of mentor teachers into teacher education courses. She concludes that making such links can help pre-service teachers link theory and practice and become more integrated into the community. At the same time, mentors or external experts are encouraged to reexamine their own practice and expand their role to that of teacher educator. In this on-line methods course, experts are integrated into the final project.

<td>What good learners get by coming here often.</td>
</tr>
<tr>
<td></td>
<td>Whether it is possible to have serious discussions on MOOs.</td>
<td>How to facilitate discussion in this medium so that it is more than a socializing activity.</td>
</tr>
</tbody>
</table>

Description of the Activity
During the first week of this four-week project, participants hand in a one-page inquiry brainstorm that briefly explains a problem that she has or anticipates in her language classroom. The participant also describes her learners and their goals and proposes a variety of possible solutions to the problem. Participants then find an external expert who is willing to facilitate the development of a solution. Participants find experts through professional electronic discussion groups, a Web search of similar topics, a review of the literature associated with the topic, or a recommendation from the instructor. Participants consult with their expert during the development of a technological solution to the problem that they outlined. Participants are responsible for contacting this colleague and for the interaction that they have. Along with the solution, participants complete and turn in a reflection, which describes

- How the project a) solves the problem posed and b) meets conditions for optimal learning.
- How/whether the participant’s learning goals (new skills or knowledge) for the project have been met (difficulties/problems encountered and how they were solved).
- How the solution could be improved in terms of the 8 conditions for optimal classroom language learning discussed in class (if more time/money/skills were available).
- How the professional colleague helped (or didn’t) and what difference it made to the project.

One of the criteria for grading was the degree of interaction with colleagues, inside of class and out.

Impacts

Participants’ projects range from designing authentic grammar activities on the Web to creating lessons that integrate technology for other teachers to use. In their reflections, learners noted that “my colleague gave me lots of useful suggestions” and “I really appreciate my colleague...Hopefully, this project can really assist EFL high school students.” Some of the participants interact with more than one “consultant” to get several views of their solutions; often, participants receive help with technical problems from one expert and content ideas from another. One student noted that for her it was “an unforgettable and

Broader than the idea of classroom community, integrating experts into this project helps participants to understand and become more a part of a wider community of practice. In addition, through the combination of working on a personal inquiry project and doing so with colleagues external to the course, learners come to think of themselves as less dependent on the course instructor and more able to use their own resources to develop effective solutions to classroom problems and to find collaborators within the community.

Strategy 3: Small Group Case Studies

Learning with case studies can offer participants a variety of opportunities to expand and extend their skills, problem solving abilities, and grasp of contemporary issues in today’s classrooms (Sudzina, 1999). Working on case studies also helps participants to build on shared experiences and promotes team building and a sense of community among learners (McLellan, 1998). The small group case studies used in this course allow participants to work closely with two or three of their classmates on a problem scenario that is closely related to their teaching contexts. The discussions within teams take place in a team space or chat room found in the course’s electronic forum. This discussion is open to other participants and the instructor, and participants in each team are encouraged to critique, provide encouragement, and recommend ideas to help other team efforts.

Description of the Activity

At the start of the course during a recent semester, the instructor surveyed participants about their interest in and commitment to teaching various levels of learners (elementary, secondary, and adult). Three case study scenarios were then designed to encourage participants to work on issues and concerns related to using technology in the language classroom. Participants were placed in teams to work on a case that, as far
as possible, related to their interests. The instructor also attempted to group participants based on their
diverse learning experiences and expertise with technology.

Participants began planning and organizing tasks for their project by using the course's chat room
facility on the conferencing forum. These synchronous chats were aimed at helping team members to
brainstorm ideas for the project and to work out task assignments among the team members. Participants
continued working on the project using the course's asynchronous conferencing forum. Several electronic
folders were created to help participants organize this content. This included a Proposal Sample folder that
contained guidelines, a Resource folder where participants could point others to related works, and a
Discussion folder for participants to work through ideas on the case study and attach works-in-progress. The
goals for these asynchronous discussions were to build on and refine ideas for the final product.

Impacts

Working through the case studies, participants develop a continuous sense of collegiality with their
on-line classmates. This leads to the creation of invaluable support groups in the class. Since the team has to
decide on solutions within a limited time (five weeks), many participants use a wide variety of tools and
strategies to interact with their peers. Through this process, their thinking about the issue at hand becomes
deeper and more meaningful than if they were to complete the project on their own. In addition, participants’
reflections reveal that through working on case studies in small groups using different communication
modes, they feel:

- encouraged (“...great job!! this chat is encouraging me to work harder ...”);
- they optimized and extended their abilities (“I found the courage to do some summarizing and push for
development of our ideas”), and (“I don't usually take a leadership role, but was able to do so to some

- their efforts were rewarding (“I learned a lot from being able to develop something WITH other
working with a variety of educators was very enriching”); and
- they learned other useful skills (“There are also lessons about management”).

Several considerations were taken into account when designing the case studies for this class that
can be used as a guideline for similar courses. First, instructional and learning strategies in CALL learning
environments as discussed in assigned readings were integrated. In addition, the case studies addressed the
contexts for which CALL-related instructional strategies were designed and implemented. This involved
having participants discuss the learning conditions and consider possible administrative constraints faced in
these instructional settings. The need for participants to interact and share ideas in various ways (e.g., e-mail,
chat rooms, document exchange, etc.) was made an integral part of the activity. Finally, opportunities for
feedback (such as formative assessment and reflections) were built into the discussion as well as into the final
report.

Conclusion

There are many ways for participants in an on-line methods course to become members of a class or
wider community, but these opportunities must be carefully planned and well facilitated. In L530, the
computer-assisted language learning methods course, the three strategies of MOO field trips, integration of
experts, and use of a case-based format impacted learners in important ways. These strategies encouraged
learners to think deeply about the course content and its applications, create bonds with other members of the
community of technology-using language teachers, and to reflect about their teaching practice. By both
helping participants overcome the sense of isolation that too many is inherent in distance education and
providing alternative ways for participants to receive support for learning, these strategies are assisting us in
meeting our goal of delivering quality distance teacher education.

Technology in the classroom: Implications for Teacher Education

Warren E Wessel
Faculty of Education
University of Regina
Regina, Canada
Warren.Wessel@uregina.ca

Abstract: This paper argues that if ICT is going to become an integral part of instruction in elementary and secondary schools, then changes need to be made in preservice and inservice programs for education students and practising teachers. Suggestions for assisting students to understand pedagogically appropriate uses of ICT are described. In addition, a proposal for an instructional sending studio and receiving classroom is made. Uses for the facility are described and include applications at the undergraduate and graduate levels. The facility could be used to provide much needed research about the best uses of ICT in elementary and secondary classrooms.

Introduction

Rural and Northern areas in Saskatchewan have small student populations; however, the demand for an extensive range of courses has not decreased. Budgets are not large enough to allow hiring of specialists in all subject areas; nevertheless, students need these courses to fulfill requirements for entry to many post-secondary programs. In spite of legislation requiring provision of equitable programs, they are becoming more difficult to deliver with limited funding.

Information communication technology (ICT) is capable of resolving these educational concerns to some extent. A variety of alternative program delivery systems/mechanisms are being suggested as means to provide equity in education in rural and northern settings. Televised and on-line courses originating from within or outside the province can be found for most subject areas. Within Saskatchewan, a few urban schools televise physics, calculus and other courses to areas where only small numbers of students want to take a course. Other courses, which originate inside and outside the province, are available on-line. However, in Canada, education is a provincial responsibility; there is no federal department of education as in the United States. Consequently, individual provincial departments of education are concerned about the quality of courses available on the Internet, and whether or not they adhere to provincial guidelines.

The purpose of this paper is to explore some of the implications on teacher education of the increased use of ICT in delivery of curricula. The initial section describes the assumptions used to limit the scope of the paper. The next section presents a discussion of potential uses of ICT and some concerns/myths about the use of ICT in education. The third section is a discussion of teacher education and professional development for practising teachers including some ideas about distance education. The final section describes a research facility that the author would like to see established at his university to further the study of ICT in teaching and learning.

Assumptions upon which paper is based

Because ICT has an enormous range of potential uses, some assumptions are employed to limit the scope of this paper. The assumptions are, of course, open to debate. Because of my professional classroom experience I have a good understanding of the realities of classroom teaching and learning. The suggestions made within this paper are intended to be manageable for faculties of education, school administrations and classroom teachers.

First, teachers are assumed to be doing a very good job in the classroom. They are well educated and care very strongly about their profession and their students. Teachers have a professional attitude toward the
quality of the instruction they provide and understand much more about what actually goes on in the classroom than most computer business persons. Second, the goals and policies of education in our province (and other Canadian provinces) are delineated in provincial education documentation. In Saskatchewan this documentation (Saskatchewan Education, 1999) has a sound philosophical base and is probably the most consistent package in Canada. The uses of ICT must fit within provincial programs and philosophy. Third, some use of ICT is inevitable and desirable; however, ICT is surrounded by an enormous amount of hype and many claims, which are not supported by research. Fourth, much more goes on in classrooms than the explicit curriculum lay out in curriculum guides. In classrooms throughout Canada implicit educational goals are achieved which are not written down but are intended nonetheless. These implicit goals are of great importance in the development of citizens and must not be unintentionally eliminated through the use of ICT or any other instructional strategy. Finally, it is assumed that whatever funding is spent on ICT cannot be spent on other school programs. The result of spending considerable amounts of money on ICT means that some program is discontinued, some building repair is not made, or some teacher is not hired. Franklin (1999) argues that when technology is introduced we should remember that students matter more than computers, and that planning to implement the use of technology should be aimed at minimizing disaster.

Uses, Myths and Concerns of ICT in Classrooms

Some uses of ICT in education are more likely to occur than others. The most obvious applications for students to learn to use include, word processing, spread sheet usage, data base creation and access, presentation, multi-media software and web design software. Students will increasingly use these types of software applications as tools in completing their assignments and presenting their work. Just as obviously, teachers will increasingly use ICT for administrative and professional purposes. Computers are now routinely used to record marks, attendance, student information, and to generate reports to parents. Teachers will continue to increase their professional use of ICT for lesson planning, instruction and communication. Communication by computer between teachers and administrators is now routine and will probably grow to include some form of communication with parents.

The Internet sites are increasingly being used as resources for students and teachers, especially as budget limitations reduce the purchase of other kinds of resources. Teachers, students and parents will use email communications more extensively, and new forms of communication will almost certainly include visual images. The chat room facility of web-based software is being used by students to communicate among themselves because its asynchronous nature allows them to work together on their own schedule.

ICT is being used to provide alternative delivery of curricula, especially at the secondary and post-secondary levels. Whether with one-way or two-way student-teacher communication, courses will be offered at a distance. Teachers at the receiving end may be able to assist in facilitating learning for those students who access such instruction. Teachers involved in the sending of distance instruction will have to learn instructional skills that are not normally taught as part of teacher education courses.

Software for classroom use is targeted at each subject area in every grade level. Teachers have to learn to evaluate this software as to its suitability in their classroom situations, and learn how to use appropriate software in meaningful ways with their students. Because of limited computer resources within individual classrooms all students will not be using the computer(s) at the same time. Software and hardware are used to collect and manipulate data in senior science laboratories. Drafting software and graphic design software have been adopted for use in practical and applied arts courses. Many high school year books are being created exclusively through the use page maker software and scanned images.

Educational research has discovered a great deal about how students learn and what types of experiences are most appropriate for particular age and developmental levels. Some proposed uses of ICT in classrooms are not appropriate to the developmental level of the students. We know certain types of activities and instruction cannot work at lower grade levels because these students do not yet think abstractly. Many proposed uses suggest that students will learn on their own with little supervision. For example, some suggestions for ICT involve elementary students learning at home with little or no teaching supervision sitting in front of a computer screen working through computer assisted learning exercises. This approach may be appropriate for adult learners who work from more intrinsic motivation, but it is not likely to succeed for
younger students. Caring and interaction from teachers is an essential part of learning, especially for younger children. Students must interact with people to learn how to work with them. These abilities are developed as part of every activity and all interactions in all K-12 classrooms. While some communication skills can be developed in isolation using computers, other important forms of communication cannot be. Reading non-verbal signs are extremely important in understanding others; body language and facial expressions are not obtainable using computers alone.

The adoption of technology has led to a downgrading of personal experience in education (Postman, 1991; Franklin, 1999). Human beings are tending to devalue their common sense about educational decisions. For example, common sense tells us that ICT cannot replace teachers. Yet, in spite of this knowledge we listen to arguments that performance of students taught by computer is as good on standardized tests as those taught by teachers and begin to wonder if teachers can be eliminated. Parents in rural communities in Saskatchewan are very clear about the expectation that their children should be in the presence of teachers and other students (Fleming & Pain, 1996). Yet, in spite of this common sense conclusion we persist in considering the replacement of teachers with ICT.

A claim frequently heard is that students will be able to interact using email with the scientists (or writers, or other professionals) who made discoveries (or wrote a book). The argument goes something like, “who better to explain the discovery than the person who made it.” Sooner or later, reality will set in. First, scientists (and other professionals) do not have the time to interact with a significant number of students, any more than famous actors and actresses have time to answer their fan mail. Second, a teacher may well be able to explain a discovery better than the scientist to students in his/her classroom. Scientists who work at the frontier of knowledge are not known for their ability to communicate their ideas in ways that are clearly understood by adults, let alone children. Some of the hype and dreams that pass for policy development are just that, hype and dreams.

Lastly if we look at predictions made about computers made in the last decade or so, many have not come to fruition in quite the manner predicted. Computers have a have life expectancy of less than five years, meaning that they must be replaced much more frequently than imagined. I recall someone (maybe Bill Gates) arguing not long ago that no one would ever need a computer with more than 64 kB of memory. The quality of computers has increased as they become faster and have greater memory capacity; however, the demands of new software are constantly increasing requiring ever more powerful machines to run them. The wonderful “486” of a few years ago has become a paper weight or doorstop as a new piece of software is chosen with memory requirements that exceed those of the “486”. This is perfectly planned obsolescence.

The most important criterion in adopting any ICT for classroom use is that the use be pedagogically appropriate. Teachers require workshops and other experiences to assist them in understanding the uses and limits of ICT. Appropriate uses are not necessarily what are advertised by manufacturers. Teachers have to be helped to understand that as professionals they can develop new and creative uses for ICT on their own.

**Teacher Education and Professional Development**

Fewer educators at the elementary, secondary, and post-secondary levels than is optimal are integrating ICT into their classrooms in ways that are meaningful to students and pedagogically appropriate. Without appropriate teacher education and professional development ICT resources can be wasted. For example, computers sit idle, or are used by students to “surf the net” with no direction or plan. In spite of the great range of wonderful resources on the Internet, it can be a very ugly and unfriendly place to explore. Without supervision and censorship, students (especially younger ones) are in some danger if allowed unlimited access. Preservice and inservice teachers require workshops and other developmental opportunities in order to learn about pedagogically appropriate uses of ICT. If teachers are going to use ICT in their classrooms, then they must use it well and in such a manner as to improve education.

Preservice and inservice teachers both require assistance in learning to integrate ICT into the curricula. Inservice teachers generally have more practical experience and background than do preservice teachers. Inservice teachers are more experienced in classroom decision making. In the following preservice teachers are presumed to be enrolled in university teacher education programs and gaining their ICT experiences as part of their courses. Inservice teachers are presumed to access some form of professional
development that could be part of a university program, but is more likely outside of a university setting. The ICT component of professional development and teacher education will in many cases be very similar.

Most advocates argue for the integration of ICT into the curricula of all subject areas. That is, ICT should not be restricted to computer science courses and computer labs; rather, students should have access to computers in each classroom for use in all courses. This approach is recommended because students need to learn to use ICT while performing problem based and authentic tasks in all subject areas. If ICT is to be available in all classrooms, then teachers will have to acquire some technical knowledge of ICT, and considerable knowledge of how to choose appropriate instructional uses for ICT in their classrooms.

Constructivist teaching, student-centred classrooms, critical and creative thinking skills, problem solving skills, and facilitation of student learning have been presented as reasons to adopt more ICT in classrooms. While all of these are desirable goals for classroom teaching, none is dependent on ICT, or even made more easily obtainable by ICT. Any and all of these characteristics can (and should) be developed with or without computers; however, achieving them is dependent on the structure of the assignments given to students, the choice of instruction, and the relationship developed between teachers and students. Constructivist teaching does not imply a particular style of instruction, rather it describes a particular model (theory) of student learning which teachers use to interpret learning in their classrooms (Millar, 1989).

Teacher education programs will still need to prepare their graduates with solid foundations in instruction, planning, educational psychology, learning theory and classroom management. None of these skills and knowledge is required in less degree if ICT is integrated into the curricula. No one is arguing that teachers need only to be able to install and to turn on a “learn to read” or some such program, and then stand back and not interfere with the “computer as teacher”. Current teacher education programs need to incorporate ICT as appropriate to specific subject areas but not at the expense of other instructional skills and knowledge.

Students in teacher education programs need opportunities to incorporate the use of ICT in their studies. Preservice teachers need access to a variety of software and hardware with which they can experiment. They need opportunities to develop skills that will enable them to assess and evaluate software for use in their classes. Classroom use of ICT must be consistent with the goals of each curriculum and be age/grade appropriate. Because of the rate of change of titles and limited budgets teacher decisions must be made wisely.

Another issue, which must be addressed, is which aspects of ICT are to be included at which grades and in which subjects. Integration of ICT into the curricula seems like a simple directive, but the reality for classroom teachers is that they have so much to choose from that the task has become impossible. What are the appropriate aspects of ICT to be integrated into K-3, 4-6, 7-9, or 10-12? This concern is a policy issue and falls to other jurisdictions. Although several attempts have been made to delineate the appropriate skills and knowledge for grade levels, they have not been adopted in all curricular jurisdictions. More work needs to be done to resolve this issue. Do we postpone learning to write or read so that students can learn “surf the net” or use computers in some other manner?

Practising teachers who are actively developing uses of ICT for their students have additional needs to those of preservice teachers. These teachers’ concerns center around classroom uses of ICT and ensuring that their students are getting the best use of the available resources. The main problem, as I see it, is that classroom teachers do not have time in their schedules and lives to spend hours learning how to use various software and hardware in their instruction. Regardless of their dedication, they do not have great deals of spare time to spend learning about ICT. Many blockages can occur when working with computers and software, and each can bring an individual planning session to a halt. Without resolution the blockage stops all planning and tomorrow’s lessons are not prepared. Support and professional development must be provided and be on-going. Teachers simply cannot be given an hour inservice, handed the software and be expected to use it in their classrooms the next day. Teaching is a much more complicated process than is imagined. “Just-in-time” support (assistance) has been described as a better means of assisting classroom teachers (Richmond, 1997). This type of support is designed to be available to teachers on very short notice. Support personnel must be available to assist teachers as they plan to include ICT into their instruction. Richmond argues that teachers need just-in-time support because studies have shown that they abandon ICT when the are stymied by some aspect of its use. Another solution is for an individual teacher to develop expertise with a single program and act as mentor to other teachers for that program. Professional development time must be provided in some manner by school administrations. Success of this approach is
less likely to occur if development of skills and knowledge is to be achieved on teachers' own time.

Each school division or administration has unique problems and concerns in delivering curriculum. Solutions are frequently most suitable when developed locally. One way to facilitate development of solutions to problems to ICT implementation would be to allow a teacher (or teachers) to have a "developmental semester." During a semester (or other length of time) teachers would be relieved from teaching and supervision duties and charged with exploring a local ICT problem. The goal would be for the teacher(s) to develop a resolution that would be implemented at the end of the "developmental semester." Teachers who know about the resources and personal in their communities could construct a viable resolution to the concern or problem. University faculties of education could provide advice and support to these teachers and could report in a formal manner on the locally developed solutions. Solutions could be published as research reports, but would be more useful in an electronic format in order to be more accessible. In some cases the work accomplished by teachers could fulfill part of the requirements for a postgraduate degree.

Distance education requires separate consideration because the teacher and students are not at the same location. Distance education courses can be delivered through correspondence, television or the Internet. Some form of distance education is very likely to be in rural and northern schools. Although most people think of the teacher who teaches from a distance, an increasingly important role exists for teachers (and other persons) at the receiving end. The role of assisting students who access distance education has not been discussed to any great extent. In some models of distance education, persons at the receiving location may become an important component in distance education.

In preparing this paper I talked with two instructors who have taught using televised forms of distance education. One taught calculus and geometry to grade 12 students; the other taught university courses to students off-campus. Both instructors indicated that the flow of instruction was quite different from their regular classroom experience. This characteristic was the result of not being in the presence of the students. No immediate feedback was available and this lack made pacing of lessons different from regular teaching. Students were in contact by phone, but this type of communication was not the same, or as immediate, as personal face-to-face contact in a classroom. Both instructors thought that the sending teacher should be a specialist because of the skills required for this form of instruction. In distance education lessons have to be scripted more. Even referring to notes or lesson plan was perceived differently in distance education than in a regular classroom. Teacher education programs should develop courses and facilities to assist teachers in building skills and knowledge necessary for this type of instruction.

The second role in distance education is that of the supervising teacher (or person) in the classroom at the receiving end. Very little seems to have been written about his/her role. Courses or workshops could be developed to provide these persons with opportunities to learn how to assist students who are taking courses through distance education. Students need not learn completely on their own. This type of course would also have application for classroom teachers who are assisting students using computer-enhanced instruction. Models of distance education usually assume that students work independently without assistance. Teachers and other persons in the proximity of students are going to be asked questions, but little has been done to examine how these interactions can be made most effective.

A Proposal for a Research Facility

In closing this paper I am proposing the creation of a facility to explore research and development of the use ICT in educational settings. Establishing an ICT research facility at (or close to) a university would facilitate research and development into ICT, as well as, provide a range of opportunities for teacher education and professional development for teachers and administrators. The kind of facility I am suggesting would have state of the art equipment, which would be acquired through partnerships where possible to avoid the costly replacement every few years, and have access to the current educational software. The facility would be designed around an ICT classroom that could act as both a receiving classroom for distance education and as a classroom to model the use of ICT in practical use. In addition a sending (or transmitting) room/facility would be located in the same building so that feedback about instructional strategies could be provided immediately.

Such a facility would have uses for all educators and payback to the partners who contributed to the
Preservice teachers would be able to use the facility to develop skills and knowledge required for appropriate classroom use of ICT. They could also explore various means of distance education at both the receiving and sending ends. The realities of classroom ICT use and distance education could be experienced first hand. The sending facility could also be connected to classrooms in nearby schools thus allowing elementary and secondary students to be part of the process. Teachers could experience strengths and weaknesses of distance education, and would be able to provide developmental criticism to those at the sending end. Elementary and secondary students could point out deficiencies and strengths of a particular distance education approach more rapidly than any group of adults.

During the school year or in the summer, workshops of varying lengths could be held for teachers and administrators. These workshops would be designed to assist participants in understanding the strengths and weaknesses of ICT and to help them design other uses for their individual situations. Graduate students could interact with these persons to design research that would examine various components of projects. Graduate programs of research at masters and doctoral levels would be able to make use of this facility to evaluate or develop educational uses of ICT. Partners would benefit in that they would receive feedback about the hardware and software from educators in a variety of educational roles. This type of facility would benefit all members of the educational community in Saskatchewan (and probably a lot of other places).

Closing Thoughts

Public demand will ensure that some ICT makes its way into the classrooms of Saskatchewan and other jurisdictions. The most important consideration is that ICT act a resource and tool for students and teachers, and not come to drive education in the province. Student learning will always be a slow, challenging process and teacher instruction will always be a challenging and rewarding process. Learning is a cognitive process that occurs in minds of children (and teachers) as the result of knowledge construction that individuals carry out to make sense of their experiences. ICT will not change the way people learn. Knowledge building is an individual process that cannot be handed over to computers. ICT must not be portrayed as a technological panacea for educational concerns.

Introducing ODL in Teacher Education - an On-Line Course on How to Create On-Line Learning Environments

Bodil Ask, Agder College, Norway, bodil.ask@hia.no
Harald Haugen, Stord/Haugesund College, Norway, harald.haugen@hsh.no

Abstract: Learning through practice has always been a sound principle. In this case it concerns learning how to construct ICT based ODL material by attending an Internet course that demonstrates the content and uses the ‘learning by doing’ slogan. The guidelines are based on experiences from different national and international ODL projects. It provides a basic understanding for newcomers and will hopefully also demonstrate new ideas for experienced developers in the field. The target groups are teachers, developers and providers of ODL, working or intending to work in the field of ODL, providing opportunities for life-long learning. Further on parts of the course seem to be of general interest for people collaborating across boarders. They seem to have a need for common competence in order to exchange information and knowledge. The learning environment in which the course takes place, is created as a series of examples of how to design and implement a virtual learning environment using multimedia.

The On-Line Course
Background

The NITOL group (Norwaynet with IT for Open Learning) (Ask, B., & Haugen, H., 1999) has for more than 5 years designed and created net based on-line courses. Based on demand for sharing our experiences from several projects and courses a new course was designed. This new on-line course on Pedagogy in Open Learning has been offered to national and international audiences since 1996. Every term it has undergone some revisions and it has gradually evolved into the form it has now. A major objective is to provide guidelines for the development, implementation and running of open and flexible, net-based learning environments. The guidelines are based on experiences from user trials and evaluation of several national and European projects, as well as on theoretical discussions. Experiences from earlier versions, have been worked into the new course. It has become part of IT-curriculum for teacher training at several institutions, and has been accepted for credits in different countries, with reference to the ECTS - European Credit Transfer System.

Target groups

Target groups are teachers, developers and providers of ODL, working or intending to work in the field of ODL, providing opportunities for life-long learning. Providers of in-service and further education for teachers are of particular interest as a target group. Teachers in secondary schools, academic staff at universities and colleges, personnel in charge of training programmes for corporations, companies and public administration, staff at adult education institutions, lifelong learning programmes etc. Students of pedagogy, of ICT or teacher training, will also benefit from the course. In their future jobs they need to be qualified for organising learning environments that exploit the potential of ICT. Parts of the course seem to be of special interest for people who collaborate across boarders and who work internationally.

Main goal
The course Pedagogy in Open Learning (PiOL) intends to prepare a basis for development and applications of ODL material that uses ICT as a medium to supplement and/or offer an alternative to traditional ways of learning. In Norway every teacher is supposed to engage in ICT in two ways: to use ICT for learning purposes and to learn ICT for using purposes. This course forces them to do both. The students of this course shall learn how to design and implement learning material and environments that are open, flexible and readily accessible for different groups of users in search of education.

In addition, adult learners and people working in international organisations need a common competence in order to share knowledge and information. Parts of this course seem to be relevant for upgrading them.

The candidates shall be trained to act in the society in general and in the educational system in particular, as resource personnel for the exploitation of new ICT to
- create a basis for providing lifelong learning
- prepare 'just-in-time' learning facilities (when and where it is needed)
- implement new ways of teaching and learning
- offer courses to satisfy needs for new knowledge and skills
- assist in the process of creating a fruitful learning environment using multimedia technology

As part of teacher training this serves two purposes to:
- it introduces ICT-based ODL students and teachers attending further and in-service training
- it forces - or offers - the teacher trainers to engage and experience ICT-based ODL.

Content

The course is intended to function as net based background guidelines for development, organising and running ICT based ODL activities. It thus has to cover a wide variety of topics. On the basis of experiences, the following main topics are covered:
- Introduction to ODL and to the technical basis for ICT based ODL
- Theories of learning; cognitivism, constructivism, situated learning etc., related to ODL
- Structures of learning material, hyperstructures, different modes and media
- Creation of a web based learning environment
- System dynamics and simulations as learning tools
- Design and development of learning environment, net based support, discussions etc.

In addition, adult learners and people working in international organisations seem to have special interest in these topics:
- Collaborative learning; net based resources and facilities for interaction
- Learning organisations and lifelong learning
- Applications of networks and communication (Internet, www, collaborative tools etc.)
- Examples, demonstration of courses and lessons based on ICT/Internet

Most of the themes mentioned above, are fairly self-explanatory. The intention is to introduce some concepts and models relevant to ICT-based ODL, based on experiences and on-going work from the institutions responsible for the course. The students' own knowledge and skills are important resources in the learning environment of the course itself. Participants with theoretical and practical background in education and pedagogy, are particularly valuable for the further development of the learning environment. The practical approach also demonstrates advantages, difficulties or challenges, general freeware tools and possible drawbacks of on-line learning.

1 The term 'netbased' should be construed broadly enough to include emerging technology such as high-bandwidth networks, wireless telecommunications, interactive video etc.
Technical and organisational aspects

Most of the course activities are now (1999) technically based on Internet and World Wide Web environments. A multimedia computer and network literacy is a prerequisite. At the same time it is assumed that a great part of the target group are not necessarily IT professionals, but do rather have their strengths in pedagogy or other professions. Several of the themes in the course concern issues related to practical applications of the relevant technologies, demonstrating examples and encouraging the students to practice a variety of tools themselves.

A particular challenge for educators developing ICT based learning material, is the inherent potential of hyper structures as compared to traditional, linear presentations of information. All ‘lessons’ of the learning material of the course are distributed through a fixed web address with links for downloading modules. Other parts of the learning material are based on other techniques, e.g. use of synchronised, interactive video and presentation programmes, use of collaborative tools such as Team Wave, in order to exchange information and know how.

In the EuroCompetence project (EuroCompetence, 1999) the parts of this course that are relevant for adult learners and people in international organisations will be offered as a separate course, called Learning to Learn by ICT. The course will be running during the spring 2000.

Discussions are mainly performed on News conferences, by links to individual ‘workbooks’ or collaborative tools. Personal messages are exchanged by e-mail and mail lists. But there are also options for automated support, e.g. FAQ, SOS, Oracle services and for synchronous net meetings etc. for exchange of views. Thus the exchange of experiences between all participants implies the opportunity of better understanding and insight into the problems arising.

It has been an active choice not to use proprietary software. The courses are developed on bases of general tools, Internet, www etc.

The figure shows an example of one way of organising a learning environment. In this learning environment there is a combination of video presentation synchronised with a power point presentation. The list to the left indicates keys or links to switch between subtopics.

Pedagogical and methodological approaches

Students of this course are supposed to have a certain background in general educational theories. The main idea behind presenting guidelines as an interactive course is based on the learning-by-doing principle. The focus is on the process rather than the outcome. The learning environment in which the course takes place, is created as a series of examples of how to design and implement a virtual learning environment using general tools and multimedia. For example, within this learning environment, the use of hypermedia is described as well as used as tools for management of the environment. When the students attend the
course, they meet a learning environment that includes facilities to help them to manage their own learning environment. By implementing different guidelines/handbooks telling students for example how to create a WebPages, how to download files etc. students can immediately start to manipulate their learning environment. Access to facilities like on-line oracles as well as guidelines are components that add to a learning environment.

Different tools for collaboration between participants are necessary part of the course. Furthermore, collaboration between teachers at different institutions occurs as an interesting component in this environment. A variety of professional profiles at the co-operating institutions strengthens the whole environment and even makes teachers take on the role of 'students'. In effect, learners, teachers and practitioners collaborate in constructing a hypermedia based learning environment. Electronic hypermedia based learning material constitutes a forum among and between students and instructors/teachers. It allows a high level of interaction for everyone, especially in raising questions and sharing access to the continuous discussions.

In a net-based learning environment like this, the role of the teacher is no longer defined by tradition, and learning is no longer seen as the passive acquisition or absorption of an established and often rigidly defined body of information. The former role of the teacher has been to acquire formal knowledge, find efficient ways of sharing it and to determine whether the students have learned what has been taught. This has been the traditional role of the teacher, to have the major responsibility for what and how the students learn. But to-days learning environment opens up for a discussion of what the role of the teachers is going to be: A sage on the stage or a guide on the side? A virtual learning environment seems to indicate that teachers' tasks are moving from lecturing and 'teaching' towards supervising and assisting students. Students are becoming more responsible for discovery and self-learning while teachers take on the role of facilitators. Occupying a seat in a physical classroom for a specific period of time may soon become the exception rather than the rule.

In this learning environment both the teachers and the students will be challenged to adapt to their new roles. Teachers are asked to articulate more clearly their goals, objectives and expected outcomes, while students are asked to take on more responsibility for their own, self-directed study and learning. The use of 'notebooks' forces students to be part of a learning material 'production'. Access to each others 'notebooks' enriches the total environment and may create lots of professional discussion. The notebook also serves as part of the assessment procedure.

Visions

The PiOL course is created in order to prepare higher educational institutions and staff members for future requirements. The International Council for Distance Education, ICDE, predicted already in 1994 that there will be shifts:

- from objective, general knowledge to constructed, adapted knowledge
- from an industrial to a knowledge based society
- from teaching and lecturing to facilitation of learning
- from books and paper based hand-outs to applications of ICT based material for learning
- from traditional universities and colleges to new structures not yet defined

The driving forces behind these changes are:

- pushes' by the new information and communication technology, the information explosion and political/economic desires to increased productivity in education,
- 'pulls' by the changing job structures with new skills and knowledge requirements, R&D challenges within higher education, and a general desire for more education and better qualifications among the general public - a trend of lifelong learning.

In this environment ICT based open and flexible learning systems seem to be the nearest solution. Technology is continuously improving, providing faster, broad-band and more flexible systems that can offer even better learning environments than can be demonstrated today. Students of the PiOL course
should therefore not believe that they are fully trained for future tasks in the field by the time they pass their exams. But they should have learned how to learn, how to collaborate and how to develop new learning arenas for their own future students and have in mind that education should produce individuals who have a sound working knowledge base, who can use that knowledge when called upon to do so, and who are willing and able to continue the learning process after schooling. In order to meet these challenges, our prediction is that the field of ODL will develop and expand very rapidly in the years to come.

International collaboration and joint development implies a higher and broader spectrum of professional skills and backgrounds. Teacher trainers and researchers in education are considered to be key personnel in this evolving of new learning facilities. Models presented here are only a first introduction to future development of ODL projects, intended for reaching larger audiences and making more learning ‘available when and where it is needed’.

A New Program for the Inservice Training of Computer Studies Teachers
Through Distance Education.

Ms. E.J. Naudé
Departement of Computer Science and Information Systems
University of South Africa
South Africa
E-mail: naudeej@alpha.unisa.ac.za

Abstract:
There currently exists a crisis in education in the natural sciences (mathematics, physical science, computer science and biology) in South Africa (Arnott et al:1997). One reason for this crisis, is the huge shortage of qualified Computer Studies teachers. This paper will discuss some of the reasons for this shortage. It will then focus on a new innovative learning program (leading to a degree in science education) being developed at the University of South Africa (Unisa) for the preservice and in service training of Computer Studies and Computer Literacy teachers. Training will be done through distance education. The proposed didactical and subject related content of the new program will be discussed.

Introduction
There currently exists a growing demand for Computer Studies teachers at secondary school level and computer literacy teachers at primary school level in South Africa. Because of this great need, schools often use teachers from other disciplines (eg. mathematics, physical science and accounting) to teach Computer Studies. These teachers have no formal training in computer science and therefore don't have the necessary subject knowledge to teach the subject. The new program being developed at Unisa will specifically address this need.

Reasons for the Crisis in Computer Studies Education
The crisis, as far as teachers are concerned, can be attributed to a combination of two related causes:

- There exists a huge shortage in Computer Science teachers.
- This shortage has led to a large numbers of teachers from other disciplines, without any qualifications in Computer Science, being appointed to teach Computer Science.

One of the main reasons for the shortage of Computer Studies teachers, is the fact that the teaching profession in South Africa is currently typified by low morale. This is due to increasing difficulties in maintaining discipline and the inability to handle racial and other conflict amongst pupils. Parents are placing undue pressure on teachers to obtain unreasonably high results (especially in so called up market schools). Furthermore, teachers find it difficult to adapt to new teaching paradigms (eg. outcomes based education) being employed by a new government.

Another reason, not unique to South Africa, is the relatively low salaries, which lead many teachers to the more lucrative business sector. Computer Studies is probably the school subject suffering the most due to this “greener pastures syndrome”. Trained Computer Studies teachers are in high demand from businesses offering computer literacy training courses, companies training their own employees and even governmental technical colleges (which offer, if not much higher salaries, then at least higher “prestige” and less discipline related problems). Many ex-teachers simply start their own businesses, working from home, offering private computer literacy or programming courses. Some teachers even discard teaching completely and take up positions as programmers or other computer related careers.
A third problem, more unique to South Africa, is the so called “brain drain” experienced by the country since 1994. A great number of young, newly qualified teachers, leave the country to teach and gain experience, mostly in Britain, where they seem to be in high demand, and other European countries.

A problem that new teachers find very annoying and time consuming, are the prevention and elimination of viruses and the repairing of damage caused by hackers. Computer Studies learners are often highly gifted individuals with their own computers at home and too much time on hand to experiment. It often gives them great satisfaction to hack into or disable the computer network at school.

Many teachers have to teach in a school environment where they get little or no support from colleagues and principals who do not understand the unique nature and problems facing the Computer Studies teachers. They normally are the only teacher teaching the subject at their particular school. For the beginner teacher this means that no advice from experienced teachers is available. They often have to set up the computer centre, take responsibility for the everyday functioning there of, and help administrative personnel with any computer related problems. For many beginners, this daunting task is the final straw to break the camel’s back.

Problems with Current Training Programs

The new program should cater for the training of new teachers (thus students fresh from school) and the in service training of current teachers trained in some other discipline, but teaching or planning to teach Computer Studies. Even teachers specifically trained as computer studies teachers experience problems when first entering their profession. Thus before embarking on the development of a new program, the deficiencies in these teachers’ training need to be considered in order to better equip new teachers.

From a preliminary study into the problems experienced by current teachers, the following aspects, were mentioned.

- Their knowledge pertaining to the installing and administrating of a networked computer centre for the school, is not sufficient.
- Some teachers (especially females?) feel that they possess insufficient knowledge on computer architecture and the newest hardware developments.
- They experience some problems related to the assessment of practical work (programming) done by their learners (mark allocation in particular seems to be a problem).

Currently Unisa does not offer any courses specifically geared towards the training of Computer Studies teachers. Teachers have to do either a BSc-degree in Computer Science or a B.Comm degree in Information Systems and follow this up with a post graduate teaching diploma, where only one module (Computer Studies subject didactics) is related to Computer Studies teaching.

This prepares students well for computer related careers (programmers, database administrators, etc.) but not well enough to be good Computer Studies teachers.

Teachers who have some post-school (tertiary) training in education (trained to teach other disciplines) may be aware of a variety of teaching methods. However, because of the fundamental deficiencies in subject knowledge, they are unable to teach innovatively since they lack the confidence acquired by a solid grounding in computer science. In addition, much of the teaching theory was acquired in a context substantially different from the environment in which they work, and they have insufficient knowledge or opportunity to develop meaningful practices appropriate to their situations.

In view of this, great care need to be taken with the development of a learning program for preservice and in service teachers who may or may not already possess a secondary teaching diploma.

New Program

The current higher education system in South Africa has to be remodelled by creating a single co-ordinated higher education system (National Commission on Higher Education: 1996). This has led all Universities to design new and redesign old curricula. The new program in Science Education (Stream: Computer Studies) is one of the new programs being developed.
A program is a purposeful and structured learning experience designed to enable learners to achieve pre-specified exit level outcomes (Jordaan & Kilfoil: 1999). It can therefore be defined as a coherent combination of units of learning (modules) expressed in an outcomes-based format which leads to one or more qualifications, serving an academic and/or vocational purpose (Reynhardt: 1999). A program should have recognised entry and exit points (qualifications) and usually comprises core modules (compulsory for all students on a particular program) (SAQA: 1998), elective modules (a group of modules from which a choice must be made in order to achieve the purpose of the qualification and to attain the required number of credits at a specific level) (SAQA: 1998), and fundamental modules (modules which form the basis needed to undertake the education, training or further learning required in the obtaining of a qualification) (SAQA: 1998).

A module is a coherent, self-contained unit of learning, designed to achieve a set of specific learning outcomes which are assessed within that unit of learning (Reynhardt: 1999). A program is composed of a number of modules. A module has a standardised size and a designated credit-weighting in the overall program (Reynhardt: 1999). One module should require 120 notional study hours (Jordaan & Kilfoil: 1999). Notional study hours are informed estimates of the average time (spent in any variety of ways e.g. attending lectures, tutorials, practicals, independent reading and writing) that an average learner, entering with the correct level of assumed knowledge, would need to master the specific outcomes of a unit of learning (Reynhardt: 1999).

The qualifications that can be obtained in the program are:
- a national higher certificate after completion of 12 modules;
- a national diploma after completion of another 10 modules;
- a B.Sc. degree (Science Education) after completion of another 8 modules (thus 30 modules in total).

The program will offer students recognition of prior learning in order for students who already possess a teaching diploma to be exempted from doing the education related modules. The proposed program was designed to meet both the SAQA (South African Qualifications Framework) requirements mentioned above, and the specific needs of teachers, as well as to eliminate the problems with the current training programs.

The Specific Outcomes of the Program

Students who have completed the program, will:
- Have acquired the knowledge necessary to teach secondary school Computer Studies. This knowledge includes:
  - Basic computer concepts, terminology and definitions
  - Computer architecture and networks
  - Some basic mathematics and statistics
  - Be able to assist learners in acquiring this knowledge
  - Be able to use an integrated computer package and assist learners in acquiring the necessary knowledge and skills to use such a package
  - Be able to analyse a problem and develop an algorithm to solve the problem
  - Be able to translate this algorithm into an executable computer program by means of critical and effective use of a programming language
  - Be able to assist learners in acquiring these programming skills
  - Be able to provide help concerning the use of computers to other members of staff in an educational institution.
  - Be a responsible computer user
  - Convey an attitude of responsible computer use, taking ethical aspects into consideration, to learners
  - Effectively manage a computer centre at an educational institution

Target Market of the Program

- Current teachers from all disciplines who are interested in teaching computer studies.
- Current Computer Studies teachers that don't have the necessary qualifications.
- Adults (not currently teaching) wanting to become Computer Studies teachers.
Lecturers at teachers training colleges and technical colleges wanting to lecture Computer Studies/Science (Degree).

Modules for the Certificate

**Fundamental modules:**
- **Basic Computer Literacy:** This involves the use of an integrated computer package.
- **Elementary Statistics:** Specifically related to education eg. calculation of means, modes and variances of learners' marks.
- **Elementary Mathematics:** The elementary arithmetic and algebra needed for Computer Studies.
- **English Comprehension Skills:** A module specifically developed to teach English second language students (the majority of the South African population) scientific reading and writing skills.
- **Educational Themes I:** Learning and teaching strategies in the adolescent years.

**Core modules:**
- **Introduction to programming I and II (2 modules):** Basic programming skills using Pascal.
- **Computer Concepts:** Basic hardware and software concepts.
- **Social Impact of Computers:** Issues such as computers and the law, computers in education, computers and medicine, ethics, privacy etc.
- **Computer Studies Classroom Practice I:** Didactical issues specifically related to Computer Studies.

**Elective modules:**
Any 2 modules from:
- **Theoretical Computer Science I**
- **Introduction to Business Information Systems**
- **Linear Algebra**
- **Applied Linear Algebra**
- **Precalculus Mathematics**
- **Applied Statistics**
- **Gifted child education**

**Additional Modules for the Diploma**

**Fundamental modules:**
- **Educational Themes IIIA:** General teaching methods and classroom management.
- **Educational Themes IIIB:** Media science, critical assessment and classroom research.

**Core modules:**
- **Computer Studies Classroom Practice II:** Didactical issues specifically related to Computer Studies, with special reference to assessment.
- **Computers in Education:** Issues related to the use of computers in education e.g. CAL, CAI, multimedia.
- **Introduction to programming III:** Programming in C++, including an introduction to recursion and elementary data structures such as arrays and files.
- **Data structures I:** Pointers, linked lists, trees, graphs, stacks and queues using C++
- **Data structures II:** Recursive and iterative searching and sorting methods on data structures discussed in Data structures I.
- **Computer organisation:** The digital logic level, microprogramming level and machine level of the computer; assembly language programming.

**Elective modules:**
Any 2 modules from:
- **Any of the elective modules not done for the certificate.**
- **Theoretical Computer Science**
- **System Analysis**
- **System Design**
Additional Modules for the Degree

Core modules:
- Operating Systems and architecture
- Computer Networks
- Principles of databases
- Database design and implementation
- Computer Science Education and Logical Thinking Skills

Elective modules:
Any 2 modules from:
- Theoretical frameworks in education
- The education system and school management
- Multicultural education
- Education law and professional ethics
AND any 1 module from:
- Advanced programming
- Theory of computer science
- Advanced software development
- Software project management

Vocational Opportunities

- Certificate: Teacher at secondary school (up to grade 10)
- Diploma: Teacher at secondary school (up to grade 12)
  Lecturer at a vast number of private institutions offering computer courses.
  Programmer
- Degree: Same as for the diploma
  Lecturer at technical college/teachers training college
  Computer Specialist/Professional
  Data base administrator
  Depending on choice of elective modules:
  Systems analyst/designer/developer
  Project manager

Conclusion

A familiar cycle of mediocrity, whereby inadequately qualified teachers are turning out students who are themselves poorly prepared for either the job market or tertiary education, has become prevalent in South Africa. The need for teacher upgrading and the delivery of new, well qualified teachers, is thus undisputed. It is believed that there is scope for a diploma and degree course specifically geared towards the training of Computer Studies teachers. Due to the fact that the majority of students that would benefit from such a course, are in service teachers, the distance education offered by Unisa would go a long way in alleviating the crisis in science education in South Africa.

Meeting the needs of Distant Learning through the use of PowerPoint and RealPresenter

David Cary, Department of Finance, CSU Northridge, USA, dcary@csun.edu
Wayne Smith, Business Technology Center, CSU Northridge, USA, wayne.smith@csun.edu

Introduction

The changing demographics of colleges and universities are creating new challenges for faculty. The traditional student who attended college full time for four years after graduating from high school is now in the minority. At my university, the average age for undergraduates is over 24 years old and is over 34 for master level students. Given that most of the students in the College of Business Administration are juniors and seniors, our average undergraduate age would be even higher. Most of our students work between 20 hours a week and full time with a typical student taking between ten and twelve units per semester, instead of the 16 required to graduate in four years. Colleges and Universities are also exploring the ability to teach courses off campus to be able to reach a larger student population through distant learning classes.

One way to help to try to meet the challenges of these non-traditional students and programs is through the use of computers and the World Wide Web (WWW). But being a relatively new, and a rapidly changing and growing, medium, most faculty have done very little to tap the power of the WWW. In a survey of my students last semester, approximately 75% had access to the internet from either home or work, making the internet an accessible resource for most students. With the number of libraries that have internet access increasing, and student labs on campus, the argument that students do not have access will soon be a thing of the past.

The two areas where the Internet has been used are as a virtual library and as a means of communication. Other than posting syllabi, class schedules and reading lists, little has been done in the area of content creation on the web.

The virtual library aspect can be seen in the use of the web as an online resource to find information for class reports, including up to date financial statements, stock prices and news. Many journals and newspapers are now posting their issues online which can make it easier for doing research.

Communications can be done in both synchronous and non-synchronous modes. Chat rooms, even if currently somewhat inefficient as a result of our unfamiliarity with talking with a keyboard, and in the future, real-time two-way audio and video, allow for conversations through the web. Non-synchronous communication can include email, news groups and message posting.

However, I feel that it is in the area of content creation where computers and the web may have the largest impact on meeting the challenges of the ‘new’ university. This paper will discuss creation of online lectures including both the visual and audio components. The method used is within the capabilities of most faculty without needing TV studios, technology experts, or expensive equipment.

Procedures

A relatively unknown feature of Microsoft’s PowerPoint 97 program is the ability to record audio files while doing a presentation. RealAudio has taken advantage of the feature by creating a plug-in program for PowerPoint 97, called RealPresenter, that can convert the PowerPoint slide file plus the audio files into a synchronized RealMedia file that can be used with low bandwidth and streamed from a server.

The first step in creating the RealMedia file is to create the PowerPoint 97 slide file. A few points need to be considered when creating the file. The RealMedia conversion does not incorporate any builds or animation, so if a build is desired, the first part should be put onto a slide, then the slide copied and the second part added. The sequence of the two slides will appear to be a build up of text. Another point to consider is that the PowerPoint
slides are compressed into .jpg files and any small detail is lost or distorted in the compression. Finally, for some unknown reason, if the slides are numbered with the automatic numbering feature, they all come out as slide ‘number 1’ during the conversion.

The recording of the audio files can be done either live during a classroom lecture, or prepared outside of class. When I am going to miss a class due to a conference, I will prepare a lecture in advance for the students to watch while I am gone. I have also prepared lectures in advance that review materials the students are expected to know when they start the class. A high quality microphone will greatly improve the sound quality. For recording during class lectures, I have purchased a wireless Sony microphone which allows me to walk around during the presentation.

To start recording the lecture, click on the ‘slide show’ button on the top menu in PowerPoint and then on ‘record narration.’ You will need to click the box in the lower left-hand corner of the dialogue box that says to link the files and click on ‘Settings.’ The audio setting you select is somewhat a function of your voice. I have found that ‘11,025 Hz, 16 bit, mono’ works well for me. That creates about 21KB of sound files per second or about 50-60 MBs per 50 minute lecture. Note that in the conversion process, the 50 MBs of audio files will be compressed down to 1 or 2 MBs. When you click ‘OK’ on the record narration dialogue box, the slide show will start and the audio will be recorded.

During the slide show progress as usual. The only limitation is that you can not go backwards and re-show a slide. If I have a question on a previous slide, I will stay on the current slide and discuss the previous slide. Going backwards would write over the original audio file which would then be lost. You may use the pause recording feature and then resume if you want to take a break. When you finish the presentation, a couple of dialogue boxes will pop up asking if you want to save the timings and click yes. It will also ask you if you want to review the timings and I usually say yes. I then save the file to make sure that the timings have been saved.

The next step is to create the RealMedia file. I had previously downloaded RealPresenter from http://www.Real.com for $39.95 and installed it. It is a plug-in on the PowerPoint Tools drop down menu. After selecting ‘Publish to RealMedia’ you are asked a series of questions. I usually use the ‘Internet’ target audience so that the file can be played over a 28.8 modem. It then asks for a file name, ending in ‘.rm’ for RealMedia. You can then enter a title, the author’s name and a copyright. When this is complete, the program converts the slides into ‘.jpg’ files, compresses the audio files and synchronizes the two into a final RealMedia file. When completed, you have the option of listening to the file which I usually do just to make sure it worked properly.

The final steps are to post the RealMedia file on a server and link to it. Most web servers can be used for the RealMedia file. However, RealAudio offers a specialized server package that is designed for streaming audio and video. The link to the file actually requires an intermediate step. A link from a web page must go to an intermediate text file that has a one line that starts ‘pnm://’ followed by the address of the RealMedia file. For example, if the RealMedia file is stored at ‘media.your.edu/presentations.rm,’ then the one line would be ‘pnm://media.your.edu/presentation.rm.’ The intermediate file allows the RealMedia file to start downloading into a buffer and after about thirty seconds the file will start playing while continuing to download in the background.

Conclusions

The use of RealPresenter to convert PowerPoint slide presentations and recorded audio into RealMedia is a relatively easy way of creating online content that incorporates both audio and video. The RealMedia files can be used in distant learning and for student review. The program has a low bandwidth requirement and a low production cost which makes it feasible for many faculty to start using immediately without extensive support from Instructional Media centers. While the future may bring in greater bandwidth and full screen video, this method of presenting lectures online can be currently put to use.
New tools for assessment in distance education

Abstract: This paper describes a strategy for improving the quality of distance education assessment providing a set of complementary tools to help on formative evaluation. Regular forms to assess learning are analyzed and Kirkpatrick's model for evaluation is described as well as a set of tools to provide capability to assess according this model. The set of complementary tools includes consensus, tracking, voting and self-evaluation.

1. Introduction

Learning assessment became a challenge to those working with distance education. In its definition of learning assessment, Bloom, Hastings and Madaus (Mendes 1998), proposed that the evaluation process should includes a great variety of evidences that go beyond the traditional final examination pencil and paper based. In a face-to-face context, professors use more than just formal mechanisms to evaluate students. Body language, participation, quality of questions proposed by students are good indicators of learning. In distance education what normally occurs it is the use of form mechanisms only. It occurs not only because of the lack of accessible mechanisms that can assist instructors on this task, but also, because many professors prefer to work with more traditional methods of evaluation.

However, thanks to evolution of networks and computers and especially the Internet, mechanisms, that can fill this gap started to show up. Tools became available, to keep track of students activities and interactions with learning environment, with colleagues and with the professor. These kind of information present new opportunities for monitoring the way students learn and for learning assessment.

The use of the Internet for distance education assessment offers many advantages:
- Reduction of the distribution costs;
- The corrections and updates are simpler, therefore they are carried through in an only site, being immediately spread to all students;
- Several techniques for evaluation are possible using multimedia for the between professor and students and between students;
- The Internet facilitates collaborative writing;
- The student has more easiness in sending feedback allowing formative and evaluation.

A research conducted by Dirks [Dirks] with instructors of distance learning MBA programs presented some questions like: Considering all the time you spend on this course (100%), how much of that time do you think you spend on student assessment (writing tests, grading, giving feedback, and reporting scores)?

Answers indicated that the newer teachers, 2-9 years teaching, spent over half their time on assessment (56%), those with 10-19 years experience spent less time on assessment (46%), and the career instructors, 20+ years teaching, spent the least amount of time doing assessment (35%). The primary reasons given for having assessments include providing feedback, giving grades, and motivation. The four types of assessment most commonly mentioned are: case studies, exams, papers, and projects. All of them requires extensive time to grade and are very difficult to get automated help to do the evaluation.

Other researches point also that what is often used for assessment in distance education are the
following:

- individual works developed individually and sent by regular mail or by email
- assessment based on contributions for group discussions
- tests (automatically handled by computer program)
- term papers (analysed by professor or assistants)
- oral or written tests conducted in the presence of the instructor (some times through videoconference) or with a remote assistant.

Learning theories state that group learning has significant relevance and must be supported also in distance education. Participation in group activities, cooperation and collaboration must be supported and graded. But there are a lack of good tools to help evaluate the participation of the distance education student in group activities.

Slowly, thanks to evolution of networks and computers and especially the Internet, mechanisms, that can fill this gap started to show up. Tools became available, to keep track of students activities and interactions with learning environment, with colleagues and with the professor as indicated in figure 1.

![Figure 1: Internet as mediating tool](image)

These kind of information present new opportunities for monitoring the way students learn and for learning assessment.

As stated by Tucker (Tucker 1998) the CMDL (Computer Mediated Distance Learning) classroom is routinely a far more scrutable educational environment than the physical classroom. The virtual classroom's electronic data storage, retrieval and exchange system (i.e., the text of student and faculty transactions, communication logs, file structures and information presentation algorithms that exist on the file server's hard disk drives) represent concentrated, structured and highly accessible artifacts of the learning transactions. These artifacts can be retrieved, analyzed and reported via highly economical, automatic processes operating in the background of the communications system.

This work presents a proposed solution for assessment on distance education mediated by Internet using innovative approaches based on Kirkpatrick model for evaluate training problems and will describe how they where implemented.

2. Assessment models and tools

There are today some systems, available in the market, that provide detailed information on the evolution of the student working at distance mediated by Internet. Examples of this kind of system include, CyberQ, WebCT and AulaNet. Statistics of usage and regular approaches for testing like multiple choice quiz and term papers are usually possible in these kind of systems.

Donald Kirkpatrick developed a model of evaluation, used in training programs. It recommends a
division of the evaluation process in four levels (Kirkpatrick 1998):

- Level 1: **Reaction** - level measures how those who participate in the program react to it. It may be called a measure of student satisfaction.
- Level 2: **Learning** - can be defined as the extent to which participants change attitudes, improve knowledge, and/or increase skill as a result of attending the program.
- Level 3: **Behavior** - can be defined as the extent to which change in behavior has occurred because the participant attended the training program.
- Level 4: **Results** - can be defined as the final results that occurred because the participants attended the program.

Mendoza is another researcher that it is also relevant to investigate student context to find out which aspects of course contents he/she is in the know (Mendoza 1999). So an aspect to be also considered is the lack of suitable tools to assess their current level of knowledge and skills. Mendoza recommends utilization of techniques, other than conventional ones, to collect data and suggest formative evaluation as well as summative evaluation. To achieve formative evaluation is important to make easy for the students not only inform their opinions and feelings about how course is going on but see this contributions being handled and considered.

To help in all these tasks and also support evaluation as proposed in Kirkpatrick model one should have a tool that would help organize polling and receive data in a suitable form to allow counting and summarizing results. To do this, it was designed a system aimed to support flexible and dynamically built of enquete for polling. The system has a WWW interface that allows designing of different kinds of multiple choice questions. Basic data informed are question and alternatives. Depending on type of desired measure the system ask for:

- a) Feedback for each alternative
- b) Indication of correct answer
- c) Nothing more, just counting incidence of selections on each alternative

Option a is used for questions inserted in the learning path to ask for active response. Option b is used for testing and give grades. Option c is used for polling purposed. This system was designed to complement regular tools used to assess distance education students. The following mechanisms have been selected to assist in the evaluation process in this framework:

- **Tool of consensus**: based in the Delphi technique, allows on time creation of enquete proposing instigating questions, as well as the collection and tabulation of responses. The tool has the capability to keep track of each student's level of contribution to the discussion as well as enquete responses.
- **Tracking tool**: the register of learning activities (accessed page with dates and time) is important because it allows the professor to monitor the progress of students through the course. The collected information will show that type of access the student has made (visited units, tools used, etc), as well as the time spent on it.
- **Voting tool**: aimed to provide conditions for a fast feedback for the instructor on specific subjects.
- **Self-evaluation tool**: allows the dynamic building of enquetes for self-evaluation by professor and by students.

It is important to stand out that this proposed work is not an alternative approach to assessment rather it is a complementary one and is supposed that may be used together. Each one of this tools are supposed to be used to help evaluate at more than one level in Kirkpatrick model.

To implement the tracking tool, a generic interface was designed to intermediate all the interaction of the student with the server. Interactions are processed in real time (for authentication purposes) and periodically in batch to generate records in a student data-base.

To implement the voting, consensus and self-evaluating tools a set of CGI programs where developed to allow dynamically create pages with questions and propositions (HTML forms) that are presented to students and collect their answers (Tarouco 1997).

**Conclusions**

It is our believe that formative evaluation plays an important role to get distance students motivated because
they feel a sense of not being lost in space. Just the opposite, they feel that being closely monitored and having their opinions being asked often is more like having a personal tutor that pay attention on way they do and what they say. This kind of attention provided by the system helps to minimize solitude that sometimes is referred as main desisting factor from students.

Distance Education Insights from Eight Case Studies in TESOL Teacher Preparation

Lynn Henrichsen
Department of Linguistics
Brigham Young University
United States
Lynn_Henrichsen@byu.edu

Abstract: This paper presents vignettes from eight case studies in which distance education was employed in the preparation of ESOL (English to speakers of other languages) teachers in various locales around the world. The teacher educators involved in these cases employed a variety of communications media and information systems, and they worked with both pre-service and in-service teachers. The course objectives varied widely also. Nevertheless, out of the diversity in these cases emerge a number of lessons of great value to all professionals involved in teacher education at a distance. Foremost among these lessons is the fact that quality distance education involves considerably more than simply offering a traditional classroom course at a distance via modern technology. Success in distance education calls for an understanding of a number of complex, interrelated factors. It also requires overcoming a variety of instructional/learning challenges that do not normally occur in traditional classroom settings.

Overview of the Cases

In recent years, information communication technology has been widely and enthusiastically employed to facilitate learning in educational settings where teachers and learners are at a distance from one another. The preparation of teachers of English to speakers of other languages (TESOL) is certainly no exception to this trend. Distance-learning courses for preparing teachers of ESOL exist in a variety of innovative, interesting forms around the world, as the following vignettes illustrate.

The University of South Florida (USA) offers a Web-based training program for K-12 teachers who live in remote areas or who have responsibilities that preclude them from attending a traditional course. The nature of this distance-learning program has evolved through several stages—from a traditional, information-transmittal format, to one that is much more interactive, and finally to one that is now both collaborative and constructivist in nature. Working in teams and individually, teachers engage in readings, role-plays, case studies, lesson evaluation/adaptation exercises, and group discussions that leave them better prepared to teach mainstreamed limited-English-proficient students more effectively.

In the Middle East, the Open University of Israel offers courses for teachers of English as a foreign language. An in-service EFL methodology course for practicing teachers has been offered in two forms—via two-way interactive satellite television and by e-mail. In both of these, participants learn about the nature of communication, classroom management, integrated group work methodology, the whole language approach, and other such topics. Comparing Israeli teacher educators' experiences with these two different delivery systems reveals the relative advantages and disadvantages of each. These advantages are related to factors such as course content, student population, accessibility of institutional facilities, and available staff.

Since 1992, the University of Saskatchewan (Canada) has been developing and offering a distance-learning program for teachers and potential teachers who are not able to study on campus. This pre-service program uses a wrap-around model—with audiotapes, videotapes, and a CD-ROM supporting a print-based core consisting of a course guide, textbook, and package of article reprints. The university offers six different courses leading to a certificate in teaching English as a second language and aimed at developing teachers' classroom techniques for building students' language skills. Aligning these courses with established indicators of quality distance education (University of Wisconsin, 1996), such as "Know the learners" and "Design for active and effective learning," has been part of the course designers' quest. In the process, they have learned
that successful distance education involves much more than simply delivering an existing on-campus course to remote learners. They have also come to the conclusion that distance-education programs must be evaluated on their own terms, not in comparison to face-to-face instruction (Shale & Gomes, 1998).

The English Language Institute of York University in Toronto, Canada, collaborated with the Regional English Language Centre (RELC) in Singapore a few years ago to create a distance-learning program intended to develop the teaching and language skills of local teachers of English as a foreign language in Thailand. In this program, as in the one originating in Saskatchewan, print was the primary delivery medium, but audiotape and videotape support was also provided. Teachers relied on the local postal system for delivery, and phone calls constituted the primary means of communication between tutors and participants. Despite the apparent simplicity of this arrangement, educators encountered a variety of complex, interrelated challenges not usually present in traditional classrooms, such as participants' feelings of isolation and their lack of communication with peers.

Teacher educators at Brigham Young University in Utah (USA), are piloting a flexible, video-anchored "professor plus" distance education model to meet the challenge of preparing hundreds of widely scattered K-12 teachers who are seeking a state Bilingual/ESL endorsement. The current program has evolved from a live course offered over a statewide, state-sponsored, two-way audio/video transmission network to its current form. Through their experiences the educators involved have learned the importance of not only using appropriate telecommunications and information technology but also designing and employing the most effective pedagogical approach.

At the University of Northern Iowa (USA), students earning an MA degree in TESOL go through a one-semester teaching practicum experience. Although students in this practicum teach at a number of schools throughout the state, they are still required to participate in weekly seminar meetings. These meetings are now conducted via the Iowa Communications Network, a two-way voice and video interactive environment made possible by fiber-optics connections. In this way, although the participants are in classrooms across the state, they can interact as if they were sitting in the same room together. Nevertheless, communication is still occasionally hampered by other, social and experiential characteristics of the teachers involved.

Indiana University (USA) offers 19 Web-based courses for teacher development and basic teacher preparation, including one on computer-assisted language learning. More than 1,000 people have taken these courses, which employ a variety of Internet-related telecommunication systems and information technologies (ranging from basic e-mail and class listservs to video conferencing and streaming). Developers of these courses strive to meet the challenge of creating an electronic classroom learning environment that models the pedagogical concepts that they teach.

On the coast of the Arabian Gulf, local English teachers upgrade their language skills and work towards a BA degree at the nine different centers of the United Arab Emirates University Distance Learning Program. Their instructors work diligently to meet the challenge of creating and delivering semester-final examinations for courses at these widely scattered centers. Maintaining the exams' reliability, validity, security, and cultural sensitivity is a special challenge in this setting.

Insights from the Cases

All of the above vignettes represent full, detailed case studies that will soon appear as chapters in a book to be published by Teachers of English to Speakers of Other Languages, Inc. (Henrichsen, 2000). These cases clearly demonstrate that distance learning is very much a part of the preparation of ESOL teachers around the world today. They also illustrate the important point that quality distance education involves much more than simply taking an educational program that has been developed in a live, face-to-face context and then delivering it at a distance using technology. Success in distance education calls for an understanding of a number of complicated and interrelated factors including, but not limited to, educational technology. Successful distance education also requires overcoming a variety of instructional/learning challenges that do not normally occur in traditional classroom settings.

As can be seen from the vignettes, the cases themselves took place in a variety of settings—four different states in the United States (Florida, Indiana, Iowa, and Utah) and four other countries around the world (Israel, Canada, Thailand, and the United Arab Emirates). The teacher educators involved in these cases employed a variety of communications media and systems—traditional print, telephone, audiotapes, e-mail,
satellite television transmissions, videotapes, the World Wide Web, and two-way interactive voice and video networks. The courses involved both pre-service and in-service teachers. The course objectives varied also—ranging, for instance, from the development of basic language teaching skills, to the sharing of insights and information gained during a teaching practicum, to the creation and implementation of Internet-based tests that are not only valid and reliable but also culturally sensitive and secure.

Despite their variety, these cases had a number of things in common, and out of their diversity emerge several insights of value to all professionals involved in providing teacher education at a distance.

1. First among these lessons is the already-mentioned fact that quality distance education involves considerably more than simply offering a traditional classroom course at a distance via modern technology.
2. A corollary lesson derived from these cases is that teamwork and flexibility are crucial to the success of distance-education efforts.
3. Further, a common challenge addressed in most of the case studies is how to overcome isolation and supply the elements of human interaction and community that are usually taken for granted in face-to-face teaching situations but are often missing in distance-learning arrangements.
4. Yet another important lesson emerging from these diverse cases is that the use of more complicated technology does not necessarily translate into better teaching or learning. In fact, each information communication medium has its own strengths, and in a well-designed program, rather than competing with each other, these different media can work together in a complementary fashion. Also, in many remote areas, simple, "old fashioned" communication systems may actually work better than the newest, complicated information technology.
5. Furthermore, in any setting, technologically simple distance education can still be advanced in other important ways, such as its instructional design. This final point—that the pedagogical approaches employed are just as important as the content or communications systems themselves—may be the paramount lesson learned from these eight distance-education cases.

Conclusion

The insights gained from studying and comparing these eight different cases involving the use of distance education for preparing ESOL teachers can help develop our understanding of important challenges common to distance education in any setting. Providers of teacher education at a distance frequently encounter similar difficulties, regardless of where and how their programs are offered. The experiences of others, as presented in these case studies, can teach us how to avoid these common problems, or at least how to deal with and overcome them. In addition, even when their challenges are non-typical, the experiences of ESOL teacher educators in various distance-learning settings around the world can inspire other teacher educators working in distance-education programs to face their particular difficulties and eventually achieve success.

References

Entering the new millennium with the discussion of diversity and technology are signs of educators addressing two important factors that provide the sparks that can improve the future. The papers in this section are few but impressive. They suggest ideas and concepts that can be used as an initial beginning or an extension of existing programs. These ideas bring people together because by bridge the gap between cultures through the use of technology.

The papers are all unique in that they stress the importance of helping all young people reach their maximum potential through the use of technology, their gateway to the future. The papers are grouped based on the theme, “bridging the gap through diversity and technology.” For example, the first paper by Foster and Snider at Texas Woman’s University discuss the importance of bridging the gap between the students who have full access to the latest technology and those who do not. They focus on three essentials that would keep what they call the “digital divide” from getting wider. The inadequate quality of technology use, teacher preparation and exposure to technologically proficient role modelsug models in the home present problems that can be solved through a commitment of training and support by administrators and teachers.

The papers by Snow from Northern Arizona University, and Bennett project director for the Navajo Education Technology Consortium, support each other by focusing on a project that involves 13 school districts in three states, two universities, two community colleges, two departments of education, and the National Indian Telecommunication Institute. Snow’s paper focuses on the project design through goals and objectives, training sessions, and first year accomplishments. Bennett’s paper describes the project from the director’s point of view. He discusses staff development, cultural inclusion and the infrastructure improvements that are being used to usher the Navajo culture into the electronic age.

Continuing in this same vein is the paper by Chisholm from Arizona State University West. He focuses on preparing the young by starting with preservice teacher preparation. The author provides students with an authentic experience that develops diversity awareness and multicultural teaching skills with a secondary purpose of modeling technology integration and expanding student computer competency. Preservice teachers participate in many activities that do not mirror a conventional university course. Aided by technology, the author discusses the limitations and the benefits of working with preservice teachers in this fashion.

The paper by Suarez from the University of Alabama provides another experience grounding teachers in cultural pluralistic concepts that help them move beyond print media, by developing and implementing activities designed for all students. This technological multicultural course provides students with a unique way of developing a meaningful way of sharing aspects of their culture and community.

In another paper, gender representation on school web pages is an important issue investigated by Maboudian from the University of Houston. The study uses semiotic methods to examine web site visuals for evidence of differences in gender presentation. Because pictures send such an important message to the public and to students who view the sites, the author discusses the cybiotic design of visuals on a web page that may suggest either stereotyping or equity. This paper gives guidelines to creators of web pages.

The second set of papers bridge the gap of cultures through an international flavor. The paper by Carey from the University of British Columbia, Canada focuses on investigating and comparing how 12 students (5 ESL and 7 native speakers of English) negotiate meaning in an on-line bulletin board or face to face mode of communication environment. The author studied the interaction of how students from diverse backgrounds were influenced by and negotiated meaning of inadequate academic content schema. The use of the virtual seminar and how it facilitated the second language acquisition process led to a gradual increase of participation in course seminars. The final paper by Biazus from the Universidade de Caxias do Sul of Brazil focuses on using art education in a digital environment. The main purpose of the study was to verify how and whether the digital environment can provide a practice that is effective for students. This process invites a challenge that is clearly a new way of entering the millennium. Bridging the gap through electronics promotes a quality education for all.
"At-Risk" Learners and the "Digital Divide":
Exploring the Equity in Access Issue

Abstract: Education has been considered the "key to success," and technology, in recent history, has been considered "the great leveler"—capable of providing "keys" to all learners without regard to their race, ethnicity, or gender. Most recently, the term "digital divide" has surfaced, referring to inequitable access to technology. Within this divide, the "haves" are more likely to enjoy greater access to technology than the "have-nots." The long-term negative effects of this phenomenon are being felt by those in certain segments of society who are effectively marginalized by a lack of equitable access to technology. This paper focuses on at-risk learners by examining the factors that contribute to the "digital divide," the possible long-term effects of this phenomenon, and effective classroom uses of technology that challenge the negative impact of the "digital divide."

Introduction

While technology is assuming an increasingly important role in our society, the "digital divide" between the "haves" and "have-nots" is widening at an alarming pace. Sculley (1997) describes this era as "an opportunity that is given only to few generations in history ... if we respond with our best creative energies, we can unleash a new Renaissance of discovery and learning" (p. 142). In order for all members of society to assume full membership, however, it is imperative for them to have equitable access to the emerging technologies that will fuel this "new Renaissance."

The term "digital divide" has been applied to a phenomenon wherein the "significant growth in computer ownership and usage overall ... has occurred to a greater extent within some income levels, demographic groups, and geographic areas, than in others" (McConnaughey & Lader, 1995, p. 2). Historically, the U. S. telecommunications policy's goal has been to provide affordable access to telephone service to all Americans; however, McConnaughey and Lader contend that "while a standard telephone line can be an individual's pathway to the riches of the Information Age, a personal computer and modem are rapidly becoming the keys to the vault" (p. 2). Consequently, the "digital divide" has become a national concern. Those who do not have access to state-of-the-art technology are marginalized in a society that increasingly relies on electronic literacy to navigate everyday existence. Not surprisingly, the effects of inequitable access are being felt in our schools as well as in the larger society.

In reviewing research literature, six themes emerged. Four of these themes emerged as contributing factors in the inequity of access referred to as the "digital divide." Two additional themes emerged related to probable consequences of and possible solutions to the "digital divide."
Factors Contributing to Inequity

Quality of State-of-the-Art Technology

A large segment of the American society is marginalized, or unable to assume full membership, because technology is not as readily available to them as it is to other segments of society (Lichtman, 1998). Neuman (1990) adds light to this phenomenon saying "it has become a truism that wealthy school districts [which have fewer at-risk students] own more computers than impoverished ones and that they augment their numbers so rapidly that the gap between rich and poor schools is widening rather than shrinking" (p. 158). Trotter (1996) further dissects the problem positing that although schools have, in general, lowered their ratios, "27% of school computers are . . . all-but-obsolete models" (p. A17).

According to Coley, Cradler, and Engel (1997), "the ratio of students to computers goes up as the percentage of Title I students increases" (p.12). The relevance of this observation to at-risk learners is explained in Cunningham’s and Allington’s (1994) assertion that "socioeconomic status is highly correlated with academic success" (p. 1). Thus, children who are served by Title I resources are often characterized as "at risk for school failure" and are the students with less favorable student to computer ratios.

Differences in student to computer ratios show that access to emerging technologies in schools has changed over time. Coley et al. state that, historically, Title I funds have been used to provide technology resources, and in the past, Title I schools were more likely to have more favorable student to computer ratios than non-Title I schools. More recent figures, however, suggest that Title I resources are no longer able to maintain a state-of-the-art status (Coley et al.). Often Title I schools that were able to build technology resources continue to show favorable student to computer ratios only because much of the available hardware is the obsolete equipment which, when originally purchased with Title I funds, was state-of-the-art. This explains the Coley et al. 1997 overall figures for student-to-computer ratios that show only a slight difference between high-spending districts (9.7 to one) and low-spending districts (10.6 to one). When these figures are disaggregated, however, figures for state-of-the-art computers, in Title I and non-Title I schools illustrate a vastly different comparison. According to 1997 figures, “schools where less than 20% of the students qualify for Title I have a ratio of about 22 students per [multimedia] computer, compared to a ratio of about 32 students per computer in schools where 81% or more of the students are eligible for Title I" (Coley, et al., p. 15). These figures illustrate that children in schools with higher numbers of at-risk students must share their state-of-the-art computers with more students. Thus, there is a much greater gap in access for state-of-the art computers than for computers in general.

Inadequate Quality of Technology Use

Compounding the problem of inadequate quantity of state-of-the-art technologies for at-risk students is the problem of inadequate quality of use. While the "haves" often use technology in ways that promote higher order thinking skills, the "have-nots" are more likely to be involved in activities that employ the lower order thinking skills (McAdoo, 1994). Possible activities that promote higher order thinking skills are projects that require access to
the Internet as a resource for research topics. The information students have analyzed and synthesized may subsequently be shared with presentation software. Additionally, the "haves" who are involved in these activities may attend schools that "are more likely to use computers to teach higher order literacy and cognitive skills through the use of programming languages and sophisticated graphics and simulation tools for mathematics and science instruction" (Emihovich, 1992, p. 501).

Conversely, the "have-nots" may be more likely to employ lower order thinking skills utilized in programmed learning, (i.e., computer-generated drill and practice activities with a limited focus). At-risk students often use computers to promote the development of specialized skills, and in the process, they are placed in a passive role with the computer controlling the environment. Using instructional technology to address skills is "often called computer-based instruction (CBI) or computer-assisted instruction (CAI)" (Grabe & Grabe, 1998, p. 82). Grabe and Grabe divide CAI or CBI into the following categories: tutorials, simulations, drill and practice, educational games, and exploratory environments. They report this type of instruction is moderately effective, providing "positive--but incomplete--experiences . . . [and they suggest] that guiding the student, especially in ways necessary to develop complex mental skills, is frequently beyond the capabilities of present applications of technology" (p. 111). Furthermore, Clements (1994) maintains that "the most promising uses of computers have nothing to do with programmed learning" (p. 33). He suggests programmed learning be replaced to a large degree with authentic purposes for integrated computer use that include word processing and publishing, computer simulated mathematical manipulatives, programming, computer painting tools, and problem-solving computer activities. These authentic uses of technology sharply contrast the programmed learning at-risk students often encounter.

Inadequate Teacher Preparation

The third factor that contributes to the "digital divide" is how teachers use technology in their classrooms. Technology in and of itself is not a cure; its efficacy is determined by how it is integrated into the curriculum (Clements, 1994; Fabry & Higgs, 1997; Kongshem, 1996; Laffey & Musser, 1998; McAdoo, 1994). While the availability of ample, high-quality technology opportunities is crucial, teachers' attitudes about and abilities with technology also greatly affect students' equitable access to these tools. According to Fabry and Higgs (1997), only 16% of all teachers are willing to try new ideas and are successful users of technology. This might be attributed to a lack of time to develop skills and confidence in abilities, limited spending allocated to training, and a scarcity of technical support personnel.

Teachers' fears, inadequate training, and lack of support are compounded by teachers' perceptions of technology's impact in the classroom. Laffey's and Musser's research subjects voiced these beliefs: "computers . . . [have] a higher value . . . in the future work environment than in the future school environment . . . [and they] will interfere with the teacher-student relationship" (p. 236). Cunningham and Allington (1994) described an added dimension to these concerns. They maintained that in schools with large at-risk populations, "teachers are instructed to 'teach the basics.' The basics usually referred to are the three r's--reading, 'riting, and 'rithmetic" (p. 181). Thus, basic skills become "the real work" and children are exposed to technology only in a skills practice environment or after "the real work" is complete. Additionally, the difference in the types of technology that different
groups of students are exposed to is often decided by educators who assume that “children must demonstrate competency in lower level skills before they are ready to progress to more complex cognitive skills” (Emihovich, p. 501). Emihovich refutes this notion, concluding from her studies of children who scored low on standardized tests, a determining factor for at-risk status, that their low scores did not preclude them from learning high-level computer concepts.

Adequate teacher preparation is an essential catalyst of any effort to close the “digital divide.” In addition to providing teachers with instruction in how to integrate technology in the classroom, with technological support, and with the time to develop these skills, teacher preparation must also address attitudes about technology’s place in the classroom. A goal is to replace the perception of technology as an “add on” for students who have mastered basic skills with a perception of technology as a basic skill. Thus, educators meet the needs of their at-risk students by exposing all learners to the kinds of technology experiences that will offer a greater chance for success in our technological society.

Inadequate Exposure to Technologically Proficient Role Models

Although at-risk students' exposure to rich technology experiences in school greatly affects their level of electronic literacy, the home environment also plays an important role. Often, at-risk students reside in technologically poor households with less exposure to technologically proficient role models (Lichtman, 1998). According to Lazarus and Lipper (1994), parents in more affluent homes are supplementing their children's technology education. They report that "whereas 48% of households with children whose family income is $50,000 or more have a child using a personal computer, only 7% of households with family income under $20,000 do" (p. 10). Consequently, in many cases the children who are at-risk and experiencing inequitable access to technology in school are the same children who are least likely to have access outside school.

Access to computers in the home is but one component of the role of the home environment. Lichtman (1998) reports that the parents of at-risk students often lack experience with computers. This may make them reluctant to encourage their children to pursue technology because they are unfamiliar with emerging technologies and possibly apprehensive about potential negative effects of technology on their children's lives. This perspective is in sharp contrast to that in homes where “as family members become techno-literate at home and at work, they are coming to regard computers as an important tool for education” (Trotter, p. A17). Consequently, at-risk children who are often technologically underserved in the schools also have fewer opportunities to encounter technologically literate role models outside the school environment.

Effects of Inequitable Access

The effects of inequitable access to technology can be felt socially, politically, and financially. Inequitable access marginalizes segments of society and creates an “information underclass” of people who are “digitally dispossessed” (Topping, 1997, p. 11). Lichtman (1998) contends that considering "the increasing importance of the Internet in political and social discussions ... the disadvantage of the disconnected becomes a critical problem for our society as a whole" (p. 47). Menchaca (1997) further details the phenomenon taking the position that future social and economic viability hinge on access to technology and its role in access to learning and power. Furthermore, Lazarus and Lipper (1994) assert the premise that "as businesses lean more heavily on telecommunications and electronic technology, American workers must increasingly learn the ways of electronic communications just to carry out their day-to-day responsibilities" (p. 7).

The long-range potential ramifications for students with underdeveloped electronic literacy skills are daunting. As these students mature and enter the adult world of employment, they will find that employers increasingly expect workers to be able to navigate technology and use it effectively, and the rewards for possessing these abilities will be manifested in better-paying jobs (Lazarus & Lipper, 1994; Lichtman, 1998; Trotter, 1996).
Electronic literacy is becoming more important to employers as jobs increasingly demand "both basic literacy . . . at a relatively advanced level, and information technology skills" (Lazarus and Lipper, 1994, p. 7). The consequences for those who are unprepared to respond to the demands for proficiency with the new technologies are felt in less attractive employment positions. Recent figures show that two thirds of college graduates use computers at work compared to fewer than one tenth of high school dropouts, and in 1992, a college graduate earned 83% more than a high school graduate (p. 8). Thus, research literature highlights the "digital divide’s" potential for long-range detrimental effects on financial viability.

Effective Uses of Technology

The use of technology as a scaffold "that is specifically engineered to assist learners in performing tasks for which they would otherwise be unprepared" can lessen the impact of the "digital divide" (Laffey, Tupper, Musser, & Wedman, 1998, p. 75). Kongshem (1996) describes effective scaffolding where computers are used "much like carpenters use hammers--as tools to construct authentic, personal, and meaningful projects" (p. A21). This quality of computer use is in sharp contrast to drill and practice programs with repetitive practice of basic skills intended to increase fluency.

Effectively integrating technology in the classroom requires a foundation comprised of state-of-the-art technological tools and an environment conducive to integrating these tools seamlessly across the curriculum. In this type of environment, “computers are active agents, extending the users' abilities, enabling them to create new problems and to devise new solutions. When used actively, the tools help the user to accomplish personal goals and objectives” (Bowman & Beyer, 1994, p. 22).

The nature of the environment most conducive to effective integration is one that includes the changing roles of teachers and students and provides effective scaffolding. Such an environment integrates technology across the curriculum and implements it as a tool to facilitate connectivity, integration, and productivity. The traditional direct instruction model, sometimes referred to as “chalk and talk,” has been widely accepted as effective for delivering predetermined content. Such a construct does not effectively prepare students for a technology-rich society that requires a great deal of synergy and non-linear productivity. Today's classrooms are evolving to reflect the following modern model offered by Tapscott (1999) by realizing shifts in thinking about teaching and learning from

- linear to hypermedia learning;
- instruction to construction and discovery;
- teacher-centered to learner-centered education;
- absorbing material to learning how to navigate and how to learn;
- school to lifelong learning;
- one-size-fits-all to customized learning;
- learning as torture to learning as fun; and
- the teacher as transmitter to the teacher as facilitator.

A model such as Tapscott’s recognizes our society’s evolution from the Industrial Age to the Information Age.

Conclusions

Education has long been considered the “key to success;” however, in order for education to truly unlock the door to a successful future, educators must address equitable access to high-quality technological experiences. When they are designed for all learners, these experiences prepare them to be contributing, successful members of the “New Renaissance.” Effective professional development can raise teachers' comfort level with technology and afford more opportunities to integrate technology in the classroom, but in order to
positively impact the "digital divide" and realize equitable access for at-risk students, teachers must also understand the importance of electronic literacy for all students (Coley et al., 1997; Fabry & Higgs, 1997, Kongshem, 1996; McAdoo, 1994; Neuman, 1990). At-risk children who are limited to using remedial and drill software in order to acquire basic skills are kept from the kinds of technology exposure that will offer their best chances for success in our technological society. The "programmed learning" format places the user in a passive role, yet all children, including at-risk children, need to "become aware that they control the technology and it does not control them" (Emihovich, p. 502).

In order to remedy this situation for at-risk students, the focus for administrators and educators should be on professional development opportunities for teachers with a goal of seamlessly integrating technology as a tool. This integration would be for the benefit of all students, bringing at-risk students into a common arena and challenging the "digital divide."

An integral element of professional development includes a commitment in terms of exploration time and technical support. This commitment would allow teachers opportunities to build the skills and confidence necessary for weaving technology into the very fiber of the classroom. In this way, classroom technology becomes a transparent tool, and teachers and students use technology to support learning and express new knowledge. Thus, teacher preparation and common goals for implementation will have contributed to equitable access and opportunities for all learners to reach their highest potential as contributing members in the society of the information age.

Integrating Standards-Based Instructional Technology

Abstract: The Navajo Education Technology Consortium/Education Technology Improvement Plan (NETC-ETIP) project is just entering its second funding year. This unprecedented project involves 13 school districts in three states (Arizona, New Mexico, and Utah), two Universities (University of New Mexico and Northern Arizona University), two community colleges (San Juan College and Dine College), two departments of education (Arizona and New Mexico) and the National Indian Telecommunications Institute (NITI). The project serves 2,749 teachers in 13 isolated, poor, rural school districts across the 25,000 square mile Navajo Indian Reservation. It is a technology training and integration project funded by a grant from the United States Department of Education under their Technology Innovation Challenge Grant Program. This paper includes a general project overview, a synopsis of year one objectives and accomplishments, and a detailed analysis of the year one Arizona training sessions including results and outcomes.

Project Overview

The project uses a ‘training of trainers’ model. Each school has designated a training team consisting of one administrator, two teachers, and one parent. Training teams receive instruction in technology and technology integration in one of four regional training centers (Window Rock, Arizona; Kayenta, Arizona; Gallup, New Mexico; or Shiprock, New Mexico). The two Universities (University of New Mexico, UNM and Northern Arizona University, NAU) staff and operate the training centers in their respective states in partnership with the host school district. The training focuses on providing teachers the knowledge and skills needed to create standards based, culturally relevant, technology based curriculum.

The project uses a scaffolding approach to training curriculum. Each school team returns to the regional training center annually to build on what they learned and implemented the prior year. Upon training completion, teams return to their respective schools and instruct all remaining teachers. Each teacher team member is asked to develop at least two standards-based, culturally-relevant, technology-based curriculum modules for use in the classroom. Additional modules are being developed by other teachers. A newly awarded STAR schools grant will take selected curriculum modules (approximately 100 each year) and further enhance and develop them into professional products. These revised modules will then be distributed via NETTrain, an interactive, on-line, instructional technology training web page. In addition they will be available for distribution via CD-ROM.

An important feature of the NETC-ETIP project is year-round, on-site technical support for the training teams. Each center site employs a full-time training coordinator. This coordinator (a University employee) facilitates training sessions held each summer (with an exception in year one which had one training sessions in the winter and one in the summer). In addition, the coordinator also provides continuous technical support to the training teams throughout the school year as they train teachers at their schools and integrate the training into their classrooms. Site coordinator support has included additional training, hardware and software assistance, providing additional resources, assisting with the school-based trainings, presentations to stakeholder groups, and more.

The training curriculum is referred to as the Integrated Technology Training Curriculum (ITTC) and is developed by each University with local district input. Each center site employs a full-time training coordinator. This coordinator (a University employee) facilitates training sessions held each summer (with an exception in year one which had one training sessions in the winter and one in the summer). In addition, the coordinator also provides continuous technical support to the training teams throughout the school year as they train teachers at their schools and integrate the training into their classrooms. Site coordinator support has included additional training, hardware and software assistance, providing additional resources, assisting with the school-based trainings, presentations to stakeholder groups, and more.

The training curriculum is referred to as the Integrated Technology Training Curriculum (ITTC) and is developed by each University with local district input. Overall, the project director provides guidance to insure training uniformity at all four training centers, but actual training session content is flexible through site-based management and local superintendent input, in order to fit each district’s long-range technology plans. The ITTC is competency based and incorporates a full range of concepts and skills integral to successful use of technology in the classroom, based upon the International Society for Technology in Education (ISTE) Foundation Standards. Moreover, the ITTC also includes instruction on the integration of state academic
Year One Objectives and Accomplishments

This project had very aggressive objectives for the first year. They included:

1. Recruit and hire a Project Director, University project directors and training center coordinators,
2. Set-up technology training centers, organize the training teams and schedule them for training,
3. Plan and formalize the ITTC training curriculum content (Level I); conduct pre-training workshops with all trainers; and conduct all ITTC Level I training activities (five days each team in the winter),
4. Plan and set-up NETrain designed for on-line training, classroom resources, help desk, and electronic discussion groups,
5. Provide support to individual schools for conducting teacher training at their schools,
6. Plan and formalize the ITTC training curriculum content (Level II); schedule summer training sessions; conduct pre-training sessions with all trainers; and conduct all ITTC Level II training activities (eight days each team in the summer),
7. Project evaluation conducted by project staff, project management committee, evaluation oversight committee, and external evaluator throughout first project year (and subsequent years),
8. Faculty advisory councils created and maintained by each University for articulation and implementation of training curriculum into the teacher preparation programs.

Even though the first year had very aggressive goals and the project was funded late (notification not received until early October with an October 1 start date) all project objectives were met during the first year. During the winter of 1998-1999 (year one), each teacher team received five days of instruction (in one of the four newly created training centers). Teams returned to their schools and provided training to other teachers during spring 1999 (some more thoroughly than others). In addition, some team members created curriculum modules (primarily PowerPoint presentations with some web pages). However, each teacher team member did not produce two modules each as originally planned. Technical assistance and support was provided on-site to the training teams during the spring semester.

During the summer of 1999 (still the first year of the project), teams returned to their training center site to receive the next level of training. Eight days of training were provided to each team. Teams then returned to their schools and most began providing training to other teachers in August and September. Additional training is expected to occur throughout the 1999/2000 school year. In Arizona, each team created a student-centered, problem-oriented curriculum module based upon the Norton model presented in training during the summer session. Each teacher is expected to create at least one more additional module during the school year using the same (or similar) student-centered, problem-oriented approach. An aggressive on-site technical assistance and support campaign was launched in September and continues today.

Analysis of Year One Arizona Training

Winter 1998/1999 (Level I ITTC)

The winter training was composed of five days of training delivered from December, 1998 – May, 1999. Sessions were conducted at both training center sites. Day one was conducted during four sessions in December. Days two through four of the training were completed with each team by early February. The fifth day was completed on-site at each school during the school year. This approach was used to minimize classroom absence for teachers. Comparatively, New Mexico took a different approach and held training over five consecutive days starting in late January and concluding in March.

Of the nine school districts and 39 schools, full participation would have been 156 team members. Some schools sent more than two teachers or more than one administrator and overall 159 team members attended at least part of the winter training sessions (88 teachers, 37 administrators, and 34 parents). Only four schools did not have an administrator attend any of the winter training. All schools had at least partial representation at the winter training sessions.
Day one was entitled “The Forest” and was designed to give the team members the big picture or an overall view of the five-year project and the types of curriculum (culturally relevant, standards based technology modules) that will be produced over the length of the project. A project overview, cultural overview, introduction to standards, and a hands-on session previewing culturally relevant technology curriculum (PowerPoint and Web based) was presented.

Day two focused on “Basic Technology Skills.” This day started with a discussion of change using the Joel Barker video “The business of Paradigms.” A majority of the day consisted of hands-on sessions including Internet navigation and accessing appropriate Internet resources (including search engines); basic word processing including incorporating pictures and text from the Internet; and an introduction to Excel spreadsheets and graphing using a popular classroom math lesson.

Day three was divided into two topics 1) Integrating standards based curriculum, and 2) Peer coaching strategies. Teachers analyzed their progress towards integrating standards, aligned a curriculum with standards, and created a thematic unit with the assistance of technology that was cross-referenced to the standards. They also learned about constructivist teaching techniques and taught a mini-lesson to their peers.

Day four was entitled “Integration and Application.” Each team learned PowerPoint while developing/creating a PowerPoint based curriculum module based upon the thematic unit they created in Day 3.

Day five was conducted on-site back in the team’s district and school. Joel Barker’s “Visions” was used as an introduction to “Building the Team and Creating a Plan.” Each team developed a vision and action plan for implementing the spring teacher training within their schools. In addition, communicating on-line, including how to use the project created email discussion list, was covered on-site at each school.

All sessions were evaluated by Northern Arizona University using a five-point scale. From day two forward a standard evaluation form was used for all sessions. The five-point scale used is shown in (Tab. 1).

As you can see from the data table (Tab. 2), each day except for day one exceeded the expectations of participants. Day five approached “excellent.” The days that were mainly focused on hands-on activities (days two and four) were evaluated much higher by the participants, especially day four which was the “integration and application” activity of creating a PowerPoint module. An independent evaluation by SouthWest Laboratories (random sampling of 11 school team members were contacted for a phone interview) corroborated the above data finding the PowerPoint session rated as “The best for you.” Why asked why those interviewed responded because it was “practical and operational.”

Table 1 – Evaluation Scale

Table 2 – Evaluation Results for Winter Training (Arizona), conducted by NAU
Summer 1999 (Level II IITC)

The summer training consisted of eight days of training delivered from May to September. The first seven days were delivered in the summer at the two training centers; the eighth day was a combined day for all Arizona participants in September. A variety of formats were offered to accommodate the participants during the summer: seven consecutive days, four consecutive days followed by three consecutive days, and three consecutive days followed by four consecutive days. In order to accommodate summer schedules for the teachers (including attending summer school, teaching summer school, vacations, and more) teachers were even allowed to crossover between center sites if space allowed.

Of the nine school districts and 38 schools (one school in Utah dropped out of the project prior to the summer training), full participation would have been 152 team members. Eighty-seven percent of the team members attended at least part of the summer training sessions: 75 teachers, 22 administrators, and 35 parents.

The data tables indicate (Tabs. 3a and 3b) all summer training topics except for the Dine Culture (which used a different evaluation scale) exceeded the expectations of the team members. Of particular note were topic two (web page creation), topic four (integration of standards/embedded assessment), and topic eight (Dr. Knight's presentation on Equity and Excellence in the Classroom) approached "Excellent." A significant difference in overall evaluation averages existed between the two center sites (in most cases at least .5 difference). As different presenters were used for the same topic, this may account for some of the variation. Buy-in levels also differed between schools in the two center sites. The site with lower buy-in had the lower evaluation scores. Southwest Laboratories has not yet conducted an independent evaluation of the summer training conducted in Arizona for comparison and validation.

2. Web Page Development using Communicator (1 1/2 days). NITI provided web page design training using a Corn Activity. Teams then developed their own web page and created a lesson on the web.

3. Zerkonian Activity (1 day). Teams worked together on a lesson that integrates standards, technology and culturally relevant material and modeled the student-centered/problem-based approach. Teams were required to work in groups to create a trip prospectus for aliens visiting the Navajo Nation. The activity required teams to organize, plan, research information on the Internet, do cost analysis using Excel, do a trip itinerary using Word, and develop a PowerPoint presentation to present to peers.

4. Embedded Assessment (1 day). Northern Arizona Literacy Enterprise or G2 Consultants spent a day on the Arizona State Standards and embedded assessment strategies.

5. Dine (1/2 day). In this session (presented only during two training sessions/40 participants) Dine Community College presented PowerPoint presentations on Geology and the Navajo learning philosophy.

6. CD/Access (1/2 day). A lesson was delivered on the use of educational CD-ROMs in the classroom including how to find and evaluate products for classroom use. Samples of different educational CD-ROMs were provided for team members to try. An introduction to Access (a database), using step-by-step lessons from the Microsoft web page, was also provided.

7. Teamwork/Presentation (varied 2 days – 2 1/2 days). Each team was given time to develop an integrated lesson using the Norton Model as a guide. The lesson had to be a student-centered, problem-oriented, culturally relevant, and included embedded assessment for the measurement of content standard achievement. During the last day of the trainings, teams presented their lesson to their peers.

8. Dr. James Knight speaking on "Excellence and Equity in the Classroom" – a presentation that provides teachers with ten things they can do in their classroom to promote student excellence for all students.

All summer sessions were evaluated by Northern Arizona University (NAU) using the five-point scale (Tab. 1) and the standard evaluation instrument for all topics except topic five. Topic five was evaluated using a form provided by the presenters. Three questions were asked: (1) How interesting was the session to you? (2) How understandable was the session to you? (3) How useful was the session? A standard five-point Likert-scale was used with 5 being high and 1 being low. The overall average for topic five is included in the data table (Tab. 3b) for comparison purposes.

As the data tables indicate (Tabs. 3a and 3b) all summer training topics except for the Dine Culture exceeded the expectations of the team members. Of particular note were topic two (web page creation), topic four (integration of standards/embedded assessment), and topic eight (Dr. Knight's presentation on Equity and Excellence in the Classroom) approached "Excellent." A significant difference in overall evaluation averages existed between the two center sites (in most cases at least .5 difference). As different presenters were used for the same topic, this may account for some of the variation. Buy-in levels also differed between schools in the two center sites. The site with lower buy-in had the lower evaluation scores. Southwest Laboratories has not yet conducted an independent evaluation of the summer training conducted in Arizona for comparison and validation.
The evaluation instrument also included collection of qualitative data. Five open-ended questions were asked: (1) Aspects which made attendance worthwhile; (2) Can use the information in the following ways; (3) Suggestions for improvement; (4) Additional training on today’s topic needed; (5) Identify future workshop topic/suggested presenter(s); and other comments. The written comments had a few consistent themes across all topics and all sessions:

1. Need more time.
2. Need follow-up training/more training and/or time to practice and use.
3. Can use the information with lesson planning and with students in the fall (or see the potential to with more practice/follow-up assistance).
4. Need more sample lessons developed by other teachers to show during training.

### Results and Outcomes of Arizona Training

#### Skill and Application Growth

A technology questionnaire was delivered to project participants in December during the ‘Day 1’ training session. During those sessions 85% percent (n=130 of 156) completed the questionnaire. A follow-up questionnaire was administered during the fall with a 17% (n=26 of 152) completion rate. The five-point scale used on the technology questionnaire was:

1=Not at all; 2=Limited; 3=Some; 4=I am comfortable using; 5=I could teach someone else

Table 4 summaries the results of the two technology questionnaires. Prior to training, participants expressed comfort in one area only – “I have used a computer”. Many areas were below 3.0 indicating very limited, if any, prior experience. With the limited follow-up sample, growth was seen in all areas. Obvious growth appeared in areas where teachers were trained for new skill/software (PowerPoint, web pages). In addition, significant growth also appeared in areas that have a direct impact on students. Using computers with students started close to “some” but is now approaching “comfortable using.” Developing lesson plans that
integrate technology, standards, and/or Navajo culture components (the main objectives of the project) started in the "limited" range and now all three categories are in the "some" range after only one year of the five-year project.

Table 4 – Technology Questionnaire (administered to Arizona participants)

Currently, a standardized survey instrument is being developed for both Arizona and New Mexico participants. The instrument will be on-line and both team members and teachers at their schools will be asked to do a self-assessment at least yearly to track growth in skill development, application, and integration into the classroom.

Implementation in School/Classroom

SouthWest Laboratories conducted random sampling phone interview with eleven of the team members from Arizona schools in spring 1999. Results demonstrated that although most teachers were not able to conduct all the training topics at their schools. However, they were making an effort to conduct some training with teachers at their schools, despite some barriers. Team members were asked if they had conducted training at their schools, all but one (91%) responded they had conducted some training. When asked about the response from their colleagues to the training, 45% had a favorable response; 18% indicated busy schedules/more work being an issue for a favorable response, 18% indicated mixed response, and 9% said they ‘didn’t say much.’ (There was one non-response to this question.) When asked what training had not yet been delivered (of the training they themselves had received) and why the answer focused mainly on the Office software packages (Excel, PowerPoint) with the reasons being 45% did not have the software, 18% did not have time, 9% had hardware issue, 9% was still organizing their team. (There were two non-responses to the ‘why’ question.) They also asked ‘of the training you received, what has been implemented in the classrooms’? Thirty-six percent said none, not much, or don’t know. The remaining responses included: scanning of pictures, word processing, email; library—look for research, writing letters, word processing; Internet research, digital camera, scanning, PowerPoint; Word, Excel, PowerPoint. The evaluation report indicated: “It is anticipated that as the teachers’ technology literacy increases through the scaffolding of training, increased use of technology in the classroom will emerge. The evaluation, at this early time in the project, was focused on documenting the efforts to develop increased technology literacy among school professionals. Later evaluation efforts will focus more on the impact of the training associated with student achievement and the use of technology.”
Technology and the Navajo - Its Time Has Come

Jerry A. Bennett
Project Director
Education Technology Improvement Plan Project
Navajo Education Technology Consortium
jbennett@gmcs.k12.nm.us

Abstract: This paper describes a comprehensive technology project that benefits the Navajo People. The Navajo live in a sparsely populated region of the West that enjoys few of the amenities of larger urban settings. Isolation and remoteness have created a situation where Navajo children have been unable to get an equal education because of lack of access to modern communications and equipment. This paper briefly summarizes aspects of staff development, cultural inclusion, and infrastructure improvements that are attempting to assist this population enter the electronic age.

The Navajo Education Technology Consortium is an organization designed to meet the needs of a group of people who, like many other people living in rural America, have little access to technology. They do not have equal access to a quality education. In many areas, they can not make a telephone call or use any other distance communication.

The Navajo live in a vast land encompassing parts of three states (Arizona, New Mexico, and Utah). The largest geographic school district in the continental United States lies within the reservation, some 5,500 square miles. Many of the roads are unmarked and unpaved. Few telephone companies care to invest in providing service because of the anticipated low return on investment. Lack of running water and electricity is common. Children have died because parents were unable to find anyone with a telephone to call for medical assistance.

In 1998, twelve public school districts in New Mexico, Arizona, and Utah, one private school, and one BIA school joined together to form The Navajo Education Technology Consortium (NETC). That year, this group, which is comprised of the superintendents from each school district, applied for a Technology Challenge Grant from the US Department of Education to train their teachers how to work with technology.

Partnerships were formed with two universities (Northern Arizona University and University of New Mexico), to provide training. In addition, four training sites were set up in different corners of the Navajo Nation and 102 schools sent teams of four people (one principal, two teachers, and one parent) for training. The teams then returned to their schools and began training the rest of their staff in the material covered in training. Microsoft provided a substantial amount of software for the project. The National Indian Telecommunications Institute provides instruction and guidance on cultural components.

During each training session, the teams learn about different types of software and hardware. They then produce lesson modules which address state standards, contain culturally appropriate material, and have some type of embedded assessment. Digital photography, video production, web page design, and investigation techniques for exploration of the Internet for appropriate resources are taught, then used to include material in modules.

The NETC sought, and was funded a second grant that assists the first grant. A STAR Schools Grant was awarded that will establish an Internet data base browser so that all modules can be accessed by teachers within the Navajo Nation (and elsewhere) via the Internet. Four studio sites are also included in the project that will fine tune teacher produced modules by adding computer animation, studio quality sound, and cultural components. Teacher education students within the universities are sought to assist in the "fine tuning" process. Since some schools on the reservation have little or no Internet access, the project is also testing satellite up and down link capabilities in ten school sites. In others, modules will be available on CDs or DVDs. The emphasis is on sharing information that is relevant to the population of students served, The Navajo.

During the first year of the ETIP grant, 102 school teams were given 13 days of instruction. In the Gallup McKinley County School District (the largest of the consortium districts), the superintendent has mandated 3
days of staff development on technology during the 1999/2000 school year. The principal of each school submits to a university trainer an instruction design for the 3 days of training. The university trainer then offers support to the school teams to address the training desired for that school. In this particular school district, all teachers have three years to become proficient in Microsoft Office (or equivalent) and the use of the Internet as a teaching tool.

The impact for teachers coming out of teacher education colleges is profound. By 2002, all students in Gallup McKinley County School District will expect to use technology in their educational experience. New teachers will be expected to be technologically proficient, not only by the district, but most importantly, by the students.

We don't know what the impact on students will be but one device we are developing is an instrument that will try to determine how a Navajo feels about being a Navajo. In the past Navajo students have not seen themselves in texts, the news, or in films. We are attempting to change that. We are embedding familiar pictures, stories, and aspects of the local environment into curriculum. School becomes a place less foreign and less frightening. We expect to see a positive difference in our students, both academically and socially. The Internet and other technologies offer a bridge over isolation. The Navajo are a proud people living in a world apart from many of the conveniences of more urban settings. This project attempts to allow them to participate in a contemporary educational setting with the advantages of the rest of the population while also allowing them to preserve their cultural heritage.
A Multifaceted Approach to Integrating Computers in Multicultural Preservice Teaching

Inés Márquez Chisholm
College of Education
Arizona State University West
Phoenix, Arizona
ines@asu.edu

Abstract. Research indicates that few education faculty consistently model the use and integration of technology in their instruction. At the same time, few in-service teachers feel well prepared to integrate technology into classroom instruction. As faculty ponder how to bring educational technology into preservice education, they frequently consider its use as an either-or choice: teach asynchronous on-line courses or teach synchronous courses in a classroom. This paper presents a hybrid approach used in an undergraduate multicultural education course. This approach more closely mirrors the reality found in most classrooms.

Introduction

Technology has become a pervasive element in higher education and it plays an increasing role in course design, delivery and content across all academic fields. For example, the 1998 National Survey of Information Technology in Higher Education found that 33.1 percent of all college classes use Internet resources and 22.5 percent of college courses use the WWW for class materials and resources (Campus Computing Project, 1998). Data gathered jointly by the American Association of Colleges for Teacher Education and the National Council for Accreditation of Teacher Education in 1996 (Persichitte, Tharp, & Caffarella, 1997) show similar trends in schools, colleges and departments of education (SCDEs). Faculty at 45% of the responding SCDEs regularly use computers, televisions and VCRs as part of instruction. Similarly, 40% of the SCDEs reported requiring students to design and deliver instruction incorporating various technologies.

Nevertheless, a 1995 report from the Office of Technology Assessment (OTA) indicated that “technology is not central to the teacher preparation experience” and that educational technology instruction most often “is teaching about technology...not teaching with technology” (p.165). Further, the OTA (1995) found that faculty do not model the technology. In part, this lack of integration may be the result of faculty's perception of technology as a means to enhance teaching, rather than to change teaching (Perisot, 1997). Yet in 1996 the National Commission on Teaching & America's Future challenged schools of education to model how to teach in multicultural contexts and how to use technology in doing so. Notwithstanding, research indicates that few education faculty consistently model the use and integration of technology in their instruction (Lewallen, 1998; Chisholm, Carey and Hernandez, 1998). Indeed, many faculty continue to rely on the blackboard, overheads and, occasionally, slides and videos (Sammons, 1994). Others remain uncertain of technology’s appropriate use and educational value and benefits. It is not surprising then, that the National Center for Education Statistics (NCES) in 1999 found that few teachers (20%) report feeling well prepared to integrate technology into classroom instruction.

Within the next decade, some 2 million new teachers will be hired (NCATE, 1997). If these future teachers are to integrate technology into their teaching, they must first feel competent and knowledgeable about its use and instructional integration. Yet students from traditionally underrepresented groups enrolling in teacher education often lack the personal and professional experiences with computers and interactive technology. These students need equitable access to that technology. However, access to technology is not simply a matter of availability of hardware and software; technology access also means opportunities to use varied applications, to develop technological competence, and to experience their use for authentic purposes. Given the number of nontraditional college students
with families and the many who work to support themselves while attending school, technology access is
determined also by time. Teacher preparation programs need to find ways to not only provide the access, but also to
model its educational applications.

Because teachers are central to the equitable and effective use of technology in our increasingly diverse classrooms,
it is imperative that colleges of education not only graduate technologically competent teachers, but teachers who
can skillfully integrate technology in culturally diverse classrooms. In preparing future teachers, we must remember
that “today’s teacher candidates will teach tomorrow as they are taught today” (NCATE, 1997, p. 4). Our preservice
teachers will replicate in their own teaching what they observe teacher educators and classroom teachers doing.

Integrating Technology

Historically, colleges of education have endeavored to meet the technological challenge by adding a technology
course to the teacher preparation curriculum. Typically such technology courses are taught by an expert technology
faculty member in a specially equipped classroom or lab setting. Preservice teachers have acquired their computer
competency in a manner that is disconnected from other education courses. This additive, nonintegrative approach
has taught future teachers how to operate a personal computer, use specific software and, often, how to
assess the educational value of software programs. Unfortunately, it has not taught them how to integrate technology into their
teaching.

As more teacher educators become convinced of the need to integrate technology in preservice education, one
common misconception continues to serve as a deterrent. Educational technology is frequently seen as an either-or
proposition: teach asynchronous on-line courses or teach synchronous courses in a classroom. However, alternative
and hybrid modes of instructional delivery are also possible and effective. Indeed, modeling technology integration
for preservice teacher requires a hybrid approach that more closely mirrors the classroom reality found in most
schools where technology and the WWW are used as one portion of learning activities, not as a total system of
instructional delivery. Moreover, as we move into new ways of teaching, we must build on what the past has taught
us about effective teaching practices and integrate these practices with our new resources.

Underlying Theoretical Principles

In developing this hybrid approach for preservice teacher education, the author applied an eclectic approach based
on several theoretical constructs. The basic underlying principles stem from theories of experiential learning,
constructivism, and social learning theory (see Kearsley, 1999 for summaries of these theories).

Experiential Learning

According to experiential learning theory, minimizing external threats maximizes assimilation of learning that is
threatening to the self. The teacher’s role here is to create a positive environment for learning. Since multicultural
education by its nature evokes emotional responses, this principle served as a cornerstone for an undergraduate
multicultural education course taught by the author. From the beginning, the instructor conveyed and modeled the
concept that a multicultural learning environment is one in which diversity is appreciated and differences are
respected, including differences of opinion. In fact, evaluation of students’ chat room dialogue was weighted for
respect for different opinions.

Experiential learning theory also holds that learning occurs when the subject matter is relevant to the learner’s
interests, the learner actively participates in the learning process, and the student has control over its nature and
direction (Kearsley, 1999). The instructor’s role is to balance intellectual and emotional components of learning.
The teacher shares feelings and thoughts with the learners, but avoids dominating or imposing ideas. One way to
create relevancy and to give students control over their learning is by offering choices within a framework.
Consequently, individual students selected readings based on their particular interest from lists of links centered on
course topics. Students then actively participated in classroom dialogue and on-line discussions.

In addition, experiential learning sees the role of the teacher as a facilitator who organizes and makes available
learning resources. In developing the course, the author created 28 web pages based on the major course themes:
The Nature of Diversity, Personal Identity, Classroom Culture, Teaching in Diverse Classrooms, Teaching Content Areas Multiculturally, and Collaborating with Parents. These web pages provided numerous links to a variety of on-line readings. The richness and currency of on-line multicultural materials led the author to choose this route rather than assign a commercial textbook. In addition, students could use a resource book of multicultural readings as an alternative in case technical problems prevented their accessing the on-line readings. Fortunately, there was only one instance of such problems during the semester.

Constructivism
One of the major concepts of constructivism is that learning is an active process in which learners build on current or past knowledge to construct new ideas or concepts. Learning takes place when students create their own knowledge in an environment where students and instructor engage in active dialogue. Throughout the course students were encouraged to relate their readings and class discussions to personal experiences and classroom observations. Following the constructivist approach, the instructor and students engaged in a lively, Socratic dialogue both in the chat rooms and in class. The instructor responded to all individual chat room postings by first affirming the students' views and then posing additional questions to expand and deepen their critical thinking. For example, when a student commented in the chat room that teachers needed to make all their students feel comfortable and accepted, the instructor responded by agreeing that this was truly important and then inquiring what specifically the student would do to achieve this in her own classroom. On another instance, a student commented that illegal Mexican immigrants are a drain on our economy as they pay no taxes and make use of various economic assistance programs. The instructor responded by indicating that illegal immigrants are indeed a problem in the United States and the asking the student what facts substantiated the claim that illegal immigrants had a negative effect on the economy. In turn the student responded by doing an Internet search on the topic. She then responded that she had found some articles that contradicted her original statement and made her think about how often misconceptions are based on opinions rather than facts.

Social Learning
Bandura’s social learning theory emphasizes the importance of observing and modeling behavior. In recent years, Bandura has also focused on the concept of self-efficacy. The author’s major goals in creating a technology-supported course were to model the integration of technology for learning and teaching, as well as to develop students’ sense of competency in using computers. The instructor also modeled the integration of technology by creating in-class presentation materials as web pages that could be projected on a screen at the front of the room with an overhead projector. Thus students saw how PowerPoint presentations and web pages could be used to present topic outlines, pose discussion questions, and provide examples.

Course Format
A Multifaceted Approach
In teaching a three-credit undergraduate course in multicultural education, the author applied a multifaceted instructional approach that combined both synchronous, face-to-face instruction and asynchronous, on-line learning. The instructor addressed the issue of equitable access by providing two hours of face-to-face in-class discussion and instruction and one hour of on-line course readings and activities. The on-line work could be completed either on campus at a computing center, in the classroom lab where the course was offered, or at home for those with computers and a modem. In addition, the instructor remained in the computer lab during the third hour to provide technology support and one-on-one discussion of topics or assignments.

In creating this course, the author principally used three programs: (a) CourseInfo, a licensed course management tool which served as the structural framework and starting point for course work; (b) FirstClass, which provided email communication with the instructor and could be accessed through CourseInfo; and (c) Netscape Communicator, which provided access to the instructor-created web pages and on-line readings. All students received a free email account and free training in the use of First Class, the university-supported instructional email program.

At the first class meeting, students enrolled online into CourseInfo and acquired their individual user name and password. Once enrolled, students could access the syllabus, read announcements from the instructor, read about the instructor, see classmates’ photos and web pages, link to the instructor’s web pages for each course topic and enter
their randomly-assigned chat group. Opening the instructor’s web pages in Netscape, the students found links to a variety of readings focusing on a course topic. These readings ranged from personal opinion pieces to scholarly journal articles and represented a variety of perspectives, such as differences in sexual orientation, special needs, race, ethnicity, language, and religion. The instructor’s web pages also provided links to the chat rooms in CourseInfo and to FirstClass email. In addition, students could reference the instructor’s in-class presentation materials that were placed in a lesson folder within CourseInfo.

**Peer Learning**

Collaborative learning was an integral part of the on-line chat groups and in-class discussions. Students met in class with their chat group, visited the assigned instructor’s web page and chose their readings for the following class session. Each member of the chat group chose different on-line readings. These readings were then shared with the other members in the chat room via a summary and reflection on its implications for teaching. In class, the students read their group’s chat room entries and then shared what they had learned from their readings with the entire class. The instructor provided guide questions for class discussion and opportunities for small group work. In addition, chat groups collaborated in developing and presenting multicultural teaching activities for content areas. These collaborative projects included in the evaluation rubric peer evaluation of members’ contributions, timely work, degree of collaboration and respect for others’ opinions and suggestions.

**Limitations and Benefits**

Although the author has taught this course over a seven-year period, this was her first comprehensive attempt to integrate technology. The results of this integration proved beneficial for students, but held several challenges and limitations for both the students and the instructor.

**Limitations**

Time. One of the major limitations to the development of this web-supported, hybrid course was the amount of time required. In addition to the usual time needed for the creation of a syllabus, lesson preparation and development of course materials, this combined format required additional preparation and on-line time commitment. This extra expenditure of time is one that not all institutions support, recognize or reward. Time is a crucial resource in identifying appropriate materials, organizing the on-line resources, creating course web pages and developing CourseInfo pages and links.

Rethinking of course delivery, course content and organization occurred during the Spring semester prior to the Fall offering of the course. Reconception and restructuring of course topics led to the new course format. Although the author had identified and bookmarked multicultural on-line resources over a span of several years, she needed to verify the continued existence of these pages and their current URLs. She also had to identify additional on-line resources to expand the available reading choices for students, include new topics, and offer multiple perspectives on every topic. Hence, she spent innumerable hours adding to her list of bookmarks for the course.

The creation of the web pages also required vast amounts of time. During the summer prior to offering the course, the author spent approximately 168 hours in creating the main web pages for the course and an additional 10 hours in setting up the CourseInfo pages.

Throughout the semester, the instructor spent an average of 5 hours per week reading chat room entries and responding to each student individually. In addition, the instructor also read and replied to individual students’ email messages which averaged about three messages per week.

**Computer competency and access.** Though nearly 80% of the 24 students enrolled in the course owned a computer, the remaining students had access only on campus or at work. However, some of the students who owned a computer had low-end computers which did not allow them to access the on-line materials from home. Similarly students’ self-reported computer competency varied considerably, from a student planning to become a computer design expert to several whose only occasional encounter with a computer was for word processing. One non-traditional student had such a high computer phobia, that she opted to drop after the first class session.
Accessing on-line materials became an issue for the first two class sessions. Some students enrolled late for the course and had to be registered into CourseInfo during the second week of classes. Others forgot their passwords or user names the first few times. These students had to re-register into CourseInfo during the second week of classes.

Of course, the instructor’s own computer expertise and competency also comes into play in the development and delivery of a web-supported course. Although the author is comfortable using either a PC or a Mac platform, the majority of her work is done on a PC. Due to scheduling problems, the course was offered in a Mac computer lab and the instructor often had to learn by trial-and-error during the class session how to perform certain tasks on a Mac.

Benefits

**Increased computer competency.** Though most students had some level of computer competency, the majority had no experience in using chat rooms or using on-line course readings. By the end of the semester, many students commented on their learning how to use a chat room, their increased confidence in using a computer and their altered thinking about how they will use computers in teaching. Those who initially indicated little computer expertise stated that they had greatly improved their computers skills and felt comfortable navigating web pages.

At the same time, the instructor expanded her own computer competency by using CourseInfo for the first time and by working in a Mac environment. Her occasional learning of the Mac by trial-and-error in class also served as a way to model life-long learning and the continuous nature of computer competency development.

**Student-Teacher Communication.** One of the most beneficial outcomes of this multifaceted approach to teaching was increased student-teacher interaction and communication. Students readily emailed the instructor questions and concerns. Four sent their assignments as attachments to their email. All students received comments and questions from the instructor to all their chat room entries. As a result, the students and instructor engaged in some interesting, interactive email and chat room dialogues around multicultural issues. These on-line conversations often transferred into the classroom as students shared with the class what they had been discussing and thinking about in these two-way conversations.

**Diversity awareness.** The primary purpose of this course is to increase diversity awareness and develop multicultural teaching skills. The first half of the course was devoted to defining terms, identifying the nature of diversity and developing awareness of diversity issues. Students expressed feeling safe enough to voice their opinions. They also found topics relevant to their interests and experiences. For example, one young man indicated that he had had mixed feelings about dealing with gay and lesbian students, but after choosing to read all the on-line readings provided from this perspective, he now had changed his opinion and had a new perspective. Other students made such comments as “this really opened my eyes” and “I hadn’t thought about this until we read and discussed it.” This increased awareness resulted not from the instructor trying to change opinions, but through students’ selection in readings, chat room conversations, in-class discussions of topic questions and the instructor’s Socratic probing.

During the second half of the course, students used the on-line readings and resources to develop chat group presentations of multicultural teaching activities for language arts, mathematics, science and social studies. Chat group members planned their activities both on-line and face-to-face in the classroom. They integrated what they had learned about diverse populations, including children with special needs and language differences, and applied their knowledge of multicultural teaching strategies. Their presentations evidenced an awareness of the nature of multicultural education and provided for diverse learners.

**Conclusion**

The focus of this instructional experiment was to develop diversity awareness and multicultural teaching skills. A secondary purpose was to model technology integration and expand students’ computer competency. Both these main goals were successfully achieved. Evidence that the students have come to value their experience is the fact that they requested access to the course pages after the conclusion of the course. Several students indicated that they would like other instructors to use this same approach. The vast majority expressed having learned a great deal,
changing their perspectives and acquiring multicultural teaching skills. The time and effort required both of the instructor and the students was well rewarded.

“From Tatters to Tapestry”: Technology and the Weaving of Cultural Education in the Mainstream Classroom

Debra A. Suarez

USA
dsuarez@bamaed.ua.edu

Abstract: A basic tenet of multicultural education suggests that the learning, sharing, and integration of culture is necessary for the academic success of both majority and minority students. With the shifting demographics of the population, even small towns and rural areas are facing this challenge of the cultural education of the ESL student and the majority student in the mainstream classroom. However, the instructional use of print media alone is limiting and can inadvertently create reductionist cultural portrayals. With a theoretical grounding in cultural pluralist concepts, this paper suggests ways that teachers can move beyond print media alone, and use technology to develop and implement cultural activities in which both the majority and minority students participate in creating cultural portraits of different cultural groups represented in that classroom. In such cultural activities, technology may be used as a tool for tracing how our students’ unique cultural threads weave together the larger, common tapestry of our multicultural classrooms.

Introduction

In the name of national unity, a pervasive notion in the United States has been that cultural and linguistic diversity should be harnessed through an assimilative process, into one culture and into one language. This assimilationist perspective of the teaching of culture has historically affected the education of English as a Second Language (ESL) students in the United States in that their heritage cultures and languages have been, at the very least, absent from the curriculum (Ovando and Collier, 1996). However, a basic tenet of multicultural education affirms that not only is it possible, but also necessary, to affirm heritage cultural and linguistic roots while simultaneously sharing a set of societal principals (Banks and Banks, 1997). Therefore, this basic tenet of multicultural education suggests that the learning, sharing, and integration of culture is necessary for both majority and minority students. The differing views of assimilationism and pluralism form the basis of the reciprocal roles of culture in education, and cultural education. And these differing views form critical foundations upon which teachers, of both majority and minority students, will base their curriculum. Therefore, it is necessary to examine these differing views and the implications for the teaching of culture in the majority, or mainstream classroom. This paper explores the theoretical foundation of this basic tenet of multicultural education. With this theoretical grounding in cultural pluralist concepts, this paper discusses how technology can be used to reveal the cultural tapestry that is our mainstream classroom.

What are the Assimilationist and Pluralist Views of Culture?

The assimilationist view of culture holds that it is necessary for all members of a society to share a set of cultural ideas and ideals in order to achieve “national unity.” This national unity is desirable in order to maintain the nation’s steadfastness against other, possibly threatening, nations of the world. The assimilationist view of culture has traditionally held high expectations for the schools: The schools have
been hailed as the purveyors of the mainstream society—the vehicle through which immigrants will learn the one, common culture; the one, common language; the one, common shared set of civic notions and ideals that are necessary to be considered “an American.”—“one of us.” In this light, the assimilationist view of culture has seen the schools as a unifying mechanism (Dewey 1916; Handlin 1951; Hechinger 1978). Since the idea is that cultural diversity will lead to differing, contrasting, and opposing views, the schools have been charged with the task of replacing heritage culture with that of the mainstream culture. What has occurred in the schools can be considered a “deculturalization” of immigrants. In contrast, a basic tenet of multicultural education is the concept of cultural pluralism. This basic tenet affirms that not only is it possible, but also necessary, to affirm heritage cultural and linguistic roots while simultaneously sharing a set of societal principals. In the cultural pluralist view, the differing groups can, and do, maintain unique values and ideals, while strengthening and adding to the mainstream group. Within the cultural pluralist view, schools therefore are, and can be, the instruments for discovering and valuing different cultures.

What May Be the Ramifications of the Assimilationist Perspective upon Majority and Minority Students?

Deculturalization has taken root by portraying the dominant culture in the classroom via texts, activities, teachers, and personnel. Deculturalization, at the least, simply does not include the minority cultures in the curriculum. At its worst, deculturalization has taken root by the inclusion of, but negative portrayal of, minority cultures in the curriculum. The result can be detrimental upon majority and minority group members. The majority student may not see that the minority group is, and probably has been, a constant influence on the majority culture. Instead, the majority student may only see the difference or the “otherness” of the minority student. This separateness and idea of seeming newness may cause the majority population to be perhaps fearful of the perceived economic, cultural, and linguistic impact that the minority group may have in the communities. Negative perceptions and in, extreme cases, hostility and/or violence may ensue.

These concepts also have, of course, negative impact upon minority students. Research indicates that the positive or negative perceptions of the mainstream population toward the minority population can affect the academic performance of language minority students as they internalize the perceptions of the mainstream population towards their minority culture (Ogbu, 1978; Skutnabb-Kangas & Cummins, 1988). Further, research indicates that another impact of cultural stereotyping is the negative influence upon self-esteem. As Ogbu 1992 has argued, lowered self-esteem can negatively affect the “locus of control”, or the perceived control that one has over one’s environment. Decreased self-esteem as a result of cultural stereotyping may therefore lead to the inability to see the relationship between one’s actions and the response of the outer environment to those actions. The idea that “no matter what I do, it doesn’t matter—the teacher will still not expect very much from me; the other kids still will not like me; even, my parents will not understand me etc., etc.,” can lead to hopelessness, and abandonment of plans. Racial and cultural discrimination, whether it is real or perceived, examined or unexamined, is a reality in culturally pluralistic communities. And this reality of cultural and racial discrimination often first becomes a reality for the minority student in the classroom (Cummins 1986, Ogbu 1992). Considering the above points from the literature, it is necessary to integrate the teaching of culture in the mainstream classroom, for academic well being of both the majority and the minority students.

Why Should Technology be used in the Integration of Culture into the Mainstream Classroom?

There has been a great deal of literature, both research and theoretical literature, which offers advice on how teachers can integrate culture through print media and through published synopsis about the cultural minority group. However, as has been noted by Ovando and Collier (1996), often the necessity to present conclusions about a group can lead itself to a cultural reductionist view of that group—in effect, creating or perpetuating a stereotype. For example, there may be an emphasis and an oversimplification of historical
outlines, cultural traditions, foods, and dress. This is one of the disadvantages with using print media alone. This is one of the disadvantages to using, in particular, print media about a group that has been created largely by the dominant group for majority members. In addressing this problem, or we may think of it as a challenge – in addressing this challenge of taking a fresh look, of unburdening oneself of one’s own preconceived notions, it is necessary to invite members of that community which we are examining to help construct cultural knowledge that is not static nor merely descriptive. In attempting to move away from prepared, published cultural synopses, we will, by necessity, begin to seek cultural information from our students and from our communities. By viewing our students and our community members as the “cultural experts,” we will begin to focus upon the unique culture of our students and our communities, rather than focus upon generic cultural portrayals often presented in published synopsis. It is in this light, in the moving beyond print media alone, that technology can, and must, play a part.

How can Technology be used to Develop Cultural Activities?

First, it is necessary that as teacher educators, we encourage our teachers to expand their notion of technology. It is important that we encourage our teachers to think of technology in terms of mechanisms by which we communicate. As such, “technology” can include: Audio, Video, CD-ROM, WWW, Telephone, e-mail. An occupational hazard shared by many teacher educators is the often-heard sentiment: “But I don’t have technology in my classroom, school, district.” A lack of readily accessible “technology” is indeed a challenge. Therefore, while encouraging our teachers to expand their notion of “technology,” it is important that we encourage teachers to use the technology that they do have. This shift in thinking can assist teachers to move beyond the concept of technology as “a computer” and being wistful for what they could accomplish “only if” -- toward thinking about technology as mechanisms by which we are already communicating. By expanding our notion of technology and using what is now accessible to us, we can begin to develop technology-based cultural activities that can, and possibly already do, have a meaningful role in our students’ everyday lives. Secondly, it is necessary to consider who will be part of information gathering for cultural projects. Research literature abound with the importance of parental and community involvement for the academic well being of students. Therefore, it is necessary to consider the community members who can, and should, be included. There is no need to think of this as an overwhelming task – one need not try to reassemble the local chamber of commerce for one’s classroom activity! Community members of that cultural group usually are present in the school and local community. These are community members with whom the children come into contact with during the normal course of the day: teachers, aides, lunch room attendants, janitors, neighbors, candy store owners, day care providers, those who run the video parlor, or the produce stand, or take tickets at the movie theatre. Of course, we will also add the members of the virtual community – all of them are the threads of the cultural tapestry that we will be tracing. Third, it is necessary to try to focus upon the information that is being gathered about that group. In contrast to the assimilationist perspective of culture, the pluralistic view contends that it is the accumulation of cultural, socioeconomic, and linguistic detail that is the basis for a realistic understanding. Pedagogical innovations using technology must, and can, focus upon rooting out such an accumulation.

When developing technology-based cultural activities that “root out” the cultural, socioeconomic and linguistic details of a particular group, one needs to begin with guiding questions that will help our students “dig” and “discover.” Consistent with this paper’s thesis of multicultural education, the guiding questions of our cultural activities need to open a path toward an understanding of the particular group itself – by examining the group itself in contrast with the other group – and also as a part of the other group. Consistent with this paper’s metaphor of the cultural tapestry, the guiding questions of our cultural activities need to open a path toward tracing the individual cultural thread – by examining it as a unique thread with its own color and texture that is unique – and also as a thread which is part of the larger design. Some guiding questions that teachers can use to develop cultural activities are suggested below:

1. How is ethnicity reflected in the immigrant or indigenous status of the group?
2. What is the socioeconomic role that the group plays in the dominant society?
3. How has the group historically influenced the history of the dominant group?
4. To what degree is the group a stable or mobile population?
5. How has minority status, or acculturation, or both affected the relationship between the younger and older generations?
6. How is wealth distributed in the community?
7. Which community members tend to have higher status in the group, and why?
8. What are the perceived socioeconomic rewards for literacy and school achievement?
9. What are the socioeconomic costs and benefits of membership in the particular group?
10. How is language viewed by the group? (Ovando & Collier 1996)

These kinds of questions try to illicit information about the group's own concepts of power, economics and social strata. Because these questions prompt the information gatherers to move beyond preconceived notions, such questions can encourage our teachers to design cultural activities that move beyond pre-prepared print media alone. Because such questions prompt information gatherers to seek real-life community informants, such questions can encourage our teachers to design cultural activities that require that students make meaningful use of accessible technology.

**How can Technology be Used to Implement Cultural Activities?**

Research literature abounds with the idea that certain types of technology can best practice particular language skills. For example, it is well cited that the use of audio can develop listening skills; the use of word processing can develop writing skills, etc. However, often the use of technology coupled with cultural education is scarcely dealt with in the research literature. (Shrum & Glisan 1999) Therefore, it is further critical to remember that cultural activities, with technology, encourage the practicing of all the language skills: reading, writing, listening, speaking, presenting, viewing, critical thinking. Using technology in the development of cultural activities discussed here can be part of most of the content area classrooms: social studies, science, math, as well as language arts and ESL. Therefore, using technology in such cultural activities can be helpful for the academic progress of both the majority and the minority student.

When deciding upon the focus of the cultural discovery activity, as guided by the suggested questions above, specific technologies can prompt different means of accumulating cultural knowledge about a particular group, and hence, address the guiding questions. Table 1: Types of Technology-Based Cultural Discovery Activities delineates suggested activities with the appropriate technologies.

Table 1: Types of Technology-Based Cultural Discovery Activities

Consistent with the pluralist tenets discussed in this paper, the major purposes of these activities are 1) to involve the students with the community members in a meaningful and realistic way, and 2) to encourage the students to uncover how the minority group is distinct — yet how it is, and has been, and possibly will be, a part of the majority group.

Conclusion

Cultural stereotyping and misunderstanding, whether it is real or perceived, examined or unexamined, is a reality in culturally diverse communities. And this reality often first becomes a reality for the minority student in the classroom (Cummins 1986, Ogbu 1992). Mere inclusion of cultural portraits in the form of print media and published synopses alone can sometimes fortuitously create or perpetuate stereotypes. However, with accessible technology, teachers can develop meaningful cultural discovery activities that encourage our students to discover and share the various cultures alive in their own classrooms and communities. Technology-based cultural discovery activities can help our students to see that their own unique cultural threads are not tatters — rather, their unique cultural threads, together, weave the larger, common tapestry of our multicultural classrooms.

Gender Representation in Visuals on School Web Pages  
Course For In-Service Teachers

Wendy Maboudian  
Industrial Technology Education (ITEC)  
College of Technology  
University of Houston  
United States  
wmab@uh.edu

Abstract: This paper is based on the findings of a qualitative dissertation that examined K-12 school web sites in a large U.S. school district. The study used semiotic methods to examine web site visuals for evidence of differences in gender representation. Educators who design or oversee school web sites should be aware that visuals published on their pages may have more than one possible interpretation and that the school web site itself influences the viewer. The authority of the school, when published in public domain web pages, can be an impressive credential to the visuals on the school web site and the meanings that those visuals deliver to individual students. Based on semiotics, a concept entitled cybiotics explains how the context of visuals are changed on a web site, and a revised model of, What You See Isn't What I See (WYSIWIS), guides review of visuals to avoid gender stereotyping (Maboudian, 1999).

Introduction:
There are an increasing number of school web sites on the Internet. Entering the words: school web site can produce approximately nine million hits. Photos of children and animated gifs on the pages of school web sites represent what the school deems appropriate roles and behavior for the children who attend that school. Whether the web site is meant to be a brochure for prospective parents, or is actually accessed by the students, a message is intended by those responsible for authoring the web site. It is important to understand the nature of the web and the identity of the student viewer to fully understand the impact of visuals on gender.

The Power of the School Web Site
The introduction of computer technology in schools has been described in literature as promising students greater equity and opportunity to learn by its inclusiveness of gender (Kaufman, 1998; Wolf, 1998). However, for female students who see photos that sustain gender stereotypes, technology provides a new format for the familiar issue of inequity. There is a diachronic relationship of gender representation on school web sites and stereotypical illustrations in school textbooks (Apple, 1980; Apple, 1993). Just as gender stereotyping in textbooks has been denounced, computer magazines and games have also been criticized in recent literature (Weinstein, 1998). The visuals in school web pages have not received as much attention. Part of the reason may be that some of the photos are selected from what really occurs at school and are used as a journalistic format to illustrate events. Who would object to a photo of elementary school children in a garden project? If the photo shows the boys standing in the foreground with signs, shovels, and plants while the girls are standing in mixed groups behind them, possibly without tools or plants, then the photo may highlight a situation that, while a factual record, is less than equitable. One might say that this was a candid shot of the children. However, this particular photo was posed and, more importantly, the photo was singled out for a web page showcase. Consider the possible meanings that a student viewing the web site might interpret from the photograph. The representation of the event is more than a slice-of-life photo in a newspaper. The photo represents that which is valued by the school as an authority publishing onto the school web site. The web page is sent out beyond the school walls and is available for frequent access, symbolizing acceptable student behavior, not just an event during the past week. The question could be asked of the school web designer whether a different photo should be used.
This introduces the issue of selection and of determining the meaning of what is selected and the impact of the medium of the school web page.

The term selection is used because the appearance of visuals goes through a selection process. The arrangement and selection of visuals is an author's choice, limited by stakeholders who have a claim on the decision-making process of the web site appearance. Whether created specifically for the school web page, or selected because they represent an event or student behavior, web site visuals are meant to send a message to a world wide public. The selection of visuals and the authorization to publish them on a district's school web site, a new and highly respected technology, imbues these visuals with authority, as well as the meaning interpreted by the student who views them.

The school yearbook has visuals that represent the students' interactions in the arena of a school, yet it is generated once a year and is in paper format, which students take part in creating and use as a keepsake and autograph book. The textbook, which interjects visuals into the student's educational experience, is from a source external to the school and is not generated electronically at this time. The school newspaper is developed by students with faculty supervision. While it is a school publication, it is a student effort and a learning tool. The technology bringing the visuals to the student through the school web page is an adult enterprise. The selection of the visuals may be made by adults as well. The differences in the nature of the school web site indicate the need for educators to be aware of the impact of visuals through this medium. The visuals in the school web site at this time are often published by faculty or administration to represent the school's approved student activities and behaviors. If boys are in the forefront; if there are more boys represented in computer labs than girls; if the girls are seen chatting in the computer labs while the boys are working with the computers; or if the animated gifs depicting computers can be interpreted as male personifications, then the message that the visuals send may not be equitable. The caption might not indicate differences when one reads, Computer Lab, but the visuals may.

Cybiotics

An analysis of school web site visuals includes examining the medium itself. The PC monitor becomes a lens through which the individual views the school web site. Meaning derived from a visual is interpreted by the individual. The fact that the visual is seen through a monitor on a web site builds more meaning into the visual. The publishers of the official school web site are state or private institutional authorities. The visual represents the view of the educational authority, or logically, the visual would not be published. The selection of these visuals are, in a sense, academic engineering in that the visuals are brought into a new relationship to one another within the PC monitor. The computer club may be one click away from the home page representing the mission of a school. The sports activities may be represented on the home page itself. The absence or placement of other school activities can make a statement regarding their value.

Cybiotics (Maboudian, 1999) is the concentration of information on the web page of a web site, putting it into a different context of meaning because of the web site design. The familiar photos of students in school activities are concentrated and arranged via navigation and separate pages. They are labeled according to what the visuals represent to the school. The cybiotic design of limited numbers of visuals on the web page necessarily leaves some students out, and some activities out. Certain visuals are seen immediately and others are accessed beyond the home page, perhaps after scrolling or clicking through other material that was designed to be accessed or seen first. There may be, then, a rating of importance, embedded in the design of the Web page. In actual examples from the district studied, one high school showed an animated cheerleader (a real student), going through an abbreviated routine on the school home page. The same high school had a photo of a male student in a technology-based art project (a magazine with their own photo on the cover) and another page had a photo of girls in their cheerleading costumes sitting on hallway stairs. On another page in the same site, the language lab had computers populated by male students only. Another page had girls pointing to the door of an administration office, while still another page had a photo of girls in their cheerleading costumes sitting on hallway stairs. A student viewing these pages within their school web site may get an impression of the school activities that are not proportionate to the actual participation of students or academic value. This is the nature of the cybiotics (Maboudian, 1999) in web design.
Possible Interpretations of School Web Site Visuals by the Female Student

This section explores the possible interpretations of the messages in visuals based on student gender identity. Muffaletto (1994) explained that the visual is reproducing a pre-existing meaning, which communicates concepts to the viewer because there is a relationship between the concept and the way the viewer understands it. "It is through ideology, the relationship to the 'way' things are perceived to be, that the individual comes to know her/himself." (p. 300). This idea -- that the meaning of a visual is derived through the individual's relation to its concept based on ideology and identity -- is at the core of this paper and explains why the educator selecting visuals should attend to the cybiotics of the web environment, and, above all, to student identities.

An object, a visual, or any artifact we view holds a meaning that is pre-existing in society, but is also based on the way the individual views it in relation to self. The relationship is based on the social identity of the viewer. We have seen historical visuals depicting the female identity of other eras. It is often easier to comprehend the female identity through old photographs. The more common the meaning is in visuals, such as those which we see today, the more difficult it is to recognize the social construction of gender identities (Berger, 1998; Chandler, 1998). If we cannot recognize gender identities and stereotypical limitations of those identities, it is difficult to avoid those limitations. The acceptance of common inequities in gender differentiation in a school web site, can have far-reaching effects in other spheres and can become accepted as natural (Rakow, 1992; Simon, 1996).

Not only does the female identity exist, but it exists in diverse forms. "Within a picture, there are meanings assigned to colors, objects, relationships between objects, genders, races and ages." (Muffaletto, 1995, p.302). The interpretation of a visual depends on the social identity of the individual, which includes gender, and which directs behavior through a role-taking action that is culturally appropriate by groups within a society (Carspecken, 1996; Muffaletto, 1994; Simon, 1996; Wiley, 1994). The visual representation of female gender in the school web site needs to reflect multiple female identities. The identity of the female student may incorporate that of a cheerleader, or an A student...or it may not. The visuals in a school web site that do not address a variety of possible female identities limit students or exclude them. Visuals that present stereotypical representation of females are abundant in clipart and animated gifs (Knupfer, 1997). Photos that represent an absence of female students in an activity appear in web sites. The presence of stereotyping and the absence of female modeling in the area of computers both discourage female participation.

Semiotics, the system of signs (such as those in visuals) that have social meaning (Chandler, 1998), supports the examination of the social interpretation of the viewer. Awareness of semiotics when selecting a visual in a school web site can help the web designer understand the variations in student interpretations. According to Berger (1998) semiotic 'Codes are highly complex patterns of associations that all members of a society learn. These codes or 'secret structures' in people's minds, affect the ways that individuals interpret the signs and symbols they find in the media and the ways they live." (p.26). Berger reminds us that codes can be so commonplace that they seem to be natural. The codes are not only the elements we see, but are the meanings we learn to give them.

According to Muffaletto (1995) these codes construct the identity of the reader. A juxtaposition of a male student at a computer working and a female student at a computer, turned in her chair, chatting, are meaningful outside of the context of the photographic moment and within the cybiotics of the school web site. The student reading a visual in the school web site will read not only what is there, but also what is not there. A male student sitting alone at a computer can mean the absence of a female counterpart. The absence of girls at computers may communicate an unspoken expectation of a behavior that literature describes as hidden curriculum (Apple, 1998; Carspecken, 1996; Noble, 1998). In this case, hidden curriculum can possibly prohibit females from using the computers in ways that the boys use them and, in a larger sense, could prevent female students from going into higher paying, prestigious jobs in computer technology fields.

The information in Tables 1 and 2 is a variation of the model developed for the dissertation upon which this paper is based (Maboudian, 1999). The information within the grids is based on three sources on semiotic analysis, Van Zoonen (1994), Berger (1998), and Chandler (1998). These tools can help the educator examine visuals that are intended for a school web site. Using these grids as guidelines, the web
designer can observe the visual and ask a series of questions about possible meanings. While these matrices are not complete (more qualitative analysis should be done) they provide a start towards awareness of the possible interpretations female students may have regarding a visual.

The first step is to look carefully at the visual, viewing the elements as listed in Table 1 to become aware of the content of the visual. Possible codes exist in visuals that provide information about the meaning. Examine visuals for the following qualities:

<table>
<thead>
<tr>
<th>Personal</th>
<th>Situation</th>
<th>Technical</th>
<th>Contextual</th>
</tr>
</thead>
<tbody>
<tr>
<td>Posture</td>
<td>Background detail</td>
<td>Lighting</td>
<td>Composition on the page</td>
</tr>
<tr>
<td>Attitude</td>
<td>Props</td>
<td>Distance</td>
<td>Page format</td>
</tr>
<tr>
<td>Pose</td>
<td>Secondary characteristics in the shot</td>
<td>Definition</td>
<td>Relationship with Caption/Text</td>
</tr>
<tr>
<td>Gesture</td>
<td>Spatial relation between people</td>
<td>Contrast</td>
<td></td>
</tr>
<tr>
<td>Activity</td>
<td>Clothing</td>
<td>Animation</td>
<td></td>
</tr>
<tr>
<td>Eye contact with the reader</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Signs of social role or position</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 1. (Sources: Van Zoonen 1994; Chandler 1998)

As each element stands out, the next step is to ask questions about the elements and how they work to form meaning that can be understood, as seen in Table 2. Part of the process here is to identify what everyone would be able to see and determine how it fits into possible identities. Think about what various individuals with their own experiences might think of the visual. Don't be satisfied with one point of view. For instance, an old fashioned picture of a little girl in a schoolhouse raising her hand to answer a question could be interpreted in many ways. Her pose may be interpreted as being a good student. However, a student might see her as a teacher's pet. Another might see her as a sissy who can't play sports. Still another may find that the time frame of the forties presents a time when the female's role was limited.

Table 2. (Sources: Van Zoonen, 1994; Berger, 1998; and Chandler 1998)

Conclusion

The selection of visuals to be used in a medium that is an official representation of the school requires an understanding that a message sent is received and its meaning is then interpreted. The effect of visuals on behavior can be seen in something as common as our use of visual representation to decide which restroom to use. The unwritten sign on the door, marking it male or female, indicates the appropriate choice of restrooms based on gender. In a similar way, the visuals on the monitor screen influence the viewer.
As educators are learning how to create web pages, attention is given to the techniques of design and the technology of successful publication, with navigation and animation, "bells and whistles", and adherence to student privacy and to copyright laws. Is as much attention given to gender representation? While educators are aware that there is a lack of gender equity in computer technology, the use of the school Web page can possibly address the need for equity. The first step is to be aware that every picture tells a story and that the story may have a different ending for different viewers. The process for selecting the photos for publication on a school web site should be reviewed carefully. Photos of convenience, already in web-compatible format, or animated gifs that are "cute", should be examined for possible semiotic interpretations before putting them "up" for students to view.

More effective processes may be developed to select visuals that provide role models for equity, not simply to eliminate bias. Foucault (1984) described how architecture changes human behavior. Put a fireplace inside a home and the activities there change. The visuals in school web sites may also help engineer the role of the female student. Changes in stereotypes through visual representation on the school web site can engineer more choices that compromise the female student's identity. If not, then the continuance of stereotyping in the female student's representation can impede her progress in areas of computer use. Visuals can limit what the female student can and cannot do within the definitions of her identity (Knupfer, 1997).

By developing a process for the selection of visuals for school web pages that incorporates an awareness of student interpretation, and the effects of cybiotics, educators can avoid visuals that either stereotype students, or fail to provide an greater opportunity to expand student roles. While the selection of visuals for the development of a school web page is done with the good of the students in mind, there is more potential good to be done and potential harm to be avoided. The school web pages that comprise the site can promote female participation in computer-based activities by leading the way through visual representation.

Within Student Comparison of ESL Acquisition-Through Content Between Virtual and F/F Seminar for ESL and Native Speakers’ Negotiated Meaning

Stephen Carey
Department of Language and Literacy Education
University of British Columbia
Canada
stephen.carey@ubc.ca

Abstract: A comparison of virtual and F/F seminars for academic content and ESL acquisition by ESL and NS graduate students studied the nature of discourse analysis and negotiated meaning. On-line asynchronous WebCT bulletin boards allowed for recording and subsequent analysis of students contributions on-line. Tape-recordings of student live-seminar participation were analyzed and compared to virtual seminar participation by both NS and ESL students. Analysis of these negotiated meanings as well as formative and summative interviews and student diaries revealed a complementarity and synergistic relation between the on-line and F/F seminars. ESL and native speakers claimed efficient academic reading and writing improvement and that these gains transferred to their oral performance in the F/F seminar.

Introduction

Constructivist versions of academic content acquisition through a second language and second language acquisition through academic content learning place a strong emphasis on the opportunity for extensive utilization of all components of throughput (Carey, 1999a,b). These components of throughput include successive intake samplings from the input concurrent with successive interpretive attempts to assimilate the input in terms of their prior learning or schema and subsequently successive constructions of output in terms of interpretations of how that output will be received and perceived as appropriate output appropriate by the imagined audience and their interpretation of the output, Carey,( 1999a,b). In my flow chart which conceptualizes this process, I propose that both ESL and native speakers of English may make successive attempts to interpret or assimilate the input or message in a seminar as provided by either an on-line bulletin board or a comment or question provided by a professor or student question in a seminar. Typically, in either case, the student will sample with successive intakes from the input to assimilate this information to existing linguistic and academic schema. An inadequacy in either linguistic or knowledge schema will result in disequilibrium causing successive iterations of this cycle of intake samplings in an attempt to comprehend the input (assimilation) or modify the schema (accommodation) which constitutes learning. In this research, we tried to investigate and compare how ESL students and native speakers of English would negotiate meaning in either an on-line bulletin board communication or a Face to Face (F/F) mode of common course delivery. In particular, I wished to study the interaction of how inadequate academic language schema, which varied between ESL and native speakers, and inadequate academic content schema, which varied across students due of differing prior knowledge, would influence negotiated meaning by individual students and by collaborating students. I recognized that both variables constituted a continuum and a study of the interactions between these variables and on-line bulletin board activity or live face-to-face seminars could provide insights on the role of negotiated meaning and language and content acquisition. The study of inadequate prior knowledge of language or content could also be represented as a continuum in terms of the degree of communication channel capacity that inadequate linguistic and academic schema might require. I also wished to further consider the continuum of automaticity of information processing that such diverse situations might entail. Carey,(1984).

A graduate seminar of 12 students engaged in graduate work on second language acquisition research (5 ESL and 7 native speakers) that had equal on-line and F/F required components allowed an opportunity to study how both ESL and native speakers would differ in their discourse between on-line bulletin board discourse and live F/F discourse and the interaction between the two. Students enrolled in the graduate seminar on Narrative as Inquiry were required to participate in both the on-line bulletin board virtual seminar (50% of course grade) and the live weekly F/F seminar (50% of course grade). Several of the ESL students were recent arrivals from Asia who had
minimal TOEFL scores of 580 and varied in their ESL communicative ability. Other ESL students included Europeans who had attained higher levels of ESL performance and had received their university education in English. The native English speakers all spoke a second language with considerable proficiency and taught that second language.

This design which I have used previously in research on other courses, Carey, (1999a,b; 1998); Carey & Crittenden, 1998 permitted a within-subject comparison of virtual seminar discourse and F/F seminar discourse for both ESL and native speakers of English. It also allowed between-subject comparisons of ESL speakers with native speakers in the virtual seminar as well as in the F/F seminar.

Method:

The 12 week graduate seminar on Narrative as Inquiry required that students engage in as much interaction and negotiated meaning on course content as possible in both the live seminar and the virtual seminar. Collaboration and co-operative learning rather than competition were promoted and joint projects were also encouraged. Student readings included theories of learning flowing from the work of Piaget through to Rumelhart and other contemporaries who have borrowed so liberally from Piaget's genetic epistemology. In addition the course included detailed readings and discussion of second language immersion and language acquisition through content teaching. Students were encouraged to reflect on these readings to develop their own metacognition on their second language acquisition through academic content acquisition.

The virtual seminar which utilized WebCT asynchronous bulletin boards included activities to encourage students to engage in open discussion of the process of their second language process and how negotiated meaning and collaborative learning could contribute to a greater awareness of their second language acquisition process as well as their how their interactions and negotiated meanings facilitated their academic course content acquisition. All of these social cognition activities were recorded on the electronic bulletin board and submitted to detailed analyses. In addition, the live discussion and interchange was recorded in the live seminar and the nature and frequency of comments by ESL and native speakers interventions and participation were noted daily. In addition, informal interviews of both ESL and native speakers were conducted throughout the course and students were encouraged to write diaries and keep notes on the development of their awareness of their metacognition and how their acquisition of academic content and academic English were progressing as well as how they were differentially influenced by the two modes of seminars and their interactions with ESL and native speakers. All students were encouraged to work in a collaborative manner and to help each other in academic writing and gaining knowledge of the diverse cultures represented in the seminar.

Results:

Frequency of contributions:

Since the ESL graduate students were given strong incentives through grades and consistently encouraged to participate in both the virtual and live seminars it is instructive to compare their contributions in the two modes of seminar delivery. At the outset of the course the ESL students made many more contributions to the virtual seminar than they did in the F/F seminar. They also made far fewer contributions to the live seminar that the NS and the contributions they made were brief and in some cases they were either unable to make themselves understood or they were unable to understand the response by a NS to their contribution. In spite of the very positive and forgiving ambiance in the seminar, this inevitably led to some loss of face. In interviews they reported that contributing on the virtual seminar was far less anxiety inducing than contributing in the live seminar and unlike the live seminar it allowed them time to construct and verify their response to a message in a more productive way. This was also due to the “less embarrassing” situation in the virtual seminar which allowed them unlimited time to reflect on the question and to construct or choose an interpretation that seemed most probable. It also allowed them to reflect on the question and to consult other resources and then to construct and edit an appropriate response. These ESL students also found that this added time allowed them to function in a more optimal learning environment and to negotiate meaning and to collaborate with their colleagues and to engage in co-operative learning while improving their academic reading and writing in ESL. These students also claimed that this opportunity to negotiate the content in their ESL allowed for rapid ESL acquisition and that these learning transferred into the live F/F seminar.
They also claimed that the virtual seminar made it possible for them to acquire the idiom so that they could participate in the live seminar. Therefore, there was a noticeable increase in contributions by the ESL students such that by the end of the 12 week course, the ESL students contributions in the live seminar were at a level comparable to that of native speakers. This demonstration of how the virtual seminar allowed ESL students equality of access to learning on the virtual seminar and that this equality of participation facilitated their gradual increase in participation in the live seminar stands as a reminder of how technology can promote equality of education.

However, while this was most prevalent for the ESL students it was also true for all of the native speakers as well. They also found that the asynchronous discussions on the virtual seminar allowed them to be more thoughtful, less rushed and more conducive to expressing their well formed thoughts on issues and questions. Native speakers reported that their academic reading comprehension and writing also improved from activities in the virtual seminar. These students also claimed that this thoughtful discussions that was student centered allowed for the emergence of a certain sense of a community of scholars who claimed that they felt more autonomous and empowered to discuss important course content issues and this allowed them to get to know each other and their different perspectives on academic issues reflecting their diverse prior knowledge and cultural backgrounds. Moreover, this transferred to the live seminar so that it greatly improved their level of discussion in the live seminar. This spontaneous practicum in the socialization of language and learning was an added benefit of the on-line activity.

Other measures of change in the 12 week course revealed in the interviews.

In interviews all of the ESL students found that the virtual seminar was particularly conductive to facilitating both their ESL acquisition and academic content acquisition. They all claimed that SLA through content immersion was the most effective way to improve their academic reading and writing. They also claimed that the on-line writing greatly facilitated their oral contributions in the live seminar because they would be thinking and speaking aloud as they composed and recomposed their messages to post on the bulletin board. In addition, the responses they received to their communications greatly increased their self-confidence in their ability to both express the academic content and their second language. The ESL students also offered their opinions as to the superiority of this course in helping their learning compared to other graduate courses they were concurrently enrolled in. Two of the five ESL graduate students either dropped other conventional graduate courses or changed their registration to audit status. All ESL students claimed they acquired more ESL academic reading and writing as well as more academic content in this combined live-virtual graduate seminar.

In interviews of the native speakers there was a consensus that the virtual seminar greatly increased the opportunity for the students to work collaboratively and to negotiate meaning and to become more aware of their metacognitive skills. They also claimed that they learned more than in a conventional course because they were more actively involved and the participation in the socialization of learning both academic language and content greatly facilitated their progress. Several native speakers also claimed that working with and watching the progress of the ESL students helped them to understand their own growth in academic reading and writing to a some degree.

All students agreed that the opportunity to post their term papers on the bulletin board so that all other students could collaborate and offer opinions on improving each term paper was highly useful for added learning and that the collaborative and interactive learning model promoted a higher level of learning for all students. Students also agreed that the flow chart model was a good representation of how they felt they processed the information and that the constructivist orientation was a heuristic metaphor for explaining how they learned.

VIRTUAL INTERACTIVE WORKSHOP:
a pedagogical art education view into the computer lab

Maria Cristina Villanova Biazus
Universidade de Caxias do Sul

Curso de Pós Graduação em Informática da Educação – CPGIE/UFRGS
cbiazus@portoweb.com.br

Abstract

This paper deals with educational issues one faces while interacting in digital environments. The field of art education in these environments as well as the new concepts that involve the processes developed in their use are the main focus of this study. The main concern is to verify how and whether the digital environments can provide a practice that is strengthening and effective and whether they can make it possible a teaching-learning process with excellence. Knowing how these processes engender the cognitive development of the students concerning the possibilities that these computer based environments are able to offer is our challenge. Are these computer mediated environments able to help develop creation in a constructive sense? Cyberspace, multimedia, online are every day words in the contemporary world. How can educators grasp these meanings in order to develop ways to fully integrate them into their pedagogical issues without simply transposing old practices into new environments?

Introduction

Digital technology is being used more and more by contemporary artists. Web art, net art, electronic art and other new forms of artistic production are subject of discussion by art educators who are concerned with the use of this new technology in their classrooms. This is a project which tries to articulate three areas of knowledge, integrating aspects of art-education, developmental psychology and computer science to make up a work plan based on the reference theories in each one of those areas. We are trying to answer some questionings that justify the insertion of the digital technologies as a work perspective in the pedagogical field. We are observing the educational processes in the construction of cognitive possibilities developed by the students during the interaction with the computerized environments.

Digital Technologies in Education

This study investigates how the insertion of the education professional can happen in a field that is new and that presents challenges in the construction of knowledge specific of its field. This occurs exactly due to the characteristic mobility of the telematic environments in order to place in this field the teacher’s possibilities to help develop in the student the artistic knowledge, which brings about an aesthetic awareness. This educator should be a competent critic for whom the artistic and aesthetic knowledge bring new possibilities which can be seen, according to Axt, as a “possibility to recover the already organized in the paths that have been already planned, which can be always retaken by the thought that returns, and it is worth to say that it returns on itself in the construction of the stability”.

This path of construction of knowledge in the language described by Axt, will be retaken by us in issues that deal with the output of the mental activity regarding the transformations of the object in the construction of
the virtual/possibilities. The meta-reflection concerning the person's own work and the others' makes it possible to make a connection among the knowledges and practices resulting in output movements through the visibility of the transformations.

In The Virtual Interactive Workshop we intend:
To use the new technologies of the information and of the telecommunication aiming at an integration of a synchronous combined with an asynchronous pedagogical process that facilitates the development of a sensitive, imaginative, and critical individual.
To observe how the new technologies of the information and of the telecommunication are used by the students while interacting in them in the process of construction of cognitive possibilities, the invention and the creation.
To investigate the possibilities of the educational process in computerized environments, considering their specificity.
To investigate the reconstruction and development of a critical vision, and the possibility of the students to capture the conflict among the several solution alternatives in a computerized environment where hypertextual thinking allows multiple possibilities.
To investigate the new educational environments in relation to the opportunity of decision they offer to the student, which implies working with divergent answers.
To question and to identify the new computerized environments and the interaction possibilities in the construction of a practice that allows to develop the expression and the communication in the visual arts, the significant appreciation and the understanding of the visual arts as cultural and historical product under a contextualized and reflexive perspective.
To investigate these new computerized environments and the new approaches in art pedagogical projects, as well as the development of concepts concerning the real and the virtual when working in the cyberspace.

The Context

Cyber is one of the most used prefixes in the nineties. Those who want to transcend the use of the computer and travel into the cyberspace are the cybernauts, members of an emergent culture, the cyberculture. How to assimilate these transformations and to work with these technologies, which are already integrated into the daily life of our students?

Litwin works on a focus of the computerized society in which the computer is already inserted in people's life, and consequently in the pedagogical action, as she states: "It worries us seriously that a lot of proposed reforms don't consider the changes that were produced because of the technological developments, and think the innovation as the use of the technology especially done for the classroom, without realizing that it is already incorporated, that it is part of the culture of the classroom and that the information that derives from it should be first deconstructed as part of the ruptures that should be created to favor critical thinking".

Litwin's idea finds reinforcement in the schematic differences between modernism and post modernism presented by the theorists where one sees a change in paradigms now facing dispersion, deconstruction, antithesis.

The change from the modern copper phone cable to the post modern optical fiber increases enormously the flow of information. The educator's role is in search of redefinitions in this world of amazing speeds.

On the other hand, the student is immerged in a culture of the imagery, in which the culture of the imitation (a such perfect clone whose difference between the original and the copy is almost impossible to notice) is itself the focus of innovation, and it is starting to suffer effects of some tendencies of its own phenomenon. One of these is the problem of the reproductivity in the era of the mass consumerism. The more an original is reproduced, the more the price of its original work goes up. This consumerist aura extends to all other things. It is the price of the nostalgia - memories of what was manufactured yesterday. There is an image consumerism and what is reproduced occupies the place of reality or it is substituted as a hyper reality. We live on what was already lived and of what is being reproduced.

How can an art educator deal with all these new concepts?

Pierre Lévy says that: "In the digital world, in the distinction of the original, and of the copy there is a lot that has lost any pertinence. The cyberspace is mixing the notions of unity, of identity and of location...... we are at the same time here and there thanks to the communication techniques and of telepresence".
One of the post modem world symptoms that can reflect on education is what is called zapping, or the zero conscience. The remote control, the multiple TV cable channels, the satellite transmissions generate such an abundance of options that one goes through this continuous and impatient change of channels without going deep into anything, it is like making a collage of one's own life, transforming the creation of the post modern life into an endless amnesia, according to some authors.

Another phenomenon diagnosed in the virtual world is lost in cyberspace. The infinite clicking of the mouse in the search of information, resembles zapping in the search of other channels.

This study focus on the computerized environments and telematics due to the fact that research in this area demonstrates that the educators are concerned and want to know the possibilities of this technology that presents new developments every day, fostering and enlarging the possibilities of the traditional interactions in the educational environments.

Development:

Interactivity, the arts, and computer technologies seem to be reshaping the art class, the computer lab and education.

We are working at The Virtual Interactive Workshop challenging the students to look for their own answers to the questions. The activities developed by them in the project are interactions in the computerized environment. They use the Internet for their research.

The use of the electronic means of communication makes it possible to propose themes for discussion involving the visual reading of the own students' environment and of the ones that they interact with during the process.

Students dialogue with the researcher, they send their folios and their reflections about their own production, and they chat among themselves, too.

The data picked in the sessions of the students' interaction in these environments are registered and analyzed. They interact and use the ARTEDUC site as their electronic folio.

The site Arteduc http://www.penta.ufrgs.br/edu/telelab/arteduc/inicio.htm besides facilitating immediate access to several sites of interest for people involved with art teaching/learning has links that are specific about subjects to art teaching in a post-modern world and for the Virtual Interactive Workshop.

Students' interactions with the on-line material in electronic addresses (museums, digital artists, art schools, and others) that foster work in art education lead to a development of concepts favoring aesthetic perception.

Students' art production is done with softwares such as Corel Draw, Corel Photo Paint and the use of the available hardware in the laboratory including scanner, printer and plotter.

All students have their own individual directories in the hard disk. We use the process-folio approach, where all the student's work is saved and a part of the process to be evaluated. These folios are made up of graphic works they make, material they research on the Internet, reflections regarding their own production, projects they write and send to their peers. Students go through their production and make up their own personal folders and include a reflection about it.

Outcomes:

Some of the expected outcomes present some partial data up to now. It can be observed, starting from the production of the students that take part in the research group that:

There is an increase in the awareness processes related to the works of the universal culture which can be accessed in the world wide web - Internet.

The computerized telematic environment facilitates and helps, through its wide access, the analysis and the taking up of decision regarding the choice of works for the development of the art works.

Students appropriate with dexterity of the works on the net and they work on transformation processes, which includes deconstruction, construction and reconstruction of works. The students' own local cultural products are shown integrated in the reconstruction processes and outcomes.

These environments and the possibility they offer of exchanging information with students from other towns and countries seems to increase the feeling of citizenship.
Students seem to be able to grasp the new possibilities offered by the computerized means and of the processes that they make possible. This gives birth to what has been called the planetary hypersubject who transcends the mere technological system of connections.

The work accomplished by the students using the electronic mail and sites of the Internet shows that there is an understanding of the dimensions of the communicational neotechnologies.

The interaction in the computerized environment seems to favor the development of cognitive processes which engender creative thinking.

ALICE - a case study:

Girl - 12 years old - 6th grade. Public school. No experience with computers before starting classes in the Virtual Interactive Workshop Project.

In the 1st and 2nd classes she makes scribbles on the screen with the mouse and in the 3rd one she starts drawing a human figure.

In the 5th class the design of the human figure is getting to be more complete.

In the next classes she prints some pictures of Sandy Skoglund’s work displayed on the Getty site.

As a next step, she makes interferences on these images on the screen changing the background and the form colors.

After a field trip to some of the town’s landmarks, Alice designs a simple form of construction that she names: the Grape Festival Pavilions, (a traditional Fair in town) to which she applies resources of the software and obtains very interesting overlapping effects.

From the 38 to 40 classes, besides the gray scale of tones, she works on a whole set of images of the house which changes into different geometrical forms and she uses distortion.

In the 43 and 44 classes she goes back to the theme of the house, naming the file Stone, as a reference to the Stone House, a tourist attraction that she visited in her town and makes 7 works using the same theme. She applies effects and modifies her own work changing the color, the textures, the form, and so on.

This girl, who started in the project doing computer scribblings, a conduct which we have identified in our Master’s dissertation: The Graphic-Plastic Development of Children in Interaction with the Computer, shows a new attitude facing her work in a real researcher manner. She accomplished, in the 63rd class, 8 works during the period of the class, always looking for new graphic solutions for the same work. These works show the reconstruction and development of a critical vision, and the possibility of the students to live the conflict among the several solution alternatives in a computerized environment.

At first, Alice’s initial drawing of the house revealed a very simple front view form, not even going into any tridimensional perspective. Later on, this is reached through the effects that the software presents which she got to when looking for new possibilities.

This large number of attempts seeking for new solutions of problems leads us to believe that these digital environments favor the search for divergent answers.

We have also observed in this study the fact that to work on an image and try another way of representation from the same original work, without affecting its original form, which can be saved untouched, seems to help the processes and start a delightful and intense experimentation.

The hypertextual availability of the environment as well as the multiple choices of the graphic software allow students to take up their own decisions thus constructing new possibilities.

Conclusions:

New technologies bring about anthropologic changes. These can be identified in the re-presentation of objects, the simulation of something that does not exist, and in that new ways of communication that bring about change in the educational processes.

In which ways do these changes affect our object of study?

Will these processes be able to help develop potentialities such as perception, imagination, observation and sensitivity?
Will they foster new ways of knowing and new ways of constructing meaning?
Can the processes of imagery reconstruction, spatial re-organization be improved in the digital world?
Certainly we cannot think of a synchronous education without contact with the outside world anymore but we also cannot accept an asynchronous education in the traditional ways. Thus, research in this field must be continued.
We don’t have answers to all these question yet, but we do have a lot of questionings to conclude.

Abstract: Project FOCAL Point is a multi-strand project designed to increase female participation in the computing sciences. The project targets two crucial groups: high school computing teachers and female high school students. Features include a two-week teacher workshop, where teacher participants are introduced to technology-related gender issues and collaborate to develop female friendly technology lessons, and a one-week Computer Camp for Young Women, during which teacher participants hone their gender equitable teaching skills. This paper focuses on the teacher participant responses and reactions to the two-week teacher workshop.

Few people doubt that technological skills will become increasingly important as our country enters the 21st century. In view of the high percentage of Caucasian males currently employed in the computing fields and ongoing concern with affirmative action, businesses continue to seek out qualified women and people of color. However, despite acknowledged career opportunities and known financial advantages, these groups continue to be under-represented in the professional work force and in technology-related post-secondary education. The nation suffers, too. Currently, there is a critical shortage of information systems professionals, a shortage that is expected to escalate in the near future at least. We simply cannot afford to have a major source of talent remain largely untapped.

Project FOCAL Point Implementation

Concerned educators must question the reasons for the continued gender imbalance in the computing fields and search out avenues for addressing the equity problem. Project FOCAL Point is one such avenue. The project seeks to get more females into the educational pipeline by working with two essential groups: pre-college computing teachers and adolescent girls. This paper focuses on the first group.

Specific project objectives as related to the teacher participants are to:
1. Acquaint teachers with gender issues as related to computing.
2. Help teachers become aware of unconscious biases they may possess regarding the culture of computing.
3. Introduce teachers to instructional practices known to appeal to women and girls.
4. Provide teachers with technology-related content knowledge and skills.
The detailed objectives were addressed mainly through a two-week summer workshop. Two cohorts of teachers participated in the summer workshop, 7 teachers (4 men and 3 women) in 1998 and 13 teachers (3 men and 10 women) in 1999. The first cohort was composed almost exclusively of senior high school teachers; the second cohort was composed almost exclusively of middle school teachers. All volunteered to participate in the project, and all reported that they taught technology-related education in their home schools.

The first goal of the workshop was to expand the teacher participants’ computer comfort zone and to help them identify more positively with the computer culture, so that they might more effectively teach all their students. The second goal was to acquaint them with features that render a lesson more female-friendly, so that they might more effectively teach their female students.

The first week of the teacher workshop was a blend of training in gender issues, computer and information systems concepts, and computer and network applications—with some portion of each day devoted to each dimension. Workshop instructors incorporated a variety of active and constructive instructional strategies and delivery methods, modeling the teaching behaviors we hoped to inspire. During the second week of the workshop, teacher participants tested their female-friendly technology lessons with middle and high school girls attending a Summer Computer Camp for Young Women.

Activities designed to raise awareness of gender bias ranged from drawing a computer scientist to developing sensitivity to gender-biased language. The active learning experiences were designed to arouse awareness of gender issues as well as inform practice directly. Guest lectures, videos, and workshops rounded out the exposure to gender issues. A concrete models workshop (where groups work together to write directions for constructing a Tinkertoy machine) conducted by the authors, for example, has repeatedly revealed consistent (and disturbing) patterns of male-female interactions and role choices when mixed gender groups work to solve a technical problem.

As enhancing teacher participants’ skill and knowledge of computer and network applications is a major project objective, the teacher participants early learned to navigate the university network. Next, they practiced with the university’s e-mail software and basic Internet searching. Workshop instructors stressed the importance of locating gender-related web sites and evaluating sites and information relative to their appeal to girls or women. During the first summer, all teacher participants learned the basics of web page production. The second-summer curriculum was more varied; options included several programming languages, word processing, and presentation graphics as well as web page development.

Specifically, the evaluation study of Project FOCAL Point attempted to answer the following teacher-related questions:

- What changes in computer attitudes did teachers report as a result of their participation in Project FOCAL Point’s two-week teacher workshop?
- What changes in computer skills did teachers report as a result of their participation in Project FOCAL Point’s two-week teacher workshop?

The Computer Attitude Scale (CAS) was used to measure changes in computer attitudes. The 40-item CAS has been shown to be valid and reliable (Loyd & Gressard, 1984; Loyd & Loyd, 1985). The CAS is composed of four 10-question sub-scales designed to measure computer anxiety, confidence, liking, and perception of usefulness. The mean for each sub-scale could range from a low of 10 to a high of 40. Items on the CAS with negative wording were re-recorded so that for all items, a higher item score indicates a more favorable attitude. The teachers completed the CAS on the first day of their project participation and again on the last day of the summer program.

Changes in skill levels are based on self-report. Data for the skill-related questions were collected on a daily basis as the topics were covered during 1998 and on the last day of the two-week workshop in 1999. As the format of the teacher workshop changed dramatically from 1998 to 1999 (a product of our formative evaluation), the two samples cannot reasonably be combined. Moreover, the small sample size of each cohort precludes inferential statistical analysis. Hence, the cohorts are reported separately, and the analyses are limited to descriptive statistics.
Evaluation Study Results for Cohort One

The results for the cohort one CAS are shown in Figure 1. Given the high initial scores (means of 37-38) and the audience, we did not anticipate dramatic changes; that expectation was borne out. The mean for computer anxiety increased slightly and the mean for computer confidence remained constant. In contrast, the mean for computer liking and usefulness decreased slightly. The individual teacher results for the computer usefulness sub-scale are shown in Figure 2.

The declines, however slight, surprised us and prompted further analysis. Some of the decline (or lack of increase) might be attributed to the teachers' expressed difficulty in reading the negatively worded questions. For example, Teacher 4 strongly disagreed with the statement “Computers will not be important to me in my life’s work.” (a question in the usefulness sub-scale) on the pre-test and strongly agreed with the statement on the post-test. Although it is possible that the two-week workshop effected such a dramatic negative change, it seems unlikely. A more plausible explanation is that the participant misread the question.

The results of the anxiety and confidence sub-scales are shown in Figures 3 and 4. Examination of the data shows that six of the seven teachers uniformly responded positively on both sub-scales, with many scores placed at the maximum possible. The results for computer liking sub-scale are shown in Figure 5. Note that other than the small dip for Teacher 4, the results are uniformly positive—again except for Teacher 7.
Teacher 7 was a Technology Education teacher, who by had done little with computers except for AutoCAD prior to his participation in the workshop. By his own admission, he found himself challenged with the content and the notion of teaching that content during the camper week. He, in fact, opted out of teaching web page development to the campers in his "class," teaching them instead to use AutoCAD. This teacher's experience prompted a change in the format of the second workshop. In 1999, teacher participants worked in teaching teams rather than each participant having his or her own "class" of two or three students.

The teachers were asked to complete a self-assessment of their computer experience on the first and on the last day of the two-week workshop. Figures 6 to 9 show the before/after difference in reported computing experience levels. A comparison of the before and after means show that perception of electronic mail and web page development experience increased dramatically. The latter statistic is not surprising since five out of seven teachers (71%) had not constructed a web page prior to their participation in the summer workshop. Ability with Internet searching increased slightly, and assessment of general computer experience dropped slightly. Since perceptions of experience were (unnecessarily) tied to other project evaluations and therefore reported anonymously, it is not possible to definitively attribute the dip to Teacher 7. It is possible to hypothesize that he overestimated his experience level before he observed what others were doing.

Not surprisingly (given the audience), 83% (five out of six teachers) of the respondents agreed or agreed strongly to use e-mail in their teaching. More interesting would be the reasons for the lone respondent who responded in the negative. The teachers astutely observed that "some female students might not want to ask the
questions in person, but they would ask questions through the e-mail.” The authors add that this observation is probably true for more reticent males, too. From these responses, it is possible to conclude that e-mail will play an important role in the future teaching of the respondents. Five out seven teachers, (71%) responded that they wanted to use Internet searching in their classroom.

**Evaluation Study Results for Cohort Two**

![Graph](image)

Figure 10. CAS Results Cohort Two

![Graph](image)

Figure 11. Scatter Plots—Individual CAS Results

Figure 10 shows the aggregate picture for the scores on the CAS. The high initial responses all increased over the two-week span of the workshop. The scatter plots of the individual responses suggest that a ceiling effect was in place, with the majority of the scores clustered near the maximum score of 40. Moreover, almost all scores fell above the reference line, indicating a higher post-test score than pre-test score.

As indicated earlier, the format of the 1999 workshop varied from that of 1998. During the inaugural year, all participants studied and taught the same topics (with the exception of the lone teacher who taught AutoCAD). In 1999, all teacher participants were introduced to the university network and email software during the introductory sessions. Thereafter, they worked in small groups; each teacher participant studied and taught two classes. The results for the small group instruction is reported in table form rather than charts as the small numbers render the data easy to interpret.
The level of email experience is shown in Figure 12 and the comfort level of teaching email is shown in Figure 13. The movement out of the "low" category is heartening, especially as reported in the participants' comfort level with teaching the topic. Moreover, eight participants strongly agreed and four moderately agreed with the statement that they would use email in their teaching.

The movement completely away from the "low" and "none" categories and into the "high" category is encouraging. Moreover, 19 respondents strongly agreed and 4 respondents moderately agreed that they would incorporate the topics they studied and taught in their instruction. In conclusion, we believe that the data support the hypothesis that the workshop enjoyed some success in accomplishing its objectives.

Major funding for Project FOCAL Point is provided by National Science Foundation Programs for Gender Equity grant HRD-9711023.

Many of the teacher education programs are facing great changes in what pre-service teachers are taught, how they are taught and what is expected of them. These changes are affecting all subject areas, but none more than the educational computing course. NCATE standards are leading the teacher education programs to an integration of the technology in the methods courses and the subject areas themselves, which would lead to the end of a separate computing course. During this transition period, though, many innovative approaches to the computing course are being implemented across our country, and others, as colleges search for effective models for restructuring the educational computing course.

In the NCATE report “Technology and the New Professional Teacher: Preparing for the 21st Century Classroom,” (1997) available online at http://www.ncate.org/projects/tech/TECH.HTM, it is asserted that “teacher education programs should pay careful attention to the National Standards for Technology in Teacher Preparation, developed by the International Society for Technology in Education (ISTE). ISTE recommends that all teachers acquire competencies in basic computer/technology operations, in personal and professional uses of technology, and in the application of technology for instruction. Few, if any, teacher education programs are currently meeting all of these standards.” The teachers of the future should be fully prepared professionals. “This will require new understandings, new approaches, new roles, new forms of professional growth, and new attitudes.”

Several of the papers in this section reflect the changes that are being made in the teacher education programs and how they are impacting the educational computing course. The first paper by Wiencke and Ekhamel, “Insuring the Future: Development of an Exemption Exam for an Introductory Educational Technology Course”, describes the streamlining of the certification process and integrating technology into the courses. By allowing the students the opportunity to take an exemption exam, additional options in their course of study can be provided.

The second paper by Ring and Foti, “How Can We Help Johnny Compute?”, contends that students entering the computing course now are more advanced in their technology skills and that we are teaching them what they already know. Because of the students’ more advanced skills, the educational computing class should be more context-based around conceptual themes so that the teachers can develop technology-rich lesson plans.

The next two papers speak of specific changes that need to be made to the educational computing course. In “Technology for Pre-Service Teachers: What is It?”, Bailey tells of the required course in their program that was reduced to one hour and that the students were expected to have certain technology skills before entering the course. The first trial semester of this changed course allowed the college to confirm topic selections and identify “areas of refocus, better preparation, simplification, and, best of all, political tensions”. In “Preparing Pre-Service Teachers to Use Technology to Teach the Content Areas in Elementary Schools,” Bhattacharjee and Chen describe the technology component for their teacher education program as being composed of five three-hour workshops and a development of an instructional unit by each student. This approach provides “intensive hands-on practice with technology applications in the classroom”.

The next two papers deal with the theory in the educational computing course. In “The Impact of Theory on Technology Use in the Classroom,” Fulton, Courus, and Maers describe a graduate class whose purpose was to create a “theoretical model that could drive and reflect appropriate ways for technology use in the classroom”. This model delineated the characteristics of the role of the teacher, the role of the student, the subject matter and the environment. In “Constructing Technology-Based Constructivism: A New Approach to the Educational Computing Course,” George and Sparrow tell of the drastic changes that were made in the course that allowed students to be much more responsible for constructing their own knowledge about technology and its uses in the classroom.

The next paper by Jin and Nasara “Collaborative Team Teaching Approach in a Technology Course”, depicts an experimental team teaching experience in the educational
computing course. The purpose of this was to "reduce the frustration of students who had limited experience with technology, to enhance advanced students according to their level, and to provide better learning environments through access to various types of technological equipment and groups".

To wrap up this section on the restructuring of the educational computing course is the paper by Ropp and Brown, "Beyond Applications to the Essential Processes of Technology Integration: Designing an Educational Technology Course to Reflect ISTE Standards and to Model Best Practices for the Future". They restructured the course based on the ISTE recommended foundations in technology for all teachers. The course is based upon the three major themes with a macro-view, reflective papers, projects and discussions that all lead to a continued integration of technology based upon the best practices modeled in the course.

The next paper by Swain and Ring, "Integrating Electronic Portfolios into Undergraduate and Graduate Educational Technology Courses at the University of Florida", asserts that use of portfolios will change the way we teach and how the students learn. "Students begin to realize that learning is an on-going process that does not necessarily conclude with a test or a course". Educational technology is about teaching and learning, not computer applications. Students have to reflect on creating portfolios as well as their learning processes and progress.

The next two papers, "Teachers' Comfort Level, Confidence, and Attitude toward Technology in a Technology Course" and "A Comparison of Student Teachers' Attitudes Toward Computers in On-Line and Traditional Computer Literacy Courses: A Case Study" both report findings comparing two different approaches to the educational computing course.

The next paper "What are we Talking About? The Impact of Computer-Mediated Communication on Student Learning" reports the results of a study done to see if online discussions can affect the learning outcomes for students involved in distant learning activities. And the last paper in this section, "Information System Design of Undergraduate Education: Combining Lectures with Practice", proposes that more hands-on experiential learning be provided to help students design and implement systems in the business world.
Abstract: Colleges of Education are under pressure to make their programs more efficient while ensuring that graduates are competent in an increasing number of areas. The College of Education at the State University of West Georgia established an introductory technology course for all teacher education majors to provide needed background in instructional technologies and classroom integration strategies. Although feeling the same pressures to streamline their curriculum as other teacher education programs, West Georgia decided to allow students familiar with technology to exempt the course and take alternative courses, rather than make the technology course optional. It was anticipated that a large number of students would take advantage of this opportunity. However, this has been far from the case. Although the test is well publicized, few sign up for it; of those that do, only a small percentage actually sit for and pass the exam.

Introduction

Colleges of Education are under pressure to make their programs more efficient and at the same time insure that their graduates are competent in more and more areas. This dichotomy of purpose is also apparent in many institutions' decision to eliminate the instructional technology courses to streamline their programs, while national studies show a woeful lack of technology competency in today's teachers (Solmon, 1998). The need for teachers to be proficient in computer skills has long been recognized. A 1986 National Assessment of Educational Progress (NAEP) study, A Framework for Assessing Computer Competence: Defining Objectives noted that "some students know more about computing than their classroom teachers" (NAEP, 1986). It is an accepted fact that proficiency in computer use is an increasingly necessary skill as our world becomes more technologically dependent. Thus the need for teachers to be computer proficient is greater than it was thirteen years ago and will be greater still for years to come.

The College of Education at the State University of West Georgia established an introductory technology course for all teacher education majors to meet the needs of our graduates. This survey course provides students with a background in various instructional technologies and classroom integration strategies. Feeling the same pressures to streamline their curriculum, West Georgia decided not to eliminate the course but to provide an opportunity for students familiar with technology to exempt it. Those exempting the course would be able to take additional classes in their content area. This presentation will provide an overview on how the course and the accompanying exemption exam was created and implemented, as well as its success in providing students additional options in their course of study.
Since early 1980s, the College of Education at State University of West Georgia had traditionally taught two technology courses, an introduction to computer utilization and a basic instructional technology course (both required). Special Education programs. Like many states, Georgia began limiting the total number of credit hours in its undergraduate programs to a maximum of 120 hours. In addition, the Board of Regents, responding to both internal and of content courses required for middle grades and secondary education majors. In response to these required Educational Technology”, and is required for all students entering a teacher education program.

Although combining the two courses reduced the total credit hours, there was a common perception that such a course probably was not really necessary because many students entering college had already acquired the necessary skills during their secondary education. There were further discussions between the College of Arts and Sciences and College of Education faculty and administrators to allow particularly the Arts and Sciences students taking secondary education certification courses in the College of Education the possibility of exempting the introductory course if they had the necessary skills. Students who obtained a satisfactory score on an exemption exam could reduce their total number of hours or replace the technology course with an additional course in their content area. Students in the College of Arts & Sciences would reduce their total course load by passing the exam. However, College of Education students would be required to take another course to replace the credits lost.

In addition, there were concerns by the College of Education faculty, particularly in the Middle Grades program that their students needed to have the necessary computer and presentation skills prior to taking their methods courses. They were convinced that only a few students entering their program would have the necessary technology skills. The faculty wanted to make sure that specific skills and knowledge were covered in an introduction to educational technology course and that students should only be released from the requirement if they proved their abilities through an evaluation procedure. Consensus was achieved on this need, and an exemption exam was developed based upon the topics covered in the course.

How the Course and Exam Were Developed

Media and instructional technology faculty teaching the technology courses were asked to develop the new introductory course and its exemption test. Meetings were held to review the new course objectives and content based on the International Society for Technology in Education (ISTE) Technology Standards for Students (ISTE, 1998). It was also agreed that the knowledge, skills, and attitudes to be conveyed in such a course not only should help the students to succeed in their future profession, but also would provide support in other courses in their teacher training program. Additional meetings were held to involve the faculty who teach the methods courses in the College of Education in the development of the course to insure that the needs of their programs were met.

Topics covered in the course include, Windows operating systems, email, list servers, online resources, word processing, data base development, spreadsheets, and presentation software. Although specific skills in the use of these technologies are covered, the integration of these technologies into the curriculum is also emphasized. Course assignments are primarily project based requiring the students to demonstrate their ability to use the programs.

Exam items were designed to emulate the projects assigned in the course. This was achieved in all areas except in the use of email, list servers, and curriculum integration strategies. Competency in these areas are evaluated through short essay questions that form the written portion of the word processing section. Examinees are given a time limit of four hours to complete the exam. The following are examples of how the competencies are evaluated in each of the topic areas:

- Operating Systems - Examinees are given two flexible disks. They must format the disks, create a folder (subdirectory) and copy specific files from the hard drive of their computer to specific areas of the flexible disk. All the remaining projects are saved to the disk. At the end of the exam, the examinee makes a backup copy using the second disk.
- Online resources - Examinees are given topics on which to obtain information through online resources such as ERIC, library catalogues, and the Internet.
- Word Processing - Examinees are given specific format requirements for margins, fonts, headers, and footers to evaluate their word processing skills while completing the short essay questions on email, list servers, and integration strategies.
- Data Base - Examinees are given a set of data and are required to create a data base with sufficient fields and records to hold the information. In addition, reports are generated to answer specific questions based on the data provided.
- Spreadsheet - Examinees are given a budget and a list of items to purchase. They must create a spreadsheet to itemize the expenses and show a running total and balance.
• Presentation - Examinees are given information about a specific topic. They must create a PowerPoint presentation covering the information provided. There are specific requirements for the design of the presentation and how the show should be displayed.

To confirm the validity of the exam, the final draft of the exemption test was reviewed by the dean of the College of Education, selected COE chairs and faculty representing the various departments, adjunct instructors teaching the course, and a professor of business education who teaches technology specific courses.

How the Exam is Administered

The exam is offered twice a semester during the Fall, Spring, and Summer terms. The selection of the dates corresponds with advisement periods to allow students to use the results when planning their schedules. It is always given on a Saturday to avoid conflicts with students’ classes and courses that use the school’s computer lab. The exam is widely publicized by posted flyers, advisement by student’s consolers and announcements in classrooms. In addition, criteria for each section of the test is made available to potential test takers in the school’s resource library.

Since the exam is entirely performance based, the number of students who can sit for the exam is limited by the number of computer stations in the lab. To insure that all examinees will have a workstation, students are required to register for the test with the Media & Instructional Technology department. The contact information is also used to remind prospective test takers of the date, time, and location of the exam.

How the Exam is Graded

The exam was designed to follow as closely as possible the projects assigned in the course. Each section is evaluated as a separate project and assigned a grade based on the number of correct responses and/or actions. The section grades are then averaged to establish a final grade.

The passing score for the exam was originally set at 85%. The rationale for this decision was that students needed more than a minimal score: a high "B", to show enough competence to exempt the course. After administering the exam twice, this minimal score was lowered to 80%. This was done to better reflect the passing rate of students in the course, than to increase the passing rate on the exam.

To date, approximately half (53%) of the students who sat for the exam have passed it. About a third of those who were not successful quit soon after the exam began when they saw the items to be covered.

Outcomes

At the outset, it was anticipated that a large number of students would take advantage of exempting the course. However, this has been far from the case. Although the test is well publicized, few sign up to sit for it, and of those that do only a small percentage actually show up. Typically, three students a session, six or seven a term, actually attempt the test. A survey at the beginning of the semester of students who enroll in the course has shown that many believe that they have the necessary skills in word processing and email but lack knowledge of the other areas covered in the course. There is a good possibility that the perception that students come of college already prepared with technology skills is false and that a course in technology should remain in the program of studies.

Feedback from those who signed up but failed to participate revealed that some, after reviewing the published criteria, decided that they did not have the necessary knowledge to pass the test. Others cite the inconvenience of spending four hours on a Saturday on such an endeavor. However, a more important factor for College of Education students seems to be the requirement that they take an additional course to replace the credit. They feel that knowledge of technology will be beneficial and if they have to take a course anyway, it should probably be in instructional technology.

Conclusions

The 53% passing rate indicates that the exam is sufficiently difficult to insure that those passing have an understanding of the subject matter and skills covered in the course. However, the exam is not providing the anticipated option for students to open their class schedule to take additional content area courses. It is unclear from the information we currently have if participation would increase if students who passed the exam would not have to take an additional course. Additional publicity is planned before the next administration in an attempt to obtain more participation.

The additional possibility, reflected from the survey results of students in the course, is that the students entering college do not have the necessary skills to exempt the class. The original perception of that students are acquiring a strong background in technology while in their secondary program is false. The tentative conclusion is that technology must not be lightly dismissed as an unnecessary component of a teacher preparation program in an attempt to balance the credit load scales. An exemption exam seems a viable alternative to omitting such courses.

Abstract: Given the rapidly changing field of Educational Technology, it is difficult to maintain a course curriculum for very long. In this paper we use data gathered from our own experiences teaching introductory educational technology courses as well as the experiences of our colleagues. Although we are constantly updating and revising our courses, there is evidence that our efforts are falling short due to an overemphasis on “hot” technologies. This article reviews changes being made in college courseware and research related to the skills of entering students. In addition, we suggest an alternative way of addressing technology skills development.

Introduction

Students are entering our undergraduate classes with much more computer knowledge than ever before. In a recent study of preservice teachers enrolled in an introductory educational technology course 92-98% of college students reported word processing, sending email, and doing web research as simple tasks, while design and programming were rated as being more difficult tasks by at least 80% of the students. (Foti, & Ring, 1999) This study prompted additional questions such as: What are we teaching our college students? Are we (college professors) teaching our students what they already know? How are our courses changing to address the needs of a changing student population? Are these changes appropriate?

What are we teaching our students?

After completing an informal review of educational technology courses' syllabi on the world-wide web, conducting a survey of educational technology professors, examining proceedings from several educational technology conferences, and surveying undergraduates in our Introduction to Educational Technology course over a four year period, we have concluded that educators are duplicating their efforts in many K-12 curricular areas, while avoiding others. In other words, we are teaching our students what they already know (web-related skills), and overlooking topics such as programming, design, and issues related to the future. This means that students are entering college with a basic understanding of email and the internet, yet, lack a basic understanding of more difficult tasks such as data structures, databases, and design. Once reaching college, the problem continues. Whether it is because the web is on everyone's mind, or that it has a high "cool" factor, college instructors seem to be focusing on web-related skills that are often already embraced by their students. In addition, our education classes are not addressing 21st media-related issues that students may encounter in their classrooms such as cognitive overload, conceptual addiction, and issues related to privacy.

For example, it is quite clear that students know how to use a word processor, yet we continue to teach word processing. Databases seem to be taught superficially even though a deeper understanding of databases, and information manipulation will become an important 21st century skill. The Office of Technology Policy reports (1999) that the ability to access, manipulate, synthesize, and evaluate
information, is a necessary skill for the job market of the 21st century. Virtual representations are becoming more commonplace in schools and businesses, however, many educational technology courses are not attending to design skills.

According to Seymour Papert (1996) the content of the typical computer literacy curriculum is a grab bag of superficial knowledge about the parts of a computer and current office software selected primarily because it is easy to teach with very limited numbers of computers. Our research confirms his statement. It appears that most introductory courses are addressing skills development using productivity software, but that these courses are not concentrating on learner-centered goals. Although learning how to build a web page is important, our curriculum must include more than skills development.

Are we teaching our students what they already know?

“As millions of college students head back to campus, only 23 percent report using the Internet for games and/or chat while more than triple that many - 71 percent - use it to conduct research for academic or business needs” (Becker, H. & Reil, M, 1999). Yet, we continue to teach college students how to e-mail, type a letter, and use the Internet. In her 1998 study Janet Pollack reported that “Fully 75 percent of the males and 90.9 percent of the females in the sample reported logging on for e-mail at least once per week.” According to Pollack: “a well-wired campus with clusters of discipline-dedicated computer labs, several public computer labs and fully-mediated auditoriums may mean that students who have spent three or four or even five years in the midst of this new technology may only be making the most rudimentary use of it” (1999). Our research confirms her findings, as Figures 1 and 2 below indicate. While technology educators must make sure that our courses evolve, we must also ensure a balance between fundamental productivity prowess, communication capability, and the development of vision in our students.

How are our courses changing to address the needs of a changing student population?

Over the past several semesters, we have made a number of changes to our introductory educational technology course. According to our research, ours is not the only educational technology curriculum that is undergoing change. Professors responding to our questionnaire confirm changes in their curriculum, commenting that: “we plan to drop instruction in the email system,” and “we model both the Mac and Windows platforms.” Many of the courses surveyed have an online component which supplements the course, while others have developed a distance introductory course taught almost entirely online. While many courses continue to teach word processing, a number of the courses have added a mail-merge segment which integrates databases into the word processing assignment.

Just two years ago many of the introductory educational technology courses surveyed taught students about the Internet, and how to surf for information. Now, 90 percent of the courses surveyed are requiring students to make personal webpages. Given the fact that many students have created web pages on their own, it would seem that a more profound change in curriculum is required. Courses must begin to address 21st century concepts such as context, collaboration, communication, and problem solving. (Clouse, 1997; Thornburg, 1997)

Why should our courses continue to change?

Our research shows that entering college students are showing little or no improvement in several key computational areas. Figure 1 compares the percentage of students finding the following activities difficult in Fall 1995 and in Fall 1998: designing a simple presentation, creating an interactive game, creating a interactive (non-linear) presentation, creating a digital video, and writing a computer program.
As can be seen, with the exception of creating a simple presentation, very little progress has been made. By comparison, consider the gains made in internet related topics: using the internet for reference, accessing information, shopping, finding music, and sending e-mail (See figure 2).
How should our courses change?

Because students are entering our classes with more technological knowledge, we can begin to focus more on context-based scenarios. Current curricula in subject areas such as science and social studies frequently attempt to cover as much content as possible, regard all content as equal, and divide content into artificial categories that bear little relationship to how individuals use content in the work beyond school (Fennimore and Tinzmann, 1990). By working with conceptual themes drawn from under-represented areas of the curriculum, technology instructors can develop technology-rich lesson plans that support “the disciplines” and simultaneously focus on technology and media understanding.

By modeling teaching using technology-rich lessons, multiple perspectives, and ill-structured knowledge domains, we illustrate new approaches to teaching and classroom management. Students take part in activities which involve problem-solving in a real-world sense. Properly constructed, lessons illustrate that there are multiple solutions to problems, and that technology may provide unique pathways to some of those solutions. In addition, the lessons do not attempt to usurp other forms of knowledge acquisition or development.

Is it possible to teach technology skills, procedures, and applications in a highly contextual setting? We think so. While examining a single core concept, multiple investigations may be established which use varying methods of inquiry. Each perspective may pose a unique problem, or research question. The student must solve the problem, do the research, undertake the activity, or do whatever is appropriate to fulfill the requirements of the investigation. Appropriate methods might include interviews, reviewing literature, charting statistics, building a model, recreating a historical scenario, running a simulation, etc. Then, the student (or group of students) must decide how to communicate the findings to the class or larger group, using appropriate media strategies. Ample opportunities for applying databases, spreadsheets, drawing programs, animation programs, programming languages, and other software applications exist in this learning environment. By putting the education back into our technology courses, we can provide students with models of instruction that assume technology rather than targeting it. In other words, we can help our students understand how teaching with technology works, rather than teaching them only how technology works.

Summary

Agreement on an appropriate model for a K-16 curriculum seems to be escaping us. Technology teachers across the grades seem to be focusing on similar skills, rather than making sure that students are competent in many areas. In particular, design and programming skills seem to be poorly represented in our curricula, in favor of reference and communication skills which students may be learning on their own. School districts and colleges must attend to the skills and processes required to make students better problem solvers given the assist technology brings. We believe this can be accomplished by creating a dovetail between content and pedagogy in an environment where technology is assumed.

Baileyl@byuh.edu

Abstract: One of the most exciting and rapidly changing fields in education is that of technology because obviously, technology itself is rapidly changing. For preservice teacher course and program designers, constant revision of the contents of the technology component is a necessity with choices hinging on range and availability as well as pedagogical congruencies. This paper reviews a current case of "technology refocus" in a preservice program resulting in choices including video and multimedia as well as assistive technologies for the special needs student.

Introduction

Having been caught up in a university-wide curriculum review, our School of Education found itself in the position of having to provide an approvable degree in less credits. When push came to shove, the technology component came under scrutiny, the credit allocation was cut in half and the course given the mandate to focus the contents of the new course more squarely on the needs of today's and tomorrow's schools. The ensuing review of what was relevant and available that would assist teachers in their future roles in the classrooms of the world and could be learned in a 1 credit course is the subject of this paper.

Review

A recent review of technology for preservice teachers (Higdon, 1995) follows the evolution of the concept "computer literacy" from computer construction and simple programming through to hypermedia, telecommunications, ending at multimedia. Not only is the technology changing but so also is the perspective with which technology is viewed. Technology as a computer which ran programs out in left field has now moved to the position of a vehicle which will with style, color and pizazz, deliver course content either as a main player or as a support player to the teacher.

Exemplary technology teacher education programs (Vagle, 1995), recommended and reviewed by 184 prominent individuals on the "computer mountain" in education, showed that while all programs required an introductory technology course and had available labs for hands-on experience, exemplary programs required their course to be taken in the third or fourth year as opposed to any year, and required students to do more computer graphics editing than video camera/player editing, more integration of components and more internet communication, more presentation software. Programming in BASIC or LOGO was reduced significantly as was the focus on productivity software ie wordprocessing, spreadsheets, databases and desktop publishers.

Since 1995 technology has flourished even more. The internet has become ubiquitous, omnipresent and is working on becoming omniscient. It is viewed as crucial to all meaningful preservice programs (Provenzo, 1999). Multimedia authoring has taken the form of Hyperstudio and has a multitude of instructional uses
Preservice teachers will need help in finding meaning in their struggle to capitalize on these resources in tomorrow's classrooms (Schaffer, 1999; Weber, Schoon & Gonzalez, 1999; Scheuermann, Larsson & Toto, 1999). Wise (1997), President of NCATE, recommends that teachers be taught to adapt to technology changes by deepening their understanding of the impact of technology on our society, recognize new ways to access information, teach students to find, organize, and interpret information in a reflective and critical way, participate in formal and informal learning groups which use technology, and finally, demonstrate "an attitude that is fearless in the use of technology, that encourages them to take risks, and inspires them to become lifelong learners". He reasons further that preservice teacher programs fail in the area of technology because faculty don't understand the impact of technology themselves, they lack the technology for student use, and the faculty don't know how to incorporate technology into their teaching. The NCATE task force, whose work he is reporting, recommends that teacher education programs should create a vision in their students minds by their own use of technology, develop a program plan which implements technology program-wide, experiment fearlessly themselves, and provide for a technology infrastructure, faculty incentives, sufficient access and technical support, and networks with schools and funding groups.

In summary, technology has changed. It has simplified, moved down a generation, and teacher training programs are struggling to keep up with the play. There is much to be done because the community expects the teachers of the future to be technology literate. So here we were with an opportunity to put in place a meaningful program in a sliver of time.

**What Happened**

The solution to the School of Education need for a relevant and useful technology course in one credit began by making a list of all possible applications of computer technology in education. Each faculty member checked the list for completeness and prioritized the topics as they saw the need each of the three program i.e. Elementary, Secondary and Special Education. Several topics once considered integral to Computer Literacy are now expected to be learned elsewhere before entering the program. These topics included wordprocessing, spreadsheets, databases, desktop publishers, e-mail and internet searching. Other topics were felt best addressed by other faculty as components in their courses, some being demonstrated and others being assigned as student tasks. A large selection of the Special Education assistive technology topics were reserved to a second course required of their students only. This course is currently being used as the basis for an appropriation to place assistive technology in the library computer labs.

The final list of topics were gathered under the headings school survey, digital basics, video capturing and editing, presentation software, multimedia software, internet construction tools, and assistive technology. The school survey involves visiting and surveying of local schools, finding out what technology is on-site, how it is organized and how it is used, supported, funded, and how it fits into the overall school plan. Video capturing requires the students to film interviews and sites to create an edited video. Digital basics requires the students to digitize pictures and photographs, sounds, and video clips, as well as use clipart and video clips for use in the next three projects.

Presentation software requires the use of Powerpoint to create a serial slideshow. Multimedia involves Hyperstudio to create a multilinked slide presentations using the previously mentioned digital basics. Internet homepage construction using Frontpage or Visualpage involves one main page with five related linked other pages. Making the student themselves the subject of each of these projects provides for security and the guarantee that they have done most of the project albeit with help from lab assistants. Other topics demonstrated in the internet section include videoconferencing, webcams, and e-commerce.
The final topic, Assistive Technology, enables students to see demonstrated alternative input devices and alternative software for people with special needs.

Conclusion

The initial run of the course was most useful in confirming topic selections and identifying areas of refocus, better preparation, simplification and best of all, political tensions. Since we relied upon the facilities of the university for our labs, and they had previously provided a form of the course, it was a challenge to run with them but in a way in opposition to them. What they had previously designed to prescribe as good for the academic divisions was being challenged and it tested the very meaning of the term “academic support”. But true to their role, they supported.

The challenge in such a course as this is to provide the simplest but most complete task enabling the student in the minimum of time to gain the maximum experience with technology. This approach is based upon the elaboration theory model of task analysis proposed by Reigeluth and Merrill (1983).

With respect to the NCATE steps suggested to resolve the technology problem in teacher education programs, we have agreed as a faculty to be technology-“with it”. Time has yet to prove us true to our word, however the university has built a multimedia classroom in the School of Education building to enable this to happen, while portable projection trolleys are available for other rooms. We have limited means to experiment but we do have a plan and there is access and support. Our network with surrounding schools has yet to develop and we see little chance for us to enter into a technology project funded by an external sponsor given the focus of our institution.

Our political concerns are abating now that we are partners with the library in the quest for assistive technology in the library labs. This technology will not only serve our Special Education students but also any student enrolled in the university who has a disability.

Abstract: This paper describes the technology training and the implementation of this training. An example of the pre-service use of this training to prepare units, lessons, and activities for centers in the curriculum course will be provided.

The mission of the Department of Urban Education at the University of Houston Downtown (UHD) is to prepare future teachers who will enhance the chances of academic success for at-risk children and adolescents in urban schools. In order to provide its pre-service teacher with experience in using technology to enhance instruction, this department is integrating the educational computing component into its existing interdisciplinary block structure.

This paper describes the technology training and the implementation of this training. An example of the pre-service use of this training to prepare units, lessons, and activities for centers in the curriculum course will be provided, also.

The technology training is a one hour credit course which is held in the lab entitled: "The Way to Go: Integrating Instructional Technology Initiatives into a Teacher Education Program." As described in the syllabus for the course, the five technology sessions are integrated into the first block for the pre-service teachers at the Department of Urban Education (http://www.dt.uh.edu/degree/urbaned/home1.htm). The course is offered in the format of five workshops of three hours each, which are spread throughout the whole semester.

The titles and brief descriptions of the five workshops (3 hours each) currently offered are provided as follows:

Workshop I: E-mail & Internet Discussion:

The instructor starts with an introduction to the use of different professional teachers' forums over the WWW by showing pre-service teachers how to follow the threads, respond to interesting topics, and start their own subjects. This activity usually will raise students' interests and attention since they have heard of people talking about chat rooms and other related topics. After a short break, the instructor assists students in creating accounts with a web-based e-mail program such as Hotmail and Yahoo. The instructor then demonstrates the ways to check in-coming mail, compose out-going mail, send documents as attachments, forward and respond to mail, set up distribution lists to send to multiple recipients, set up automatic signature files, organize read e-mails into different folders.

Workshop II: WWW & Web Search
The instructor starts by demonstrating the CS1105 class web site created just for them (http://www.dt.uh.edu/~chen/cs1105.html). The web site consists of different applications and examples of WWW uses in K-12 classrooms. Examples include: Spanish-English online translator, Webster's interactive dictionary, web site of the White House, lesson plan archives, askERIC archives, TEA (Texas Education Agency) homepage, TEKS (Texas Essential Knowledge and Skills) web site, etc. The choice of web sites to be included are customized to meet the needs of different groups of students. Examples might include a demonstration for the bilingual education groups which will emphasize Mexican culture and Spanish language arts; a demonstration for the secondary education groups will emphasize different content areas. Students also learn how to download texts and graphics from the Internet while sharpening their web search and web research skills at the same time.

Workshop III: Desktop Publishing & Graphic Organizers

The instructor starts with demonstrations of previous students' works including newsletters and flyers created for school activities or professional development. Pre-service students usually are amazed by the good jobs done by the previous students. They also are made aware of the high standard the instructor expects from the homework they are assigned. The instructor then guides the students with the creation of a simple flyer and a newsletter while allowing them the flexibility of applying clip art, word art, colors, and content to enhance their ownership of the product. After this, the instructor explains the different looks and uses of graphic organizers and demonstrates the creation of a thematic unit with the fundamental building blocks of graphic organizers such as text, circles, lines, and colors.

Workshop IV: PowerPoint Presentation

The instructor starts with a demonstration of previous students' PowerPoint presentations, including some that need to be improved and several that resemble pieces of art. The instructor tries to evoke the students' higher order thinking skills by explaining the strengths and weakness of the slide shows and the rationales. Following an activity guide, the instructor leads the students in creating two simple slides with headings, text, graphics, and charts. The workshop ends with the showing of the more advanced functions of PowerPoint such as animation, sound, transitions.

Workshop V: Hardware & Software Evaluations

Since few pre-service teachers are aware of the different parts that make up a computer, the instructor brings in an old computer, takes it apart, and explains the different functions of the parts. By so doing, it is hoped that the students' anxiety level in using the computer will be lower. Students are then instructed in hardware evaluation. The hardware session ends with a twenty-minute activity called "The Price Is Right!" This activity is a search on the Internet for a brand new computer system with features that are comparable or better than those described in "The Price Is Right!" hand-out. The purpose is to equip the students with the skills required for them to do their own hardware search. The software evaluation session starts with software demonstrations including Story Book Weaver, Body Works, Amazon Trails, Just Grandma and Me, and Encarta. Students are then instructed in software evaluation. The workshop concludes with the students filling out software evaluation rubrics so that they will become comfortable judging educational software.

Technology is used as one more tool in today's classrooms, therefore; this training gives a strong base to pre-service teachers for planning and delivering instruction in the classrooms. Pre-service teachers plan units, lessons, and center activities in the areas of science, social studies, mathematics, language arts, and ESL. The procedures for planning and preparing a unit are explained as follow.

The pre-service teachers visit a selected classroom in the home school. They proceed to conduct a formal and an informal assessment of children's needs. They determine the interests of the students using a KWL (what the students know, want to know, and have learned) diagram. Based on this information, the pre-service teachers select the theme and areas of study for the unit. They access the Internet to find resources for the units. They have already acquired the basic Web search skills from Workshop II WWW &
Web Search. The general steps to finding information about Africa for example or any other specific topic are:

Step 1:
Log on to the www.go.com search engine. From the authors' observation, this search engine usually offers the best search results for education related topics.

Step 2:
Type in the search words "African Resources" and hit the FIND button. You may replace the search words with your own topic.

Step 3:
Browse through the "hits" or "results" to read the site descriptions and follow some interesting hyperlinks. Use your judgment to decide which are the most appropriate to use for your classroom. The go.com search engine has already applied its selection standard, which is indicated by the percentage number next to the web site description.

Another way to do a search is to access specific educational sites such as:

- [http://www.yabooligans.com](http://www.yabooligans.com)
This site is very popular with young children. It has topics such Around the World (countries, food, and holidays); School Bell (Language Arts, Math, and Social Studies; Science and Nature (Space, Animals, and Dinosaurs); Arts and Entertainment; Computers and Games; Sports and Recreation.

- [http://www.davilaelementary.org/](http://www.davilaelementary.org/)
This is a school web site customized for visitors, students, and teachers. It offers visitors specific information about the school. It also shows resources for teachers and students by subject. It is an interesting site to see samples of students' work and lesson plans.

This is one of the most complete web sites for teachers and students' resources. The site is divided in three areas: kids, teen, and college & beyond. It has links to 75,000 scholar-selected Internet resources. It has more than 14,000 lesson plans, Internet integration ideas and monthly topic for teachers. This site has tutorials for students in various areas and grade levels. It is an invaluable resource for teachers.

All these ideas are an excellent beginning to survey the resources needed to plan a unit. Teachers, however, need to include in this planning the objectives also. In the state of Texas these objectives are called Texas Essential Knowledge and Skills (TEKS). The TEKS indicate the skills that teachers need to cover by subject and grade levels. The pre-service teachers have access to this information on line. The address is http://www.tea.state.tx.us/teks/#Grade. They also use the results of the TAAS (Texas Assessment of Academic Skills) scores in planning the unit. The pre-service teachers include in the unit several objectives where the children in the TAAS test did not performed at grade level. This information is also available on line by school district. In summary, the unit indicates the objectives that will be covered in a classroom for a specific period of time. The unit must be the result of formal and informal assessments conducted in the classroom where the unit will be implemented. To see some samples of the units developed by UHD bilingual pre-service teachers, please visit http://www.dt.uh.edu/bilingual_education/.

After the pre-service teachers have completed the planning of the unit, they are ready to design the lessons for that particular unit. The lessons have to include some type of technology for example software, encyclopedia or Internet. Again the training the students received in the technology class is used in the planning of the lessons and the use of technology to deliver instruction. The students are encouraged to do a search online to review different types of lesson plan. Some interesting addresses are:

- http://faldo.atmos.uiuc.edu/CLA/

This collaborative archive has included lesson plans and activities from preschool through college. The viewer will first pick up a grade level and then follow the subjects. The contents are provided in a discussion listserv format, which allows people to respond and expand on the original ideas.

- http://ericir.syr.edu/Virtual/Lessons/

The US Department of Education endorsed these collections of lesson plans. Users may select from a list of subjects that are followed by intradisciplinary content areas. The user can type keyword to search the entire AskEric Lesson Plans Collection for a specific lesson.

Pre-service teachers also use the objectives from the unit to plan the activities for the centers. It allows them to individualize instruction in the different content areas utilizing technology. Technology is a
major component to meet the individual needs of each student in a classroom. Activities are planned with children's different levels of ability in mind. The activities go from guided tutorial to created activities. Children have the freedom to work by themselves, with a partner, or in small groups to complete their selected activities. For examples of activities for centers see the following address (http://www.dt.uh.edu/bilingual_education/).

In conclusion, pre-service teachers need extensive training in technology to meet the challenge of educating children for the new millennium. Technology allows teachers to individualize instruction and meet the needs of each student in the classroom. However, for technology to be effective, teacher preparation programs need to provide not only extensive but also intensive hand-on practice with technology applications in the classroom.

Abstract: This paper examines some aspects of a graduate course in educational technology at the University of Regina, Canada. The focus of the course (offered in the Fall 1999 semester) was to examine how aspects of learning theory can impact the use of technology in schools, and to develop a theoretical model that could drive and reflect appropriate ways for technology use in the classroom. In this paper we describe the course content, provide an overview of the processes involved in developing the theoretical model, and propose characteristics of a model for effective technology-curriculum integration.

Description of the Course

The course under discussion in this paper was designed for graduate students who are familiar with basic computer-related technology skills and concepts and their pedagogical appropriateness in the K-12 classroom. Specifically, the course was designed to explore the effective integration of the Internet into the curriculum. Students examined ways in which the Internet might be integrated into the curriculum, analyzed different learning theories to determine which (if any) related to the current (or future) use of the Internet in the classroom, and developed a working learning-theory model that could be used to influence the appropriate use of the Internet in the classroom. Modules on various topics were presented by groups of students who were expected to participate as students on WebCT by contributing to the chat room and Bulletin Board, and as instructors, by creating directories and pathways through which they posted the various course modules on WebCT. A WebCT course developer expert gave the class a summarized overview of how to create pathways and directories, and of how to upload documents. This was helpful for learning the technical aspects of WebCT. After the initial orientation to the course and WebCT, we began the process that would lead to the development of our theoretical model for technology integration.

The entire course is posted on WebCT at the University of Regina site [http://webct.uregina.ca:8080/ -- click on course listings, then on "Internet and Curriculum Integration" and then log in as a guest; (user id: guest; password: guest)].

The Importance of Theory

Richard Skemp stated, "There is nothing so practical as a good theory." (Personal correspondence, 1991). He states that "an essential feature of a theory is that it helps us to understand the invisible causes which lie
beyond the visible effects" (1989, p.46). The abstractness and generalities of theories gives them their power to be practical. In our class discussions, we were led to believe that a theoretical model for technology-curriculum integration could be general and practical and could be used to drive and reflect the effective use of technology in the classroom. We therefore embarked upon a quest to create a theoretical model for the effective use of technology in the classroom.

The Process of Developing a Learning Theory Model

We began the process of developing a theoretical model by examining how the provincial on-line curriculum is attempting to integrate technology into and across subject areas. The Evergreen Curriculum is located at http://www.sasked.gov.sk.ca/docs/evergrn.html. One of the on-line curriculum designers presented the class with an update of all the new features on the first night of class. The course instructor also led the class through some introductory theoretical work that was a review of different belief systems, and an overview of two different models of learning. Small groups of students choose topics that they would research, present in class, and post on WebCT. Topics selected for review by students were:

- Learning Theory.
- Virtual Architecture
- Filamentality
- Virtual Environments

The first of these topics examined current learning theory and the other three focused on some popular ways in which educators have organized Internet-related frameworks for technology-curriculum integration.

Using Schwab's (1973) Commonplaces as the heuristic, we compared the respective roles of the teacher, the student, the subject matter, and the environment as they apply to two belief systems or paradigms and two current learning theories. We then looked at some frameworks for integrating technology into the curriculum and attempted to analyze these to determine which theory of learning (if any) could be identified. We also compared articles by supporters and critics of technology and noted some of the issues related to the appropriate use of computers in the classroom. We also discussed what a classroom might look like where technology was being successfully integrated. We took into consideration what we believe to be the most essential, most appropriate, and most effective features of a technology-rich classroom environment, based on the presentations of the groups, the issues arising from the critics and our on-line and in-class discussions, and our own experiences as teachers. These considerations contributed to our theoretical model. The following is a summary of the topics presented in class.

Belief Systems

Although there are several philosophies concerning what and how students should learn, two beliefs systems or paradigms primarily influence our current teaching practices. The most widely influential has been the objectivist paradigm (frequently known by other names such as traditional, transmission, teacher-centered) where the teacher's role is to teach - that is to dispense or transmit knowledge. It is the teacher who determines what is to be taught and how it will be transmitted. The student follows the teacher's direction, learns the information and gives it back. The subject matter is generally pre-determined and is often developmental and specific. Evidence of knowledge acquisition is determined by observable outcomes and behaviors exhibited by the student. The learning environment is generally structured where students work independently.

The second paradigm that has had the most impact on teaching, though not as widely practiced as the former, is the constructivist (practical, interpretive) paradigm. It is based on the premise that students learn best when the subject matter is meaningful and related to their interests and experiences. The teacher's role in this orientation is one of a guide or facilitator who provides a stimulating learning environment that promotes hands-on experiences, intellectual risk-taking, and cooperation. The student's role is to be inquisitive, creative, collaborative, and reflective. The subject matter is holistic and customized to the needs, interests, and prior learning of the students. It is often divergent or open-ended with groups of students working in an area of interest. As students reflect on their experiences, they generate "rules" or "mental models" to make sense of their experiences. In other words, they construct
their own meaning from the experiences. In this context, learning is believed to be a process of continually adjusting the mental rules and models.

Two Theoretical Models of Learning

In this course, class members explored two current learning theory models: Barbara Rogoff's Communities of Learners (1994), and Situated Cognition (Brown, Collins, & Duguid, 1989). We believed these theories to be relevant to technology integration in the classroom.

In the Communities of Learners model (Rogoff, 1994) the author asserts that “learning occurs as people participate in shared endeavors with others, with all playing active but often asymmetrical roles in sociocultural activity” (p. 209). This view of learning contrasts with the one-sided learning models typical of European, American, and Asian schools where adults are in control of the learning. It also differs from child-run models that are “based on the assumption that learning is the product of discovery by oneself or Community of Learners theory, learning is a process of transforming participation where “both mature members of the community and less mature members are conceived as active; no role has all the responsibility for knowing or directing, and no role is by definition passive” (p. 210). In this view all members of the community are at some time both a teacher and a learner.

Situated Cognition, (Brown, et al, 1989) has some similarities to the Community of Learners theory. Both models acknowledge that learning is best accomplished when it is authentic and related to the interests and experiences of the students. In the Situated Cognition model however, the adult serves as a mentor and the student is an apprentice. Learning is considered meaningful only if it is embedded within the social or physical context in which it will be used. One way to create authenticity in learning so that it more closely resembles what practitioners do, is to “enculturate students into authentic practices through activity and social interaction”, based on the successful and traditional apprenticeship model (p. 37).

Herrington and Oliver (1997) note that the principal theorists (and critics) of situated learning have identified a number of important characteristics of the learning environment which have added to the evolving theory of situated learning. In attempting to identify those characteristics that are most applicable to the instructional design of interactive multimedia, Herrington and Oliver suggest that the learning environment should:

- Provide authentic contexts that reflect the way the knowledge will be used in real-life
- Provide authentic activities
- Provide access to expert performances and the modelling of processes
- Provide multiple roles and perspectives
- Support collaborative construction of knowledge
- Provide coaching and scaffolding at critical times
- Promote reflection to enable abstractions to be formed
- Promote articulation to enable tacit knowledge to be made explicit
- Provide for integrated assessment of learning within the tasks.

In the characteristics outlined in the cognitive apprenticeship and community of learners models we identified the roles of the teacher, student, subject matter, and environment. It is interesting to note that some of the roles have elements of both the objectivist and constructivist orientations. For a summary of the four commonplaces as they apply to the two paradigms and two learning-theory models see the following site: http://education.uregina.ca/courosa/site2000/overview.htm.

Organizational Frameworks

The next step in our theory development process was to examine the work of educators who have developed frameworks for organizing the Internet and curriculum-related activity. The works of Judi Harris (Virtual Architecture), Bernie Dodge and Tom March (Filamentality), and Chris Dede (Virtual Environments) were of particular interest because of the innovative ways these educators have discussed the use of the Internet and technology in classrooms. We also looked at the work of Cynthia Leshin (Internet Adventures,1998) who has developed an extensive list of Internet resources for teachers, and Seymour Papert (Mindstorms, 1980), the developer of Logo, the first computer programming system for children.

Judi Harris (1998), and also see her website at http://ccwf.cc.utexas.edu/~ibharris/Virtual-Architecture/, uses the metaphor of a house to organize the ways teachers and students might use the
Internet to extend learning. She compares the rooms in a house to educational activities that can be structured to serve different purposes. And, just as rooms in different dwellings might have similar purposes but can function and look quite differently, so can "the same activity structures . . . be used to help students at different levels and with different curricula learn in differentiated ways that are best suited to their interests and needs" (p.42). Within the "house" are several areas where students can use computers in a variety of ways to accomplish different learning objectives. For example, the basement provides the foundation or rationale for the framework, the kitchen is for telecollaboration, the study for teleresearch, the bathroom for designing projects, and the yard for assessment. For an overview classroom activities that could be accomplished through telecollaboration, see http://rbe.sk.ca/webactivities.

Harris (1999) cautions however, that the activity structures for telecollaboration must be combined with seven action "c-quences" to help the students "plot the steps they will take as they use the activity's structure to engage in active learning" (p. 43).

Bernie Dodge and Tom March created filamentality, an interactive, fill-in-the-blank web site for guiding teachers through the process of designing Internet-based instruction. Teachers pick a topic, search the Web, identify good Internet sites, and turn the Web resources into activities appropriate for learners.

One currently popular aspect of Filamentality is the WebQuest. A WebQuest "is an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web. WebQuests are designed to use learners' time well, to focus [learners] on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis, and evaluation" (Dodge & March), http://edweb.sdsu.edu/webquest/overview.htm. Also see http://www.ozline.com/.

WebQuest is only one instructional method within the Filamentality organizational framework. Other suggestions include creating a hotlist of good sites, developing a scrapbook with multimedia links and other resources, having the students gather information about a subject through a treasure hunt, and developing a subject sampler of a half-dozen intriguing sites organized around a main topic. Filamentality offers a variety of curriculum-based activities for all levels of Internet users.

Chris Dede of George Mason University has focused his work on how emerging technologies may reshape our views of distance education into an alternative instructional paradigm – distributed learning (1996, p. 1). He and his colleagues have also worked on the use of ScienceSpace Virtual Realities (VR) to help learners understand complex scientific concepts (Salzman, Dede, & Loftin, 1995). The work on distributed learning is of particular significance to educators as local and regional school governing bodies are looking for ways to reduce the costs of education. Dede believes distributed learning can provide opportunities for "learning by doing" and for interacting with virtual communities in ways that complement face-to-face interactions. He suggests, however, that if distributed learning is to fulfill its potential as an economically viable and pedagogically valuable way for students to learn, research is required on the following issues a) instructional design, b) knowledge webs, c) virtual communities and d) shared synthetic environments. He reminds us that as the new technologies become part of our everyday existence, it will be important to keep a balance between virtual interaction and face-to-face interaction and that the new media "need not eliminate choices or force us into high-tech, low-touch situations" (p. 24). More information on Virtual Environments can be found at http://www.virtual.gmu.edu/index1.htm.

Cynthia Leshin's work provides extensive and practical ideas for accessing web resources. She has also compiled lists of web sites that can be used for a variety of thematic units in a classroom. Her work will save teachers several hours of searching for appropriate web sites when developing WebQuests or other activities where children will be using Internet resources. One difficulty with Leshin's work, however, is that it will quickly become dated as the Internet grows. For more information see http://www.xplora.com/xplora.

Seymour Papert's creation, Logo, which allows children to learn the principles of computer programming by commanding the movements of a turtle on a computer screen, has greatly influenced the development of educational technology and our understanding of how children learn. In Mindstorms (1980), he discusses the importance of children being able to manipulate objects in order to increase cognitive development. He demonstrated that children can learn mathematical concepts with computers or 'objects-to-think-with', and that by articulating what they do as they create programs in Logo, they are learning to think about their own thinking. Papert developed the idea of a microworld - an authentic classroom environment created by the teacher, within which specific concepts could be learned, specific questions asked, and where students and teachers could interact and work together.

Each framework described above gave our class several ideas for a model classroom in which technology is successfully integrated. The frameworks also helped us to begin to formulate our own
theoretical model for using technology as a tool for curriculum integration in the classroom. The next step was to determine where the class participants were in their own theory development. We posted some questions to the bulletin board and asked our classmates to respond. We wanted to determine if they were aware of any belief system or learning theory that guided their use of technology in their classrooms. We also wanted to know if their thinking or practices had changed since they had started the course or began using technology in the classroom. Generally, we found that through taking this course or through integrating technology in the classroom, some participants were better able to articulate their teaching theories that had previously been unexamined. Some questioned their existing theories and for others, technology was the catalyst for transforming constructivist beliefs about teaching and learning into actual practice. A summary of the participants’ responses can be found at http://education.uregina.ca/courosa/site2000/participants.htm.

Our Theoretical Model

Near the end of the course, a clearer understanding of our personal philosophies of teaching began to emerge. We felt we could finally describe the constructs of a learning theory model that would reflect what we believe to be the effective use of technology as a learning tool in the classroom. These constructs are derived from no single theory or belief. When we examined our working charts to determine the most appropriate constructs for our evolving theoretical model, we selected some from all the theories and beliefs that we studied. Although the model has a constructivist orientation, we were surprised to find that we had included some constructs that are more dominant in the objectivist paradigm. Again, we turned to the Commonplaces to provide the heuristic for our analysis. The chart below briefly summarizes the main characteristics of the model we called the Technology-Curriculum Integration Model.

Figure 1 The Technology-Curriculum Integration Model

In our model the roles of the teacher and student are, for the most part, interchangeable. The teacher has primary responsibility for structuring the classroom environment, but students can also participate in the design. As well, the teacher is ultimately responsible for and accountable for the assessment of students, but students can play an active role in self and peer assessment. The subject matter is flexible and determined in collaboration with students and teachers, but again, the teacher must ensure that students are learning the skills and processes outlined in the curriculum. The learning environment might be characterized as ‘freedom without license’, where students have freedom to make curriculum and learning choices, and are free to choose where and how they work within the context of a structured, respectful, collaborative learning community.
Conclusion

Our intention in this course was to examine learning theory as it related to the effective use of technology in the classroom. In the process of examining theories, we discovered that no one theory is best for guiding technology and curriculum integration. We therefore developed a theoretical model that has components of other theoretical models and belief systems. We came to the conclusion that knowledge of the theory that informs our practice is absolutely crucial if we are to provide meaningful learning experiences for students. As well, theory is necessary if we are to justify our pedagogical decisions, and the importance of technology in classrooms, to those who see little value in using computers in schools. Knowledge of theory helps us to articulate and implement our beliefs about teaching and learning, and ensure that our practices are congruent with theory. Theory is a powerful and practical vehicle that can drive and reflect our practice.

Acknowledgements

We gratefully acknowledge our classmates for the modules they posted on the WebCT bulletin board that provided the background for this article. We also appreciated their contributions to the development of our theoretical model and their thoughtful critique of this paper. Modules were prepared, presented, and posted by the following people: Dale Finch, Pat Harlton, Brian Strachan (Situated Cognition; Community of Learners); Julie Machnaik, Gail Smith, Jo Anne Szostak (Virtual Architecture); Jann Porritt, Violet Smotra- Cook, Cathy Zhao (Filamentality).

Abstract: This paper describes the experience of making wholesale changes to an introductory Educational Technology Course for teacher education programs at a state university in Florida, which has just completed developing brand new curricula for each initial teacher certification program it offers. Constructed from the ground up and based heavily on research and theory, the new curricula ensure that technology becomes a core element of every course offering in the new programs. The dramatic changes in the curricula called for, and even inspired, equally dramatic changes in the Educational Technology Course. Just completing the first semester of this new course, the authors discuss how the course evolved into its present form, cognizant of the unique mission of the University and the College.

Introduction

Florida Gulf Coast University's College of Education has just completed a complete curricular revision process in order to receive authorization from the State of Florida to certify teachers. This process has also helped the College ensure that the College will be prepared to work towards the NCATE 2000 standards over the next three years. As Florida's newest state university, FGCU opened in 1997 with a number of important objectives, including the appropriate use of technology throughout all curricula on campus. All of the initial Teacher Education programs were merged into the new campus from a former regional campus of the University of South Florida. Authorized by the state to continue using the USF courses for three years, FGCU has spent the last 18 months preparing for this dramatic change. Since technology is a key component of the campus, state, and national objectives for teacher education, the Educational Technology Course quickly became an important focal point for these upcoming changes.

Florida Gulf Coast University was proposed as a university for the 21st century, and has been built and operated with very high expectations for the use of information technology. A key element of the initial proposal, the strategic plan for technology indicates that FGCU “will constantly embrace information technology in creative, experimental, and practical ways to enhance and maximize the creation and delivery of instructional resources and to develop and strengthen its administrative support systems.”

As an additional focus, the university planners established a structure to support Distance Learning as a central part of the university. In doing so, all campus classrooms are now fully connected to the network infrastructure, enabling two-way video to be broadcast to distant locations from virtually any location on campus. The side-benefit of all this “connectedness” is the universal availability of a variety of effective educational technologies to every instructor and every learner on campus.

In November 1999, a new academic building opened which included the first classrooms on campus designed specifically for the needs of Education courses. Modeled by the architects after classrooms they’d built for local middle schools, these classrooms allow teacher-education coursework to more accurately represent the environment graduates will face. Perhaps the most important component of
the inclusion of five-station mini-computer labs(93,164),(926,950). The availability of these computers in almost every classroom where teacher-education courses are taught will enable a new level of technology integration to be realized within the College of Education degree program offerings.

From the outset of the university, Education embraced the wide availability of technology. The first and still only academic unit to operate its own Web and intranet servers, technology was quickly integrated into a wide variety of educational experiences for future educators. More importantly, the emphasis has always been on how technology can support learning, and not simply how to use technology for technology’s sake.

Because a core goal of the faculty in the College is to grow towards achieving NCATE accreditation in as short a time as possible, deeply integrating technology into the curriculum has been perceived as essential by virtually everyone. The NCATE 2000 standards are much more stringent in their expectations of technology use, and also expect that technology related experiences are integrated into every course by every instructor. In a 1997 statement on technology, NCATE commented,

It should be a goal to have every NCATE-accredited institution accessible through the World Wide Web. Web technology can be used to provide information about programs, faculty, courses, and the conceptual model for preparing teachers; to promote and enhance communication between and among faculty and students; to provide students with access to learning resources; and to facilitate the accreditation process, to name but a few uses. Education units at NCATE-accredited institutions should be leading the way in the multiple uses of web technology. Graduates of these institutions should be thoroughly skilled in professional and classroom applications of web technology. (NCATE, 1997)

Designing the Course

When the University opened in 1997, the Educational Computing Course was not an integral part of any degree program. Though it was a required course, it could be taken at any time during the four semesters of a student’s degree program (Florida is a 2+2 state). This simple fact created significant problems because students in the classes ranged from entering students to students who had already completed their student teaching experiences. Fortunately, the state changed this required course to a pre-requisite course in 1998, and students are now required to complete this course prior to admission into any Education program.

In its initial format, the course taught David Jonassen’s concept of “Mindtools,” and used his book Computers in the Classroom, Mindtools for Critical Thinking as the core text. Mindtools is grounded in constructivist theory and encourages the use of technology to support active, reflective thinking. Through this type of technology use, students engage in critical thinking to an extent not easily possible without Mindtools, and very different from the traditional approach to the use of technology in learning situations.

Though a very successful course, one continuing problem was that it relied heavily on a text that has proven to be very difficult to access by learners with little or no professional experience in educational environments. Because of this, the course relied on a lecture format to teach the fundamental theory, while relying on a constructive approach to teach the essential computer-related skills like word processing, spreadsheets, databases, and e-mail.

The Need for Change

Near the end of virtually every semester, students would be understanding the idea of constructivist learning enough to ask a rather obvious question: “If the theoretical foundation of this course is to encourage a constructive approach to instruction, why is this course taught primarily in a direct instruction (lecture) format?” The only reasonable answer this author was able to provide was similar to this comment: “When I figure out how to teach constructivism constructively, I will.”

These comments nagged this course continuously, more because of their obvious truth than because of any particular obligation to our programs. Teaching constructivism constructively would require that students “construct their understanding” of what the rather complex theory of constructivism means. Add to that, students would also need to add to that construction how computers could facilitate constructive experiences. The course had also always been responsible to teach basic computer skills to all future teachers.
The curriculum development process of the new College of Education focused the instructors on the research and the requirements of NCATE. With the new standards for accreditation, all courses in an Education degree program will be required to integrate technology more than ever before. For the new curriculum, this translated into the Mindtools-style use of technology to teach all of the education courses themselves. If every course in each degree program will implement extensive use of technology, the entire nature of an introductory course in Educational Technology changes. This realization forced the instructors to examine just exactly where this course now fit within the entire program, and what needs must now be filled by this course.

The Research Connection

All new curricula of the College of Education are deeply grounded in constructivist theory. A constructivist approach to learning can utilize technology, allowing students to construct and produce knowledge (Jonassen, 1996). Constructive learning is reflective, and inherently draws on prior knowledge (Duffy & Jonassen, 1992). Jonassen (1996) argues that software tools can help students to organize, reflect on, and assess what they know. “When learners actively construct knowledge, it is more meaningful, applicable, and memorable” (Jonassen, 1996, p. 13).

Piaget’s cognitive and developmental perspectives and Bruner and Vygotsky’s interactional and cultural perspectives provide the foundation for constructivist learning theory (Driscol, 1994). Constructivism is rooted in the belief that people are active seekers and constructors of knowledge (Nicaise & Barnes, 1996). “Constructivism assumes that knowledge is built by individuals from within” (El-Hindi & Leu, 1998, p. 3). Jonassen (1996) argues that all learners mentally represent their own reality, and that constructivist instruction must allow learners to actively construct knowledge.

Technology in classrooms has traditionally been used with expensive software that uses repetitive drill to reinforce curriculum (Rice & Wilson, 1999). Computers with even basic software can be used for research, creative thinking activities, organizing ideas, problem solving, and information gathering. Research of any topic has become quick, streamlined, and essentially free for many students (El-Hindi & Leu, 1998). Jonassen (1996) describes the role of the teacher changing from information provider to coach, scaffolded, and problem presenter. Social collaboration is an essential part of the development of knowledge in constructivism as students work with peers to develop their interpretation of their environment. Additionally, students must engage in self-directed learning. The learner must have control over both the direction and content of their learning (Nicaise & Barnes, 1996).

Part of the process of creating an updated course including looking at what other courses are doing around the country. This was accomplished by looking at what others were teaching in similar courses, as reported in the SITE Annuals for 1998 and 1999. Many of the main ideas presented in these articles were similar to these comments:

- "Students were introduced to dozens of different software programs and the educational resources of the World Wide Web." (Gunter, Gunter, and Weins, 1998) - http://www.coe.uh.edu/insite/elec_pub/HTML1998/ec_gunt.htm

- "The course content at the four universities provides the education students with the computer concepts and skills which they are expected to know for their future teaching: word processing, spreadsheet, database, multimedia, presentation, e-mail, Netsearch, and integrating technology into instruction. An education student with these computer skills and knowledge will become a qualified teacher who can prepare the children in our nation to face the challenges of the modern world." (Leh, 1998) -http://www.coe.uh.edu/insite/elec_pub/HTML1998/ec_leh.htm

- "Several required activities are included in the curriculum that introduce students to word processing, draw, paint, desktop publishing, email, the world wide web, web page development, presentation software, and multimedia. Students are then required to do four projects that expand their knowledge about four of the technologies. The last requirement is a teaching unit in which at least three of the technologies have been integrated." (BUMP, 1998) - http://www.coe.uh.edu/insite/elec_pub/HTML1998/ec_bump.htm

- "The learning theory backbone of the class enables them to make decisions about how different types of computer programs can support different learning goals, how to select software that meets learner needs, and how to evaluate new educational technologies from a student learning perspective. The connections they make between learning theories, their own learning, and educational technology provide a solid experiential base that will serve them well in the teaching
Only a very few courses, such as the last one, appeared to utilize a constructive approach. This was not a lot to go on, knowing that the new course needed to constructively teach both constructivism and the constructive use of technology to support instruction. Instead, the instructors took the best of what we knew about constructivist theory and Jonassen's interpretation of it for Mindtools, and went to work designing a new curriculum.

Establishing the Syllabus

Our first decision was to throw out the book - all books - at least for the first portion of the class. Instead, we decided to teach the course with two stated objectives: first, the course would be a “wash-out” course; and second, the course would have as its fundamental goal how computers can support the construction of knowledge in content areas. These two ideas were a significant departure from previous courses and from many of the courses offered elsewhere (as described above).

Becoming a “wash-out” course was certainly something we deliberated on carefully. We defined this as a course so fundamental to the goals of the larger program that students who failed to do well in this course would recognize that perhaps these particular programs were not a good fit with their skill-base. We believe that technology is simply too important of an element in the preparation of new teachers today to let weak students pass the class. While significant help and assistance is available, we decided to make it very clear at the beginning of the semester that we will not coddle students in the class. Every student is responsible to learn the bulk of the application learning outside of formal class - finding tutors if necessary (just like students in calculus or accounting might).

In the fall of 1999, we also believe that it is now a reasonable expectation that students enter our class with basic computer literacy skills. The title of the course clearly indicates that this is “Introduction to Computers for Education,” not just “Introduction to Computers.” Students who do not yet have basic word processing, e-mail, and web surfing skills are to be warned to acquire those skills prior to taking this class. It was important to make it clear that there is now an expectation that students enter the course with a minimal set of computer skills if they expect to be successful.

The sixteen-week semester was broken roughly in half, introducing databases, Inspiration, spreadsheets, and web pages during the first nine weeks, and then interpreting the experience and constructing understanding of the role of technology in education today during the last seven weeks. Most importantly, however, was the nature of the instruction during the first nine weeks. All instruction was designed to be consistent with the concepts outlined in Mindtools as being constructive in nature. That is, every computer experience that was to be provided would be done only though the use of constructivist methodology. A great deal of reflection was also to accompany this instruction.

It must be noted that the most important part of this new course is NOT the instruction of the skills. Rather, it is the modeling of constructive uses of technology to support content learning. At mid-semester students would begin reading a number of carefully chosen articles from a variety of Educational Computing Journals, and discussions would then help students begin to piece together not only the concept of constructivism, but also how technology today is a fundamental aspect of knowledge construction.

Deciding on the topics to be included was challenging. The heart of the course was to be constructivism and Mindtools. Jonassen introduces the Database application first in his coverage of the Mindtools concept, primarily due to its rigid structure and ease of use. We decided to start here as well, but to do so without also trying to introduce an actual computer application (Microsoft Works). Instead, we would utilize a locally programmed web site that provides the ability to manipulate a complete database in a manner very similar to working in an actual database application. Separating the higher-level, constructive nature of database manipulation from the lower-level, skill development process of learning a new program was important to us, and was the reason for leaving the database application out of the initial stages of the syllabus.

Continuing with constructive tools, we decided to introduce Inspiration next. Inspiration is a visual tool for semantic mapping, brainstorming, and many other applications, and Jonassen’s text emphasizes the importance of using this type of tool to help students reflect on what they know, and how they know it. Providing more direct experience with this tool would be important since it is new to virtually all students. Nevertheless, students would still need to be responsible to utilize the help files and other resources to master the program. Constructive learning is student centered, not teacher directed.
Two additional tools would be introduced, spreadsheets and the web, and like the first two, would be taught only minimally, requiring the learners to seek out the help and advice necessary to be successful in the learning process. Finally, the course would conclude by using recent journal articles to tie these experiences together and facilitate the construction of the courses “big ideas.”

Teaching the Course

We were prepared for resistance. Most of our students are choosing to enter teaching and report that they enjoyed school and how they were taught. Since most schools today still generally employ directed instruction methodologies, most of our students are actually reporting that they like being taught to in a directed instruction style. Our very first statements in class warned students of the rather dramatic change in instructional style from what they might be used to or comfortable with, and included a discussion of how most students preferred to learn. We were careful not to “give away” our philosophy, but helped students reflect on their learning experiences to date. Students were also warned about the need to have basic technology skills upon entering the course, and also about our approaching this class as a “wash-out” course. (We lost a handful of students from the first to the second sessions of each course section.)

Once we began covering the actual course topics, students experienced our methodology right away. Students were expected to set up their own e-mail accounts (on a university web page), and then to send e-mail the first night. They were given an assignment to “experiment” with the e-mail software. Although we briefly discussed what the email was capable of and what some of terms meant, specific instructions were not provided. The help files were introduced, as well as the concept of working with a partner, where to go for help (the computer lab), and how to find e-mail at home to do some of the same things that we encouraged them to explore (mailing lists, sending attachments, etc.)

Next we had the students begin exploring the databases. Our discussion of databases began before the actual use of one, which followed closely with the Jonassen text as to their uses, functions, etc. Later, we introduced the online database, and briefly introduced the concepts of sorting and filtering. Students were given time to “play” (experiment) with each of the tools, followed by a structured time to reflect on how a database could be useful to learning. Through this process, students were encouraged to make some statements (predictions) as to why the databases (and their tools) are useful, how could they be used with content, what conclusions learners could make from manipulating this data, and how students might use them to better understand information that they might be given or the might collect. During the third session, only after students were provided adequate time to process these “big ideas” about the constructive use of databases, a database management application was introduced (MS Works). The program was modeled extensively in the classroom, but only basic instructions on how to use this tool were provided (along with reminders where help was available).

Each major tool, Inspiration, Spreadsheets, and the Web, were introduced in a similar fashion. Very little direct instruction was provided, although extensive resources were made available and office hours were clearly identified.

Constructing Constructivism

Throughout the semester we faced students unhappy with the amount of “support” we provided. Conditioned to a direct instruction learning format, students expected to receive direct and specific instruction on skills needed for the class rather than guidance on how to gain these skills on their own. Weaning students from the expectation that all information and skills they needed would be provided to them caused the expected strife and yet also set up some interesting discussions among the students. However, conditioned also that learners only have to answer predictable questions in class, truly engaging discussions were difficult to start and sometimes even more difficult to continue. As might be expected, non-traditional students were typically the most responsive and the largest participators in class discussions. Students who reported that their high-school learning experiences involved little direct instruction (only a handful of students reported this) were also the most receptive to the ideas introduced.

The essence of the course, the whole purpose of its existence, was to be found in the students’ ability to construct a conception of constructivism. We note here the difference between “getting it” and “buying it.” Our goal at this early stage of their professional education program is to help students’ “get it” so that we might initiate the process of “buying in” to the theoretical foundation that underlies the rest of
our curriculum. As noted earlier, we did expected resistance. In fact, we expected a lot of it. And resistance is just what we found. Interestingly, though, only late in the semester did resistance to the concept itself begin to develop. We perceive this as positive because in order to resist the underlying concept, the concept itself needs to be understood to some extent. Since understanding the concept was the primary goal at this point, we feel like we have achieved a level of success we had not achieved in prior semesters using the more directed approach.

Continuing the Course

As with any new program, there are kinks to be worked out. At the time this paper is being written, the semester has two weeks remaining. Final projects need to be negotiated and completed, and the entire semester reflected upon. Ongoing discussions with the students have pointed out a number of areas to work on for next semester, including the need to significantly modify the expectations for any spreadsheet projects and also the consideration of using Inspiration as the initial software application.

Other challenges exist for the upcoming semester, including a new instructor who comes to the course with limited experience in enabling constructivist learning in the classroom, and an increasingly older set of lab computers that are less able to support our growing needs. In addition, as a 2+2 state, we will begin working with our local community college to encourage a consistent approach to this common course for students completing this pre-requisite as part of their Associates Degree.

Conclusions

The Educational Technology Course has become a foundational course in the development of professional educators, but not in the way that many believe. Too many programs still approach this type of course as the one chance to be sure that prospective teachers acquire the majority of technology instruction they'll ever need. This approach is too narrow, and will simply fail to meet the requirements of NCATE 2000, not to mention the needs of the future teachers themselves. Teachers must acquire and continue to develop skill in computers and computer related technologies throughout their entire set of professional coursework. To do any less cheats not just these learners, but cheats every future student of each of our graduates.

This new recognition of the role that technology will play in every teacher education course places an entirely new set of expectations on the Educational Technology Course. Simply providing a core set of specific skills will not enable success in our new curriculum. Instead, this introductory course now serves the purpose of beginning a transformation in future teacher educators from a consumer of information to a constructor of understandings, and from a mere gatherer of facts to an active constructor of knowledge, all facilitated by the power of computers used as Mindtools.

Recently, the College of Education adopted a “Statement on the Use of Technology” which will appear in all future University Catalogs. In a few sentences, it captures the fundamental reason for redesigning the Educational Technology Course in the format that we have. It states, in part, that the College “does not treat the variety of technologies used in the education process as a separate subject or content. Instead, technology is merely one additional means of facilitating the educational process within the College and within the educational communities our programs serve. Because of this philosophy, we expect all learners to be proficient with education related technologies.... Technological proficiency is expected as a pre-requisite skill, similar to the expectation that all learners can write, use appropriate grammar, and access library resources.”

The role of technology in learning has changed dramatically in the last few years. The role of the Educational Technology Course must change even more dramatically if we expect to be able to provide teachers prepared for the challenges of the 21st century learning environment.

Abstract: This paper describes the collaborative team teaching experience in a technology course. In this study, a collaborative team used a reflective approach from constructivist perspectives and involved students as well as two instructors in planning, conducting, and evaluating processes. The goals of team teaching were to provide each student with opportunities to choose from different instructional styles and formats, to enrich the learning experience by sharing and collaborating, and to facilitate a supportive and constructive environment through in-depth interaction with each student. The purpose of this study was to examine the effectiveness of this collaborative team teaching approach. The surveys, individual/small group interviews, observations, class notes, course evaluation, and students' feedback were used to find the students' satisfaction level, the effects of learning, and the significant factors in the team teaching approach.

In the beginning, when technologies were introduced in K-12 classrooms, most pre- and in-service teachers were at the starting level of learning technology and had minimal or no experience in using technology. With the growth of availability of technologies and teacher training programs, pre and in-service teachers have varied experiences from using word processing, spreadsheets, and the Internet to developing multimedia. Also, the usual pattern of students' technological capability in technology courses has been changed. Students who possess different knowledge, interests, and skills in different subject areas created a complex learning environment. The gap of technology skills between beginning and advanced students has been dramatically increased. Many students who have minimal prior experience with technology are overwhelmed by other advanced student's capabilities as well as information overload.

With the complex learning environment, we realized that instruction focused on one group is not appropriate in a multi-group classroom. To help each student achieve personalized learning goals and to minimize students' anxiety about other advanced student group, we tried a collaborative team teaching approach in an integrated technology course. The major goals of our collaborative team teaching were 1) to provide each student with opportunities to choose from different instructional styles and formats, 2) to enrich the learning experiences by sharing and collaborating, and 3) to facilitate a supportive and constructive environment through in-depth interaction with each student.

The purpose of this study was to examine the effectiveness of the collaborative team teaching approach. The surveys, individual/small group interviews, observations, class notes, course evaluation, and students' feedback were used to find the students' satisfaction level, the effects of learning, and the significant factors in the team teaching approach. In the team teaching approach, we tried many different formats such as whole class presentations/discussions, individual/small group activities, and tutorial sessions. Usually the classes started with the whole group session and then each student chose a learning activity according to her/his needs. Two instructors rotated their role from small group tutorial sessions to individual/small group activities. While one instructor took care of a tutorial session to beginning students, the other supported the exercise of students' own creative abilities. This paper describes the teaching strategies implemented in our collaborative team teaching approach, reports the results caused from our efforts in details, and suggests effective ways to implement team teaching for future courses.
The Study

Participants in Team Teaching

A technology course was taught by Cleveland State University (CSU) faculty during the 1999 fall semester on campus at Lorain County Community College (LCCC) as a course in the University Partnership program of CSU and LCCC. The course was offered for graduate students in the Partnership at LCCC just as if it was being taught at the CSU campus. 34 students enrolled in a technology course were divided into two sections. Initially 21 students in one section were assigned in the PowerMac lab that provides access to both Mac and PC environment, and 13 students in the other section were assigned in the IBM lab that provides only PC environment.

About 90% of students enrolled in this course were pre-service or in-service teachers in K-12 and higher education. The majority of students entered the program to receive a Master's degree in Computer Uses in Education or certification to teach technology in K-12 schools. There were few students who took the class to improve their professional development with technology in a Non-degree program. The whole group consisted of 29 female and 5 male students represented a diverse range in age and experience.

While traditional teaching in higher education requires one instructor to teach his/her students in a course, two instructors from CSU designed, planned, conducted, and evaluated the course with different styles and viewpoints as a collaborative effort. Although the instructors had common agreements on many educational philosophy, teaching area, and flexibility, they were different in gender, experience, and expertise. In this study collaborative team involved students as well as two instructors in the teaching process as much as possible. The students were expected and required to engage in collaboration of goal setting, presentations, discussions, in-class activities, and evaluations.

Course Design

This was a pilot study that implemented a team teaching approach in a technology course. The main purpose of this collaborative team approach was to reduce the frustration of students who had limited experience with technology, to enhance advanced students according to their level, and to provide better learning environment through access to various types of technological equipment and groups. Team teaching in this instance encouraged students to set their own goal of learning and to explore their own values, team teaching enhanced collaborative learning by sharing ideas, experiences, and viewpoints. Team teaching also provided a wonderful opportunity for team learning.

As we developed the course, we tried to provide students with opportunities to articulate their own beliefs, create their own knowledge, and evaluate their learning progress. The course requirements included in-class activities, reflecting on a reading, a comprehensive exam, four mini projects, and a final project that represents comprehensive understanding and skills. Usually each class began with a chapter presentation by instructors or a small student group and then the class topic was discussed in depth through sharing of experiences and perspectives. To incorporate student's knowledge constructed through class discussion and presentation into a real context such as their classrooms and work places, in-class activities were required in a small group or by individual. During the in-class activities, the students were given the option of practicing in-class activities, working on their own, or attending tutorial sessions based on their prior experiences, need, ability, and progress of learning. While one instructor conducted the tutorial session, the other guided students in the different group.

With a collaborative team teaching approach, we emphasized the student-centered instruction. Two instructors tried to change the fixed role transmitting knowledge toward the flexible role of a facilitator of student's activities. The students were involved intellectually in critical-thinking or higher-order thinking process instead of passively taking notes from instructors' lectures. For one semester, the students were engaged in four learning phases:

- exploring/inquiring,
- sharing,
- developing
Inquiring/Exploring

The students were required to review some articles to understand fundamental theories/practices and integration strategies for integrating technology into their teaching or professional practices, and to develop their own technology plan to be used in their classroom teaching and work. Two instructors introduced some useful examples and resources as a guided instruction. After the students reviewed information, they were expected to analyze the findings through critical thinking skills and to connect their knowledge to real life experiences.

Sharing

All students were required to participate in a presentation of at least one chapter to the whole class from the textbook, *Integrating Educational Technology into Teaching* (Roblyer, Edwards & Havriluk, 1999), through a collaborative effort in a small group. Each group was encouraged to incorporate presentation tools such as PowerPoint, HyperStudio, or Web site in a professional manner. The main focus of chapter presentation was on the creative ideas for applying knowledge and presentation strategies rather than the content itself of the chapter. It was essential that all team members contribute to organizing and presentation. To do this, each student took responsibility for participating in team discussions and planning process to develop a main frame and strategies for the group presentation.

Developing

The students were highly encouraged to integrate technology into their classroom teaching where possible when they develop instructional materials or projects. Many students selected students or parents in their classroom as a target user group when they develop instructional material or projects. In the developmental level, they developed problem-solving or critical thinking skills to design an effective material and to find practical solution when they encounter some problems. The students gained frequent feedback or input from the instructors, peers, and potential users to revise the prototype. When they were satisfied with their product, they were motivated to use their product in the real classroom. For examples, some students used the instructional material developed in the course for their classroom teaching, disseminated the classroom newsletter to inform parents with special events in their classroom, or presented the project in a parent-teacher conference.

Evaluating

In this course, two instructors assessed students in a constructivist manner instead of traditional type such as grading on a bell-curve. The focus of assessment was on learning progress of individual learner rather than achievement of predefined learning objectives. Students' projects were reviewed several times by peers as well as two instructors so as other to make improvement based on suggested ideas. Most assignments were evaluated by a recursive approach that focuses on revision processes rather than a final outcome. However, to provide general guideline for the assignment and to avoid student's confusion in the process of evaluation, the instructors provided minimal criteria for each aspect of the project. The final grade for each assignment was given by agreement of two instructors and recorded in the master grade sheet.

The Method

The effectiveness of team teaching was examined in six different ways: the 1) surveys, 2) individual/small group interviews, 3) observations, 4) instructors' notes, 5) course evaluation, and 6) student's
feedback. The purpose of this was to find the students' satisfaction level, the effects of learning, and the significant factors in the team teaching approach.

The surveys were conducted in the beginning and middle of the semester with a semi-structured format and open-ended question items. The first survey was conducted to examine the students' background information such as their teaching areas/grade level, prior skills/experiences with technology, and expectations of learning and answered by all 34 students. The second survey questionnaire provided multiple options from strongly disagree to strongly agree (1-5) in the first part and included open-ended questions in the second part. The second survey was conducted anonymously and responded by 24 out of 34 students. The survey examined the degree of

1) meaningful learning
2) suitability in graduate level
3) engagement of learning
4) interaction between instructors and students
5) recommendation for the next semester
6) willingness to apply what they have learned to their teaching.

Informal interviews with three individuals and three students in a small group were conducted in the end of semester to find the their satisfaction level of learning and the strengths/weaknesses of team teaching approach. Two instructors observed and reviewed each class to examine what worked, what did not, and what should be changed to provide meaning learning environment in the next sessions. Students' feedback and requests via e-mail and short conversations were reflected according to agreement with other students as well as two instructors.

The Findings

Interaction between Instructors and Students

Over 75% of students indicated that team teaching approach enhanced students' meaningful learning through individualized comments and feedback and they had opportunities to see different styles of planning and organization, as well as methods of class presentation. There was more and faster interactions with instructors as indicated and preferred by most students. One student mentioned that trouble shooting took less time and handled in various ways. With team teaching approach, they could get double feedback from both instructors on their projects and presentations. As a result, the students acquired a greater depth of understanding of the subject matter and mastered skills to incorporate technology into their teaching from different strategies and viewpoints.

Suitability of Team Teaching Approach in Graduate Level

One of the main characteristics of most students in the graduate level program is self-motivation. With team teaching environment, the students collaborated with other students in many different aspects/various groups. They shared different models of presentation and discussion style and learned various strategies for problem solving and organizing information.

Student Attitudes

In the collaborative team teaching, the blending of each instructor's expertise strengthened the content of the lessons and the way they were presented. Most students reported that they learned to be more flexible, to focus on individual strengths, and to prioritize concepts. About 55% of students marked on the strongly agree or agree about intention level to apply team teaching approach in their classroom teaching and more than half of them recommended the team teaching approach for a technology course that will be taught in the next semester.

Disadvantages of Team Teaching
Speer and Ryan (1998) pointed out several common problems in collaborative team teaching. One of major problems is that teachers may feel insecure and tense while doing collaborative team teaching, due in part to different levels of experience and expertise in relation to the course and or different statuses. The second major problem with collaborative team teaching is its lack of institutional support.

In our case, these problems were handled very smoothly. Two instructors who are very flexible enough to try innovative teaching ways to improve the quality of teaching and had common understanding about teaching philosophy from constructivist perspectives that emphasize student-centered learning. In addition, this pilot study had a great support and encouragement from administrators that recognize the benefits of team teaching for professional development and for improving our courses.

Critical Factors in Collaborative Team Teaching

Major concerns in the collaborative team teaching were to set the course goal, to determine roles in each part, setting agendas, keeping records, setting procedures for evaluation, and scheduling class activities and assignments, etc. Through the collaboration work, we found several essential factors to successful team teaching.

Mutual respect and trust

As Cruz & Zaragoza (1998) mentioned, to establish mutual respect and trust between two instructors is critical for successful team teaching. Two instructors had a common understanding about instructional strategies and learning objectives from constructivist perspectives. The instructors also respect students’ viewpoint and invited students to share their experiences with the whole class.

Communications

Some educators mentioned that in team teaching, you spend less time developing and teaching the course than was normally spent by the individual instructors (Morganti & Buckalew, 1991). However, we revealed that the collaborative team teaching in a constructivist way requires large amount of time and high level of energy in all processes. Our major concern in the team teaching was to improve the quality of teaching and learning from epistemological perspective that knowledge is constructed by social interaction among group (Austin & Baldwin, 1991). In practice, we spent huge amount of time preparing each class and evaluating our students’ assignments. In the most cases, the initial plan by individual perspective was negotiated with other instructor and students.

Responsibilities

Before-class meetings, the instructors reviewed individual responsibilities on content coverage, preparing hand-outs, and their roles in the class. Some students worried about the evaluation of their assignment by two different instructors and record keeping of learning progress. To minimize students’ common confusion by two instructors, we kept master database that recorded a track of students’ learning progress. The instructors provided a guideline and criteria for each classroom exercise and assignment. Over all, in our collaborative team teaching, the responsibility of learning was shared with all students as well as with partner instructor.

Reflection

The instructors evaluated each class to review differences between what was planned and what the students are achieving and refocused on the subject matter. The evaluation was conducted right after each class for 30 to 40 minutes and recorded in instructors' log document for teaching in the next semester. In addition, reflective input or feedback by students was welcomed and encouraged to improve the collaborative teaching and learning environment.
Conclusions

Although many studies of team teaching approach indicated positive results such as reducing teacher isolation, and increasing students’ satisfaction, much of team teaching efforts happened in primary or secondary school level (Walsh & Snyder, 1993; Solomon, 1994). In many higher education institutions, the typical pattern of teaching is still largely based on an individual instructor bearing responsibility for students in a course with limited interaction with colleagues. Although students may learn or discuss about the team teaching concepts, but this does not take the place of being a participant in such an activity.

Banks and Stave (1998) stress that preservice teachers need to observe, experience, and reflect on learning activities from both student and teacher perspectives during their preservice coursework. However, preservice teachers rarely encounter team teaching in their course experiences. As revealed by many studies on team teaching, team teaching makes effective use of existing human resources without additional requirements of expensive resources or equipment to implement this method. Only rearrangement of human resources and equipment and support from administrators are required to implement team teaching.

Even though few students expressed a negative impact on resources, especially class size and classroom space, our collaborative teaching was very successful because we had common understanding of the theories and common educational philosophy. The students and instructors had very positive experiences in this team teaching approach. With combined expertise and resources, the students were actively engaged for meaningful learning to achieve personalized goals. While advanced students were enriched a meaningful learning on their own direction, the inexperienced students with technology felt comfortable with less anxiety toward overloaded information and comparison with advanced students. In addition, the instructors' role as facilitators instead of having authority in the classroom made for an effective environment for collaborative teaching and learning.

Abstract: This paper describes the evolution of an educational technology course for preservice teachers from an applications-based curriculum to a new framework that draws on the structure of the ISTE recommended foundations in technology for all teachers and expands upon the substance of the standards to meet the challenges of increasingly rapid technological innovation. The curriculum for this course was divided into the three main categories within the foundations: a) basic computer/technology operations and concepts, b) personal and professional use of technology, and c) application of technology in instruction. Connecting standards and curricular activities remains a creative and interpretive process and students were expected to produce projects that were authentic, meaningful, and intended for future student and professional use. All course activities were integrated within each of these conceptual sections thereby making explicit and modeling best practices in technology integration that many teacher candidates have never experienced as K-12 students.

Introduction

Traditionally, educational technology courses in teacher preparation programs have focused on preparing students to use a variety of software applications such as e-mail, the World Wide Web, spreadsheets, databases, and educational software. In light of the rapid pace of technological and information innovation in which new software applications are created daily and a growing frustration with impossibility of keeping pace with these changes, the faculty coordinator and instructors for the undergraduate-level educational technology course in the College of Education at the University of New Mexico have implemented changes in the vision and foundational structure of this course. The revised course now reflects this fundamental shift from applications-based instruction to a pedagogy that is conceptually and explicitly tied to the ISTE (International Society for Technology in Education) recommended foundations in technology for all teachers. This conceptual framework now focuses on the processes of curricular integration and the professional use of computers and information technologies. Course instructors also committed to model, clearly and continually, best practices in technology integration and thus engage students in the reflexive process of participating in technology activities as students and publicly reflecting upon these practices as future teachers.

Although many institutions and governing bodies at local, state, and national levels are actively developing technology competencies for teachers (Moore, Knuth, Borse, & Mitchell, 1999), the ISTE standards were chosen to provide the guiding framework for the educational technology course revisions for several reasons. The ISTE foundations for all teachers are the most widely recognized and comprehensive standards at the national level and many individual states have either adopted wholly or based their own standards on these foundations. New Mexico is among those states that have adopted the ISTE standards and added additional standards that support the multicultural nature of education in the
state. In addition, the College of Education at the University of New Mexico is expecting an NCATE accreditation review in the fall of 2000 and curricular alignment with ISTE foundations is becoming increasingly important although not yet required.

From Applications to Processes

Across the United States, many teacher preparation institutions are engaged in similar efforts to revise teacher preparation curricula to reflect and meet the ISTE and various state technology standards. Several of these programs have attempted to provide opportunities for teacher candidates to meet the ISTE standards in preparatory courses, content methods course, and student teaching experiences (Chen, 1999; Dempsey, Springer, & Holder, 1999). Strudler and Handler (1998) proposed a structured matrix for distributing the ISTE standards across the various teacher preparation courses in their article describing a systematic approach for implementing the revised ISTE foundations. In contrast, the structure of the educational technology course at the University of New Mexico reflects the unique representation of the ISTE standards within an individual course. This course serves as a foundation for methods courses and subsequent student teaching experiences in which the ISTE standards will be strengthened and enhanced through curricular revisions made possible by support from a Preparing Tomorrow’s Teachers to Use Technology grant from the U.S. Department of Education.

The current ISTE foundation standards for all teachers are divided into three main categories: a) basic computer/technology operations and concepts, b) personal and professional use of technology, and c) application of technology in instruction. These categories of standards provide an elegant and simple view of the important processes and uses of technology in educational settings. Instead of framing a checklist of proficiencies to be attained in a variety of applications, the emphasis of the revised standards reflects an important shift to the more enduring categories of uses that have the potential to withstand the onslaught of educational applications that have yet to be invented. Although the sub-standards within each category are more detailed, making the connection between standards and specific curricular activities is still a creative and interpretive process. For these reasons, the curriculum for this three-credit semester-long technology education course was divided into these three main categories and all activities were integrated within each of these conceptual sections. Instructors believed that by making this three-part curriculum explicit to students, teacher candidates might become more aware of the curriculum, the goals of course, and their responsibility to direct their own continuing professional development within these three domains beyond the life of this course.

Making Processes and Uses Visible and Explicit

In their approach to implementing the foundations in teacher preparation courses, Strudler and Handler (1998) recommended that it is helpful to “unpack” or break down the standards into clear, manageable chunks rather than clustering them together (p. 17). The new structure of the educational technology course uses an innovative structure that includes this unpacking approach and wraps it within a recursive cycle of macro and micro views over time. Specifically, each of the three major themes or sections of the course (exploring applications, personal and professional use of technology, and application of technology in instruction) is introduced through a macro-view in which the major theme and the related activities, readings, and projects are described. During the theme-related weeks, students engage in project-based activities that provide opportunities to meet the foundations standards within each category. At the end of each thematic section, students demonstrate their projects, write a reflective paper, and engage in discussions that are intended to zoom back to the macro view that connects the standards met in authentic projects with the major theme once again. This cycle is repeated two more times for the other two themes within the semester. A major element of this recursive approach is to help students formally internalize the three-part framework that will guide their subsequent studies in methods courses and student teaching experiences. That is, this approach is intended to support metacognitive awareness in students so that their learning in the domain of teaching with technology may become intentional and authentic.

In addition to explicit instruction through the thematically structured section, the course Web site with weekly lesson plans provides a continuous opportunity to connect the conceptual framework with the
activities and projects in which students participate throughout the semester. The Web site also serves as an additional model for students of how teachers might use the Web to effectively guide teaching and learning in K-12 schools and is featured as such in the section on the application of technology in instruction.

Another significant and explicit aim of the course is the modeling of effective grouping strategies within each cycle that teachers can use with students from diverse populations. Students collaborate on projects in small groups of four to five students, as dyads, and participate in jigsaw-type distributed knowledge groups. Instructors model and discuss strategies for ensuring equity in grouping for technology-based activities so that teacher candidates are able to experience best practices in technology integration as students while learning the role of the technology-using teacher.

At the end of each thematic cycle, students present their final projects as a culminating activity and they write reflective learning process papers that are focused on making connections between theory and practice. This final reflective paper and the culminating activity complete each thematic cycle and provide closure to and reinforcement for the importance of the three featured processes and uses of technology in education.

**Major Course Sections**

**Exploring Applications**

In the first section of the course titled "Exploring Applications" (ISTE Standard 1), students participate in a multi-week activity in which members of small groups become "experts" with a software application such as word processing, painting, drawing, spreadsheets, multimedia presentations, and databases. These experts are then expected to share that specialized knowledge with other members of the group as they work collaboratively to complete a project that requires the use of all of those applications. In some sections of the course, for example, students completed a "Xeriscape" activity (water-conserving landscaping) in which they formed landscape companies and developed a proposal in response to a landscaping request for proposal. This proposal included a site map, irrigation plans, employee biographies, an analysis of community input, and the use of a xeriscape database to select plants according to the results of the surveys. When the activity was introduced, these preservice teachers participated in the authentic project-based application of software tools in their role as students. Toward the end of the project, instructors shared with students the entire activity plan that modeled technology integration with math, science, language arts, and visual arts curricula. These students experienced an authentic application of technology integration that not only increased their own proficiency as learners, but also provided a replicable model of best technology integration practices that they could use with their future students.

**Application of Technology in Instruction**

In the "Application of Technology in Instruction" section of the course (ISTE Standard 3), reading assignments and activities are centered on providing the best possible learning environments for K-12 students. Students critically evaluate publicly available lesson plans from the Internet and then learn to write their own lesson plans. These students complete two cycles of lesson planning, the first with a partner and the second independently. The lesson planning cycle includes research, alignment with standards, peer review, and finally, public demonstration. Throughout this section, instructors emphasize the quality of technology integration and students continually evaluate their own and others' lessons so that the inclusion of the computer and other information technologies is meaningful, enriching, and necessary to achieve curricular learning goals.

The course activities in this particular section provide authentic models of alternative assessment and peer assessment that future teachers would be able to use with their own students to document the effective integration of technology. One of the most difficult aspects of lesson planning for novice teachers is understanding and planning for the articulation of assessment artifacts with the content standards and benchmarks that frame the lesson. Therefore, students explore and develop rubrics that guide the peer review process as well as the demonstration of the thematic projects through the culminating activity. This culminating activity serves as a performance assessment of technology proficiency and is an example of the kind of competency that teachers must demonstrate in other states such as Idaho (Coleman, 1999).
Additionally, the course faculty coordinator decided to integrate performance assessments throughout the course in anticipation of the revised NCATE 2000 requirements.

**Personal and Professional Use of Technology**

The final section of the course focuses on the Personal and Professional Use of Technology (ISTE foundation standard 2). Activities in this portion culminate in the production of a "Teacher Toolkit" that serves not only as a professional portfolio, but also as a "living" set of resources that a future teacher can use to continue learning to teach with technology beyond the technology education course. During the first class of this section, students are able to explore Web publishing, PowerPoint, and HyperStudio applications. After working with each multimedia application, students then choose which application they wish to master and they use that application to create their Teacher Toolkit. Individual toolkits might include a current resume, technology enriched lesson plans, teaching philosophy, reflective process papers, images of classroom experiences, and links to personally useful professional development or educational Web sites. In addition to serving as a portfolio that documents students' work in technology integration, the Teacher Toolkit is intended to serve as a living and dynamic electronic document. Specifically, the toolkit will provide support to students as they continue to learn to use and teach with technology beyond the technology education course into their methods courses, student teaching experiences, and their future careers as teachers. The major vision of this course and an important outcome of instruction is to increase students' confidence in engaging the process of selecting and learning to use technologies that are changing so rapidly.

**Implications for Education**

The description and sharing of this new approach to designing a technology education course for preservice teachers contributes to the field in two important ways: a) by providing a model of course design that moves beyond teaching software applications to scaffolding the enduring processes of technology integration and b) making explicit and modeling best practices in technology integration that many teacher candidates have never experienced as K-12 students. This new course design shows promise for meeting the challenges of an ever-changing technology frontier in which teaching applications-based technology survey courses is increasingly untenable.

Integrating Electronic Portfolios into Undergraduate and Graduate Educational Technology Courses at the University of Florida

Colleen Swain  
University of Florida  
United States  
cswain@coe.ufl.edu

Gail Ring  
University of Florida  
United States  
gailring@coe.ufl.edu

Abstract: The purpose of this paper is to examine the use of portfolios as a teaching tool for undergraduates and graduate education majors. We will discuss challenges faced by students when developing portfolios as part of the educational technology curriculum. Concepts such as reflection in education, collaboration among peers, ownership, and the selection of work will be addressed. A comparison of the implementation process used by undergraduate and graduate students is provided.

Introduction

The use of portfolios as an educational tool has the potential to change the way we teach as well as change what and how our students learn. Electronic portfolios afford students a method to express their strengths and demonstrate their understanding of numerous concepts in multiple formats using a wide array of media for expression purposes (Moersch & Fisher, 1995). Portfolios provide students with a richer way in which to present themselves, and encourage reflection and collaboration among peers (Paulson, Raulson, & Meyer, 1991; Hamm & Adams, 1991). This richer mode of expression not only changes students' work, but the quality of their work as well. Students begin to realize that learning is an on-going process that does not necessarily conclude with a test or course. The literature has shown that students also approach learning differently when they are not being evaluated, either formally or informally, in a traditional manner (Kent, 1997). Viewing students in this richer context enables colleges, graduate schools, and employers to learn more about the person than traditional resumes and transcripts.

The Need for Electronic Portfolios in Educational Technology

Teachers should create technology-rich learning environments that encourage the development and success of all students. The educational technology faculty at the University of Florida believes it is critical that students understand that educational technology is about teaching and learning, not simply the creation of computer projects. It is also important that students are given meaningful assignments that do not always conclude at the end of the course. Creating portfolios gives students the opportunity to create a learning environment which demonstrates what they learned, as well as providing students an opportunity to work on an open-ended project. An additional benefit of electronic portfolios is that students will leave their educational program with a product demonstrating their knowledge and abilities.

Another important aspect of students creating portfolios is the reflection that is involved in the developmental process. The creation of portfolios forces students to thinking about their work and the process of learning. Research (Paulson, Raulson, & Meyer, 1991; Hamm & Adams, 1991) regarding electronic portfolios has shown this mechanism allows students to be more reflective about their work. The
greatest advantage for students is the opportunity portfolios provide for reflecting on their learning process and progress (Ause & Nicastro, 1997). Portfolios can help teacher educators address one of the most challenging tasks they face: training new teachers to be what Donald Schon has called “reflective practitioners” (Yagelski, 1997). These factors convinced the educational technology faculty that electronic portfolios were the best method with which to accomplish their teaching goals.

The decision to use electronic portfolios in our educational technology courses was the catalyst that caused the College of Education to adopt use of electronic portfolios for all teacher education students. Consequently, the educational technology faculty has been able to provide the leadership necessary for successful strategy and implementation processes. Using Rogers’ research on innovation diffusion theory (1995) enabled us to predict potential difficulties and aid in a smoother diffusion process. This paper will chronicle the experiences of the undergraduate and graduate educational technology students.

Undergraduate Portfolio Project

As mandated by the state of Florida, all students who declare education as their major must take the Introduction to Instructional Technology course. This course addresses computer skills as well as teaching and learning issues impacted by technology. Students enter this course with vastly different technical skills, and we want to challenge novice computer-users as well as more advanced computer-users. Previously, the course involved creating web documents, and a variety of multimedia projects that students submitted to their instructor electronically. In the spring of 1999, students began developing electronic portfolios as one of their requirement assignments. We believe that changing this course to include electronic portfolios encourages students to reflect on their work, what they learned, and how their work has evolved. Krause (1996) states, “Students’ successful use of the portfolio is directly related to the variety of self-selected ongoing work, drafts, and final products, and provides numerous opportunities for the learner to think flexibly and nonlinearly about how and to what degree learning and change over time have occurred” (p.130).

The Internet was selected as the means of creation and presentation for these electronic portfolios. All students made a series of web pages containing a “Biography page,” a “My Studies page,” and a “Resume page.” The biography page contained biographical information, links to their past (their high school, where they were born, etc). The studies page contained links to the classes they were currently taking, and their course work. Each student was required to select four projects from the 10 projects they completed over the course of the semester to include in their electronic portfolio. This meant converting some projects to HTML, or capturing screen shots of other projects to include as a graphic on their “Projects page.” The actual selection and the means of presentation in the portfolio were left up to the student. Portfolios contribute to learning best when they are under-invented (Smith, 1997).

Creating the electronic portfolio helped students see that learning should not be disconnected across disciplines nor isolated within a given course, but to encourage them to make connections among and across their own learning experiences (Courts & McInerney, 1993). These pages were designed and constructed by each student in any manner they wished. For example, some of the more advanced students chose to use frames in their portfolios while the novice students simply mastered the basic skills of creating multiple web pages, linking, and providing navigational cues.

Applying the theory of perceived attributes as described by Rogers (1995) was extremely important for the undergraduates since the creation of portfolios was a required assignment. When the instructor gave the assignment, she discussed the ideas of a portfolio with students, and how this assignment would allow them to go beyond the status quo. At the beginning, students were unsure about the project and failed to see its relevance to their education. However, as they began to work on their portfolios they began to see its potential in ways previously overlooked. For example, students began experimenting with ways in which to present their work using graphics, sounds, and animation. They began to understand the limitations of a text-only interface. This is something that students understand it is still not completely understood by all faculty, as most assignments continue to revolve around text on paper. Some students also began to view their portfolio as a tool they could use to get a job, and began sending the URL to potential employers.

As students began to share ideas with each other the quality of their work improved. Novice computer users began to learn from the more advanced students, and became excited at the potential of the electronic portfolio. Frequently, the students went beyond the scope of the assignment to add scanned
pictures, animation, and reflection pieces. Students commented on how excited they were to create a product they would continue to use throughout their college career and beyond.

As the students began to change their individual portfolios, the assignment began to change. Finally, the students' knowledge and understanding of the portfolio and its contents contribute to the potential of the portfolio to inform learning (Krause, 1996). Some students created a reflection page, and because this proved to be such a powerful aspect of the portfolio the inclusion of a reflection page became a requirement for all portfolios.

As students begin to claim ownership of their work they will begin to take ownership of their education becoming better learners in the process. As students begin to reflect on their work and their experiences as learners they will become better teachers.

Graduate Portfolio Project

Graduate students in the Education Technology program reported similar experiences to the undergraduates with respect to the use of electronic portfolios, the impact of the electronic portfolios on their learning, and the uncertainty of their technical skills to accomplish the task. Upon acceptance into the Educational Technology graduate program, all students take Educational Technology and Teaching. This class provides a foundation in the field of educational technology, and strengthens the student's computer skills. Students in this graduate program have been required to create and maintain a portfolio throughout several semesters over the course of two years, however, the medium for the portfolio was determined by the student. The voluntary evolution from a physical medium (paper) to an electronic medium can be seen by comparing the number of students creating electronic portfolios in the fall semester of 1997 with those who created electronic portfolios in spring 1999. In the fall of 1997, a majority of students opted to create, produce, and maintain a physical portfolio instead of an electronic-based portfolio. Typically, the students used notebooks, folders, and included various types of storage mediums (zip disks, web pages, Hyperstudio projects, etc.) to showcase their computer products.

In an attempt to understand this reliance on the traditional physical medium, students were questioned about their choice in their oral final examination. Most of the graduate students reported that they felt more comfortable creating traditional documents, and did not have much confidence in their technical ability to create the complex learning environments required by an electronic portfolio. The insights gained from the oral exams allowed the instructor to alter demonstrations, explanations, and examples of portfolio elements. The instructor was also able to use Rogers' theory of perceived attributes (1995) with the graduate students. By demonstrating how electronic portfolios allowed students to express themselves in ways previously not possible greatly influenced students' perceptions of electronic portfolios. As students began to expand their concept of portfolios to include electronic versions, the number of students opting to create electronic portfolios dramatically increased. The graduate students also began to be more adventurous with their technical skills in creating the portfolio. During the spring semester, students were gaining confidence and the traditional portfolio began to move toward electronic documents. Students were including video, databases, and series of technology-rich lessons containing PowerPoint presentations, HyperStudio stacks, and AppleWorks projects. By the spring of 1999, all students were creating electronic portfolios. Again, as students' concept of portfolios moved beyond traditional paper representation, the instructor was able to alter the requirement to an electronic portfolio. The educational technology graduate students' experience with electronic portfolios lends support to Rogers' (1995) theory that the diffusion of any innovation is a process and frequently a time-consuming one at that. Now that a majority of our graduate students have adopted the idea and use of electronic portfolios, it is considered a typical task. New graduate students in educational technology understand that the creation of an electronic portfolio is a normal component of the program.

Conclusions

As the project evolves we continue to learn a great deal about the process of integrating electronic portfolios into academic programs. Educational technology faculty continue to improve on presenting the use of electronic portfolios as a valuable learning experience, developing a database of examples of what
these electronic portfolios could look like, and their value in assisting students in obtaining a job after graduation. In addition, this experience has greatly benefited teacher education students since all are required to complete an electronic portfolios as demonstration of mastery of the Florida Accomplished Practices. With the use of electronic portfolios in our teacher education programs, we expect to gain a richer understanding of the depth of knowledge that students have regarding teaching and teaching practices. An exciting result of having graduate students create electronic portfolios is the impact that is being made in the local schools. Many of the masters and doctoral students in educational technology are classroom teachers. These teachers report that as the technology becomes available in their schools, they are teaching their students to create and maintain electronic portfolios. Thus, students at all levels are developing a philosophy of "show what you know as you go."

Teachers' Comfort Level, Confidence, and Attitude toward Technology at a Technology Course

Amy S. C. Leh, Ph.D.
Instructional Technology
California State University San Bernardino
United States
aleh@csusb.edu

Abstract: Currently many universities are offering a technology course. The study is intended to examine the impact of the technology course on in-service teachers. Teachers' comfort level, belief, confidence, and attitude toward the use of technology are investigated. The impact of the course with different degree of technology integration is also researched. The results indicate that the course increased students' comfort level, confidence, and attitude toward the use of technology. The findings also indicate that no significant difference was found on their comfort level, confidence, and attitude between the two groups who had different degree of emphasis on technology integration.

Introduction

In September of 1997, the National Council for Accreditation of Teacher Education (NCATE) released a report addressing the importance of teachers integrating technology into instruction. The new technology standards clearly state that teachers must be competent of using technology in their teaching. At present training teachers the use of technology has become a strong nation-wide movement.

Many universities are currently offering a technology course, often called "the technology course". Content of the course and attitude of teachers toward the use of technology have been studied. Research revealed that the course content is mostly skill-based and that technology integration should be emphasized in the course. Professionals also promoted technology infusion. In addition, research noted that teachers need technology training and that many of the teachers are anxious of the use of technology in the classroom.

Does the technology course reduce teachers’ anxiety? Do teachers feel more comfortable and confident in the use of technology after they take the technology course? Does the course change their attitude toward technology? Do they believe that technology is useful for improving their teaching? Is the course content useful to teachers and applicable to their current and future teaching? Does the technology course with different emphasis on technology integration or technology infusion have different impact on teachers?

The present study is intended to examine the impact of the technology course on in-service teachers. Teachers' comfort level, belief, confidence, and attitude toward the use of technology are investigated. The impact of the course with different emphasis on technology integration or technology infusion is also researched.
Research Procedures and Methodology

Four classes, a total of 68 teachers who were taking the technology course in 1999 at a public university, were selected for the study. At this university, students who want to clear their teaching credential are required to take two educational technology courses, level I and level II. The level I course covers computer productivity tools such as word processing, spreadsheet, and database. The level II course involves multimedia, Internet, and technology integration. The course of this research study was a technology level II course. The majority of the students were full-time in-service teachers. The technology course lasted for ten weeks.

Two professors taught this course to two classes each. Based on the professor's emphasis on the integration, two classes were categorized into "Integration A" classes while the other two classes fell into the "Integration B" category. The content, emphasis, and course projects will be introduced in the section "The two categories of the courses".

At the end of the quarter, the researcher went to the four classes and asked the students to fill in a survey. The survey contained ten Likert-scale questions related to the participants' perceptions of their comfort level, confidence, belief, and attitude toward the use of technology in classroom before and after the course. The internal reliability of the survey was checked by SAS computer program. The Cronbach Coefficient alpha value of the survey was 0.85. The value was high, and the items of the survey were reliable.

The means of the ten question items were used to determine how strong the students agreed with statements that the course was useful and applicable and that technology can improve teaching. Three question items were used to examine via t-test possible differences of the two categories of the courses.

The Two Categories of the Courses

The professor of the "Integration A" classes believed that students in the course needed to learn computer applications that were commonly used in schools and should practically explore how these applications could benefit and be integrated into their teaching. She taught students how to use a multimedia program (HyperStudio) and a webpage editor (Netscape Communicator). Students used these two applications to develop two course projects—a HyperStudio project and a webpage project. Examples of the HyperStudio project are: using the software to (1) create an instruction on a subject area like mathematics, (2) develop practice items, or (3) produce a test. Learners, especially remedial students, could review what they had learned by going through the instructional HyperStudio Stack. Students could also conduct self-examination using the practice items. Teachers could use the test to evaluate students. For the webpage project, students created a webpage with many links to websites pertaining to their teaching areas, such as science, language art, mathematics, or social studies. On their webpages, they also created questions that encouraged their students to search for the answers on the Internet. The other two course projects were a research paper and a lesson plan integrating technology into instruction.
The professor of the "Integration B" classes believed that students of the course needed to learn infusing technology into subject areas and hoped that after the infusion one could not distinguish technology components from subject components. The course projects involved writing a lesson plan, evaluating four pieces of educational software, using KidPix to create a slide show illustrating the use of subject areas, as well as writing a paper reviewing articles on technology integration. For the lesson plan project, students were encouraged to integrate technology like spreadsheet, videodisc, database, or CD-ROM into their content areas and grade levels. For the slide show project, students were required to include pictures, text, and sound in the project. For the paper, students should list three implications of technology integration.

Both professors required students to write lesson plans integrating technology into instruction. Both professors also required students to conduct research. The research of students in the professor A’s classes was to investigate the availability of hardware and software of their schools and teachers’ use of technology at the schools. The students needed to collect, analyze, and report data. The students in the professor B’s classes conducted library research—reviewing literature related to technology integration. Professor A emphasized skills of using computer applications while professor B focused on technology infusion. The students of professor A’s classes spent more time than the students of professor B’s classes on learning computer applications, like HyperStudio and webpage development. The students of professor B’s classes practiced much on technology infusion by writing lesson plans and evaluating software.

Results and Discussion

The results showed that the participants thought that the course was useful (M=4.2) and that they could apply what they learned from the course in their current instruction (M=3.7) as well as future classrooms (M=4.2). The results indicated that the course content was appropriate, and that the teacher training was on the right track. Some teachers expressed that they could not apply what they learned in their current teaching because computers at their schools were inadequate or not available in their classrooms.

The participants also believed that technology was useful for improving instruction (M=4.4). Since computers entered our classrooms, educators have been engaging in a constant debate whether technology or computers are useful in instruction. Educational technologists often advocate benefits of using technology in education. Some professionals voice their doubts because research indicates that technology does not have impact on students’ learning. They argue that instructors do not need to use technology because it does not enhance students’ learning. The results of the study revealed that field teachers and educational technologists are heading toward the same direction. Both of them considered technology to be useful for improving teaching.

**Table 1.** Means on the survey. Means of A = Means of the 34 participants of the professor A's classes. Means of B = Means of the 34 participants of the professor B's classes. Means of A & B = Means of all the 68 participants.

The results showed that the students were moderately comfortable (M=3.2) and confident (M=3.2) of using technology but had a comparatively positive attitude (M=3.8) before they took the course. This indicated that the teachers were willing to use technology although they were not proficient in using it. The course increased their comfort level (from 3.2 to 3.9), confidence (from 3.2 to 3.8), and positive attitude (from 3.8 to 4.1). As we know, technology is constantly changing, and the content of the technology course is being continually adjusted. Therefore, in the technology course helping teachers feel comfortable, confident, and positive is as important as teaching them specific technology content. If our teachers are comfortable and confident in using technology, they will be more likely to succeed in overcoming obstacles and using technology in their classrooms.

Professor A's class responses on comfort level, confidence, and attitude after the course were compared with those of professor B's classes. The obtained t-values were 0.12, 0.08, and 0.24. The values did not exceed the critical value 1.98 for p=0.05. The results indicated that there was no significant difference between the two groups of
different emphasis in the course. Due to the survey questions of the study being limited in scope, we need to conduct more studies to make conclusions on this issue.

Educators have been debating on what the course should emphasize: technology skills, technology integration, or technology infusion. Some educators think that the course should emphasize skills because one cannot integrate technology without having the skills. Some educators think that the course should focus on technology infusion because teachers must be able to use technology within their content areas and grade levels. Probably all instructors of the technology course have currently included technology skills and integration in their courses. Degrees of technology integration and ways of integrating technology into instruction might vary from one instructor to another. The findings of the study indicate that the difference is not significant on students' comfort level, confidence, and attitude toward using technology.

Conclusion

Studies on the technology course at Colleges of Education has been conducted by many researchers with the attempt to find the best way to train our teachers to be technology literate in order to enhance quality of education. The results showed that the course increased students' comfort level, confidence, and attitude toward the use of technology. No significant difference was found on students' comfort level, confidence, and attitude between the two groups who had different ways if integrating technology into instruction. More studies need to be conducted to evaluate the impact of the course on teachers. Well-trained teachers will help the coming generation to be successful learners in the Information Age.
A Comparison of Student-Teachers' Attitudes Toward Computers in On-Line And Traditional Computer Literacy Courses: A Case Study

Tarkan Gurbuz, I. Soner Yildirim, M. Yasar Ozden
The Department of Computer Education and Instructional Technology
Middle East Technical University Faculty of Education
Turkey
tarkang@metu.edu.tr

Abstract: This study examined the effect of two computer literacy courses (one was offered as on-line and the other one was offered through traditional methods). Two courses were compared in terms of their effectiveness on computer attitude of the student-teachers. This study also explored the other factors that contributed to changes in attitudes of the student-teachers. The study used data from 209 (147 female, 62 male) student-teachers of which 69 of them attended to the on-line computer literacy course, and 140 of them attended to the traditional computer literacy course. Findings indicate that there is a combined effect of gender, computer literacy course type (traditional vs. on-line), whether any computer related course taken before, previous computer attitude and possession of home computer on student-teachers' post-attitude toward computers. The follow-up study results were also supportive to the results of statistical analysis, and they investigated student teachers’ perceptions about the computer literacy course they attended.

Introduction

One of the most dramatic changes in the last three decades has been the rapid development in technology, which has gradually found its way not only into business and industry but also into the classroom through computers and computer-related technologies. Many jobs in the 21st century will involve computers in some way, and members of the workforce who are not able to use them will be at a disadvantage. Therefore, it is critical for individuals to have the necessary education and skills to compete in the next information-intense century.

With the lower cost, wide usage, and increased capabilities of computers, the use of computers in education has grown rapidly. As computers became more widely available and used in schools, educators have adopted many different ways to use them. More importantly, educators have started questioning the meaning of "computer literacy". One of the basic definitions of "computer literacy" is the idea that there should be some basic familiarity with computers which all students need in order to compete in the job market, or to be well-educated citizens. The need for students to cope with daily problems in a dynamic world has led many educators to conclude that having microcomputers in education enriches the learning environment (Bitter, 1985; Fredricson, 1984; Pea and Kurland, 1984).

The new "Information Age" has brought new concepts and technologies for learning and education such as Internet, on-line learning, on-line education and some new technologies provided by development of the Internet. Today, on-line learning holds promises for both distance education and conventional learning environments. Nowadays, it is not surprising to see on-line courses and even the creation of 'virtual universities' based on the web. These circumstances led to the evolution of the idea that today each individual must become computer literate; must know how to deal with computers. Knowing how to use computers today is like learning how to read and write. Society imposes a great demand on teachers to prepare their children for the information era.

When the computer is considered as an educational tool, the most important thing is the role of the teacher. Many researchers suggests that if computers are to be integrated into education, then teachers need to be trained in computer use (Duckett and Wallet, 1994, Savenye et.al 1992). For computers to be used in the classroom, teachers must have necessary knowledge about computers. Because of this fact, pre-service and in-service programs for teachers and computer literacy courses for student-teachers were developed and offered. Computer literacy has been defined in many different ways because of the changes in computer technology.
recognized that the definition of computer literacy will be specific to the context in which the computer-literate individual must function. A certified public accountant, a doctor, an academician, and a secretary will all need different skills and knowledge to be comfortable and effective in their interaction with computers; each will need something different to become computer literate. This also applies to students and teachers. The interplay of many factors may be involved in the determination of computer literacy such as cognitive styles, mental models, prior experience, age and gender. As Randhawa and Hunt (1984) emphasized, all computer literacy programs must take into account the developmental and cognitive readiness of the learners. Curricula must be based upon the expected entry behaviors and characteristics of the students for optimal instructional impact (Woodrow, 1990).

The idea of integrating computer literacy courses into pre-service teacher education programs goes as far back as to the extension of basic education from 5 to 8 years in 1997 in Turkey. At present, the Ministry of National Education in Turkey is in the process of redesigning curricula and furnishing all basic education schools with Instructional Technology (IT) rooms. This reform has direct implications for teacher training institutions. For example, from 1998 onwards, a computer literacy course became a must course for all student-teachers to fulfill the requirements for teaching credential. Accordingly, all schools of education in Turkey have started offering computer literacy courses for their student-teachers to fulfill this requirement. The earlier attempts at preparing student-teachers to use computer technologies have been initialized by a few higher education institutions. One of these institutions is the Middle East Technical University.

The computer literacy course SCE300 “Computer Applications in Education” has been offered by traditional methods since 1994 at Middle East Technical University (METU), School of Education. This course is carried out through class sessions and laboratory sessions. The basic concepts and knowledge are introduced through class sessions in an electronic classrooms and applications are done through laboratory sessions in the computer laboratories.

Due to the need to provide computer literacy for students whose number has been increasing dramatically in the preparatory school at METU, the on-line computer literacy course IS100 “Introduction to Information Technology and Applications” was also added to the curricula in 1998. This course is designed to introduce basic computer skills, use of common computer applications and fundamentals of programming languages for computer literacy. To serve this goal, a few computer rooms were equipped around the campus with the application software by which learners are exposed to content and they can practice basic computer skills.

Offering an on-line computer literacy course has evoked another question for educators and administrators: which method is more effective to facilitate computer literacy? It is inevitable that reaching a rigid answer to this question will result from a number of studies concerning all the variables that influence efficiency. Even though the on-line computer literacy course is a new experience for the university, it is important to conduct early studies even considering a limited number of variables to understand the effectiveness of the new course. Such studies will yield a better allocation of scarce sources for pre-service teacher education.

The Study

The main purpose of this study is to investigate the effect of two computer literacy courses at METU (one is offered as on-line and the other is by traditional methods). These two courses are also compared in terms of their effectiveness on computer attitudes of the student-teachers with different demographics such as gender, whether any computer-related courses taken before, previous computer attitude and possession of home computer. The second purpose of the study is to explore the other factors that contributed to changes in attitudes of the student-teachers at METU.

The study is based upon a pretest-posttest none-experimental design and a follow-up qualitative study. Since there were no control group in the study it was not possible to conclude that the computer literacy course type was the prior factor that affect the attitude toward computer. There would be a possibility for the other factors affecting the attitude. Therefore, an additional follow-up qualitative study designed to survey student’s perceptions about the treatment (computer literacy course), and “computer literacy” concept also explore the other factors possibly affected participants’ attitude toward computer.

There are five independent variables (gender, whether any computer-related courses taken previously, possession of home computer, the computer literacy course type, pre-attitude) and one dependent variable (Post Attitude) in the study.
The study used data from 209 (147 female, 62 male) student-teachers of which 69 of them attended to the on-line computer literacy course, and 140 of them attended the traditional computer literacy course.

To obtain relevant data for the variables, the questionnaire packet used for the pre-test which contained the “Computer Attitude Scale (CAS)” and a “Computer Competency Questionnaire (CCQ)”. The Computer Attitude Scale was also used with a follow-up questionnaire as the post-test.

The Computer Attitude Scale (CAS) was originally developed by Loyd and Gressard (1984) and then, translated into Turkish and analyzed by Berberoglu and Calikoglu (1992). The CAS is a likert-type instrument consisting of 40 items. In CAS, there are four sub-scales: 1) computer anxiety or fear of computers, 2) liking of computers, 3) confidence in ability to use or learn about computers, 4) and usefulness (importance) of computers in life. Each sub-scale has 10 items and the items are rated on a Likert-type scale ranged from 1 (strongly disagree) to 4 (strongly agree). In the study the reliability coefficients for the Computer Attitude Scale (CAS) were obtained as 0.91 for pre-test and 0.93 for the post-test.

The Computer Competency Questionnaire was developed by the researcher to survey demographics of student-teachers. The CCQ included 14 items in the form of fill in the blank and alternative-response type questions in order to collect relevant data about demographics of the student. The CCQ focused on the following information: Gender, department name, the computer related courses taken previously, the programming languages that are known, previous computer experience, the places had computer access, purpose of computer use, possession of home computer, will on having a computer, interest of computer, confidence on success from the course.

The follow-up questionnaire was developed and distributed by the researcher to 124 (68 from on-line group, 56 from traditional group) student-teachers agreed to participate. The follow-up study included 9 open ended questions focused on the following areas:

1. Student’s expectations from the course, and effectiveness of the course in terms of satisfying their expectations.
2. Effectiveness of the course in terms of its helping student-teachers to develop positive attitudes toward computers.
3. Excluding this course itself, the other factors that student-teachers believe contributed to the changes in their attitudes toward computers.
4. Effectiveness of teaching activities applied in the class that student-teachers believe most helped their learning about computers.
5. Effectiveness of the course in terms of student-teachers’ professional development.
6. Student’s perception of the definition of a computer literate person.
7. Student’s perception of the qualification of the course itself as a computer literacy course based on
8. Student’s self-evaluation on being computer literate after participating in the course.
9. Student’s self-evaluation on being an efficient computer user on the basis of their skills and knowledge gained through the course.

Data collection and analysis

At the first class meetings, after a brief introduction to the class by the instructor, the researcher was introduced to the student-teachers. The volunteered student-teachers were asked to participate in the study and were given time to complete the CCQ to collect information about the participant and CAS to measure the participant’s attitude toward computers before taking the course. At the end of the semester; CAS was distributed once again to measure the participants’ attitude toward computer after taking the course and student-teachers were asked to participate in a follow-up study. The CAS and CCQ results were analyzed by using SPSS. The follow-up study results were analyzed by qualitative analysis methods.

The demographic information obtained was analyzed by using frequency distribution. Based on this information, an insight to the data was provided. Multiple Regression was performed to analyze effect of pre-attitude scale scores, type of course (traditional vs. on-line), gender, whether any computer related courses taken before, and possession of home computer on posttest attitude scores of student-teachers.

Results
Means and standard deviations of the pre and post-attitude scale scores and the frequency of males, females, whether the computer-related courses taken previously or not, and possession of home computer for the sample are presented in Table 1. The mean of the pre-attitude scale scores is higher than the post-attitude scale scores for on-line group. This indicated that the on-line computer literacy course does not have any effects on improving the student-teachers' attitudes toward computers. On the other hand, in traditional group, compared to pre-attitude scale scores, the post-attitude scale scores were higher, even though the difference was not significant. This indicated that the traditional computer literacy course has a mild effect on improving student-teachers' attitudes toward computers.

Table 2. Multiple Regression Analysis

Analysis of the responses to each question in the follow-up study indicated as follows:

The responses to first sub-question demonstrated that prior computer experience and knowledge shaped student-teachers' expectations of the course.

The results for the responses to the second sub-question were different for two groups; majority of student-teachers in traditional group believed the course itself contributed to the changes in their attitudes toward computers even though those student-teachers who already had prior computer experience admitted that this contribution was supplemental since they always had positive views for computers in education. On the other hand, the results indicated that majority of student-teachers in on-line group believed that the course was not very effective on their attitudes. This is delineated by the given responses expressing the problems they were faced with. The student-teachers who attended the course IS 100 had difficulty with the level of English used in the program and also with on-line learning itself. They expressed that they were not ready for on-line learning and felt the lack of human support in the course. However, the majority of the participants from both groups reported that the course help them slightly to develop positive attitudes.

The responses to third sub-question verified that the most important factor for student-teachers that they believed affected their computer attitudes apart from the course was the necessity and the widespread use of computers. They felt that as a teacher they also had to be computer literate and help their students with their endeavors. Analysis of the responses also indicated that possession of home computer increased teachers' access to computers and willingness to learn more about them. Finally, given the fact that pre-service teachers were also students working on their teaching credential, they felt computers provided a great asset to them in their own education and thus, it helped them develop positive attitudes toward computers.

Current research suggests that computer literacy courses somehow affect attitudes toward computers by increasing computer experience of participants. However, the literature fails to explore which teaching activities are most effective in enhancing students' computer experience and developing their attitudes. The
fourth question, therefore, was asked to determine which were the most effective teaching activities that teachers believe helped them learn more about computers and gain positive attitudes. The findings supported the view that laboratory sessions and office applications, using Internet, preparation of homework and projects in SCE 300 were most effective teaching activities for the student-teachers. This conclusion is also consistent with the results of the study (Gurbuz, Eryilmaz and Bulut, 1999). In addition to these activities, on-line quizzes and exams were signified as effective factors by the student-teachers attended the on-line course, thus it confirmed the effective potential of the exams on learning.

The responses to fifth sub-question showed that the more new skills students gained from the course, the more they valued the course, and thus the more the course contributed to their professional development. Interestingly, regardless of their previous experience with computers, the student-teachers believed that a follow-up computer course would contribute more to their professional development. Finally, in both on-line and traditional group, some respondents agreed that the course was useful, but some of them reported that the course was not satisfactory. This finding paralleled with the results of the multiple regression analysis which indicated that after completing the course there was no combined effect of pre-attitude scale scores, gender, the computer-related courses taken previously, computer literacy course type (traditional versus on-line), and possession of home computer on the student-teachers’ post-attitude.

The responses to the sixth question showed that majority of the participants in both on-line and traditional group described being computer literate as: “being an efficient computer user and being able to write programs and use different types of computers”. In both on-line and traditional group, with slight differences, a computer literate person was perceived similarly: “the person who is able to know what to do with computers, to be able to use them efficiently and to have no fear of them”.

The responses to the questions 7, 8, and 9 showed that Student-teachers in both on-line and traditional group pointed out that the course did not provide sufficient practice and the knowledge provided by the course was insufficient, or not up-to-date. On the other hand, some respondents monitored that the course could be considered as computer literacy course in spite of some insufficiencies pointed out. The majority of the respondents thought that the course they attended could be a beginning for them in terms of further studies on computer literacy.

Discussion
Participants argued that the course should be offered at least in two levels and then through the course, the difference between these levels should be minimized. Moreover, more laboratory session hours should be supplied since the participants emphasized the effectiveness of practicing with computer. This study indicated that basic computer literacy courses are most effective for those with no prior experience. The results also verified that in order for teachers to become fully capable of using technology in the classroom, a follow-up computer course is necessary. These conclusions are also consistent with the study (Gurbuz, Eryilmaz, Bulut, 1999).

This study contributes to a better understanding of how student-teachers’ attitudes toward computers change due to the participation in a computer literacy course. The data from this study indicated that student-teachers developed somehow positive attitudes, their anxiety was lowered and confidence was increased with computers following the participation in a computer literacy course. The results of this study supported the view that participation in a computer literacy course affects pre-service and in-service teachers attitudes toward computers positively (Savenye, 1993).

It is a fact that the number of student teachers who demand technology education in their pre-service education has been increasing dramatically. Therefore, teacher education institutions should innovate and adapt new formats and medium for computer literacy courses to meet this demand. This study indicated that on-line computer literacy courses should not fail in providing face-to-face interaction and learning activities for participants. It should be recognized that learning is a social phenomenon that takes place within a social context. Therefore, it is crucial for on-line computer literacy courses to ensure this social context and provide interactivity among the participants. If face-to-face or real time communication is not available for on-line courses, then more advance technologies should be adopted to provide synchronous communication and interaction among the participants.

For traditional computer literacy courses, this study indicated that student teachers sought more up-to-date content and lab activities that parallel with their needs. Therefore, computer literacy courses offered in the traditional manner should provide lab sessions with activities that reflect student teachers’ needs and up-to-date activities.
This study revealed the fact that although student teachers recognized the importance and role of technology in their lives, they failed to associate technology with their profession. Therefore, in their pre-service education, faculty members in their teaching methodology courses should demonstrate the importance and role of technology in teaching as well.

The Impact of Computer-mediated Communication on Student Learning

Sarah E. Irvine
School of Education
American University
Washington DC, USA
sirvine@american.edu

Abstract: Previous research on delivery modes in distance education and their correlation to student achievement outcomes has shown that students learn better via computer-based communication than face-to-face instruction. One explanation for this phenomenon is that the students must take more responsibility for, and be more active in, the learning process. This study looks at how the media used in one aspect of distance education, on-line discussion, can affect the learning outcomes for students involved in distance learning activities. On-line discussion within any learning environment can provide the opportunity for students to engage in thoughtful, content-based conversations about the topic under study, which may result in deeper understanding and greater learning gains. A content analysis of student discussion in listserv-based (electronic-mail) discussion, web-based threaded discussion, and chat discussion will be presented.

Introduction

In the world of distance education, one of the most important elements of a quality course is that students are able to interact with the instructor and other students as they would in a traditional classroom, and, given the computer-based medium of distance education, this is done through computer-mediation communication. This goal can be met through a variety of methods, using e-mail based discussion groups (or Listserv discussion groups), web-based discussion threads, and chat rooms. Each of these methods has advantages and disadvantages, and may or may not fit with the instructional objectives of the course. In a 1986 study, Hiltz found that the use of electronic discussions not only could offer new educational options, but in some case could be more effective than the traditional classroom. Phillips and Santoro found that computer-mediated communication could offer students greater coherence, empower students to improve their communication skills, and enable students to engage in problem-solving activities. McComb found that computer-mediated communication can create a unique environment for discussion that avoids many of the conversational limitations posed by face-to-face communication.

The most common type of computer-mediated communication in higher education today is the use of the electronic mail-based discussion group, or Listserv. An electronic mail-based discussion group allows instructors and students to send e-mail to one another simply by entering one e-mail address in the "TO:" line of an e-mail message. Messages sent to the group may be moderated by the instructor of the course, or may be automatically sent to all members of the group. From a technical perspective, the advantage of e-mail based discussion is that students are sent the messages directly without having to remember to log-on to the internet and to check out the discussion. A common disadvantage is that when the student loses a note, or accidentally erases a note, then there is no record of what he or she has said. Also, an e-mail-based discussion group has the potential to "flood" the inbox of the student with an overwhelming amount of e-mail.

Web-based discussion, or threaded discussions, work similarly to the idea of Bulletin Board Systems (or BBS). The student posts a message to the bulletin board at a specific web-address, and others respond or reply to the message when they log-in to check the board. The advantage of web-based discussion is that one can see...
exactly how the discussion or conversation has progressed. As with an e-mail discussion group, one can reply
to a message at anytime, but it might be difficult to track the specific message that encouraged the student to
respond. With threaded discussion, one can "see" exactly how the discussion progresses, with sub-headings of
replies and main headings of new threads. A disadvantage is that the student might not remember to log-in and
track the messages frequently (although some discussion groups do send out e-mail reminders when a new
message is posted to the discussion board).

Chat-based discussions are synchronous, text-based discussions. All
users must be logged in to the same
chat session at the same time. The most obvious difference between this form of computer-mediated discussion
and the other forms presented here is that all the users are logged on and talking at the same time. This may
offer a more "natural" discussion to take place, with real-time interaction taking place. A disadvantage to chat-
based discussion is that there is most often no documentation of what was said, and the pace of chat discussion
with more than 10 students (where it seems everyone types at once) can be too overwhelming for most
individuals.

Method

For the purposes of this study, all three types of computer-mediated discussions -- e-mail-based, web-
based, and chat-based -- were used across two sections of an introductory education technology. Three main
research questions guided the study:
1. What type of discussion takes place in each setting?
2. How much discussion takes place in each setting?
3. What is the quality of the discussions in each setting?

The computer course, entitled Uses of Technology in Education, utilizes hands-on instruction for the
integration of computer-based technology in education settings. The course is taught in a computer lab at
American University. Two sections were offered, in which a total of 42 undergraduate and graduate students
were enrolled. Although the course is listed as a requirement for education majors, approximately 15% of the
students enrolled in the course were non-education majors.

Findings

A total of 279 statements were posted during the spring 1998 semester. 108 of those postings were
submitted via an e-mail discussion group. 110 postings to the web-based discussion occurred, and 61
statements were made in the chat format. Participation varied among the different types of discussion formats.
Each posting to the discussion forums were cataloged and evaluated at the end of the spring 1998 semester.
Postings were then evaluated using content analysis with respect to each of the research questions listed above.
Each posting to the discussion forums were cataloged and evaluated at the end of the spring 1998 semester.

Figure one illustrates the type and number of statements made in each type of computer-mediation
communication. The first bar in each set represents procedural statements, such as questions about when and
assignment is due or where the class might be meeting. The second bar represents content-related statements,
those statements directly related to the course content. represents content-related statements, those statements
directly related to the course content.
Figure 1: Number of procedural or content-related statements in each discussion format

Figure 2: Instructor and student talk in each type of Computer-mediation communication

In the e-mail and web-based discussion formats, students were more likely to post statements that were at least four sentences in length. In the chat-based discussion, most statements were about one sentence in length. In addition, in e-mail and web-based discussion, students were more likely to provide quotes from the textbook, cite example problems, or provide links to other resources. In the chat-based discussions, students were less likely to post this type of connection to outside readings or the textbook. In the email and web-based discussion formats, students were also more likely to make direct reference to another student’s statements or comments.

In a follow-up survey conducted at the end of the semester to assess the effectiveness of the discussions in terms of their understanding and perceptions of the course content, students were asked what they found most valuable about the discussion forums. Some sample responses (from both classes) were:

- “I became aware of different points of views. In addition, sometimes I didn’t have any idea on the subject so discussions were a good start for me!”
- “I got a chance to hear many different perspectives on important issues.”
- “It provided the chance to do research on the web and share others perspectives.”
- “I enjoyed reading people’s responses because it helped me to understand the concepts and the questions in the homework.”
I was able to see aspects of a concept I might not have thought about when answering a question.

That people are interested in the class and therefore interested in giving their opinions about the topics discussed.

I found that others have the same questions as I. I found that looking at other responses helped me to answer the question I had because there were often more than one answer or way to solve the problem.

On the survey, 85% of the students who participated in the discussion indicated that the topics discussed changed or influenced their opinions, and 100% indicated that their knowledge of the content improved. In the educational technology course, 72% of the students indicated that they would use a discussion group in their own teaching, for such reasons as:

- To get my students to actively research a specific issue or topic.
- To allow students to express their ideas without worry of immediate backlash.
- To help them learn how to use email!

The survey included a question that queried students' opinion of the fairness of the assessment in the online discussion. 100% of the students responded that they felt the assessment was fair. Comments to this question included:

- We were graded according to content and apparent effort.
- I think it's very hard to assess a tool like this. Assessment was fair.
- Because you could not just say anything and get away with it. You had to think a refer to a site or reference.

Overall, the results of this survey suggest that students found the on-line discussion beneficial and useful to them. Many students felt that the on-line discussion format should be continued in future classes. However, some of students in the course felt that participation in the discussion should remain voluntary. The most common rationale supporting voluntary participation was that students felt there was already sufficient activities (i.e. homework, labs, folders, etc.) required in the course. Other students simply felt that students should be allowed to choose whether or not they want to participate in the discussions. In addition, students felt that there were benefits to active as well as passive participants on the list.

Conclusions

The findings indicate that computer-mediated discussions can be a valuable component to any traditional technology course. Students were able to actively participate in an activity that allowed them to extend the ideas of the course outside the traditional confines of the classroom. In particular for this educational technology course, students were able to think more deeply about the information presented in class in a different format. The focus of the educational technology course is generally on the technical components of "using computers" and the use of computer-mediated communication allowed students to discuss the implications of content as it relates to real-world applications.

Requiring students to participate in class discussion, be it in person or on-line, can be a formidable task. Most faculty hope that students will participate in class discussions simply because they are interested in the course content, and external reinforcement (such as giving points for attendance) can interfere with students internal motivation for participating in class. However, using a rubric can serve as a guide to help students structure their comments, and often can help facilitate discussions that are grounded in research and practice. In the online environment, students have a greater amount of time to prepare their comments, and using a rubric can assist them in preparing and reflecting on what they are going to say.

Web-based and LISTSERV discussion seem to generate much more thought and deeper consideration than either face-to-face or chat. During the early phase of chat, a lot of time is used up on procedure. In the first chat session of the semester, it can take more than an hour for students to stop focusing on the medium. In a two hour class period, only in the last 45 minutes is there any real discussion. In chat, much as in face-to-face discussions, students did not give much consideration to the views of others. They simply used them as cues to propound their own beliefs. There was more talking, but we did not notice more listening.

A much larger portion of the class did participate during chat. Even those who never speak in class could eventually be prodded into participating. Participation has been at 100% in web-based discussion. It was fairly
close to that during chat. In face-to-face discussion in class, it can be more often in the 50-60% range. The ability to send private messages during the chat discussion can prompt shy students into participating. One would not have had the same opportunity for private, personal contact in a classroom. In all but face-to-face, the instructor loses most of their ability to guide the discussion. The chance to ask further probing questions diminishes.

Technology, such as on-line discussions, must be carefully evaluated before being implemented into any curriculum. As with other types of technologies, from video simulations to computer-based tutorials, the instructor must be comfortable with not only the medium, but also the message sent through the medium to the students. In an on-line discussion format, the instructor must carefully monitor students' statements about concepts and redirect them as necessary. Monitoring the discussions requires time and commitment on the part of the instructor, as well as a desire to assist the student to come to a deeper understanding of the concept itself. It is our opinion that this is time well spent. As seen with the discussion of weightlessness in the physics example above, the instructor's role is often to not only provide the opportunity for in-depth investigation into a topic, but also to provide constructive feedback as it develops. In this way, the instructor can better integrate electronic discussions to help students come to a deeper and broader understanding of concepts from networking to equity in education.

Information System Design of Undergraduate Education: Combining Lectures with Practice

Yoshinori Fujio
Faculty of Administration
Prefectural University of Kumamoto
Japan
fujio@pu-kumamoto.ac.jp

Abstract: This paper describes the basic knowledge necessary to promote the ability that students can analyze, design, and construct information systems. The curricula and the practical teaching material are proposed, with which students can experience information system development by applying the basic knowledge of lectures. The subjects of the basic knowledge are programming, software design, information system development, database, and network. "Retail management" is taken up one of the practical teaching material for students to learn the relationship between basic subjects. Up to now students have stayed in the fragmentary knowledge of lectures. Yet, with this teaching material, they can acquire practicing ability doing voluntarily concrete analysis, design, and construction in practice.

Introduction

The use of the computer is ubiquitous in today's business communities, and is becoming so in education. However, concerning the information system design, there are few practice teaching materials which organically tie to the lecture in order to teach the latest content. Engineering skills demanded today require the ability to synthesize basic subjects into design and to be able to analyze design solution to points, ultimately leading to a high quality product which can compete economically in the marketplace. The development of this type of knowledge in our students requires us to provide them with more hands-on experiential learning.

The basic subjects of lectures are programming, software design, information system development, database, and network. Figure 1 illustrates a location of subjects by information system design. The center of the Figure 1 is a nucleus of information system design. This part corresponds to a nucleus of a computer and its nearest seeds. The technological innovation of these seeds is aggressive. On the other hand, the outside represents human society and the basis of needs for the computer. The change in needs of human society is slower than the technological innovation of seeds. The center of Figure 1 contains seeds. The display of Figure 1 becomes near needs while facing from this center towards the outside.

On the other hand, this practice teaching material starts from the information system development methodology by which the information system is defined based on users' needs and restrictions. This assists us in making programming through the software design and the database design. If the concept of object-oriented methodology (Booch, 1994) is applied, it is thought that the abstracted lecture is a class, and the practice corresponds to an object in the world of the information and computer science education.

Figure 1: A relation between the basic subjects about information system design

Basic subjects
1) Programming; We choose JAVA in our practice classes. There are three reasons for this: JAVA is congenial with the Web browser of the Internet; JAVA is compatible as an object-oriented language; and teaching the concept of structuralization and abstraction is easy.

2) Network; HTML and Web-server are taken up in the practice. The server is constructed to acquire the basis of a decentralized system which improves the performance, and the network is studied by expanding the function and operating systems.

3) Database; The relational database is widely used today. ACCESS database is congenial with WindowsNT, and for this reason, we use it (Fujio, 1996).

4) Software design; It is necessary for students to use the methodology properly according to an object area, and to know various methodologies well (Saeki, 1998). It is preferable to exercise various methodologies in practice. However, if we condense it to one methodology, recent object-oriented analysis and design is the best approach. In the case of this situation, we model an object area by using the UML (Quantrani, 1998), which is the latest unified modeling language. By using the UML, students design a use case, an object diagram, a sequence diagram, and a status diagram of the object area.

5) Information system development; We use the methodology in practice but we do not use tools. Students should interview users, operators, and managers in the object area based on methodology and examine the present situation. They research the problems, and draw an ideal system image that can solve these problems. They should also settle on the system image which can be developed actually in outline books considering: policies; social and technical constrained conditions; and the cost performance. Students should experience this process as practice and teachers should evaluate the achievement.

Practice teaching material

Retail management is taken up as a practice teaching material. Students take new requirements to the current system of a wholesale shop, and design a new system. First of all, students start with a grasp of the current business of the wholesale shop (IPA, Asupa Co., 1993), which is the object system, and they investigate it to understand the flow of information, money, and commodities between sections.

Figure 2: Flow of information and organization of the wholesale shop; new system

Students make a plan for the wholesale shop to develop the new system that includes the following
requirements for the current system:
1) The wholesale shop connects the commodity headquarters, the offices, and the warehouses with the network, and makes paper transactions electronic. The commodity headquarters consists of buyers, persons in charge of accounting and commodity control. The office means persons in charge of sales. The warehouse consists of persons who handle accepting and delivering the commodity.
2) To give the system generality and to build it cheaply, they construct the information system by using client-server systems and Intranet.
3) They make the system which corresponds easily to its evolution, expansion, and maintenance using object-oriented methodology.
4) A database system is used to accumulate a large amount of data and to process it. Figure 2 shows the new system that realizes the achievement of the plan.

Figure 3: Flow of information and slips concerning sales business
After the business reformation, Figure 3 shows the flow of information, slips, money, and goods
between the sections: persons in charge of sales; information control; accounting; and buyers. Thereafter, the design is advanced according to the procedure of the sales business in Figure 3. The architecture of this system is composed of three elements, which are human interfaces (screen), databases, and business processes (business procedure). At the stage of the framework design, it is decided how to characterize and design the outline of three elements. They must consider overall network, computer and OS, programming language and components, and databases, what is more, a trend of the industry and the business. They bring the whole system together while making these three elements detailed.

**Human interface**

The slips are human interfaces in the current system. The input and output items needed in the new system are added, and the I/O screen which is the new human interface, is designed. Figure 4 is the example of the order received processing screen.

**Database**

First of all, all necessary data is dug up based on this screen in the new system. Next, in order to remove a repetition of data, they normalize the data and make the table, that is to say, design the database.

**Business process**

Using the UML description (Eriksson, Penker, 1998), the class diagram (Figure 5) which concerns
the sales business is made by extracting CLASS/OBJECT. The order received processing procedure between the screen and the database is shown in the sequence diagram based on this class diagram. In addition, the status diagram, which expresses status transition of the order received slip, is made. Its order received slips (electric slips) are the main information in the sales processing. They are the ones taking the place of the paper slips, which are transmitted between the sections in the current system.

**Program design using components**

The system configuration is a client/server. Applet made by JAVA and database is arranged in the server’s machine. After this Applet was called from the server to the client by World Wide Web, the commodity code and the quantity of goods are inputted into the screen of the Applet, that is to say, the retrieval and the update of the commodity data are directed. Because this Applet is connected through pure Java driver (Imprise 1998) with the database on the server, the commodity data on the database is retrieved according to the retrieval instruction of persons in charge of sales, as it turned out, the commodity data is displayed in the Applet on the client’s machine. Moreover, the contents of the database on the server can be updated in the instruction of the update. JavaBeans; components made by JAVA, are used to design. It seems reasonable to use JavaBeans to design the screen and database so that making and maintaining the software becomes simple compared to programming with JAVA. Figure 6 constitutes one example of the programming code added to JavaBeans for the customer information retrieval.

```java
void customerField_keyPressed(KeyEvent e) {
    // [enter] When the key is pressed
    if (e.getKeyCode() == KeyEvent.VK_ENTER) {
        try {
            parameterRow2.setString("CUSTOMER", customerField.getText());
            // The customer code is set in the parameter
            queryDataSet2.refresh(); // The record of customer code is retrieved
            String x = queryDataSet2.getString(0); // Retrieved customer code
            String y = customerField.getText(); // Customer code inputted to screen
            if (x.equals(y)) {
                customerNameField.setText(queryDataSet2.getString(1));
                // The customer name is displayed
                addressField.setText(queryDataSet2.getString(2));
                // The customer address is displayed
            } else {
                statusBar1.setText("The customer code is wrong");
            }
        } catch (Exception ex) {
            ex.printStackTrace();
        }
    }
}
```

**Figure 6:** Retrieval of customer information based on customer code

**Conclusion**

Students plan the new system, after they understand the whole elements (seeds) which compose information systems, an industry trend, and new requirements (needs) of business. At the stage where the object system is analyzed, the requirements are analyzed and defined using the similar diagram (Figure 3) to a business flow. This diagram is more specialized for business than use-case used (Schneider, Winters 1998) by the object-oriented analysis-design. As for systems analysts skilled in the business, in order to analyze and design a novel system in a short term based on their general situation judgments, they often use
the diagram specialized on the business. As for the design of the screen, the database, and the business process in the framework of a new system, it is necessary to decide the priority, that is, which should be designed emphatically at the object system. This method is a realistic technique with which top down and bottom up are combined. The entire systems are integrated while designing each outline, and are broken down.

HTML used in the screen design, ACCESS used by database, and JavaBeans and JAVA used by business process design are an individual design element group, students must study those subjects through lectures previous to this practice. As a result, they will understand relations between the subjects through this practice. The programming, which uses JAVA, is indispensable for understanding the concept of object-oriented methodology. However, the use of common components (JavaBeans) composed of JAVA is effective to develop actual information systems if object systems are complex. Therefore, students should be skilled in usage of common components. After designing rough specifications of the screen and database, they design components, and mount components being combined, and what is more, program undefined parts of details using JAVA.

Considering students for departments of social science, this teaching material steps into the area which affects the society. Moreover, because it is possible to design from the user requirement definition to the programming consistently, students will be able to understand each position of basic subjects from experience. A basic technology of Internet and the latest object-oriented analysis-design can be experienced at the same time. In conclusion, I should note that the knowledge obtained by the lecture could be improved even to practical ability through the substantial practice.

IPA, & Asupa Co., (1993). Retail management textbook, Asupa Co., Tokyo, Japan

Seven articles in this section are grouped in the following way: (a) a response to state, regional and national technology standards and their implication for leadership training; (b) the challenge of national reform through changes in university graduate degree programs; (c) grant initiatives to promote partnerships among universities and schools; and (d) the results of a pilot training model. All of these articles are valuable reports to increase one’s knowledge of the challenges encountered while leading reform efforts, training reform agents, or developing university/school partnerships.

The first article compares the standards promulgated by state and educational organizations for technology in the classroom and the necessary educational leadership training to embrace these standards. Warren Hope, Bernadette Kelley, and Janet Guyden of Florida A&M University present as the "key component" the administrators’ level of expertise and associated abilities for utilizing educational technology. The article provides suggestions for incorporating these standards into university leadership training programs.

The second group of two articles highlight new and radically different graduate degree programs as necessary to meet technology reform initiatives. Ian Gibson asserts that upon completion of the Wichita State University’s Educational Doctorate program students become "visionary leaders of schools of the future" through an "immersion" in various technologies. Students participate in variety of classroom settings and roles. Perry Rettig, Penny Garcia, and Scherie Lampe describe in their article a new Master’s of Education degree at the University of Wisconsin Oshkosh. The program, called the Caring Intellectual Leader Model, focuses on the problem-based learning while incorporating technology throughout all levels of instruction and assessment. Two degree strands are described. One prepares teachers to use technology in their classrooms efficiently and the other prepares educators to certify as district technology coordinators.

The third group of articles report results from specific grants having in common university and school district partnerships. Steven Best, Ronald Marx, and Barry Fishman of the University of Michigan, and Deborah Peek-Brown of the Detroit Public Schools report their findings from a National Science Foundation grant to provide systemic reform to middle school science. Challenges of a large-scale undertaking are presented. Carolyn Rude-Parkins presents the design of the Technology Leadership Institute (TLI), a project initiated through the BellSouth Foundation’s Recreating Colleges of Teacher Education. A partnership between the University of Louisville and the Jefferson County Public School District, the TLI is a collaborative effort to provide new levels of technology expertise for teachers and leaders. Steven Jackson, Delores Brzycki and Mary Ann Cessna of the Indiana University of Pennsylvania reports successes and failures from their project called Advancing the Development of Educators in Pennsylvania through Technology Training (ADEPTT). Their project, funded by Bell Atlantic and Microsoft Corporation, is a collaboration of three institutions of higher learning and fifty-three school districts. Suggestions are provided for such a large project to be successful.

The final article, Reg North presents an evaluation of a multimedia CD-ROM based training program conducted by the University of Ulster in Northern Ireland to senior secondary staff in four school sites. Valuable lessons from the training design were learned and reported.

Technology Standards for School Administrators: Implications for Administrator Preparation Programs

Warren C. Hope, Florida A&M University, USA, Department of Educational Leadership and Human Services, e-mail whope@famu.edu

Bernadette Kelley, Florida A&M University, USA, Department of Secondary Education, e-mail bkelley@famu.edu

Janet A. Guyden, Florida A&M University, USA, Department of Educational Leadership & Human Services, jguyden@world.att.net

Abstract: As technology continues to have a significant role in schools, it becomes increasingly important for educators to acquire knowledge about understanding its power and capabilities and skill to use its features. Although school administrators are busy people, they are not exempt from knowing about technology's power and capabilities. As instructional leaders, it is important for them to demonstrate understanding and familiarity with the features and capabilities of technological devices. In the thrust to integrate technology into schooling, school administrators' level of expertise and ability to facilitate technology's integration into the curriculum emerges as a key component. Recently, technology standards depicting what teachers and students should know and be able to do with technology have been promulgated by states and educational organizations. Technology standards are also being advanced for school administrators. This paper identifies technology standards for school administrators and relates some of the implications those standards have for administrator preparation programs.

Background

Technology is reshaping work environments in virtually every enterprise in American society. Technology enables a more efficient method to accomplish tasks and communicate information. Technology can influence the teaching and learning processes that occur in schools. Electronic devices are being used to deliver subject matter and assist students to acquire technology competencies. Technology has also influenced administrative processes that are necessary for a school to function. Budget preparation, information storage and retrieval, reporting, and communicating with stakeholders have been made more efficient by using technology.

Electronic devices and software applications that tell them what to do can perform more efficiently and in less time many tasks previously accomplished with paper and pencil. And, the versatility, that is, the many different tasks that can be accomplished efficiently, makes using technology a realistic advantage. Technology is being used to word process documents, manipulate numbers in a spreadsheet, sort information in a database, and retrieve information from other computers. It can also be applied to other productivity and problem solving situations. Technology also supports dynamic and interactive presentations, and professional development can be facilitated via video-conferencing negating the need to travel long distances.

Given technology's complexity, its various configurations, and the many tasks it can accomplish, it is safe to say that it is impossible for one person to be proficient in all that technology can be applied to. So, a question is asked, "Are there some basics guidelines that specify a minimum level of skill in using technology?" This question is best answered in the context of the role or profession of the individual.

Recently, in education, there have been efforts by some states, namely, Nebraska and Virginia, and some educational organizations, the International Society for Technology in Education, to develop technology standards, which are in effect guidelines describing what teachers should be able to accomplish using technology. Right now, the technology standards movement seems to concentrate primarily on students and teachers. Much of the literature on technology standards specifies what students should be able to do using technology at various grade levels and what teachers should be able to do with technology.

Although it is established and well publicized that principals are key actors in the process of integrating technology into schools and facilitating teachers' adoption and use of it (Cooley & Reitz, 1997), they have...
remained on the fringe of technology professional development (training). This is evident in schools’ and districts’ professional development (training) for the use of technology where the concentration is on teachers. The technology professional development needs of school administrators (principals) have received less attention (Hope, Kelley, & Kinard, 1999). And, it appears as though school administrators (principals) are also being neglected in the technology standards movement.

**Technology Standards for School Administrators**

There are a few organizations that have proposed technology standards for school administrators. The Interstate School Leaders Licensure Consortium (ISLLC), the National Council for Accreditation of Teacher Education (NCATE), and most recently, the Southern Regional Education Board, Each organization has identified standards that it believes school leaders should have in their arsenal of abilities. The ISLLC identifies two performance standards directly related to principals’ ability to use technology. ISLLC standards list performance indicators that state that the administrator facilitates processes and engages in activities ensuring that technologies are used in teaching and learning (Standard 2) and that there is effective use of technology to manage school operations (Standard 3).

NCATE Program Standards for Educational Leadership address what a program should prepare the school administrator to do. Standard 9 focuses specifically on Technology and Information Systems and relates that programs should prepare school leaders who demonstrate an understanding of and the capability to use technology, telecommunications and information systems to enrich curriculum and instructions; apply and assess current technologies for school management and business procedures; and develop and monitor long range plans for school and district technology and information systems, making informed decisions about computer hardware and software, and about staff development, keeping in mind the impact of technologies on student outcomes and school operations.

The Southern Regional Educational Board (SREB) proposes an extensive standards model for school administrators to provide effective leadership in their schools. The standards in the proposed model cover a range of school administrator roles and responsibilities. According to the SREB, school administrators would be expected to:

1. Understand the elements and characteristics of long-range planning for the use of current and emerging technology—infrastructure, budgeting, staff development, technical support, personnel, and upgrades;
2. Demonstrates ability to analyze and react to technology issues, concepts, and proposals—community and corporate pressures;
3. Possesses a “big picture” vision of technology in education and schools—reform movement, competency-based education, standards, time allocation;
4. Uses technology to efficiently communicate with stakeholders—voice mail, e-mail, newsletters;
5. Uses technology to collect and analyze data and other information to improve decision making and other management functions—student academic achievement tests, gather data on variables not previously gathered, access to global information;
6. Understands how current and available technologies can be effectively integrated into all aspects of the teaching and learning process—application of software and connectivity to each instructional area, access to research information, multi-media presentations;
7. Understands the legal and ethical issues related to technology licensing and usage—purchasing agreements, safety and security issues;
8. Uses technology appropriately to fulfill their roles of coordinator and communicator of school programs and activities—manage the school enterprise efficiently, present information effectively to stakeholders, improve decision-making and consultation processes.

**Administrator Preparation**

The ISLLC, NCATE, and SREB’s standards are broad and quite general. It is therefore necessary for college and university administrator preparation program faculty members to interpret and translate these standards into discrete activities and experiences in course offerings. To deliver a program that provides aspiring administrators with opportunities to acquire and demonstrate the skills specified in the technology standards require professors who are familiar with numerous electronic devices and are knowledgeable about
administrative and instructional technology applications. It is also essential that they have access to state-of-the-art hardware and appropriate software applications that enable them to engage students in experiences that coincide with the administrative, managerial, and instructional leadership tasks practicing school administrators are performing in schools.

Much has been said and written regarding the perceived disconnect between what takes place in college and university classrooms and what is actually transpiring in k-12 schools. Often, it is noted, the learning being offered students at the college and university level is inconsistent with what occurs daily in k-12 classrooms. Incorporating technology standards into administrator preparation courses can be an intervention that ameliorates the discontinuity between college and university preparation and realities in k-12 schools.

Avenues for school administrators to acquire technology expertise are college and university preparation programs, through their own efforts to improve in the area of technology, and through school and district sponsored professional development activities. It is not known how well college and university preparation programs actually prepare aspiring school administrators to demonstrate the technology standards set forth by ISLLC, NCATE, and SREB. There can, however, be an equating of technology standards with the life cycle of an innovation, a new policy, or a new curriculum program. The comparison is that they are all conceived, initiated in an environment with some staff development, and then left to individuals to implement.

Often, a minimal amount of information is fed back to the initiators about how well an innovation, a policy, or program implementation is taking place and the extent of impact on the intended target. How well are administrator preparation programs meeting the intent of technology standards through course work? Are aspiring administrators prepared through course work experiences to demonstrate the competencies and skills designated by technology standards when they exit administrator preparation programs? Research needs to be done that shows how well colleges and universities are preparing aspiring school leaders with the technology skills specified by the aforementioned organizations.

There is a need for colleges and universities to do follow-up with graduates who become school administrators. This follow-up can provide information on graduates’ perceptions of how well the program prepared them to assume the technology leadership role in their present capacity as a school leader. A challenge to administrator preparation programs is to be able to provide high quality learning experiences that approximate what school leaders will likely experience in their districts of employment. It must be mentioned also that administrator preparation programs can do a good job in providing aspiring school administrators with necessary technology skills, however, once an individual is in a district and at a school, the technology facilities and availability of professional development opportunities may not lend to the continuing development of the individuals technology skills.

Faculty, Facilities, and Technologies

Faculty

As with all programs, who delivers the training is as important as the content to be delivered. College and university administrator preparation programs should have a commitment to students achieving the technology standards promulgated by ILLSC, NCATE, and SREB. Furthermore, professors should be aware of the technology standards and possess an advanced level of expertise in understanding and using technology. It is inappropriate to expect students to acquire certain technology skills and hold them accountable for demonstrating technology standards when those who are presenting the content and facilitating skill acquisition do not possess the expertise to provide the appropriate instruction in technology. It is important for administrator preparation programs to have professors who are knowledgeable of and can use technology to teach how it can be used to support (a) administrative and managerial task accomplishment, (b) personal productivity, (c) achievement of curriculum objectives and students’ learning outcomes, and (d) teachers’ integration of technology into their practice. Moreover, professors should have working relationships with k-12 schools and possess an awareness of how technology is being used in instruction and administration. This relationship can address several key issues. One, it becomes an intervention for the perceived inconsistency in teaching and learning in colleges and universities and the realities of k-12 schools. Two, it enhances the probability that aspiring school administrators will receive training that resembles what is actually occurring in schools. And three, the college, university and k-12 school relationships achieves the intent of ILLSC, NCATE, and SREB technology standards.
Facilities and Technologies

An academic program that effectively prepares students to fulfill school leadership roles begins with excellent facilities. This is especially true considering preparation to become technology leaders in schools. To provide instruction that leads to students' acquisition of ILLSC, NCATE, and SREB technology standards, administrator preparation programs should have access to facilities that have up-to-date technologies—computers in sufficient quantity, writeable CD-ROMS, scanners, printers, telecommunications capabilities, projectors, and a variety of software.

Technology rich environments are spacious, well designed, and provide various stations that focus specific technological devices on their administrative and instructional uses. Activities in administrator preparation programs should approximate what school administrators are actually doing in schools. For instance, if aspiring school administrators are learning about instructional uses of technology, and in particular, an Integrated Learning System (ILS), then students should have access to an operational ILS in order to experience its design and capabilities. If the learning to take place concerns an administrative task such as accessing a database for information, then students should have access to a database of information and practice accessing and retrieving specific data. It is important also, that aspiring school leaders practice with hardware and applications that are currently used in their district’s schools. This may entail arranging a partnership with school districts so that students have an opportunity to acquire knowledge and familiarity with the district’s Management Information System and other technology applications.

If instruction focuses on using technology for productivity purposes, then students should have access to a computer system, necessary peripherals and software. It is unlikely that school districts will use the same hardware and software. This presents another challenge to administrator preparation programs. Today, a majority of schools use technologies based on Windows 95 and 98 and the Macintosh operating systems. This becomes an opportunity for students to assist the program by informing professors of the various software and platforms being used in a district. Program coordinators using this information can plan for hardware and software acquisitions to enhance program delivery.

In a final analysis, preparing aspiring school administrators with technology competencies require programs to provide students with engagements that assists them in understanding technology’s role in teaching and learning and in accomplishing administrative tasks. These experiences ought to include practice in planning for technology, integrating technology into the curriculum, aligning software with curriculum objectives, understanding of the elements and characteristics of long-range planning for the use of current and emerging technology; staff development; technical support; security, maintenance, and upgrading existing technology.

What Administrator Preparation Programs Should Prepare School Administrators to Know and Do

Technology is viewed by many, as a catalyst that can assist in transforming schools into highly productive organizations. Even though there is little definitive evidence linking computer technology to student achievement, a significant number of people believe that technology positively influences teaching and learning. School administrators are indispensable in the process of transforming schools through technology. This transformation requires school administrators who (a) understand technology terminology, (b) are knowledgeable about the power, features, and capabilities of technology, (c) understand technology’s role in schools, (d) act as role models and encourage technology use, (e) can provide problem solving and technical assistance, (f) are change agents that facilitate technology’s integration into teaching and learning. To fulfill these roles require extensive experiences and considerable expertise in the area of technology. Administrator preparation programs should provide aspiring school administrators with fundamental skills in each of the aforementioned areas.

Technology leadership entails both understanding technologies and how they can be applied to accomplishing tasks. We propose that administrator preparation programs should prepare aspiring school leaders through engagements that enable them to move beyond routine use of technology to a level of proficiency. At the basic level we agree with Kearsley (1990/1995), that school leaders should be able to explain basic computer terms and concepts, describe major hardware and software components, and understand the elements involved in evaluating and selecting hardware and software. We also suggest that school administrators be able to use technology to accomplish those things that teachers and students are expected to do. Beyond these, school leaders should be prepared to use technology to complete administrative tasks,
facilitate teachers' integration of technology into the curriculum, and understand how technology influences the teaching and learning environment to accomplish instructional objectives.

Administrator preparation programs should provide many engagements that allow students' to use technology in real world leadership situations. It is important for aspiring school administrators to have experiences with productivity tools such as word processors, databases, and spreadsheets. Beyond these, opportunities to use presentation software, access on-line databases for research purposes, and exchange information via electronic communication should be extensive. Although not an exhaustive listing, the following are some fundamental outcomes for individuals in administrator preparation programs and are representative of what aspiring school leaders should know and be able to:

1. Use a spreadsheet to prepare a school budget.
2. Communicate with school stakeholders using various technologies.
3. Access the districts database for numerical and demographic data.
4. Understand the legal and ethical issues related to technology licensing and usage.
5. Purchase up-to-date hardware and software.
6. Evaluate software for administrative use and instructional use.
7. Plan for the purchase, support, and security of acquired technology.
8. Understand how current technologies can be effectively integrated into teaching and learning.
10. Assist teachers to integrate technology into classroom instruction.
11. Provide basic technical assistance.
13. Facilitate teachers' professional development to use technology.
14. Use presentation software to enhance communication skills.
16. Select hardware that is configured with the most recent technology advances.
17. Use word processor, spreadsheet, database, and communications applications.
18. Desktop publishing.

Conclusion

The purpose for technology standards, and their application to school leaders, is the belief that administrators should possess a vision of what technology can accomplish in schools, be able to use technology for specific tasks and facilitate teachers and students' use of technology in the school environment. Competence in understanding the roles of technology in schools and being familiar with technology's power and capabilities requires experiences across the technological spectrum. Given this reality and what we know about administrator preparation programs, we believe that one course in technology at the masters level is insufficient to provide aspiring school leaders with the technology engagements necessary to prepare them to be technology leaders in schools. There is simply too much in the area of technology and its applications in schools to cover in a semester course. We suggest two courses specific to using technology at the master's level to adequately prepare school administrators to be instructional and technology leaders. Moreover, opportunities to use technology should be integrated in all courses that prepare aspiring administrators.

Information Technology and the Transformation of Leadership Preparation Programs: A Response to Calls for Reform in Educational Practice.

Ian W. Gibson
Department of Administration, Counseling, Educational and School Psychology
Wichita State University
United States of America
igibson@twsu.edu

Abstract: This paper describes information technology usage in a radically different school leader preparation program. Ed.D students at Wichita State University are immersed in a variety of technologies from the first day of class. A collaborative, situated, problem-based learning approach to instruction requires acquisition of high levels of personal comfort and expertise with program technologies, sufficient to allow students to be efficient in their own studies, and to mentor others in various aspects of advanced information technology usage. Students incorporate technology in their roles as participant, collaborator, colleague, leader and follower in a variety of contexts: seminar, field study, content presentation, data manipulation, research reporting, group/individual comprehensive examinations, dissertation. Program graduates acquire, among other things, an understanding of the impact of information technology on their roles as visionary leaders of schools of the future and experience the transformational potential of technology on their own learning process.

Introduction

This paper focuses on the description of a doctoral program designed to prepare effective leaders for schools while emphasizing the transformational role of technology in the process. Three significant educational trends provide the background for this paper. The trends providing the foundation for this dramatic change in approach to the process of graduate education are represented by:

• increasing evidence of the change possible in the way that learning can occur in schools and in the workplace as a result of the presence of information technology;
• repeated calls for reform in educational and school based practices; and
• recognition that preparation programs for school leaders are in urgent need of reform.

In recognizing these trends, faculty from the College of Education at Wichita State University in Kansas, have demonstrated the positive impact of significant changes in philosophy and approach to the organization of graduate preparation programs for school leaders. Informal data gathered from current doctoral students and from graduates of the program indicate that the changes are positive and well supported. Responses from the field demonstrate that graduates of the program compete successfully for coveted leadership positions and are sought after by school districts in need of thoughtful, visionary and effective leaders.

Following the discussion of background information taken from the literature, the process and impact of integrating technology into the mainstream of daily practice within a radically different school leader preparation program will be described. The objectives of the program will be discussed in terms of technology-related practice. The belief that faculty must model technology integration (Blomeyer & Clemente 1997) will gain credibility through a description of faculty and student learning behavior. Further, a description of the technology infrastructure of the program, the smorgasbord of technology offerings available to students and incorporated into daily practice, and the impact of such practice on student behavior and learning will be presented. Throughout this paper, insights into a variety of program objectives and practices will be provided. These insights relate to:

• the philosophical underpinnings of the program;
• objectives of this graduate leadership preparation program including collaboration, teaming, use of authentic problems of practice, situated learning, reflective practice, cohort teams etc.;
the smorgasbord of technology options forming the integrated technology infrastructure of the program: required laptop use, access to server, communication hubs, file-sharing, e-mail, projection devices, internet access, database usage, discussion lists, chat facilities, interactive technologies;

- the importance of group maintenance
- on-going technology training and
- the practical aspects related to the planning, administration, and management of technological and pedagogical innovations in graduate leadership programs.

Literature

In their book, *The monster under the bed*, Davis & Botkin (1994) claim that the knowledge business is transforming the way we learn (P.15). Their treatise on the place of knowledge-based enterprises of the future begins with the following story.

Megan was five years old and worried about a monster that lived under her bed. She told a story about how the monster scared her, how she wanted it to go away, and how she solved the problem—now the monster lives under her brother's bed. She also drew pictures to accompany the story. They look like the kind displayed by parents on refrigerator doors. Only Megan drew these pictures on her computer and used the computer to record her telling of the tale... Megan didn't stop there. She wanted to share her story, so she sent it by phone to an electronic bulletin board club, where other kids her age could watch and hear it... Here was a five-year-old child who had accomplished all the major tasks of moviemaking. She was the star, wrote the screenplay, created the visuals, did the editing, was producer and director, and even did her own distribution. Her learning was integrated into the realities of her life. (P.14-15)

Elsewhere, a great debate ensues regarding the need for extensive reform in educational practice (Boyer 1985; Carnegie Task Force 1986; Holmes Group 1986; National Commission on Excellence in Education 1983; National Council for Accreditation of Teacher Education-NCATE 1997). In the United States, it is claimed that the “nation is committed to a course of fundamental change to improve ... educational Mojkowski 1991). Mojkowski suggests that the existing system of schooling does not adequately serve many children and is failing to keep pace with the revolutions in learning and work taking place in the rest of society. While this report goes to some length in describing the goals that should drive this massive restructuring process, there is recognition that while the goals themselves are “clear, comprehensive and oriented to results, ... they are beyond attainment unless sweeping changes are made in our education P.iii). Many of the changes endorsed by this report focus upon the belief that both technology and leadership are crucial components in the educational change process.

The process of integrating computer technology into classroom practice has been underway for twenty years. Some have reported that technologies appropriate for classroom practice have become an integral component of instructional processes (OTA, 1995). Others have suggested that the effective use of these same technologies enhances the performance of both teachers and learners (Jonassen 1996; Kauchak & Eggen 1998) and contributes to motivation levels apparent in technology based classrooms (Kauchak & Eggen 1998). In recognizing that such beliefs are not widespread, The Office of Technology Assessment (1985b) and NCATE (1997) have both stressed the need to incorporate instruction in technology into programs of teacher education in order to encourage more appropriate integration of technology use into school practices. Roden (1997) has indicated another area requiring attention if support for technology use in schools is to be optimized. He suggests that it would be inconceivable for school leaders to declare a lack of knowledge about mathematics or reading, but that many make a similar declaration about computers and the role of technology in classrooms. While it appears that most of these writers are describing what may be the beginnings of a revolution in learning occurring in schools based on the role of technology as change agent, it does seems strange that in the field of leadership preparation, discussions of reform have rarely focused upon the potential impact of technology on the thinking or the practice of school leaders.

In the field of leader preparation, undeniable conclusions have been reached regarding the need for reform. Since an agenda for the reform of school administrator preparation programs was first published by the National Policy Board for Educational Administration in 1989, others writers have agreed to the need for massive change in the preparation of school leaders (Leithwood, Begley & Cousins 1994; Murphy 1992). The fundamental underpinning of this reform movement was the firm belief that change in schools could not occur
without a change in the thinking of school leaders. Radically different schools needed radically different leaders. It followed, then, that the development and sustenance of these leaders would require a radically different conceptualization of pre-service and in-service education and training (Mojkowski 1991). Some writers have postulated that the predominance of traditional instructional paradigms in leader preparation programs agitated against the reform of such programs (Hallinger & Murphy 1991). Creighton and Yates (1999) claimed that administrators learnt skills on-site, in context and integrated with real-life applications. As though in summary, Mojkowski (1991) suggested that the process of leader preparation should integrate learning and work, emphasize action-oriented, problem solving approaches to training, focus on the development of teams and be comprehensive, coherent and continuous. In related studies conducted by The Office of Technology Assessment (1988; 1989; 1995), it was found that those administrators who were themselves, informed, comfortable and competent with technology use in their own jobs also became key players in leading and supporting the use of technology in schools.

A Radical Approach to Leader Preparation

Seven years after its inaugural intake of doctoral students, the leader preparation program at Wichita State University boasts a 100% completion rate for candidates completing the coursework component of the program. Further, students of this program have won national scholarships, have been recognized nationally as recipients of dissertation awards, and have been selected for coveted school and district leadership positions in Kansas school districts. The program itself has been described in detail elsewhere (Furtwengler & Furtwengler 1998; Furtwengler, Furtwengler, Hurst, Turk & Holcomb 1996) and will be featured in an upcoming issue of the Journal of Critical Inquiry into Curriculum and Instruction which publishes exemplary research products of graduate students in professional study. Notwithstanding this national and international exposure, the unique features of this clinically oriented, field-based, applied inquiry program in educational administration are worthy of further mention. The program distinguishes itself from traditional administrator preparation programs through a design that emphasizes: (a) rigorous admission requirements and low enrollment, (b) release time from district employment for prospective students, (c) integration and contextualization of the curriculum, (d) incorporation of field-based research studies, (e) a collaborative, team-based approach to teaching and faculty load distribution, and (f) a cohort-based student support structure. These program design features correspond to those calls for specific reform measures in preparation programs for school administrators outlined above.

In addition, this program design is supported by a confirmed philosophical belief related to the process of teaching and learning within the program. Based upon a theoretical framework derived from problem-based learning (PBL) (Boud 1985; Boud & Feletti 1991; Bridges 1992), this program functions with the belief that authentic problems of practice, explored in collaborative team settings lead to learner-directed and setting-enhanced learning. Faculty attached to this program believe that these problem situations raise the important concepts and principles associated with the content domain and that they are perceived by graduate students as real problems of practice (Savery & Duffy 1995). In the dynamic and situated learning environment that is representative of daily life within this leader preparation program, meta-cognitive scaffolding is provided by faculty and peers (Savery & Duffy 1995). The underlying propositions of constructivism (Savery & Duffy 1995), including the ideas of cognitive dissonance and negotiation of meaning, are core program components. Studies of student thinking during the initial problem analysis phase of PBL (De Grave, Boshuizen, & Schmidt 1996) corroborate the belief, clearly in evidence within this program, that exposure to different ideas in a group leads to conceptual change and that group interactions serve to encourage activation and elaboration of existing knowledge and integration of alternative views. Further, this program epitomizes the growing trend recognized by Heath (1997) for models of education which accommodate a constructivist view of learning incorporating the use of emerging technologies (Hannafin & Land 1997).

Using Technology in the Transformation of a Leadership Preparation Program
In this leader preparation program, two applications of technology can be distinguished. The first is that used as part of program functioning and required for daily use and program effectiveness. The second relates to technology usage that is experimental and evolutionary. This second type of usage refers to the incorporation of technologies new to the program, and new information technology applications designed to meet program needs and expectations for growth and expansion.

Program Expectations for Technology Use

The pre-dissertation stage of this doctoral program requires students to attend one full day of class time per week over a two year period. Class time is divided between seminar and field study time. During seminar, students meet in cohort groups along with two or three professors and explore an extensive array of topics as presented by an exhaustive reading list of books on the cutting edge of leadership thought. Field study time comprises the research-based exploration of authentic, contextualized problems derived from discussion with school board members, and district administrators from local school districts. Site selection for research studies are contingent upon the acceptance of a school district administrator as a student into the doctoral program.

Class-based interactions begin with setting up a small classroom in a conference room format with a communications hub sufficient to connect all students and professors to a department server via ethernet connections. These connections provide further access to the internet and associated data-bases, libraries and search facilities. A data projector is connected to a lap top computer, the purchase of which is a condition of acceptance into the program. An elongated power strip provides a power source for up to six students and three professors. Unrestricted access to a telephone, a fax machine, and a photocopier is nearby. Both color and black ink printers are accessible via the local network. Students and professors each have personal email addresses (another program expectation) and are provided passwords for remote access to the departmental server. When completed, this daily ritual has converted a most un-noteworthy small conference room into a high-powered research and analysis laboratory.

Software requirements mirror hardware configurations and program objectives. An integrated office productivity program incorporating word processing, data-base, spreadsheet and projection software is mandatory. A bibliographic database, and an appropriate internet browser are also required. Access to other software provided by the department includes a statistical analysis package, desktop publishing software and a relational data-base package used in the analysis of qualitative data. These packages are made available to students through site licenses maintained by faculty. Further software is provided as needed and available to support innovative and flexible additions to program requirements.

Training in the use of these hardware and software configurations begins with a summer program designed to launch doctoral study for each new cohort. Comprising six students, the new cohort enrolls in a course focusing upon technology and academic writing. The existing cohort act as mentors to their neophyte colleagues as students and professors explore hardware and software capabilities within the context of problems typical of program requirements. Learning about technology in this context is ongoing and is rarely completed as new skills, and new applications, are discovered and levels of expertise increase.

Daily information technology activity for all students and professors includes the use of email, internet searching, file sharing, program organization, project management, bibliographic referencing, statistical analyses, qualitative data analyses and functional use of all required software application programs. Familiarity with printers, projectors and interactive communications hardware is also required and usually occurs, without trauma, well before the end of the two-year course of study. The level of interactivity via email, file sharing and surfing for the sake of research continues between class sessions as semester projects and planning for seminar discussions are shared. Periodically the need for applying levels of interactivity new to this doctoral program arise and provide students and professors with an opportunity to experiment with available technology and program objectives.

Experimental Applications of Technology

Apart from the normal levels of required interactivity described above, occasional opportunities for expanding the level of technology integration in this innovative program arise. In the normal course of events,
all students in this program drive to the university to attend a full day class once a week. This represents a significant commitment, as driving time can, for some, exceed nine hours: four and one half hours of driving on either side of a full day in class. These students are still required to function effectively the following day in their role as district administrators. During the last twelve months the variable of distance has provided an opportunity to experiment with interactive television in an attempt to replicate and maintain the intensity of collaborative, team-based, group interaction across significant distances.

On several occasions, arrangements were made for some students to remain in their western Kansas locations while the rest of the class met on campus at the university in south-central Kansas. Two-way interactive television links were established between both locations. The organization for the day remained as normal as possible, with the exception of a change of location to a conference room having interactive television capability. This interactive room was rearranged to replicate the physical layout described above, along with all standard technological capabilities required by the doctoral program. Planned group research and writing activities, seminar activities, and incidental personal meetings, interactions etc. continued as normal throughout the day. An evaluation of the activity was conducted. Professors, students and technical personnel were asked to complete a questionnaire on the effectiveness of the interactive activity. With the exception of some instances of sound degradation periodically throughout the day at the remote location, no other technical difficulties were experienced. Students at the remote location expressed concern that they could not go to lunch with their colleagues although they were appreciative of the reduction of driving time. All evaluations strongly supported the use of this form of interactivity as a viable program alternative and confirmed the belief that the essence of group collaboration forming the basis of this doctoral program was capable of being maintained across distance.

On another occasion prior to this interactive television activity, a discussion list designed to supplement interaction based around seminar discussions was activated with the assistance of the university’s computer services division. A professor assumed the responsibility for maintaining the list. Activity continued throughout the semester and student reaction indicated that interactions provided through this medium were of value. This activity was not maintained, however. Plans for the future incorporation of discussion lists, chat facilities and web site usage into the smorgasbord of technology options forming the integrated technology infrastructure of this program are underway.

Conclusions

Banks, Stacey, and Omoregie (1997) claim that technology training for teachers and administrators is the key to successful implementation of technology in the classroom. In a research study analyzing the process of technology integration into K-12 curricula, Mahmood and Hirt (1992) conclude that a number of variables impact plans for integrating technology, but none so much as strong support from school and district administrators. In describing goals necessary for creating a technology-effective, and integrated learning environment, McPherson (1995) focuses upon the crucial role of school leaders in the process of information technology integration. She suggests the need to create dynamic leadership and organizational support, using the full range of technologies to promote school reform, meet national and state educational goals, and assure quality education for every student. These and other writers have recognized that a key barrier to the use of technology in schools is the lack of administrative support (Maurer & Davidson 1998; OTA 1988, 1989, 1995; Rodin 1997). By indicating that schools with effective technology curricula also have strong administrative leadership supporting and sustaining effective technology programs, these writers infer the need for technology-based reform in administrator preparation programs. Suggestions that administrators need to know how technology can restructure the teaching learning process and keep an active focus on the real purpose of the educational system are commonplace. Exposing administrators, who are likely to assume the responsibility of visionary leadership in schools of the future, to the positive changes brought about by technology is an uncommon practice. Modeling the technology reform process in education as a component of leader preparation programs is one way of ensuring a balance between technological ideals and practice.

Over the past seven years, and through the combined efforts of all faculty involved during that period, the leader preparation program at Wichita State University has met the calls for technological and program reform. This radically different program has managed the difficult transition from a highly traditional and predominantly decontextualized program, to an environment where situated, problem-based, and collaborative learning predominates. This answer to the calls for reform has been formulated through:
the inclusion of required technology components in program application procedures (purchase of hardware and software as conditions of enrolment);
the incorporation of contextualized and integrated curriculum and instruction in technology usage;
a student cohort support system and mentoring roles required as rites of passage through the program;
the construction of peer teams and adoption of group and individual responsibility for learning; and
immediate and continual immersion in the use of interactive, information technologies in exploring authentic problems of professional practice.

This program has provided school leaders with the tools to think about technology in vastly different ways and the experience to do something about it.

Abstract: Responding to the call for change in higher education leadership preparation programs, the Department of Human Services and Professional Leadership revised and further developed an existing model guiding the college in which the department resides. The Caring Intellectual Leader Model, is designed to focus on problem-based learning which incorporates the infusion of technology throughout all levels of knowledge acquisition and assessment: formal, descriptive, prescriptive and praxiological.

Introduction

American education has been at the forefront of public policy analysis since the early 1970’s when influential groups began the clamorous call for reform. With this call came a spate of critical documents which demanded substantive change in the preparation of educators and provided data indicating that current offerings are not adequately meeting the needs of the constituents, who seek greater input into policy formation and decision making. We hear continually of the need for systemic change (Feigenbaum, 1993; Murphy, 1991; Gordon, 1992; Senge, 1994) and defocusing on specific roles and issues. This focus on the “system” comes in the wake of unrelenting teacher and administrator condemnations following the national report, A Nation At Risk (National Commission on Excellence in Education, 1983). Indeed,
the problem is compounded by continual strident accusation, and the failure to address the root cause of school problems.

Johnson (1992) asserts that the new mission of education will require significant changes in preparation of educational leaders in order to meet the needs of the technologically driven societal and schooling domains. In support of this notion, Hallinger and Bridges (1999) state that most leadership programs focus almost exclusively on the cognitive dimension and rarely address the level of practice in a meaningful manner. In order to accomplish the task of preparing education leaders for problem-based, authentic learning, it is incumbent upon higher education and schools to shift paradigms (Wheatley, 1995) and reconceptualize the future needs of schools and educators in a high technology Information Age which calls for increased empowerment of staff. Johnson contends (p. 100) that: "The need is no longer simply to induce conformity to established practice among future leaders but rather to develop a critical analytic approach to the production of new practices". Zukav (1979) depicted this need well in his classic book The Dancing, when he stated that restructuring must cause us to "slip the bonds of the known to venture far into the unexplored territory which lies beyond the barrier of the obvious" (p.82).

Changing paradigms is difficult for individuals; it is more so for institutions (Senge, 1990). In general, the literature (Fullan, 1993) suggests that higher education institutions have not responded to the pressures to substantially alter their offerings or the method of instruction in educational leadership programs. Murphy (1991) conducted a study examining the effect of the reform movement on leader preparation programs and determined that only slight to moderate changes were being made in compliance with reform admonitions and recommendations. He attributed this to a lack of motivation among college preparation programs to change.

Numerous experts note the dearth of transformative preparation programs (Leithwood, 1992; Naisbitt, J., & Aburdene, P., 1986; Lampe, S. et al, 1992) and the reluctance of higher education to respond to the pressures to substantially alter their offerings or redefine appropriate pedagogy. Although the reform movement has received a great deal of attention by the popular press, it has not had as significant an effect on higher education preparation programs across the nation (McCarthy, 1988). In 1991, Joseph Murphy conducted a survey of 74 chairpersons of the University Council of Educational Administration (UCEA) and non-UCEA programs. Findings of this study indicate that the overall picture is one of slight to moderate change in response to reform initiatives, including teacher empowerment. It is very easy to discuss the empowered workplace; it is entirely another issue to deliver on this promise. One does not change long-held ideas about the organization and the power base by desire. Senge (1990) advises that substantive cognitive changes must occur before we change our behavior and beliefs: He states that "...new insights fail to get put into practice because they conflict with deeply held internal images of how the world works, images that limit us to familiar and conventional ways of thinking and acting." If leaders are to be adequately prepared for the future, higher education programs must heed the call for reform that is in accord with the needs of the times.

The single area where most higher education change efforts converge is the
augmentation of curricular efforts to address leadership issues which are consonant with reform exhortations advocating a focus aimed at developing reflective practice (Norris & Lebsack, 1992) in a problem-based learning environment characterized by the increased focus on praxis in instruction and assessment. The literature defines four levels of knowledge which must be incorporated in both instruction and assessment: formal, descriptive, prescriptive and praxiological. Praxiology, according to Mozilla (1999) is that domain of knowledge which focuses on the practice of leadership. Mozilla has developed a computer-based model (The Complete Teacher, 1999) for teaching and assessment of each of these areas. This model will be incorporated into the Wisconsin Leadership program being discussed below.

**Caring Intellectual Leadership Model**

Leading educators and researchers suggest that if substantive curricular renewal and transformation in higher education is to occur, it must be at the programmatic level (Johnston, 1992). Understanding this recommendation, the educational leadership program faculty has focused on revision at this level. Norris and Lebsack (1992), in reporting findings from a three year pilot designed to examine different approaches to the preparation of school leaders, identify necessary components which include: a) programs must have personal meaning and relevancy, b) cohort and mentor experiences are important in assisting the scholars' bonding, and c) curriculum requirements and teaching must reflect the faculty's commitment to the praxis structure. The program faculty recognized that the change from traditional leadership course work and pedagogy to one characterized by problem-based learning with technology infusion is not merely curricular nor structural, but endemic in nature. The entire paradigm must be redesigned to meet the needs of the future.

In response to the literature, research and the cumulative experience of the Educational Leadership program faculty, the following model was adopted.

The Master program in Leadership resides Department of and Professional (HSPL), College of Human Services at Wisconsin. HSPL addressed the adoption of an model that promotes personal...
growth. The heart of the model identifies the goal outcome, a Caring Intellectual, and places technology integration coursework in a unique position. Technology is the support system whereby the curriculum, personal aspects and practice all converge. Technology facilitates problem-based learning and a Constructivist approach to curriculum, which enables the Educational Leadership program to foster empowerment and a sense of self-efficacy in future leaders. The underlying philosophy guiding this model identifies the outcome component as a “Caring Intellectual” and includes the following attributes; lifelong learner, reflective practitioner, skillful professional and agent of positive change. Examination of the model includes diversity, content, culture, pedagogy, learning and curriculum.

The focal concern that was addressed by the Department of HSPL was the identification of the major issues that have the capacity to effect the terminal goal of increased student performance. Fundamental to the assessment of the Educational Leadership program was the intensive analysis of all possible elements that might contribute to this primary goal. The context is extremely enigmatic and many determinants and theories would underpin the response. Included among these might be Constructivism, the Socratic Dialogue, Case Study analysis and Problem-Based Learning. The literature and experience suggested the need for a clearly defined mission statement, program goals and assessment methods be in place for programmatic clarity and definition.

Central to the department mission and philosophy is the belief that all educators - teachers and administrators - must come to the same table to dialogue, share and envision educational reform strategies in problem situations. Toward this end, the department offers two strands or emphasis areas in technology. One is designed for teachers who envision that they will use technology as a tool within their curriculum while the other is designed for educators who wish to develop more technical expertise that could lead to certification as a district technology director. A central core of 12 hours of technology integration courses is required for both emphasis areas in an effort to insure that district administrators are sensitive to the needs of the classroom teacher and the potential of technology as a tool for curriculum delivery and assessments.

The two technology emphasis areas are detailed below. Notice that both share a common core to insure dialogue and awareness of the needs of the classroom teacher in successfully integrating curriculum and technology.

Conclusion

In order to provide appropriate preparation of administrators and teachers, educational leaders, the faculty in the Department of Human Services and Professional Leadership at the University of Wisconsin Oshkosh researched many models and pedagogies. The Caring Intellectual model was adopted and modified to clearly identify problem-based learning characterized by technology infusion at all levels of instruction and assessment.

Abstract: This paper discusses our approaches, both in theory and practice, to the enactment of systemic reform as a part of the Center for Learning Technologies in Urban Schools (LeTUS). The University of Michigan and Detroit Public Schools have partnered in this Center to develop and implement a systemic educational reform program to help middle school science educators understand and enact some basic ideas and concepts of inquiry-based science focused on the use of various technologies to assist in the learning process. Presented here are the challenges of implementing a professional development program geared toward systemic reform, along with details about the enactment and scaling of this multi-faceted professional development program. The paper also suggests a variety of considerations regarding the scaling of such programs.

Introduction

Educational reform has generally taken one of two paths in finding a way to change classroom practices, whether addressing implementation of technology use by students and teachers, or by focusing on shifts in pedagogical approaches and content knowledge. Very often, especially with respect to the infusion of technologies such as computers in classrooms, true reform has come from the grass roots; the teachers themselves. Innovative practices which involve processes of student inquiry for individualized construction of knowledge while utilizing technology were borne out of an individual teacher's ideas, and
enacted within their own classroom. They were the early “technology superstars” in the schools, making efficient and effective use of the new computer technologies to allow students to demonstrate advanced learning and thinking in a variety of ways. Occasionally, others would hear of their advancements and attempt to recreate or join their efforts. But, for the most part, these innovations were contained within a few select classrooms.

Other innovative reform efforts might take an altogether different path for their genesis. Many of the recent school and site-based reform efforts are administrative directives, the attempts of administrative leadership within the school or academic community to change educational practice by creating practices which direct individual teachers as to what to do within their classrooms to improve student learning. Sometimes, it takes the form of a new software program, a different textbook, or a set of standards and outcomes for which success (and motivation) will be determined by some form of summative assessment. While these “top-down” forms of reform efforts may have greater “volume” of impact, they too may lose effectiveness by reinterpretation by teachers, bureaucratizing of reform efforts, lack of proper support, and simple apathy of teachers who are uncomfortable with a “directive” format of change for their classrooms.

Systemic reform is a complex notion, which requires a new approach. For teachers to truly be involved in the efforts and understand both the content and pedagogy issues of the reform effort, they must be directly involved in the reform process. Yet, for the reform effort to occur throughout an entire school system, especially a large urban school system, having all teachers involved in the development of new curricula, adaptation of learning technologies, and change in approach and method of instruction would become chaotic, and would likely throw the system out of control. So, a dynamic tension is created between the two approaches. Administrative decisions must be made to properly support and motivate teachers to become involved, and teachers must take the initiative to become involved in a program encouraging their support of and enactment of innovative curricula and pedagogy, becoming collaborators in this process.

**Context and Theoretical Framework**

We have been working in collaboration with an urban school district to reform science education to be inquiry-oriented and make use of pervasive educational technology by creating professional development opportunities that will address the needs of a diverse population of teachers. Our experience comes from our work in the Detroit Urban Systemic Initiative, a successful reform-minded program focusing on the improvement of science education in urban middle schools. As a part of the Center for Learning Technologies in Urban Schools (LeTUS), the University of Michigan and Detroit Public Schools have partnered to develop and implement a systemic educational reform program to help middle school science educators understand and enact some basic ideas and concepts of constructivist educational practice.

There are challenges unique to urban environments, including high teacher mobility rates, spotty content-area and technology specific preparation for teachers (with many teachers teaching out of their specialization), a lack of a substantial and “teacher friendly” technology base in many schools and classrooms, and high poverty among students. These challenges (and others) must be addressed by professional development if reform efforts are to become successful for individual teachers and students, scaleable to the needs of the whole school and district, and sustainable in both individual classrooms and the system as a whole. The reform effort is systemic in nature, focusing on changing the way science is taught (and learned) throughout the entire district of 180,000 students, as well as other districts interested in the approach.

The professional development framework underlying our work is rooted in a larger theoretical frame called CERA (Marx, Blumenfeld, Krajcik & Soloway, 1997a; Marx et al., 1997b), which stands for Collaborative construction of understanding; Enactment of new practices in classrooms; Reflection on practice; and Adaptation of materials and practices. CERA provides the general backdrop for our collaboration with the school district and with teachers in all activities, including professional development.

The challenge of scalability and sustainability of a systemic reform program adds layers of complexity to the professional development program. This development effort calls for massive upscaling over a
relatively short period of time and requires constant modification of the model for implementation of professional development programs. For instance, providing individual classroom support for five teachers in two schools is relatively easy. Providing similar support for fifty teachers in twenty schools a short while later requires a massive growth in resources, if the same model is applied. This would be difficult for any such program, but, when combined with the underlying focus on individual student inquiry modeled within development efforts, the task becomes daunting; requiring constant change in the strategies and method of the development program. The infusion of computer-based technologies complicates this further, as the nature of the technology changes ever so rapidly. Thus, the development program itself has varied significantly from its inception, and will continue to do so as the scope of the program grows throughout the school system. As a result, a dynamic for sustainable growth is implemented within the development program, calling upon the knowledge and experiences of teachers involved early in the program to take on greater leadership responsibilities to encourage and promote growth as the program proceeds. In addition, the nature of the individual elements of professional development change, focusing on more global, pedagogical concerns as teachers add experiences that allow for reflective understanding of these concepts.

Elements of the Professional Development Program

Professional development for systemic educational reform (focusing on understanding and enactment of inquiry-based science curricula with embedded technology use) within a massive urban school district requires a variety of elements in order to accommodate the diverse needs of the teachers within the system. The primary element of this professional development program is the use of educative curricula, which are intended to provide opportunities for student learning through inquiry and technology use while providing teachers with activities and other constructs to enhance their understanding of content, pedagogy, and technology through active reflection. Other elements include more traditional development activities such as summer and weekend workshops (with non-traditional, model based activities during the workshops) with other, less-traditional events such as in-class support by curricular, pedagogical and technological experts; intradistrict, teacher-led, after-school study groups; and network-based resources designed to supplement activities and strategies provided through other support methods. This allows for individual teachers to center on their own goals and strategies within the classroom, while being a part of a massive development program.

As mentioned earlier, all of these activities are centered upon the use of an “educative” curriculum unit, designed to provide opportunities for enactment of the desired practices within a content-focused framework. These curriculum units provide a guided set of activities to engage students in the learning of science content focusing on a contextualized driving question. They are designed to remove the teacher from the role of “keeper and communicator of knowledge” to a facilitator of student learning through an inquiry and investigation process, which utilizes a variety of technological tools to help students understand relationships of the content concepts. They provide a number of opportunities for teachers to personally reflect upon the enactment of the curriculum, and engaging questions to help redirect the personal pedagogy of the teacher. They also provide the context for the professional development program to help teachers examine different practices and their impact on student learning.

The summer workshop functions as the kickoff activity for teachers involved in the program, in that it provides the orientation to the program and the underlying pedagogical concepts promoted by the Center. Teachers are introduced to inquiry-based, technology centered curricula by enacting their own investigation of the concepts inherent in the curricula they would be teaching in the following academic year. While participating in the inquiry projects, teachers are constantly encouraged to reflect upon their activities from a learner’s perspective, and develop and share strategies for the teaching of these concepts during the school year. Teachers also participate in other work sessions, focusing on understanding the underlying content and pedagogy of the educative curricula, forming a community with other colleagues in the program, and developing a strategic plan for local enactment of the curricula.

Saturday workshops held throughout the school year provide another element of the professional development program, similar in nature to the summer workshop, but held periodically through the school
year to provide a construct for teachers to reflect on practice during the enactment of the educative curricula. These workshops group teachers and administrators working with four distinct curricula together in the mornings to discuss general concepts and strategies of constructivist pedagogy focusing on technology integration and inquiry based science. In the afternoons, teachers collect in smaller groups to discuss issues relevant to the implementation of their particular curricula, which are divided by grade level and district standards.

Another very important aspect of this program is the use of in-class support personnel who assist the teachers with the enactment of the curriculum, and encourage reflection on practice. These individuals are prepared by training and immersion in the curricula and with the technological tools. All support personnel are experienced teachers with an understanding of the underlying pedagogical concepts of the program. These individuals participate in four fundamental support activities; cognitive/pedagogical understanding support, in-class teaching assistance, technology related assistance, and logistical or documentation activities (See Table 1). Regular evaluation of support personnel takes place with teachers at the Saturday workshops, in that teachers complete feedback and evaluation forms to note needs and concerns regarding in-class support. Support members also meet regularly to share ideas and concerns brought back from their experiences in the classroom to develop strategies for working with varying teacher needs. Their feedback is crucial in the development of other professional development programs, such as the Saturday workshops, the development of the educative curricula, and development of on-line resources for teachers.

</table>
In creating such a program for teacher development, we have to acknowledge and utilize the experiences and strengths of the educators involved throughout the process. The efforts of working with a small group of teachers to pilot the educative curriculum and accompanying technological tools cannot simply be replicated with a large group of teachers. Rather, as the curricula was developed an evaluated and refined, other teachers were recruited to become involved in the program. Educators inducted into the process from the beginning became more familiar with the tools, the content, and the accompanying pedagogy, and moved from requiring support to providing it for others. Teacher support constructs evolve, moving from individualized in-class support to collegial sharing of concerns and ideas, all fostered by efforts to encourage individual teachers’ reflection upon their practice and student learning. Web-based supplementation of support is now provided, to allow the variety of teachers involved in working with these curricula, technologies, and pedagogical issues other methods of communication, collaboration, and reflection. As the number of teachers involved in the reform effort increases, so evolve the professional development activities in order to make use of the teachers’ experiences and encourage sustainability within the program.

Findings and Challenges

While findings of these curriculum units are not discussed here, informal observation reveals the impact, both positive and negative upon teacher practice. Successful enactment of the curricula allows the teachers to become familiar with the content, pedagogy, and technological tools encouraged in the program. Teachers use the materials to provide learning opportunities for students which also allow the teachers to gain experience in the enactment of an inquiry based pedagogy, and in the infusion of technological tools designed to aid in student cognition regarding the concepts and relationships of the content. The reflective questions and commentary within the written curriculum documents, when teamed with other forms of support, help the teacher understand the educational impacts of their practices on students, and focus on the changes in student learning, motivation, and content focus encouraged by the curricula.

Difficulties in the enactment come, for the most part, from challenges regarding organization, time management, and a diverse and dynamic student population. These challenges have forced some teachers to cut short elements of the curricula, as administrative and personal pressure encourages teachers to move on to more familiar practices. Such enactment seems to encourage the use of the pedagogy and technologies as interspersed “activities” and “techniques” rather than an underlying change in philosophy of teaching and learning to a more constructivist approach. Such challenges highlight the need for more comprehensive integration of all of the forms of support for teachers, as well as additional needs for addressing administrative buy-in and professional development for individuals in decision-making positions.

But, the challenges for enactment do not stop there. A number of other issues face educators in a variety of ways regarding the use of the curricula and adoption of these goals and practices. Some of the teachers struggle with content knowledge and its accompanying pedagogy. Over one third of the science teachers involved in the program have no strong science background, and so part of the professional development must address basic scientific concepts for these individuals. Many teachers who feel less proficient with the content often find themselves so tied to the activities listed in the curricula that they limit the adaptation necessary to gear the curricula to their students’ specific needs and abilities. Others let their insecurities get the better of them, straying away from the design and focus of the curricula.

Perhaps the greatest barrier to enactment does not exist within the teacher, but rather within the school. Implementation of a curricula with pervasive technology use requires knowledge of and access to the technological tools utilized within the curricula. Problems with these technologies abound within the program. Some teachers have little or no access to facilities with appropriate technology within their school, either because the school as a whole is limited in these tools (though the Center made this an inherent element in the selection of schools to be involved in the program), or because these tools are used for other educational programs. The software for these curricula are specialized and require a variety of
specialized hardware and software requirements, which are often limited within some schools. And, while the software has been tested in a variety of circumstances, the tools created for this program are specialized tools for these curricula, and are continuously under development. Analysis of all of these barriers will take place in a variety of stages, including analysis of videotaped class sessions, field note forms from teachers and support personnel alike, notes from administrative meetings, and interviews and surveys of teachers and students involved in the project.

**A Final Challenge: Scaling Up**

As mentioned earlier, one of the critical and difficult elements of systemic educational reform is attempting such reform on such a large scale. Changing the practices of one teacher or school is challenging enough; changing an entire system, especially in a district with 180,000 students and 243 schools is an entirely different matter. One of the underlying goals of this program is to go beyond working with a small number of teachers in the implementation of these practices. In addition to all of the other challenges of working with a diverse population of teachers and the different requirements for professional development of all of these individuals, they professional development efforts must be able to scale appropriately while maintaining their relative effectiveness.

When this program began three years ago, it was piloted with one curriculum in two schools. Last year, 20 teachers in ten schools became involved in the program. This past summer, attendance at the summer workshop numbered over 45 from 18 different schools, and additional teachers have joined in the Saturday workshops ever since. This kind of growth is not only expected of such a program, but promoted. Teachers of science at the schools involved in Center activities who have not been involved in the curriculum enactment or professional development are encouraged to join the group.
TLI: Recreating University Programs to Meet School District Needs

Carolyn Rude-Parkins, Ph.D.
Occupational Training and Development Department
School of Education, University of Louisville
United States
cparkins@louisville.edu

Abstract: This paper describes a constructivist-based initiative to recreate a university's college of education graduate programs to focus on the concept of Teachers as Learners and Leaders. This initiative caused the university and school district partners to examine the structure of programs for experienced teachers and their relationships to real-life needs. The Technology Leadership Institute (TLI) is one of the cohort groups collaboratively developed with school district partners to meet needs for increased expertise and leadership in teaching and learning with technology at classroom, school and district levels. Documents and products of the TLI may be accessed at http://tli.jefferson.k12.ky.us.

Introduction

The Technology Leadership Institute (TLI) is one collaboratively-implemented answer to two questions: 1) How can a large school district develop and maintain building-level and district-level support for technology adoption? 2) How can a school of education leverage its limited resources and restructure its offerings to improve experienced teacher education programs?

Like many institutions of higher learning, this university's programs and faculty enjoy a level of stability that inhibits new initiatives and change. The emergence of use of technology for instructional support and delivery has not gone unnoticed but has been slow to impact the way many professors teach their courses and the courses they teach. At the same time, the school district has implemented technology for instruction for over 15 years, in a state where technology is a priority of school reform that is accompanied by state funding. With a ratio of one computer per six students and internet connections in every classroom, the district implements a technology integration curriculum and a yearly assessment with parallel professional development opportunities. The state requires each teacher to complete a masters degree and districts provide salary incentives for post-masters work.

With 150 schools serving primary through grade 12, and a similar type of staff stability, the district's need for new and experienced teachers who can use technology is critical. The development of school-level technology leadership is essential. Collaboration between institutions around the theme of technology leadership is the challenge.

As in many change projects, personal relationships, the spark of an idea and the opportunity for some reward collided to create an opportunity. The TLI attracted a cohort of 15 teachers and librarians the first year and another 45 the second year, indicating a large unmet need. University and school district technology experts collaborated to develop the courses, house the classes, identify the instructors, manage the enrollments and evaluate the results. The TLI is still a work in progress, and the partners are endeavoring to solve problems in each institution to fine-tune instruction and products, to streamline program and course approval, to fix advising and registration problems. This paper describes the design of the TLI and the design of the School of Education's initiative which fostered the TLI and other innovative projects.
Recreating Colleges of Education Initiative

The design of the TLI is based upon a school of education model that has, so far, fostered development of six teacher cohorts whose themes include writing, social studies, and the principalship. These themes have grown from identified needs of the state and the school district and of the teachers, who collaborate with faculty in development of the programs.

The University of Louisville is one of eight southern colleges and universities chosen to participate in the BellSouth Foundation's Recreating Colleges of Teacher Education Initiative. As part of the initiative, the school of education is focusing on making the concept of Teachers as Learners and Leaders a pervasive theme of its graduate-level teacher education programs, a theme already embraced in its basic teacher preparation programs. Implementing the initiative is causing a major rethinking of how offerings for experienced teachers might be restructured, particularly considering the realities of emerging new knowledge, current program evaluations and the changing marketplace.

The beliefs inherent in the design of the initiative are:
1. Teachers are leaders and inventors of quality work for students.
2. Learning occurs when students construct knowledge and make meaning based on their experiences, beliefs and values.
3. Teachers must be committed to principles of equity and social justice and provide evidence of these principles in their practice.
4. The work of teachers is to ensure learning for all students by designing instruction that is engaging, of high quality, encourages students to persist, and honors diversity in learning styles.
5. Schools are places where both the students and adults are engaged in continuous learning and where they acquire the skills to become lifelong learners.
6. Technology will facilitate student and adult learning in new directions, which we have not even imagined.

Technology Leadership Institute Cohort

Purpose. The Jefferson County Public School District (JCPS) and the University of Louisville School of Education are collaborating to offer a 30 credit-hour program for Instructional Technology Leaders, based upon technology standards developed by the International Society of Technology in Education (ISTE). The purpose of this program is to increase technology expertise of educators and to foster leadership in curriculum and school change via technology.

Cohort Group. The target groups are school technology coordinators, library media specialists and classroom teachers who wish to enhance their expertise with technology, curriculum and school change. The participants work through a two year program as part of a 15 member cohort group. The primary criterion for admission to the program is applicants' showing evidence of their potential to be leaders and change agents in the school and district. Each participant must submit letters indicating agreement to support and collaborate from the principal and two other teachers in their school. Projects during the program involve the participants with others in their schools to implement technology curriculum and leadership projects.

Admission. Each participant is admitted into a School of Education teaching major at the masters or post-masters level. Each works with the cohort's advisory committee to design a Program Plan focusing on technology, curriculum and school change. The program may include a specified number of preplanned professional development activities as well as University credit courses. The Program Advisory Committee is made up of School of Education faculty, JCPS leadership personnel, and outside experts who may be from the Board of Education, the state Department of Education, a local business, or a national / international expert who may participate via distance technologies.
Rewards. Teachers accepted for the Technology Leadership Institute receive district-owned hardware and software for their use during the courses. These resources are purchased through state allocations for technology resources. The school district allows 18 hours of inservice credit for courses taken within this program. Classes are held at a location convenient to the teachers and are taught by district and university technology experts. The school of education attempts to streamline admission, registration and advising.

**Program Design**

The school of education's initiative guidelines call for a minimum 30 credit-hour Program of Study organized specifically for each cohort to include:

1. A core requirement of a Readings course and a Research course.
2. A Curriculum Project and a Leadership Project that reflect the beliefs above. The Curriculum project is intended to be a minimum of a year-long effort to improve teacher's design of lessons and the quality of work produced by their students, related to cohort themes. The Leadership project connects to the theme of the cohort and enhances the characteristics of leadership of teachers and their students. Presentation to an authentic audience is part of the requirement.
3. Planned Professional Development experiences can fulfill an equivalency of 1 to 12 hours and should reflect opportunities for classroom, school, or district impact. Experiences should be embedded in the job and closely related to both student and teacher needs, should link school/district consolidated plans and professional standards to the cohort theme.
4. Culminating exhibitions should grow out of the work done by the cohort. These exhibitions could include presentations to the candidate's School Council, the local Board of Education, a conference or workshop presentations to the faculty of the candidate's school, a university class, a community group or organization.
5. Each candidate must prepare a portfolio of evidence documenting cohort and individual work toward meeting professional standards. It should be a work in progress that evolves throughout the program, and will be assessed at various times dictated by the advisory committee. The portfolio should reflect on the cohort experience and the implications, which affect leadership roles and classroom practices. The program advisory committee determines the audience for the portfolio.

For the TLI cohort, standards-based credit courses, developed by the university and school district partners, are taught on a regular schedule. All courses are based upon the ISTE Basic and Advanced Standards for Instructional Technology Leaders and focus on teaching and learning with technology. Syllabi and course materials are to be posted on the server as the program develops. The program starts and ends with an assessment of expertise levels on the ISTE Standards. Each course assesses participant growth on its subset of standards and course products are posted to the project's web server where they may be viewed and used by others. The first five courses are typically taught by school district technology staff to provide depth of technology expertise and to closely align with district needs and directions.

*Using Productivity Tools* integrates expertise with word processing, database, spreadsheet and communication programs with the teachers' curriculum implementation concerns. Products include lesson plans that link to the district's curriculum, demonstrate applications of the tools and use the district's standard of Macintosh and ClarisWorks. The results of this course support the district's technology-integration curriculum and yearly student assessment.

*Web Use and Publishing* emphasizes understanding the capabilities of the web, searching for, developing and using web-based instructional resources, supported by Claris HomePage. Again, the district's academic and technology curricula and assessments are the touchstones for product development in an area that is new to most teachers. Participants begin their web-based portfolio in this course by developing an introductory page which links to a resume and products developed during the program.

*Multimedia Use and Authoring* takes participants into the intricacies of graphic, sound and video files in Hyperstudio program development. *Distance Teaching and Learning* introduces the concepts of distance-delivered resources and instruction, accesses the state's two-way interactive video system with its
lessons and resources, explores web-based curriculum including the state's new virtual high school, virtual library and virtual university efforts. Projects include lesson plans and products for classroom use. Technical Support Skills enhances abilities to work with computer hardware and software, including servers, to plan software and hardware purchases and installation, and to provide support for classroom and lab resources and teachers.

The other five courses are taught by university experts in technology, curriculum, leadership and research and are intended to broaden the participants' expertise in these areas. Readings course and the Action Research Seminar bring together participants from different cohorts to expand knowledge about their cohort's theme and to develop skills with classroom research. For the Readings course, virtual discussions are successfully supported by Tapped-In (http://www.tappedin.org). Curriculum Seminar and Leadership Seminar each extend over a school year, and involve teachers, principals and students in the participants' schools to plan, develop, implement and evaluate technology and curriculum change projects.

As part of these seminars, participants are encouraged to actively participate and to present at the state technology and curriculum conference. Capstone Seminar and Portfolio Presentation provides a final opportunity to implement projects in the school and district, and to illustrate mastery of the standards through their electronic portfolios.

**Evaluation**

The school of education's initiative calls for a detailed timeline for each cohort that spells out continuous assessment benchmarks. Evidence is sought that the candidates have produced work that:

- is "real work for real purposes,"
- is based on research that is linked to the collaboratively determined needs of students, the candidates, schools, district, communities, and the University,
- demonstrates leadership at the classroom and/or school level is standards based, outcomes driven, and requires public performance and exhibitions of work,
- demonstrates expanded use of technology for curriculum design and invention of new knowledge,
- fosters new/deeper collaboration with local school district and professional development providers resulting in change in pre-service and professional candidate education.

Program standards are to be documented in the candidates portfolio, including a reflective component focused on what was learned and what should change.

The outcomes of the Technology Leadership Institute support the district's need to foster technology leadership in classrooms and schools, and are accomplished through a set of nationally accepted program standards. The products demonstrate application of technology in support of teaching and learning and are available to the public through the web-based electronic portfolios of the participants. Continuous assessments of courses, products and participants provide corrective feedback. It is clear that the most successful courses are hands-on and field-based.

The underlying construct of the university's initiative and of the Technology Leadership Institute is constructivism, as interpreted in the works of Phil Schlechty, Linda Lambert, Deborah Walker, and their colleagues. Through the TLI, we are observing a school district and a university school of education work to create change as the participants "make sense of their work and find challenging possibilities together" (Lambert et al. 1995). As the program evolves, it will become a constant source of opportunity for professional development "which includes participation in leadership processes, governance, observations and inquiry, co-planning and coaching, and new information - all of which are opportunities that involve authority, choice and responsibility" (Lightfoot 1983).

**Conclusion**

In the fall of 2000, the state adopted a standard for new and experienced teachers to use technology to support instruction, access data, enhance productivity, communicate and conduct research.
The expertise developed via the TLI becomes even more "real work for real purposes" as the participants are called upon to assist other teachers in meeting the new requirements. At the same time, the university is faced with the need to impact new and experienced teachers with these same skills. The collaboration embodied in the TLI provides a model and resources for meeting these needs. This state-level change also points out the opportunity for the partners to design a continuum of technology experiences for new teachers, experienced teachers, and technology leaders.

Abstract: This paper is a case study of the ADEPTT program, a three-university instructional technology consortium in western Pennsylvania, and the reasons for its relative success in gaining public and private grant funds and promoting the effective use of technology in teaching and learning. The paper examines the purposes and constraints of educational consortia, and in particular the limits to institutionally-mandated collaboration. The paper then examines the personal characteristics and social connections of members of the consortium as an alternative explanation for the relative success of the initiative. The conclusion is that success in a technology consortium is not simply a matter of finding "the right people" but also making sure that the group of "usual suspects" also have key connections to university leadership. The article concludes with recommendations concerning the building and maintenance of similar consortia.

"Major Strasser's been shot.....Round up the 'usual suspects.'
Claude Rains as Captain Louis Renault, Police Prefect of Casablanca, "Casablanca" 1943

How do we round up "the usual suspects"? With few exceptions, whenever a grant opportunity appears in the field of instructional technology, a group of "usual suspects" at three different universities appear, cooperate, write, apply and often are awarded grants as a consortium, a consortium that is now nearly three years old. We have all heard the hyperbole about technology enabling greater communication and cooperation, but how does this work in practice? An increasing number of both public and privately-funded instructional technology grants require or suggest consortia for funding (Dotolo and Strandness 1999). This paper will look at the institutional and social requirements for a successful consortium by examining the successful and unsuccessful experiences of a consortium of three public universities in western Pennsylvania.

Successes and Failures

Advancing the Development of Educators in Pennsylvania through Technology Training (ADEPTT) is a consortium of three Pennsylvania State System of Higher Education universities, Indiana University of PA, Clarion and Edinboro, and fifty-three school districts. More than forty faculty, administrators and technology staff located as far as 150 miles apart are working effectively on the core planning team. Located in western PA (IUP), ADEPTT was created in February 1998 via a three-year grant funded by Bell Atlantic with a matching $100,000 gift of software from Microsoft Corporation. The overall goal of the consortium is to help K-16 teachers learn to use instructional technology as mind tools for deeper learning as we shift from an instructor-centered to a learning paradigm (Barr & Tagg, 1995). Hundreds of seats have been filled at fifty-five different workshops provided by the Consortium including basic software instruction, technology tools, videoconferencing, using technology to enhance teaching and learning, using the Web, and using Web course development software. Bell Atlantic also funded one instructional designer at the IUP Instructional Design Center for a year.

Based on a August 1999 proposal from the Consortium, the Microsoft Corporation donated additional software and site licenses valued at $385,000 to the Consortium to upgrade networks and laboratories and to provide pioneer pre-service teachers, cooperating teachers and university faculty with software.

The most recent success of the Consortium was the award in September 1999 of $1.7 million from the U. S. Department of Education to Prepare Tomorrow's Teachers to Use Technology in the Digital Age. This...
three-year grant will assist us to infuse eleven key competencies needed to teach effectively with technology into core teacher education courses and eight subject areas such as music education, social studies education and so forth.

While the Consortium has achieved the successes summarized above, numerous challenges have been encountered as well. Several attempts to create a similar consortium occurred in the three years prior to its creation, all without success. During the creation of the consortium, a fourth state system university was included until several days before the grant proposal was due. But since we did not have “buy in” to the consortium concept from a top level administrator with signature authority for the ADEPTT grant proposal, that university has only a peripheral relationship with the consortium. In June 1998, the Consortium applied for a $7.5 million five-year Technology Innovation Challenge Grant which was not funded, and one university in the consortium had to drop its membership in the last days before the proposal was submitted. However, valuable lessons about how to apply for a major federal grant were learned. Additional challenges have included 1) learning to work collaboratively at the university level within a culture that rewards rugged individualism (competition), 2) identifying a plan for delivering instructional technology training effectively at the K-12 level where the culture is very different from the university culture, and 3) learning how to work collaboratively with the three intermediate units located within the Consortium.

Institutional Analysis: The First Cut

What is an education consortium? A brief definition indicates that it is "an agreement, combination, or group (as of companies) formed to undertake an enterprise beyond the resources of any one member." In education, one can further subdivide the types of consortia: Institutionally, we propose to examine the different types of consortia: pre-existing, created, vertical and horizontal.

<table>
<thead>
<tr>
<th></th>
<th>Horizontal</th>
<th>Vertical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-existing</td>
<td>Examples: Schools in districts; universities in state-wide systems</td>
<td>Examples: Intermediate Units</td>
</tr>
<tr>
<td>Created</td>
<td>Examples: cooperative relations between private, public colleges and universities, or within systems that are not created by central institutional leadership</td>
<td>Examples: University initiatives with various local school districts</td>
</tr>
</tbody>
</table>

A pre-existing consortium is one in which an institutional framework already exists for collaboration, whereas a created consortium is one in which the members actively seek partnerships where none have previously existed. Horizontal consortia are those of roughly equal members, whereas vertical consortia in education involve different levels such as primary, secondary or post-secondary schools. The ADEPTT consortium contains elements of three out of the four of the cells of figure 1. The universities which formed the consortium all belong to the State System of Higher Education (SSHE) in Pennsylvania, a group of fourteen universities which has existed as a single system since 1983, and thus are for the purposes of examining the ADEPTT program represented a pre-existing, horizontal consortium. Several of the universities indicated interest in the grant Request for Proposals (RFP) and formed their own sub-set of universities, constituting created horizontal consortia. The ADEPTT program, having gained the initial grant, in turn brought in K-12 districts and units, turning the created horizontal consortium into a horizontal and vertical consortium. The distinctions here are not simply analytical; it is a major finding of this study that some types of consortia within the matrix are more likely to succeed than others.

Why do consortia form in higher education? The short answer is that by joining a consortium, its members gain access to resources that individually they could not afford, or gain them at much a reduced rate. Those resources may be directly financial, or information, documentation, training materials, discounted software, or bargaining leverage. Furthermore, as will be noted below, success in a consortium often breeds success, as the consortium's experience and reputation makes further grants and initiatives easier to obtain. Herein lies a problem, though: to benefit from a consortium, its members must first undertake the work and the risk of a consortium before the benefits can be derived and distributed. Thus, it is important, if not imperative, that a consortium's initial effort be successful if there is to be a second effort.

Although standard line authority would entail all initiatives from the State System office coming down through the university presidents and then down into their respective technology structures, the nature of the issues and the schedules of presidents have made a formal coordination mechanism of the Chief Information
Technology Officers (CITO's) of the system a necessity for communication and discussion. A similar coordinating mechanism exists for the Deans of the respective Colleges of Education at each of the system universities. Such meetings were very important for the establishment of personal relations between key people who were involved in the creation of the ADEPTT consortium, but they played almost no role in the creation or coordination of the consortium itself. The only other role played by the State System as a coordinating system in the creation of the consortium was the administration of a competitive system-wide Faculty Professional Development Council which gave modest grants to SSHE faculty, some of which focused on instructional technology issues.

Higher educational consortia face some substantial challenges at an institutional level: first and foremost, a consortium is by its nature largely voluntary, and thus one faces a situation in which normal line authority does not apply, or if it does apply can be largely circumvented by appeal to one's home institution. Consortia have difficulty ordering members across institutional boundaries to undertake tasks. Those tasks may be undertaken voluntarily, but the normal mechanisms of reward and punishment are diminished if not totally absent. A second major challenge of higher education consortia, particularly those in the same region, is the competitive nature of their constituent universities. By and large, the three universities involved in the ADEPTT grants compete for the same pool of students in western Pennsylvania, a point mentioned by one provost of the consortium during a meeting in a planning meeting. Thus, in the initial examination of the institutional bases of the consortium we have a paradox: three universities which might not otherwise be expected to cooperate do in fact cooperate quite closely on a number of projects.

The lack of line authority and the quasi-competitive nature of higher education consortia exacerbate the collective action problems encountered in any system that exists outside of a hierarchical governance structure. First and foremost among these are the "free rider" problem encountered with public goods: some members of the consortium do the work, some do not or do less, and yet all benefit equally. An opposite problem of "glory hogs" is also possible in which one university claims all of the credit for the consortium success, or one member completely dominates the decision making of the group because of size, contribution, or expertise. And since the interaction of the members is intermittent, the chance to build and institutionalize trust-based relations regardless of individuals does not regularly occur.

Finally, any consortium faces the "minimum winning coalition" issue: given the probability that a grant will be of finite size, the addition of more members of the consortium reduces the allocation to individual members, the total grant being divided by the number of members. The optimal number would clearly be one, yet the imperative frequently found in grant RFPs for a "consortium" eliminates that option. Furthermore, since the English language has a specific term for a consortium involving two members (i.e., "partnership"), a tendency for more than two members to be in a consortium also exists, yet every additional member reduces individual receipts. Geography is a problem as well, since travel times must be multiplied by the number of campuses for meetings and their distance. Calculating the distance between system campuses, one can see that natural associations lie in the western and eastern parts of the state.

Given these challenges, it is not surprising to find that the establishment of the ADEPTT consortium faced a number of fairly significant institutional barriers, and there were a number of earlier similar initiatives that failed. In 1996 a Pennsylvania "Link 2 Learn" grant that the State System office urged system universities to apply for contained the explicit provision that collaboration exist. Preliminary talks were held between IUP, Edinboro, and California University of Pennsylvania, but nothing came of it. One participant in those early talks described them as "premature" and indicated that for at least one of the universities the talks were strictly pro forma. A September 1998 video conference between a State System university and the members of the ADEPTT consortium was held largely because the former was required by the system office in Harrisburg to open up a dialog simply in order gain access to other grant funds, but did not participate. In short, technology consortium initiatives that have come solely from the top of the system have little record of success; cooperation cannot be mandated.

Social Characteristics

If a consortium cannot be created by administrative fiat, what then explains the relative success of the ADEPTT consortium? A number of personal characteristics of the ADEPTT team members were vital to consortium building. The members exhibited these characteristics both in the original team at the founding university and across the consortium.
Commitment and Persistence. The ADEPTT team members are distinguished by a capacity for long-term commitment. Not only the technology specialists, but also other key members of the consortium had a long-standing interest in the use of technology in education and in teaching in particular. On the IUP team, for example, Associate Provost Mark Piwinsky had been interested in computers since the late 1970's, when he wanted to help small colleges access the kind of computing power mainframe computers offered to big research universities. Future faculty member Steve Jackson began a programming course in 1983. In 1982, future dean John Butzow took his last sabbatical as a University of Maine faculty member at Digital Corporation, where he worked on a distance training program on laser discs and first used email. In 1985, the 4th grade son of faculty member Mary Ann Cessna brought his parents his lessons on computer basics.

The team members shared a common vision and goals for many years. In spite of intermittent financial resources, spotty administrative support, and many setbacks, the members of the IUP core team kept plugging away, working hard for the improvement of teaching and the use of technology in teaching. Their commitment was reinforced by friendships that predated the team, both at IUP and later in the ADEPTT universities, and new friendships grew out of the team's work. Years of collaboration and shorter-term heroic efforts on specific projects and proposals developed mutual trust and further solidified the team. Several interviewees noted the unique experience that being a member of this team has been for them.

The commitment they share clearly has outlasted any one project. In fact, this commitment now extends beyond each individual campus to the consortium as a whole. With new grants coming on line, an ongoing process of enculturation has become necessary to ensure that new members recognize the primacy of the consortium over individual grants and the potential of the consortium for further opportunities.

Diversity. But what made the team strong was not only what they had in common but also the diversity and complementary skills of the members. Their talents ranged from a flare for writing (Jackson, Piwinsky) to organizational ability (Cessna, Pickering, Piwinsky), budget (Norwood, Piwinsky), editing (Brzyczki, Cessna, Piwinsky), inspiration and nurturing (Ausel, Cessna), and a critical eye that brought the team back to earth as needed (Ausel). Several interviewees noted that there were no battles among egos for control, but rather, the members were candid about their strengths and weaknesses and used this knowledge to assign appropriate tasks and roles. The members represented a variety of disciplines and colleges, including technology haves and have-nots, and they included both faculty and administrators.

The faculty-administrator mix was essential in a state system where collective bargaining agreements define what administrators and faculty can do. Professor Mary Ann Cessna commented, "Teams that include a mix of administrators, faculty and key IT staff are much stronger than faculty alone." John Butzow, Dean of the IUP College of Education, noted, "Administrators alone could not have done this.... You must hook faculty and administrators together in unusual ways. Mark Piwinsky played a key role in making this happen." In turn, Mark Piwinsky observed, "Big grants become university issues—you need to make institutional commitments.

Communication and Generosity. Among the team members were also some truly great communicators. Dennis Ausel is in the Communications Media department at IUP. Mary Ann Cessna is tireless in her efforts to keep consortium members informed of ADEPTT developments. Steve Jackson is an experienced writer and debater. As comparative politics and international relations specialists, respectively, he and Mark Piwinsky are well versed in diplomacy and the communication skills it entails.

With these skills, IUP made it clear that it did not wish to dominate the consortium, and "Clarion and Edinboro were pleasantly surprised," according to Andy Lawlor. IUP took care to rotate meetings among the campuses, and the initial presentations were deliberately left unpolished so that the future partners could have real input and participation. In subsequent projects, IUP sometimes wrote in the other schools to keep them involved, even if it was doing most of the preparation.

Recognizing the importance of their team, the IUP future ADEPTT team accepted new members and tried to fold them into its unique culture—first from IUP and later from the other ADEPTT universities. They set out deliberately to make the new consortium members part of the team as well as participants in later grant proposals, placing great stock on meetings and retreats that were structured to nurture team spirit as well as accomplish immediate tasks. For the most part, these efforts have been successful and continue to this day. They were also supportive of new roles for current members of the team and encouraged professional growth.

Connections. The highest administrator on the team, Dr. Mark Piwinsky, then Associate Provost, not only shared the personal characteristics named above but was also positioned to have access to the IUP Provost and the IT officers at the future partner universities. He was already in regular communication with the IT officers on other administrative and academic technology issues, and at the time of the ADEPTT RFP, these connections influenced the choice of partners. Dr. Piwinsky chose to approach universities where he felt he...
could trust the IT officers to work well together. Andy Lawlor observed, “It was not his idea, but Mark was the catalyst that brought the right people together.” When the consortium proposal was funded, these connections constituted a second channel of communication that became critical in the pursuit of larger grants because these individuals could marshal resources that faculty and lower administrators could not.

Both Dr. Piwinsky and Dr. Cessna knew David Gray, Vice Chancellor for Information Technology in the State System of Higher Education prior to the ADEPTT RFP. After the award of the ADEPTT grant, this connection also proved vital in communication with such other SSHE officials as Vice Chancellor for Development Chuck Agnew, who was able to direct ADEPTT toward other opportunities.

At the grassroots level, faculty connections among the member universities were limited at the formation of ADEPTT. Those that did exist, however, served to reinforce and consolidate the expanding team. ADEPTT and PTTUT, a grant awarded to the ADEPTT consortium in 1999, have expanded faculty collaboration across the consortium universities.

Social Connections

Interviewees were asked to name, from their perspective, the key people involved in the formation of the ADEPTT consortium. Since some made a clear distinction between critical and important individuals, their responses were weighted with 2 points given for a critical individual and 1 point awarded for a merely important individual. This analysis confirmed that the interviewees were themselves key individuals in the creation and success of the consortium. The Associate Provost at IUP, Dr. Mark Piwinsky, was the person who received the highest score.

In addition, interviewees were asked to identify the people they knew, whether or not they named them as key people, from a list of some 30 individuals. Analysis of these data showed that there were several layers of connections among the more than 40 participants in the founding of the consortium: faculty to faculty, top administrator to top administrator (opinion makers), and manager/staff to manager/staff. At least two of the key faculty members had previous connections with their peers at the partner institutions as well as at other universities in and outside the State System of Higher Education, substantially easing the introduction and increasing the level of familiarity and trust between the key personnel. The opinion makers (top administrators such as Vice Presidents and Associate Provosts) had connections with each other as well as upward vertically (state system officials), horizontally (IT leaders at non-partner universities and some top administrators), and downward vertically (managers and faculty in their own universities). One key manager had connections of all three types.

Most faculty had chiefly faculty-faculty connections. The person with the most connections was, indeed, a key faculty member (Dr. Mary Ann Cessna). These relationships were vital in creating the consortium and promoting a sense of trust within the fledgling organization, but they were not in themselves sufficient to create the consortium. They also helped her recognize what kind of backing would be needed to make the consortium a reality, but she could not create it without such backing. Top administrators had the most connections after Dr. Cessna. To look for possible differences in these connections, we examined the number of relationships that involved opinion makers or people with line authority. Looking at connections with both potential partner universities and the State System, we determined that the chief IT officers had the most connections with people in line authority positions, with the three having virtually the same numbers of these connections.

Institutional Analysis, 2nd Cut

Returning to the question of how to build an effective consortium in technology, we are forced to recognize that although finding key personnel who combine both a high degree of technological proficiency and a large number of social connections within and across institutional boundaries, it would be impossible to form an effective consortium without the active support and participation of university administrators.

The pivotal nature of the IT officer is still more clearly revealed when we look at failures to expand the consortium beyond three universities. In one case, the dean of the college of education was supportive of the notion of a consortium proposal, but both the CITO and Provost positions became vacant during the proposal writing period, and the effort to bring in this university ground to a halt. In a second case, the connections were chiefly those of faculty to faculty, and again the effort bore no fruit.
In summary, the analysis of Who Knew Whom showed that chief information technology officers had the most connections with other people in positions of line authority and considerable connections with faculty. All three IT officers were also named as some of the people key to the formation and sustenance of the consortium. Among all the key people named, Dr. Piwinsky received the highest rating. Finally, our analysis showed that Dr. Piwinsky demonstrated all the personal qualities that made the consortium possible. Moreover, perhaps more than any other player, he is distinguished by the leadership ability to identify and bring together the right mix of people that can be trusted to perform under pressure, and by powerful gifts of communication, persuasion, and a team outlook. Dr. Piwinsky was the catalyst of the ADEPTT consortium—the kind of person in the kind of position that could have a formative influence on the its creation.

Lessons

1. For all of the hyperbole about technology, face-to-face interaction of consortium members is indispensable for building trust and cooperation. Thus, geographical proximity remains a substantial limit on the size and extent of any potential consortium. A willingness to travel to all consortium member universities in a rotation has been an important principle in maintaining a sense of shared burden.

2. Some types of consortia are more difficult to create and maintain than others. It has been the experience of the ADEPTT consortium that the elements of the horizontal-created consortium have worked very well. The vertical aspects of the consortium have been more problematic, and pre-existing consortia are usually too large to be effective. An optimal consortium size of about three or four major institutions in geographic proximity may exist.

3. Consortia cannot be created by administrative fiat; pre-existing groups of connected faculty, administrators and often staff must be found and brought into the creation of the consortium from the beginning.

4. The building of an effective university-level consortium must also have actively involved supporters at the vice-provost level, as well as deans and other administrators. These leaders are key to the success — or

5. Failed attempts at grant writing are not necessarily wasted time, and are often essential to later successes as experience and feedback are gained. However, an early success is essential for maintaining the consortium.

6. Technological aptitude is important for some key personnel in university teams but not all; some of the most important university team members in ADEPTT are not "cutting edge" in their use of technology but do recognize its importance.

7. A cadre of dedicated faculty, staff and administrators who have a clear sense of their roles in the grant writing and administration process — "the usual suspects" to whom the university leadership can turn to and rely upon — is the most important asset for building successful consortia.

Abstract. As a part of the Education Departments' Superhighways Initiative, senior secondary school staff in Northern Ireland participated in a multimedia CD-ROM based training programme on the use of computer based Management Information System software. An evaluation is offered of the impact on the school organisation, its management practice and patterns of staff use of ICT in management two years after the training event. Outcomes indicate that the opportunities for organisational development were not fully realised, suggesting that change strategies should involve attention to the totality of the relevant school system and should provide for professional dialogue and participation in the process.

Introduction

Developing teachers' professional knowledge and skills in the use of Information Communications Technology (ICT) is a priority objective for those involved in policy formation and implementation in the United Kingdom (DfEE, 1997; Scrimshaw, 1997; DENI, 1997). ICT based multimedia and communication systems can deliver directly into schools programmes of professional training which include video-conferenced tutorial support. But effective delivery presents complex technical, pedagogical and economic questions and often leaves unexamined the relationship between in-service training and the integration of new knowledge and skills into educational processes.

Translating learned skills into operational activities that impact on learning is a distinct stage which requires schools to develop management strategies directed towards the desired outcomes. Systematic evaluation needs to be undertaken to inform future training strategies. This paper addresses these concerns and aims to contribute to the debate by exploring the impact of ICT training on both individuals and their school organisations and identifies some of the pedagogical and environmental conditions, including internal and external support systems, necessary for successful implementation.

The research and its context

The first phase of this research was part of the Education Departments' Superhighways Initiative (EDSI), launched in 1995 by the UK government to sponsor and evaluate 25 school based initiatives in the application of ICT (DfEE, 1995). A range of curriculum and organisational initiatives were supported in over 1000 schools across England, Wales, Scotland and Northern Ireland (Scrimshaw, 1997). In Northern Ireland: three selective and one non-selective schools were chosen, for their level of 'technological readiness'. In three of these, training was undertaken by the Senior Management Team (SMT); in the fourth, by the Pastoral Care Team, a total of 28 teachers (including 3 Principals and six Vice- Principals). Approximately half of the teachers considered themselves to be non-users of ICT (see North 1997). Two years later, a follow-up study examined the effects of that training experience on management practice, routine use of computer-based information systems and school-based decision-making.
Methodology

The study draws upon teachers' perceptions of the training experience as well as their understanding of the outcomes. Data was obtained from questionnaires, interviews and observations. Unstructured and semi-structured interviews were conducted with key participants. Observations of learning situations and staff planning and development meetings were recorded. Data were also collected through the self-reporting of teachers. Two questionnaires were administered to provide additional data on specific individual attitudes and outcomes.

Research outcomes

Impact of Training

The pilot training project made an immediate impact both on individuals, in terms of personal and professional development, and on the school as an organisation. It successfully equipped teachers with new ICT operating skills and knowledge, and contributed towards their personal growth, conferring in particular an increased sense of professional status and an increased confidence in their use of educational technology. A contribution towards further organisational growth was made through increased engagement of teachers in school-based issues and an improved corporate understanding, expressed in the sharing of knowledge and suggested improvements based on team work. Although evidence of these positive outcomes can be found in each of the schools, they were not acquired in each to the same degree. Schools whose organisational environment promoted professional dialogue, exchange of information and also valued professional development appeared to benefit most (North, 1997).

Implementation

The implementation phase of the project began about nine months after the completion of the training programme. On completion of their training programme, teachers in three of the four project schools appeared enthusiastic at the prospect of collectively utilising their newly acquired skills and knowledge. They were also eager for upgraded equipment to arrive, making possible development of a deeper understanding of how a Management Information Data Access System (MIDAS) could be used to improve the effectiveness of their schools. During the two year implementation period there were eleven personnel changes among the 28 original participants, including retirements, new appointments and post changes. Implementation was externally supported only by the installation of the networked hardware and MIDAS software. Schools were left to decide for themselves how to locate and use their new facilities.

The Management Information system is generally perceived by schools in Northern Ireland as an adjunct to administration. Not surprisingly, therefore, most of the networked stations were actually located in the offices of Principals, Vice-Principals and school secretarial staff. Each school also located a station accessible to members of the Senior Management Team. School C, however, which focused its training on the SMT and the Pastoral Care team, purchased eight additional stations from school resources to ensure easy access for all members of the team. Each of the four pilot schools provided participants, now totaling 25, with access to a networked PC, but levels of access to the MIDAS system itself varied from school to school.

Most teachers used the MIDAS system daily (14), and a few did so weekly (3), less than once per month (2) or monthly (1), although five teachers made no use of it. In school D, the SMT teachers did not use MIDAS themselves but telephoned the school secretary to ask her to access the system for required information ("It was quicker than starting up our machine"). Locating pupils in the school was the only MIDAS function used by all four schools. (MIDAS provides a pupil record which includes a photograph, personal details and an individual timetable.) Some teachers used MIDAS for staff information (9) and examination analysis (7), and a few for discipline (3) and subject-related matters (2).
By far the greatest perceived benefit from using MIDAS was the time saved accessing required information (18). MIDAS, compared with the paper-based pupil record system, was perceived as providing information quickly and from widely distributed access points. Perceived educational benefits were most apparent to the pastoral team in school C who cited reduction of time spent locating pupils. "MIDAS reduces the time spent on administrative chores and therefore frees up time for other activities", was a typical response. Most respondents (16) said that MIDAS software had replaced a manual retrieval system (see North, 2000).

Discussion

Recent experiences of these four 'technologically ready' and well-resourced schools offer important lessons for those responsible for the development of in-service training through independent learning systems. Although each school operated in isolation from the other pilot schools, the pattern of MIDAS use was similar in each. The schools' responses, however, as evidenced by self-reporting of changed activity, suggest that to decouple training and implementation leaves organisational understanding and practice largely unaffected. In the case of the four participating schools, these deficits manifested themselves in the following ways:

Under-utilisation of software

The most striking revelation of the study is schools' under-utilisation of software capabilities. Several change-inducing ingredients, motivational, cognitive and technical, were in evidence after completion of the training programme. For example, teachers believed themselves to be competent in the required skills, were enthusiastic and motivated by the perceived potentialities of the system and were supported by adequate hardware and technical support structures. However, the MIDAS software was only used for those functions which accessed the school's existing database. Although each school understood and valued the potential of a fully functioning system, they had not invested the required human resources or made necessary organisational changes to enable the full capabilities of the system to be fully realised. To benefit fully from MIDAS, schools would need to input updated pupil data daily and convert existing paper-based recording practices to an electronic medium. Teachers themselves were also unwilling to relinquish their personal paper-based records and entrust key tasks to a system subject to the requirements of the Data Protection Act. None of the schools used the MIDAS financial analysis module. In part, this was due to an unwillingness to shift from a current EXCEL-based system (two schools) and, in all schools, to a failure to integrate analytical financial data into the SMT's routine decision-making processes.

Lack of access to hardware

In three of the four schools, the location of hardware was concentrated in the offices of the Principal and administrative staff. This localisation not only reduced accessibility for other members of SMT but also signalled the Principal and school administrative staff as the significant system users. In two of the schools where this localisation was most intensive, only the Principal and one Vice-Principal used MIDAS. The interest, enthusiasm and sense of corporate identity claimed by SMTs after completion of the training phase seemed to have disappeared.

Limited use of ICT

There appeared to have been little extension of teachers' use of ICT for teaching purposes, attributable to their training experience on MIDAS. One teacher had begun to use a CD-ROM as part of an information-gathering exercise by pupils. The belief that the training experience would motivate teachers to develop their ICT skills and incorporate ICT in their teaching was not realised. In two schools, five teachers began to use video conferencing and there was a perceptible increased use of IT for professional tasks. It is likely that these developments are no stronger or more firmly focused than would have occurred in any case, owing to the prevailing 'social climate' of greater readiness and opportunity to make use of ICT facilities.
Limited impact of further training

One of the arguments for independent multimedia training is that it offers the opportunity for teachers to re-visit the training medium to develop their skills and knowledge further and for new members of staff to acquire the necessary operating skills. However, it was found that none of the new appointments to school used the MIDAS CD-ROM to acquire the skills - in the case of school C the three newly appointed pastoral team members were trained in the traditional 'cascade' manner by being shown how to operate the system by a helpful colleague. It is interesting to note that this Just-in-Time training took, on average, only thirty minutes. This compares with an average of three hours for full training but included only the module on pupil records. Twenty of the 25 teachers had not used the MIDAS CD-ROM since the training programme: three claimed they had done so.

Limitations of the training model

The inefficiencies and ineffectiveness of implementation are also due, in part, to the limitations of the training model and in particular to its reliance upon on skills acquisition through simulation, rather than through use of a school's real data. There were instances, for example, of teachers wishing to input school data but feeling insufficiently equipped to do so. A training requirement for participants to engage with a school's own data would introduce confidence and skill-forming incentives. Surprisingly, since no teacher had used more than a small part of software, when asked to rate their level of competence on a five point scale in the use of MIDAS, fourteen teachers rated themselves as 'highly competent', five as 'adequately competent', six as 'not competent'.

Personal and Professional Benefits

There were some gains in both improved attitude to ICT and small gains in increased usage of ICT. Most teachers claimed that the MIDAS training programme increased their ICT knowledge and skills and a heightened awareness of the potential uses of IT in educational settings. Two years after the training programme, nineteen teachers were using IT in a professional capacity, compared with fourteen before training. Six remained non-users. Individually, teachers mentioned their increased willingness to promote increased understanding of IT and the improved confidence among (some) senior staff in the use of IT. Four teachers, however, could perceive no benefit. A range of uses was identified, chief of which was management and administration. However, only one additional teacher claimed to be using ICT in the classroom, although there was a significant growth in the number of applications used. Five teachers had used the video-conferencing facility since the completion of training. All reported that objectives had successfully been met, although in each case only the basic image-dialogue function was used.

Conclusion

Training and implementation should be seen as inseparable processes. Decoupling the activities that sustain them leads to ineffectiveness, inefficiency, and leaves organisational practices largely unchanged. Necessary incentives for staff to change themselves, by undertaking self-directed school development tasks through programmes of professional self-development are removed when training objectives and processes are isolated from considerations of organisational development. Skills training programmes will not by themselves bring about professional and organisational change. The limitations identified in the CLASS project strongly indicate a need to examine alternative models of the change process in relation to ICT development and implementation in schools.

The model underlying the CLASS training reflects a Research, Development and Diffusion model (R, D and D). Strong on internal coherence, as befits its empirical-rational strategic foundations (Chin & Benne, 1974), such a model highlights the rationality inherent in an objectives-driven strategy that ignores the constitutive elements and interrelationships inherent in the diffusion process. This 'weak link', at the interface between institutional culture and experience (Becher and Maclure, 1978), allows the possibilities of changing school practice to remain unexplored.
If the diffusion strategy was designed to match a more comprehensive understanding of training processes and their link with institutional practice and renewal, dissemination strategies would have to be redesigned to confront and incorporate aspects of what Havelock (1973) termed the 'social interaction' model. There, the user is a change agent and change strategy incorporates provision for normative-re-educative experiences (Chin and Benne, 1974). These principles should also formatively influence the design, development and production of Management Information software.

In the case of the CLASS project, training was designed to employ a combination of 'Pressure' (school and individual exposure to testing and possible publication) and 'Support' (provision of CD-ROM, technical expertise and a facilitative training environment). Thus linking empirical-rational and power-coercive approaches to meet training objectives. After training was completed, implementation languished, though the essential framework and nourishment of physical and technical support were fully provided. Nevertheless, staff used elements of the new ICT facilities, when they perceived an immediate individual benefit of saving time required for carrying out existing professional tasks. Readiness to adopt the new technology was prompted by perceived efficiency gains. This is very much in-line with the findings of Wild (1992) during an evaluation of a LEA initiative in the use of computer-based management information systems. The 'natural growth' that did occur showed that schools adapted the training to their needs by achieving the greatest return with the least investment of their own time.

These findings lend support to an important and already established principle (Dalin, 1978) that for effective ICT development to take place, attention must be paid to the totality of the relevant system and, in school settings, incorporate a strategy of vertical, as well as horizontal professional dialogue.

Abstract: The purpose of this experiment was to examine variables that could influence the attitudes towards computers administrators in Malaysia. The variables investigated in this experiment were gender, age, computer skills and experience, and computer access and training. The instrument used for this experiment is the Computer Attitude Scale (CAS). The CAS is a 40-items instrument that is divided into four, 10-item sub-scales: Computer Anxiety, Computer Confidence, Computer Liking and Computer Usefulness. These four sub-scales were used to describe the four dimensions of attitudes toward computers. The findings significantly revealed that computers access and training, statistically influenced attitudes towards using computers, whereas gender, age, computer skills and experience did not. Therefore, the conclusions and recommendations based on the findings of this experiment indicated that proper training and better computer facilities should be provided by the authorities to teachers and school administrators in order to enhance the computer usage in schools and to increase the integration of information technology in education in Malaysia.

INTRODUCTION

The use of information technology (IT) in school administration is no doubt will be a plus factor for any school. According to Tofler (1991) when society have moved to IT, computer will be the tool for the societies. As for technologies, the advantage will largely depend on the usage. Correspondingly, users need to be well-versed. The government of Malaysia through the Ministry of Education (MOE) has embarked to introduce computer literacy in 60 schools throughout the country in the early 1990. This is followed by another 100 schools. Beside this, the MOE has started the Sekolah Bistari or Smart School concept. The Smart School has become one of the flagship application of the Multimedia Super Corridor (MSC) project.

Based on the Smart School Working Committee (1997), the rearrangement of school administrator to use IT will improve the administrator managing the school. The usage of computers will help the administrator manage, plan and allocates human and physical resources effectively. A lot of efforts have been done to install and provide Information Technology (IT) to each participating school. Many seminars and workshops are being conducted in discussing the usage of computers in teaching and learning, as well as in the improving the curriculum material.

Despite of the above, the usage of IT by school administrator is rarely discusses in Malaysia. We feel that in stressing of smart school teaching and learning, the aspects of school administrator usage of IT
should be emphasized. We managed to cover several studies by Chong (1995), Liong, Gan and Noran (1995) and Zainuddin (1997).

THE EXPERIMENT

Research conducted by Pelgrum and Plomp (1993) in Computers in Education Studies (COMPED) organised by The International Association for the Evaluation of Educational Achievement (IEA) among 22 countries throughout the world conclude that schools that use computers in their administrative indicate an increase in the school administration. Most school administrator also have this preception and hope that by using computers in their teaching and learning will increase schools and students performance.

Pelgrum and Promp (1993) also found that training in the use of computers needs to be considered for the effectiveness of using computers in school. This finding is being supported by another research conducted by Bird (1991) in England through Computer Assisted School Administration (CASA). The findings stress that school administrators needs to be given training in using computers beside having a fully equip hardware and software. While Kristiansen (1991) view that attitudes and confidence is an important factor in determining the use of IT in education. Computer attitudes is a difficult and complex entities to measure. However there are various instruments to measure it. Loyd & Gressard (1984a, 1984b), Loyd & loyd (1985), Koohang (1987) have found that several factors influence the attitude of user to computers such as sex, age, training, post (designation), family background, access to computer, skill and experience in using computer. Loyd & Gressard (84a, 84b) have use computer anxiety, computer confidence, computer liking and computer usefulness in their research. All these factors are relevant to the experiment that we are going to conduct. All these experiments were conducted in USA and Britain but not in Malaysia.

Figure 1: Conceptual Framework Model of the Experiment
Attitudes towards computer can be measured using Computer Attitude Scale (CAS) by Loyd and Loyd (1985). This view was also supported by research done by Gunter (1994) on work done by Kluever et. al (1992) and Bandalos and Benson (1990). They found out that CAS has high consistency rate of between 0.80 to 0.90. A experiment by Shaft and Sharfrman (1996) found out that their instrument Attitudes Toward Computers Instruments (ATCI) and Attitudes Towards Computers (ATCS) by Reece & Gable (1982) and CAS has a high correlation which is r=0.82. This suggest that all 3 instruments can measure the same dimensions.

SCOPE LIMIT

We have limit our experiment based on the following limitations:

i) we choose our respondents at random, any conclusions and recommendations derive from this experiment should apply to the same population criteria

ii) we only experiment 4 factors that is gender, age, computer skills and experience, and computer access and training in using computer

iii) access to computer includes facilities to the computer at home or school. Whether the respondents use the computer or not is not included in this experiment

iv) Different in computer facilities at school may influence the administration in using computer for administration. This factor is not studied.

v) There are other factors that can be used to experiment computer access and training. This factors are not included in this experiment.

Our dependent variables contain 40 items with Likert scale of 4 points. These 40 items are divided into 4 sections namely computer anxiety, computer confidence, computer liking and computer usefulness. The 4 independent variables are gender, age, computer skills and experience, and computer access and training. Figure 1 depicts the conceptual framework model that we conduct our experiment.

THE METHOD

Respondents are chosen at random from the various primary (elementary) and secondary (high) schools in urban and rural areas. Stratified random sampling is been used to determine the sample size. Questionnaires are posted and collected personally on a pre-determined date. We use Lakers scale of 1 to 4 for each questions.

DATA ANALYSIS

Descriptive statistical analysis were used to describe the respondents and the population whereas inferential statistics are used to describe and explain the relationships between independent and dependent variables.

FINDINGS

We distribute 100 questionnaires to the various respondents identified and we manage to collect 81 sets, which represent 81% of the population. According to Sakaran (1992), the return of 70% of the population is justifiable to conduct a statistical analysis. Our respondents were 51.9 % male and 48.1% female. Age group are as follow: Below 30 years 25.9%, 30-40 years 50.6%, more than 40 years old 23.5%. Respondents that have computers at home are 58% compared to 42%. Respondents that use computers at school are 82.7 % compared to 17.3%. Numbers of respondents having experience and expertise in using computers is for novice is 43.2 %, middle user 49.4 % and 7.4 % for expert users. This indicates that many respondents (school administrator) are average computer users. On the training side 45.7 % respondents have training and 54.3 % have no formal training. The number of training that the respondents received are as follows 54.3 % - no training, 27.2 % - 1 training, 6.2 % - 2 trainings and 12.3 % -more than 2 trainings.

In our further statistical test, we obtain a mean value of \( \mu = 98.07 \) for male and \( \mu = 94.05 \) for female. T-Test analysis is conducted which indicate the rejection at the confidence level of 95 %. This indicates

A One Way ANOVA with a significance level of 95% was conducted to compare the different mean for attitude among the respondent based on the age group. Although generally the test indicate that the mean value for the younger age group is high for all the sub-scale on computer anxiety, confidence, liking and usefulness, there is no significant difference among the age group at significance level of 95%. This indicate there is no significant different for computer attitude among school administrator in using computer. This findings justify the findings by Woodrow (1990), Kluever et. Al (1995) and Willis (1995). The result might be due to the small age gap among the age group. Other researcher used a bigger age gap between each age groups as done by Robertson et. al (1995).

t-Test analysis indicate that the mean value for attitudes toward computer is higher for school administrators who have access to computer (μ=99.97) compared to (μ=92.73) and significant at 95% level of significance for Confidence, Liking and Usefulness except for Anxiety sub-scale. Therefore we can conclude that there is a significant among school administrators who have access to computers compared to those who do not have access. This indicates access to computer can increase the attitudes toward computers because it can provide experience and confidence in using computers. This finding agrees with the findings done by Liao (1993).

Mean comparison between respondents that have basic, intermediate and expert skills users indicate that intermediate skill users have the highest attitudes for computer (μ=97.7) followed by expert skill users (μ=95.5) and basic skill users (μ=94.4). Although there is significant difference in mean at sub-scale Anxiety and Confidence but a One Way ANOVA test indicate there is no significant difference at 95% significance level generally for all sub-scale. This indicates there is no significant between school administrators that have basic, intermediate and expert skills users in using computer in school administration. These findings do not agreed with that of Loyd and Gressard (1984a), Comber et. al. (1997), Chen (1986), Koohang (1987, 1989), Gardner (1993), Liao (1995) and Huang et. al. (1995). What we can conclude about these unmatched findings are that there is an obvious different between the number of respondents in computer experience where the expert skill group is 4% compared to the other groups which is more then 40%. Beside that evaluating expertise is quite subjective in this case.

Mean analysis for attitude towards computer indicate that respondents that have computer training is high (μ=99.78) compared to those who do not have computer training is (μ=93.06). This is further strengthen by t-test which indicate there is significant at 95% level of significance for all sub-scale except Anxiety. This result is also supported by test conducted based on the numbers of computer training that respondents have gone. This can be translated that there is a significant different between respondent that has computer training compared those who do not have computer training. This result agreed to the finding done by Gressard and Loyd (1985), Reed (1990), Anderson and Hornby (1996) and Kluever et al. (1995)

Person Correlation Analyst is used to compare the relationship between the above variables and there is significant relation using 95% level of confidence between sex, access to the computer, training and skill. These support the finding done by other researchers which state that computer training and access can improve the computer skills and improve the attitudes toward computer.

Linear regression analyst using multiple regression is used to see the relationships and strength between dependent and independent variables. Our findings indicate that access to computer (β=-8.06) and training (β=-6.53) is the most important factor that affects the attitudes towards computer with significance at 95% level of significance. This is followed by sex factor (β=-3.96), age (β=-3.11) and skill (β=-2.34). This finding justify the findings done by Gressard and Loyd (1985), Reed (1990), Anderson and Hornby (1996), Huang and Pardron (1995) and Kluever et al. (1995)

CONCLUSIONS

Attitudes towards computer is among the most important factor in indicating a person acceptance in using computer. Our findings have found that access to computer and computer training are the most
important factor in determining the attitudes toward computer. These are proven by the regression analysts conducted by comparing the various factors. Access to computers also indicate an obvious different in attitudes toward computer and all the attitudes sub-scale towards computer. This statement is supported because most respondent have access to computers either at home or school. Other findings also indicate the longer a person used a computer, the more confident he has in using computer. This increased his experience and attitudes toward computer.

Another factor that we can conclude is the training factor. Respondents that have undergone training show a more positive attitude then those who do not have training. This experiment also indicates that many school administrators did not have computer training although they might have access to computers. This indirectly have an effect on their attitudes toward computers.

Finally, we recommend that school administrators should have access to computers either at home or schools. Beside that they should be given more computer training by the government.

REFERENCES

As new communications technologies impact higher education, faculty must be trained to determine the most appropriate tools for design, support and delivery of courses. The challenge for continuing professional development and renewal to adapt to this changing environment has become critical. The adaptation of existing courses to implement new technologies requires faculty to use recently acquired knowledge and new skills. The standards for teachers supporting these new skills have been developed by the professional organizations governing accreditation in each academic field.

Both the International Society for Technology in Education (ISTE) and the National Council for the Accreditation of Teacher Education (NCATE), have specified the technology skills that teachers are expected to have when they enter the teaching field. These organizational standards provide the foundation for the professional development programs designed for higher education faculty. ISTE suggests that teachers be able to meet these standards: apply tools for enhancing their own professional use and productivity, use technology in communicating, collaborating, conducting research and solving problems, promote legal and ethical use of technology, use technology to support their instruction, and plan the delivery of instructional activities that integrate technology (ISTE, 1998).

The papers included in this section address a number and variety of approaches available to meet these new standards. The papers have been grouped into five areas: 1) Models for Successful Faculty Development Training; 2) Faculty Development Best Practices 3) Teaching The Tools of Technology; 4) Research and Case Studies; and 5) Faculty Development and Preservice Education.

Papers included in the Models for Faculty Development Training group provide a variety of faculty development models. They focus on the application of existing courses to implement new technology. These models are designed to prepare faculty for the transition from the traditional classroom to the technology rich environment supported by the ISTE and NCATE standards. A critical part of training is to expose faculty to models of technology use for integration and application of today's technology tools. Blair and Madigan present a faculty development model that not only unites technology and pedagogy, but also presumes that faculty have a vital role in defining that model. Their description of their Center for Teaching, Learning & Technology chronicles the implementation of an integrated technology-pedagogy model. Kahn and Pred present the planning process, structure and outcomes of a project to provide information about the possibilities of technology to faculty in specific disciplines within the Southeastern Pennsylvania Consortium for Higher Education, a consortium of eight small colleges in and around Philadelphia. Browne, Maeers, and Cooper explore the experience of information technology inservice workshops at the University of Regina in Canada. A technology mentorship program designed to provide staff development for the teacher education faculty of a small liberal arts college is described by Milligan and Robinson. This mentoring program included the use of ISTE standards for preservice teachers in gauging the progress of the faculty that participated in the original program Beisser provides results from a specific technology mentoring experience at Iowa State University from the perspective of both the mentor and the mentee. Terwindt presents the development and implementation of a new curriculum concept for professional education at the Amsterdam Faculty of Education that has been termed "learning through producing". McCoy examines data gathered at the University of Alaska Anchorage School of Education to determine the state of faculty technology use for teaching and learning and establishes goals for further development of technology integration.

The second section of papers represents Best Practices in Faculty Development Plans. The best practice of current instruction must be preserved and renewed. Instructional and evaluative strategies that have been successful in traditional settings need to be examined and, if necessary, altered to continue their positive effects with students participating in situations with new technologies. Barry, Walvoord, and Laughner provide a Teaching Well With Technology workshop created to provide faculty members with a systematic way of thinking about desired outcomes, use of time and space, and potential impact of technology for their classes. Topp and Mortensen share the experiences of a college of education's 10-year effort to train faculty to
use and infuse technology by means of its annual 1-3 week technology awareness and training sessions. The Distance Professional Development and Support System developed at the University of Utah Reading Center and reported on by Serdiukov, Niederhauser and Reynolds is designed to offer effective and cost-efficient teachers’ professional development. Childress and Braswell address the faculty development programs at Auburn University Montgomery and Old Dominion University and the on-going evaluation of these programs. The authors also address problems perceived and overcome. Belvin and Baines report on recent research that included faculty perceptions towards technology and progress towards integration of technology into teaching. They have identified three categories of technology adoption and integration. The USE Tech Partners Program at West Chester University is geared toward full-scale integration of educational technology in teacher preparation. Newcombe and Kinslow present effective strategies, lessons learned through implementation, and future planned activities.

The third set of papers in this faculty development category center around Teaching the Tools of Technology. Teaching the tools of technology is necessary in the initial faculty development training that occurs. Training must be geared to the specific tools that support and supplement the educational mission of the faculty being trained. Maddux directs this paper to the developers of web pages to supplement traditional higher education courses and describes technical and content problems that limit the usefulness of web pages and the frustration that can occur for both students and instructors. Repman, Carlson, Downs, and Clark examine new search tools and techniques that teacher educators can use to improve the efficiency and effectiveness of their own web searching. Techniques include use of metasearch tools, improving relevance rankings with search engines, backwards searching, searching the invisible web, and use of kids’ search tools. Interactive PowerPoint for teachers and students in the tool of technology presented by Cavanaugh and Cavanaugh provides specific information for the teaching of the tools of technology needed by faculty. Baty and Moir have developed a searchable on-line database of staff development material that relates to electronic teaching resources and which operates across the University network.

Section Four contains research and case studies involving faculty development and training. A study on teacher educators’ reflections on using group response technology is presented by Hargrave, Foegen, and Schmidt. This study suggests that group response technology was an efficient means for all students to participate in class and for the instructor to monitor student progress during instruction. Galloway provides recent research on the teachers’ use of graphics in HyperStudio screen displays. Graphic displays are analyzed and the use and application of graphic imagery is categorized into discrete levels based on their level of communication. Wideman reports on a study of the implementation of two telelearning projects based on different pedagogical models and using different delivery systems. A theoretical model of telelearning implementation is articulated and related to traditional views of program implementation. An action research methodology by Schutloffel provides a self case study of a teacher education professor who investigates how to reconcile beliefs about classroom life with the implementation of technology. Bohm and Nulden describe a research project in progress about information technology use in education. They suggest how to initiate a discussion among educators to facilitate the start of a more substantial adoption of information technology in educational practice. Igonor and Soul report on a study concerning the use of information and communication technology conducted by South African University Academics. The impact of information and communication technology on job characteristics of teaching, research and administrative duties was investigated.

The last set of papers involves Faculty Development and Preservice Education. This dual mission of blending the training of the faculties of our Colleges of Education and the specific training programs for preservice teachers is of vital importance to all Colleges of Education throughout the higher education system. Funded through the U. S. Department of Education, Project PICT (Preservice Infusion of Computer Technology) was developed to enable preservice teachers to fully utilize modern technology for improved learning and achievement in their future classrooms. Vannatta and O’Bannon report on a model grounded in the collaboration between teacher education faculty, arts and sciences faculty, and K-6 teachers. Hoffman, Rosenzweig, Morris, and Faison discuss the Apple Summer Institute for Teacher Education attended by 42 participants who represented faculty teams from 17 universities. This panel discussion focuses on the results of this novel program in promoting institutional change within participating universities.

Swain describes the Unified Elementary ProTeach program at the University of Florida that is a new teacher education program with the potential to positively impact future teachers, public school children in the state of Florida, and the University of Florida community. Recent state legislation in Virginia requires teacher licensure programs to guarantee that graduating teachers are computer literate. In an effort to accommodate this mandate, faculty within the School of Education at Virginia Commonwealth University are analyzing the use of technology
in courses required for certification. Savitt, Hootstein, and Rezba discuss faculty development and preservice teachers as agents of change in light of these activities. Slobodina describes faculty development in technology for teachers of English for specific purposes by providing the current practices of faculty development in technology in Russia's universities and suggests ways of restructuring it to provide a high quality of university education in the new millennium.

The papers on Faculty Development describe innovative models and positive suggestions that have been designed and conducted to improve the use and integration of technology at institutions of higher education worldwide. Taken as a group, the methods and models provided will aid in the effective training of faculty and will address the critical need for continuing professional development and renewal to adapt to our changing technological environment.

Abstract: As more and more faculty are encouraged to develop technology-based courses within their disciplines as a response to changing student populations and the resulting need for alternative sites of learning, it is vital to create a faculty development model that not only unites technology and pedagogy, but also presumes that faculty have a vital role in defining that model. Using our Center for Teaching, Learning & Technology as a case study, this paper chronicles our implementation of an integrated technology-pedagogy model through the creation of faculty associate positions that allow faculty using technology across the disciplines to serve as liaisons among faculty and between faculty and instructional designers. In providing an historical overview of our Center’s move toward this integrated model, we profile varying levels of support, resistance, and success encountered in establishing a faculty associate program, ultimately stressing the reciprocal benefits to the university community.

Introduction

One of greatest challenges to Faculty Development Centers in post secondary education is how to incorporate technology into the practice of teaching without sacrificing either the technological or the pedagogical mission of the University. Many models within faculty development centers address this challenge by foregrounding one teaching-technology model at the expense of another. Sometimes when technology is involved in developing course materials traditional faculty development centers play a minor role if any. For example, one model may involve a faculty member “dropping off” course materials at an instructional media center to be technologically transformed for presentation purposes. This model may also presume that course materials need only be visually appealing and accessible in order to be pedagogically sound. In addition, such a model often views the use of instructional technology from a top-down perspective in that technology enhances a one-way monologue from teachers to students. A related model involves placing instructional media centers within or near faculty development centers. The initial missions of both centers presume and encourages a separation between technology and pedagogy. More recently, some faculty development centers have realized the importance of collaborations in which other experienced faculty from a variety of disciplines across campus work as consultants to instructional designers within one combined unit. Yet even within these more current models, faculty are viewed as content experts but neither technological nor pedagogical experts. Although each of the above models appear to integrate teaching and technology, there exists a continued bifurcation.

As more and more faculty are being encouraged to develop technology-based courses within their disciplines as a response to changing student populations and the resulting need for alternative sites of learning, it is vital to create a faculty development model that not only unites technology and pedagogy, but also presumes that faculty across these disciplines have a vital role in defining that model. Thus it is important to ensure complete integration of technology and pedagogy from the initial planning stage of course development through the implementation and assessment stages so that faculty have an equal and reciprocal role in the creation of technology-based learning options appropriate to their teaching styles and curricular contexts.
Indeed, any form of instructional consultation should be recursive and, as Weston and McAlpine (1999) suggest, should “integrate more disciplined-based concerns and faculty involvement” (p. 85).

Although in some cases, the possibilities and constraints of implementing any model of faculty development across campus are often budgetary, there are also those ideological constraints that maintain the separation of technology from pedagogy. From a faculty perspective, this may include the view that technology requires functional knowledge of hardware and software applications, and is therefore beyond the average faculty member’s teaching responsibilities. From an administrative perspective, there are often concerns about offering incentives to faculty for appropriate uses of technology in curricular development. These concerns are particularly significant in light of traditional tenure and promotion structures that may fail to encourage and reward faculty who recognize the importance of technological teaching and learning forums (Gilbert, 1996). For technological literacy educators such as Cynthia Selfe (1998), it is simply no longer enough to ask colleagues to utilize technology and reward them for doing so: “Instead, we need to... provide them with important opportunities to participate in making hard decisions about how to pay attention to technology issues in departments, colleges, and local communities” (p. 434).

Using our Center for Teaching, Learning & Technology as a case study, we show how we have implemented an integrated technology-pedagogy model through the creation of faculty associate positions that allow faculty using technology across the disciplines to serve first as liaisons between faculty and instructional designers then as members of creative development teams. In this model, faculty associates, instructional computing designers, and other faculty development personnel, including student network specialists and multimedia designers, work as a team toward a common goal of helping faculty recognize the potential of technological teaching environments to foster active teaching and learning styles.

As this paper demonstrates, the integrated role of the faculty associate includes actively involving discipline specific faculty in planning workshops and other public forums for critical dialogue about integrating, preparing, and evaluating technology-based teaching. Faculty associates also serve as consultants to individual faculty seeking to implement technology into teaching and learning. In providing an historical overview of our Center’s move toward this integrated model, we highlight the varying levels of support, resistance and success we have encountered in establishing a faculty associate program. Ultimately, in addition to the benefits for our own faculty development center, we stress the reciprocal, interdisciplinary benefits to the faculty associates, their departments and colleges, and to the larger university community.

**Historical Overview**

Many factors have contributed to our Center’s vision regarding the successful and responsible use of integrating technology into the teaching culture at our university. It would be irresponsible for us to imply that our current vision was the vision we began with at our Center for Teaching, Learning and Technology three years ago. Although the president of our university played a pivotal role in helping to create a faculty development center that focused on all faculty development issues, including responsible use of technology for teaching, our directives were unclear. During the first year of existence, members of our advisory board (faculty, students, and administrative staff personnel) spent several months debating our vision and mission. Common questions during those early meetings were, How much technology should the Center focus on? Should the Center be involved in instructional design? How much time should the Center and its staff devote to technology issues? How much time should the Center and its staff devote to other more traditional faculty development issues? In response to the confusion of those early months, the director and assistant director designed a series of technology workshops and a second series of more pedagogically focused workshops. And although they tried to combine technology and teaching issues in every workshop and consultation, more often than not the two sets of issues became distinct and separate, just like the two sets of workshops.

In the second year of existence, and in answer to a technology/teaching separation model, we sought to informally benchmark (Epper, 1999) our teaching/technology faculty development profile with profiles from other universities and businesses that were successful in integrating teaching/technology models. We visited faculty development web sites worldwide, and we made visits to several campuses state wide, nationwide, and in Canada that had developed faculty development centers that integrated instructional computing design with pedagogy. Our benchmarking activity revealed that only a few faculty development centers we encountered had implemented a teaching/technology model that was fully integrated. We learned that the faculty development
programs that came closest to an integrated model that we now implement always involved cooperation between faculty associates, instructional technology experts, and faculty development centers. In response to the benchmarking activity, we began to involve more faculty in facilitating our workshops. We hired student technology experts to work with faculty on teaching/technology projects. We also investigated systems, hardware and software that would allow faculty to integrate technology into their curriculums more fluidly. Finally, we began to envision an integrated program that involves faculty associates, instructional designers, and students in a team environment. As a result of our benchmarking venture, our staff began to refine our vision and our Center’s mission.

What we didn’t expect in the beginning of implementing our new model is some of the resistance we encountered from a variety of areas. For example, some faculty became vocal about not wanting to use technology in their teaching. Because new instructional technologies have only recently begun to change the way we communicate, distribute resources and share ideas with students, our university did not have a system in place three years ago to support faculty teaching/technology efforts. Even two years ago, some of our faculty did not have easy access to the Internet from their offices or from their homes. Nor did faculty have access to knowledge about how technology and teaching were joint initiatives in relation to instructional design and curriculum development. Some key administrators on campus had developed a resistance of their own toward an integrated model. Primarily, they were used to faculty development centers in which technology was bifurcated from traditional faculty development issues: Curriculum design, classroom management issues, and assessment. Thus they themselves had little experience in facilitating innovative uses of technology in teaching and learning.

Although in the beginning this kind of resistance worked against the integrated faculty development model, we came to understand and learn from some of the issues related to the resistance. We learned that faculty needed better technical assistance and access in their daily teaching and research routines. We learned that they needed a secure environment in which to distribute course content and communicate with students and colleagues. We learned that they needed and wanted forums for discussing and assessing appropriate and responsible uses of technology for teaching and learning. We learned that they needed a reward structure consistent with their discipline specific guidelines for toward tenure and promotion. From what we learned, we fashioned the faculty associate program that we detail in our next section.

Implementing an Integrated Model

Fostering a reciprocal relationship between faculty and our Center staff has involved a triangulation of forums that are meant to complement one another and contribute to our theoretical goal of integrating technology and pedagogy, including theoretical seminars, individual consultation, and hands-on technological training.

Technology/Pedagogy Seminars

Once we hired our current faculty associate, the Director, a newly hired coordinator for instructional development, and the faculty associate brainstormed ways of encouraging faculty to become more actively involved in discussions relating to effective uses of technology in the classroom. In our first phase of the program, our faculty associate coordinated three special topics seminars meant to contextualize online teaching around issues of development, management, and assessment. The first session, “Integrating Technology in Teaching and Learning: Perspectives and Problems,” was co-presented by the faculty associate, an English professor who utilizes web-authoring tools in electronic writing classrooms, and another faculty member in communication studies who utilizes web-based communication technologies in large lecture classes, with each demonstrating their web-based course materials and communication forums. The workshop addressed the question of when and why to use technology in teaching, as well as how to develop online pedagogies that foster alternative learning formats. To facilitate interactive discussion of these questions, breakout sessions allowed faculty to brainstorm online pedagogical possibilities appropriate to their instructional formats and disciplinary content and to share their discussion with the larger group.

A second session, “Preparing for Online Learning: Course Management Possibilities,” asked participants to consider what course materials they commonly utilize in teaching and which ones would be suitable for online distribution. Similar questions addressed the advantages and disadvantages of transferring communication strategies between teachers and students as well as among students themselves from a face-to-
face setting to an online forum. In addition to a hands-on opportunity to work collaboratively with faculty from a wide range of disciplines—Geography, Family and Consumer Sciences, Art—a team of course developers shared their experiences in planning and implementing a totally online philosophy course, first as a pilot course and ultimately as a successful multi-sectioned offering in the department.

Finally, a third session, "Evaluating Student Learning Online," addressed the ways in which various technologies available to teachers, from e-mail to the World Wide Web, can be used both as tools for student assessment and as forums for student self-assessment and course evaluation. Faculty presenters included a music professor who utilized online quizzes for the assessment of basic concepts and a technical communication professor who employed electronic portfolios of student work in a course on online documentation. Despite the differences in curricula and online assessment options, both faculty stressed the preparation required in developing and monitoring online assessment strategies and helped faculty to consider the ways in which students could participate in evaluating the success of their own online learning to aid in curriculum revision and general assessment options.

Rather than foster uncritical enthusiasm for online learning forums, however, these sessions encouraged faculty to question the relative contribution of technology to both curriculum and instruction. For instance, an education professor attending the workshop was skeptical about the role of online discussion forums in fostering dialogue. While the professor could see the benefits of online groups for larger, lecture-oriented courses, he already had a smaller class of thirty students for whom creating and managing face-to-face group activities seemed sufficient. A follow-up email the next day from this professor to the faculty associate co-presenting at the seminar revealed a more reflective stance, recognizing the benefits of online discussion for a summer course in which some aspects of the curriculum could function online as well as face to face. Instead of wholeheartedly embracing this online alternative, the professor expressed concern about the perception by others in his department, as well as his own students, that he wasn't teaching because the class would not always be meeting in the traditional face-to-face environment. Currently, our Center staff has worked with the faculty member in identifying technological options to match his pedagogical goals, maintaining both a face-to-face and an email dialogue for his questions and concerns. As this example demonstrates, the successful integration of technology into the curriculum requires support of the faculty member's academic labor by students, colleagues, and departmental and college administrators whose ideological values about teaching and learning may be steeped within a traditional, teacher-centered educational paradigm.

**Individual Consulting and Technological Training**

Our faculty associates consult with discipline-specific faculty to establish a sense of continuity between the technology/pedagogy workshops and the actual application to classroom practice. In these consultations, the faculty associate and a Coordinator for Instructional Development, both with shared expertise in technology and pedagogy, facilitate dialogue with faculty about what teaching and learning forums they currently employ; what technological forums are available to foster equally successful student learning opportunities; what preparation is required by faculty for effective utilization of online teaching environments; and what additional training, in the form of online tutorials and hands-on workshops, will assist the faculty member in the development process.

Despite the apparent benefits of this program, Barone and Luker (1999) remind us that "Tensions on campus run high as institutions of higher education face social and economic pressure that their cultural and value systems, embedded in traditional modes of instruction, do not accommodate" (p. 68). As a result of this pressure, faculty can sometimes be caught up in the *rush to technologize*, a situation in which the *whats* and *hows* of technology are more important than the *whys*. And because, as Barone and Luker further note, "The classroom lecture and its concomitant social relationships have been dominant forms in universities for centuries" (p. 68), faculty may initially have a more transparent view of technology. From this perspective, technology is simply another medium of the traditional mode of instructional delivery. This contrasts to a view that holds technology as potentially transformative educational media, the co-production of knowledge between teachers and students. Even for those faculty who hold this latter perspective, however, it is important to remember that simply to "add technology and stir" does not ensure a recipe for transformative educational practice. Techno-pedagogues such as Donna LeCourt (1998) stress the need to challenge links between transformative pedagogy and computer-mediated instruction that presume computers to be defacto tools of educational empowerment. In response to such concerns, we encourage faculty to plan their online course components in ways that allow for participatory learning. Examples of this might be the use of online forums for group projects, or online surveys to allow students to provide midterm feedback about a course.
In these consultations we also stress that integrating technology can and should be progressive, not requiring technological mastery on the part of faculty. The belief that that faculty must be masters of technology in order to teach with technology may discourage them from developing technological learning forums in the first place, fearful of the loss of their status as experts. For instance, in a study comparing writing instruction in traditional vs. computer-mediated environments, Palmquist et al. (1998), noted that "One of the most common concerns teachers express is that they will not know how to help students..." as well as concerns about "losing face in front of students" (p. 9). To aid in developing more technological knowledge, each consultation addresses the necessary skills-building process for a faculty member's successful integration of technology in the classroom. Skill-building can be both self-paced, where a faculty member can work with a student technology consultant, or involve workshop-oriented activities in which faculty attend sessions that provide hands-on training. Regardless of whether training is individual or group based, the faculty associate ensures that even within these skill-based sessions, technological training and pedagogical concerns continue to be co-equal. In the case of workshops, the faculty associate secures additional faculty participants who use technology in their teaching and who are invited to demonstrate various online materials within the workshops, sharing time with the instructional development coordinator who conducts the more skills-based training within these sessions.

Conclusion

Throughout the range of theoretical seminars, individual consulting, and hands-on workshops, our integrated model presumes the role of faculty, faculty associates, and instructional/technical designers as members of a creative development team. While Moore and Kearsley (1996) suggest that faculty scheduling demands may initially make them reluctant members of the team and limit their role as designers in terms of both willingness and expertise, our experience has been that the role of faculty in this process must be that of both instructor and co-designer in order for the technology-based course development process to be effective. In addition to providing the theoretical and practical training for such teamwork to occur, we also see the importance of Moore and Kearsley's call for technical and instructional design staff, including faculty associates, to themselves become knowledgeable about the criteria for effective technology-based learning. While some of this knowledge comes from formal courses and self-instruction, it must also stem from a willingness to listen and learn from faculty, administrators, and students across the disciplines. For members of our Center's staff, this knowledge-building has a direct impact on their professional development, for just as Owen Hicks (1999) suggests, those serving as consultants often attest to the improvements in their own instruction "that occur as a result of acting as advisers to colleagues" (p. 15).

Yet in order to support the integrated model we have described throughout this paper, we depend upon continued institutional and philosophical support for our Center's technology/pedagogy initiatives. For example, our English department is supporting our current faculty associate by working jointly to consider the possible impact of this position not only on her individual teaching and scholarship but also on larger departmental initiatives, including the development of online courses as well as grant-writing projects to fund such initiatives. In addition, our philosophy department granted a course release for one faculty member and provided a graduate assistant for another faculty member to develop web courses to meet the needs of student populations both within and outside the university. At the college level, our graduate college has recognized the importance of supporting faculty associate positions from a variety of disciplines. Thus they have allocated funds for three additional faculty associates for the upcoming year. Moreover, our Center has initiated regular dialogue among Deans to discuss the value and changing reward structures for both academic units and individual faculty attempting to integrate technology into instruction. This also includes adding two associate deans to the Center's advisory board to better involve them in the existing dialogue, a process that supports and reaffirms our mission. Without continued self-assessment of the recursive benefits to the faculty associate, the faculty development center, and the university, the model remains static, rather than a dynamic response to discipline-specific goals. Finally, without these varying levels of support from those administrative units providing the funding and those faculty and departments directly benefiting from our current and future technology/pedagogy initiatives, the model cannot succeed.

Abstract: Higher education faculties have been slow to integrate technology into their college courses. In a single small college, the logistics of providing the information professors might need about technology in their subject areas are daunting. The result is that the integration of technology into college courses is a haphazard process, fueled only by the enthusiasm and commitment of individual faculty members. This presentation will present the planning process, structure and outcomes of a project to provide information about the possibilities of technology to faculty in specific disciplines in an eight-college consortium.

The Southeastern Pennsylvania Consortium for Higher Education (SEPCHE), a consortium of eight small colleges in and around Philadelphia obtained funding from a private foundation to educate their faculties on the use of technology (web resources and software) in their college teaching. The pilot program, which took place in January of 1999, consisted of two workshops, one for education faculty and one for science faculty, held simultaneously on two of the eight college campuses. Subsequently, funding was obtained from the same foundation to do six other workshops in January of 2000, also simultaneously, on the six other campuses. These workshops addressed the following topics: Psychology and Sociology; Art; Business, Mathematics and Economics; Nursing and Allied Health Professions; Philosophy, History and Theology; and Languages and Literature. One objective of the workshops was to educate college faculty about ways to integrate technology into their courses. A second objective was to create an opportunity for faculty members from the eight separate campuses to collaborate on an academic task. The overriding objective of the workshops was to improve the quality of the college education provided on each of the eight campuses. This paper presents a model for doing such faculty development, and describes the results when this model was used.

Needs assessment survey

The first step was to survey the faculties of all eight colleges, to find out what equipment they had, what use they made of it, and how technology was used in the courses taught at each college. The survey made it clear that most faculty members knew enough about word processing and other applications to use technology to do their own work – e.g., record-keeping, syllabus creation, desktop publishing. It was also clear that the lack of equipment and infrastructure (Internet connections in offices and classrooms) was a significant factor that kept faculty from making more extensive use of technology in their teaching.

The survey showed that teachers did not use technology in their classroom teaching. It was decided to design workshops in which teachers could become acquainted with websites and software for their
disciplines. We reasoned that browsing time was needed, in an environment where technical support was readily available. We also determined that a discussion of assignments and strategies for including technology in college courses would be helpful. This would be an opportunity for faculty members from all of the eight colleges in the consortium to get to know each other and to exchange information on the ways in which they each individually included technology in their courses.

Planning the workshops

Notifying faculty
We received the grant from the Barra Foundation, designed to pay two people to plan and conduct the workshop, 25 to attend, three to present software or Internet activities, and one to evaluate the workshop. We designated two people to plan and conduct the workshop so that the workload would be shared and so that the workshop would not be jeopardized should one person be unavailable (e.g., due to sickness or family emergency) We planned the workshops for the January intercession. We chose that time because everyone would be available to attend two days of workshop sessions, and it would be possible for professors to think about the classes they were planning to teach that spring, and make slight adjustments in their assignments.

In September, a notice was sent out to all education faculty members at all eight colleges, informing them of the dates of the workshop. Notices were also sent out to department chairs. In these notices, chairs were informed that they would be asked to choose three members of their departments to attend the workshop, and also to identify possible presenters.

By October 15, signup sheets had been mailed to all education department chairs, asking for the names, addresses, phone numbers (home and work), and social security numbers of workshop participants.

Gathering materials
During the fall of 1998, the directors of the education faculty workshop began collecting handouts to be used during the workshop. We found handouts that identified websites for specific topics (children's literature, instructional planning), as well as handouts on evaluating software and websites, and on using search engines.

Selecting evaluators
An evaluation team designed a evaluative survey to be administered during and after the workshop. Both quantitative data (a Likert scale questionnaire) and qualitative data (solicited comments on the questionnaire and unsolicited comments during and after the workshop) were collected and analyzed.

Conducting the workshops
The first two workshops took place on January 6 & 7, 1999. Twenty-four professors, representing all eight colleges, took part in the education workshop. On Wednesday the workshop was structured so that each participant had his or her own computer, thereby insuring that each person learned how to access websites and so forth. Even so, considerable collaboration took place almost immediately as members of the group showed each other what they had found or helped each other deal with problems. A technical expert was available to help deal with problems. On Wednesday, at the end of the day an evaluation form was distributed, and participants were reminded to bring a syllabus from one of their courses to the workshop on Thursday.

Presenters were volunteers from among the faculty participants. One demonstrated the use of a commercial website for setting up a webpage. A pair of presenters talked about educational software, some of which was available in the lab for preview. On Thursday morning, an assistant professor illustrated the use of a website to articulate a concept addressed in her Educational Psychology class. The workshop leader described the final task, which was to create an assignment that involved the use of web technology. Each participant was encouraged to work with another professor teaching a similar course at another college. By the end of Thursday afternoon, all the workshop participants had presented to the group.
assignments they had designed for use in their college courses. All of these assignments involved the exploration and examination of web resources.

Evaluating the workshops

Quantitative evaluation

Evaluations were done at the end of each day, consisting of a questionnaire that participants filled in and signed (copies of the questionnaire are available upon request from jkahn@mciu.org). In addition throughout the two days, individuals commented that they valued the time to explore websites and also the time to work with each other. They mentioned the quality of the handouts, and the wealth of valuable addresses and information they had received.

Statistical analysis of questionnaire data was conducted by the project evaluator, Robert Pred. Some observations about the data are offered here. Items 1-7 remained constant on both the Wednesday and Thursday questionnaire. Scores on all items improved on Thursday, which we understand to indicate an increase in the level of comfort and sense of competence of the participants. To enhance the reliability of assessment, Items 1-7 were summed to form two scale totals, one for each workshop day. The average scale score obtained from participants on the second workshop day was higher than the average scale score for the first workshop day. This increase was shown to be statistically significant using a repeated measures methodology. A paired samples t-test showed significant improvement ($p < .01$, $t$ paired samples test $= -3.359$, df= 16, 2-tailed significance = .004) in the scale scores over the period of two sessions.

Items 8-10 on Day One addressed issues of incorporation, and the content in question was various websites, which participants had explored, perhaps for the first time, that day. They responded that they would not only be comfortable using websites in their teaching but overwhelmingly indicated that they would use websites and could see value in doing so. For example, over 95% of participants indicated “Strongly agree” when responding to the opinion expressed in Question #10 (I clearly see benefits to incorporating the use of the World Wide Web in developing my courses).

Items 8-10 on Day Two addressed issues of usage, but also asked professors to assess the value of the structure of the workshop and the value of the content of the workshop for their particular teaching situations. One hundred percent of respondents agreed with the statement in Question #8 (I was introduced to websites/software that I feel can be useful in my courses). In addition, over ninety percent of respondents agreed with Question #9 (Working in groups to learn new software with professors from other institutions was valuable). To Question #10 (I was able to design some valuable activities for my course(s) using the software), ninety-five percent indicated agreement.

It was also interesting to note that, when asked in what courses faculty members would use technology, all respondents named two or more courses (they were given four blank lines), although the assignment of the workshop had been to design an activity for just one course.

Qualitative evaluation

The qualitative evaluation reflects the enthusiasm that was apparent during the course of the workshop. Participants were involved in their activities, using the information that had been supplied to pursue their own interests. They also shared what they had found with colleagues from their own campuses as well as with new acquaintances who taught similar courses on other campuses. The energy level was high, conversations were animated, and handouts were accumulated and carefully consulted. Even frustrations when websites were not immediately available did not dampen spirits.

All participants designed activities for use in their courses and presented their activities willingly for the other participants. Many participants partnered with one or more colleagues from other colleges in order to complete this assignment, working together for the first time in most cases.

There was space on the bottom of the questionnaire for “additional comments about this workshop.” Thirteen of twenty-two participants used that space and the comments were entirely positive (one person

BEST COPY AVAILABLE
We also asked participants if they would be willing to identify themselves so that we could conduct a brief follow-up survey. All participants contributed their names and phone numbers to a database, and seventeen professors indicated willingness to take part in a follow-up survey.

Participants' written comments identified several valuable components of the sessions. Faculty members identified the time to explore the World Wide Web by themselves as being valuable. It is our assessment that this time was made more productive because they had reference materials about search engines, Web addresses, and especially the support of an instructional support person who answered technical questions.

The chair of the education department at one college wrote:

"Please accept my commendations for a well-planned workshop! The organization of topics, as well as the delivery methodology was appropriate for the neophyte as well as the seasoned Internet traveler. The handouts were valuable and will provide a vital resource when we implement the skill that we acquired. The individual help that you gave us was very much appreciated. Once again thanks for such a valuable program."

Another identified value of the workshop was the opportunity to work with colleagues from other campuses. A good example of this is the following comment,

"This was an outstanding two days – the opportunity to explore technology applications and to network with other education faculty."

One participant wrote specifically about the value of meeting professors from consortium colleges with whom she could share expertise. This respondent chose to identify herself (as almost all respondents did) so we know that she was one of the presenters. She had demonstrated a sophisticated use of Web resources for the rest of the group. It would have been understandable if she had complained that she had not learned anything new, but in fact, she reported that she found the experience valuable in its collaborative aspect, and suggested a follow-up session.

"Really good to meet others teaching similar courses at other colleges. I like this kind of workshop where we had time to interact with those who teach same subjects. I wish we could have another session in a few months in which we came with something we have accomplished in our class as a result of the work we did today, and share that with 1) our subject area colleagues and 2) all of the other professionals in this workshop."

The enthusiasm with which the workshop was generally received is illustrated by the following remark:

"The two-day professional development sessions were very beneficial to me. Very practical and very appropriate! Great job!"

There were unsolicited notes and email messages from seven participants. Each of these comments was in a personal note addressed to the workshop leader indicating that they felt so positively about the experiences offered at the workshop that they took the time and effort to provide additional feedback.

One participant wrote,

"I want to thank you for your preparation, your enthusiasm, and the valuable learning provided. Your work was a real and professional service."
Another participant wrote:

"The workshop was great. In addition to previewing the Early Childhood Education software, I obtained some great articles and titles of texts that I can use for these new special education courses...We all seemed to enjoy the fellowship as well."

Still another participant indicated that she would use what she had learned immediately in her courses.

"As a result of our workshop, I am revising my own syllabi in my language arts courses to integrate more projects and assignments using website resources."

In planning for the next six workshops, we kept in mind the lessons of the first two. It did not seem to matter that participants varied widely in the level of their experience and comfort with the technology. It did not seem to matter that they came from different campuses with different levels of technology available to them. What did matter for them was that they were provided with time, resources and structures that made it possible for them to explore and use what they found to improve their teaching. They perceived that their level of knowledge and comfort regarding this technology increased substantially over the course of the workshop. They also began to understand new ways to incorporate technology into their courses. Participants suggested possible topics for follow-up workshops and indicated their willingness to attend such workshops.

This model has several features that seem to be critical. These components are 1) the subject-specific nature of the workshops; 2) the pedagogical focus; 3) the balance of structure and exploration; and 4) the opportunity to collaborate. Each of these factors had something to do with the success of the first two workshops, and each has been built into the next six workshops. Faculty again are organized into groups with those who teach the same subjects at the other colleges, and technology resources specific to those subjects are being gathered for presentation. We again suggested that faculty members each bring a syllabus and design an activity, and we provided guidelines for structuring and assessing those activities. Within the two-day workshops, we again provided opportunities for exploration of websites as well as structured presentations and tasks to be completed and described. We encouraged faculty to work together on their assignment with their counterparts from other campuses, creating an opportunity for conversation and collaboration.

By any measure of success the first two workshops qualify. Assessment data from the next six workshops will be analyzed at presented at the SITE2000 meeting in San Diego, and will be available by email from jkahn@mciu.org. We had specified four outcomes for the workshops in our original proposal, and informed participants of these outcomes in a handout that read as follows:

The purpose of these workshops is to bring our faculties together to collaborate on the creation of web pages and to review software. Faculty will identify and assess web sites and software, and consider ways to integrate technology into their various college courses. If the pilot program is successful and additional funding is obtained, workshops for six other discipline groups will be scheduled on the six other campuses for the winter of 2000.

There will be four separate outcomes of this project.

1. The creation of working relationships among the members of our separate faculties as they discuss their syllabi and assignments.

2. The creation of a nucleus of computer-using educators who can return to their individual campuses and serve as resources for other faculty members.

3. The creation of Web pages to provide faculty members with a lasting resource of their own invention.
The enrichment and improvement of education courses by the thoughtfully designed use of technology.

It is clear from participants' comments that the first outcome was achieved. We have described the ways in which these working relationships evolved over the two-day period. We expect to find evidence that the second outcome has been achieved when we do follow-up surveys. Certainly during the initial two workshops our participants served as resources for each other, and we expect that they will stay in touch and maintain some level of interaction as they need to. We did create an Education faculty Web page, which can be found at http://www.chc.edu/sepche.htm/. This Web page identifies sites selected by participants and organizes them by topic (reading, mathematics, special education and so forth) as the participants suggested. Finally, we are certain that faculty members from each campus will be incorporating technology into their courses in ways that help them accomplish their instructional goals.

We began this project with the expectation that professors of the SEPCHE consortium would benefit from a workshop in which they had both sufficient time to explore Web and software resources and an extended opportunity to talk to each other about the courses they teach and the resources they use. Every indicator we have shows us that we were entirely justified in this expectation.
A Faculty of Education as a Community of Learners: Growing to Meet the Demands of Instruction and Technology

Abstract: This paper explores one Faculty of Education’s experience with Information Technology inservice workshops. Expert students knew the IT content and expert faculty worked with the expert students to ‘deliver’ the content to the faculty and to debrief and extend the discussion to appropriate classroom learning using IT. A Community of Learners model was used, along with cooperative learning and social interaction, to develop the faculty members’ understanding of IT skills and curriculum appropriate use. Recommendations for other faculties embarking on a faculty IT journey are included.

Introduction

For several years our Faculty of Education has offered short workshops introducing faculty to new software and hardware so that we can learn to use the resources and their capabilities in our research and teaching. In the last couple of years, the World Wide Web and faster processors have meant that new developments and technologies have emerged at a very fast rate, and we who are teacher educators have had to devise new ways of working together so that our program is also developing rapidly in relation to technology and its many educational possibilities. At the University of Regina, our desire to learn about and with technology was in part initiated by the context in which we work: a provincial context where Directors of Education and others have told us that schools require new teachers to be competent in the instructional uses of technology, an institutional context that changes slowly (see Maeers, Browne & Cooper, 1997) and includes students with a wide range of technological skills and abilities, and a curriculum context where resource-based learning is central. Technology is considered an important resource for teaching because of the extensive electronic on-line curriculum – located at http://www.sasked.gov.sk.ca (see Maeers, Browne, & Cooper, 1997, 1999, and Couros, SITE 2000).

Some teacher education programs in Canada have mandatory computers in education courses and some provinces require that for teacher certification purposes all students must take a computers in education course. Other countries (for example, USA) have national and/or state teacher accreditation standards for information technology. In the province of Saskatchewan we have no external technology standards.
Accreditation or graduation requirements, and this has freed the Faculty of Education to incorporate technology in ways where we see the best fit with curriculum and instruction.

Since we are well acquainted with our provincial and institutional context, some faculty members in curriculum and instruction areas have developed a vision of the technological path to follow. For example, the authors designed an action plan to be implemented over the four-year concurrent Bachelor of Education program (see Maers, Browne, & Cooper, 1999). Also, we have had supportive administrators who have seen the necessity of funding technology innovations. Our vision and action plans are more focused on the integration of technology into the curriculum, and on developing the pedagogy that supports appropriate use of technology as a resource for learning. We understand that our plans will continually undergo regular revision as technology and contextual changes occur.

In assessing what to do, we realized we had the vision, the action plan, the hardware and software resources, an efficient state-of-the-art Internet and multi-media computer lab, and the curriculum experts. These curriculum experts, however, constituted a mostly middle-aged faculty who would have to ascend a steep learning curve in order to pursue any technology vision. We lacked the technological skills to use the resources that we had and lacked the time to think through and work out the pedagogical application of our newly acquired skills. We knew that acquisition of skill knowledge would be a relatively attainable goal with these experienced learners, and that, given an opportunity to experiment with the technology resources, curriculum appropriate educational applications would follow.

Well aware of the need to create a safe space where faculty could learn the skills in relation to particular applications, the authors envisioned offering workshops where faculty could learn the skills and then immediately discuss how to apply them to teacher education situations. These workshops would be education-oriented rather than skill-oriented. For example, e-mail has been taught on campus, but we wanted to discuss with our colleagues the teacher education and school applications of e-mail, such as e-pals, electronic mentoring, and ask an expert. This teacher education focus was an important part of our workshop approach.

We used a community of learners approach to implement the faculty inservice (Rogoff, 1994). This approach is founded on a leadership which listens respectfully, takes people's problems seriously, promotes roles that are asymmetrical, and provides for a variety of learning styles and needs. This approach follows a tradition of collaboration and shared responsibility that is well established in areas of our faculty.

We debated who should teach the workshops and hiring a consultant was considered. We knew that such a person could teach the skills, but were less sure about their ability to make the connection to education and apply the skills in the specialised curriculum areas. We resurfaced the idea of having expert students teach faculty (in 1995 the authors had participated in a conference called New Frontiers for Education, a conference focused on technology in the classroom, where many conference sessions included school students as presenters). We were confident that technologically-skilled students (in this case Education students) could teach us the skills, but again, we had concerns about their ability to make the connections to education. In the latter option, we could see the benefit in discussing the educational connections together, while we learned the technological skills from them. As reciprocal mentors, we would work together on making the educational connections. Using Vygotsky's notion of social interaction and learning (Krauss, 1996), and the idea that what one can learn cooperatively today (from a more experienced learner) one can do alone tomorrow, we hoped that this pairing of students and faculty would provide both groups with the knowledge and attitudes to independently learn the skills and apply them in appropriate curricular ways.

We designed 12 workshop topics and implemented six of these in group workshop situations in the computer lab. We hired six technology advanced students and each student selected two workshop topics to research, create a handbook for, and work with us to develop a plan for how they would teach their topic to faculty. Workshop topics included: advanced word processing, advanced e-mail, advanced web searches, web page development, drawing/painting programs, multi-media authoring, spreadsheets and data bases, subject-specific software, presentation software, newsletter publication, distance education, and WebCT. The workshops were quite successful in drawing people out of their offices into the computer lab, in developing skills, and in the application of these skills to curriculum areas. The reasons for the success lie in how the faculty learned from the expert students and from each other, and in how faculty members were able to apply the learning in their courses.
The development and enactment of the faculty workshops has followed a process similar to other curriculum innovation projects in our faculty. The details of this process will be divided into three sections: developing a sense of a community of learners, understanding the necessity of invisible work, and refocusing on instruction—asking how could technology be used as an effective instructional tool?

A Community of Learners.

In Barbara Rogoff's (1994) explanation of a community of learners approach she describes the workings of an Arizona school based on this philosophy. From this experience she lists and describes several criteria for a community of learners approach. The community of learners model provided us with guiding ideas and tools for analysis as we came to understand our faculty's progress in learning about and with technology. Her criteria are italicised in the following text.

Some faculty members knew what they wanted to learn and others needed assistance in devising their learning goals. We wanted the workshops to be relevant to people's work and we wanted to foster inherent interest. One memo said "You may not know specifically what you want to learn, but you know that you would like to feel more comfortable either using the computer for yourself or using them in your classes. Please let us know if you would like someone to consult with you as to potential areas of learning." Twelve faculty members (out of a total 45) asked for individual consultations to help them decide what they wanted to learn, about twelve other faculty members listed what they wanted. We contacted those needing consultation people and helped them select, and compiled a list of everything that everyone wanted (resulting in the above 12 workshop topics). This compiled list was once again distributed to all faculty—those who had told us what they wanted requested more than they had initially stated. This list also helped some faculty who had not previously listed a topic now list one or more workshops they would like to attend. Initially 20% of faculty responded, but as lists were distributed and announcements of the individual 2-hour workshops were posted in the mailroom, 80% of the faculty attended at least one workshop, and 20% attended 3 or more. Interest and participation in the workshops evolved such that we had to offer multiple sessions of some workshops (e.g., web page design). Most of the workshops were scheduled for Saturday mornings.

The workshops were established on an invitation-to-participate basis. This meant that participation and products would vary according to participant ability and desire. No one end product was envisioned. A person might make one card of a Hyperstudio stack or 10 cards. People understood that they could come and listen, learn, and apply what they could without being evaluated.

The student experts prepared the workshop hand-outs and presented the material clearly. The authors attended all the sessions to support learning and to facilitate the discussion of educational and curriculum application. In this leadership situation asymmetry of roles was evident as the two types of experts, technology and pedagogy, conversed and learned from each other.

These were productive sessions as workshop participants, who understood the tremendous gains they could make, discussed the relevance and possibilities of technology as it related to teaching and research. People supported each other's learning, talking in dyads and group discussion, acting as facilitators for the learning of others. Student experts saw faculty supporting each other and worked with us similarly. It was a cooperative system with faculty members learning skills from students, and skilled student experts learning about pedagogy with the help of faculty. There was continuous learning for all who were and are involved as we devised and revised ways of teaching and researching with technology.

In this way people who might have seen themselves as on the periphery could attend a session, learn what they wanted to as legitimate peripheral participants (Lave and Wenger, 1991) then become part of the mainstream of technology learning.

There were a few signs of culture shock, for example, when a person expressed discomfort when one workshop was paced too fast for her sense of success. The biggest shock was during one session where faculty needed to get a particular access password in advance in order to log on to the computer lab network. Participants were told to go to the lab before the workshop to get a password. When we arrived at the workshop only one had obtained the needed password and could sign on to the system. Others had assumed that because they could log on in their office they would be able to do likewise in the lab. Most of that session was spent obtaining passwords, learning how to sign on, and accessing the lab network. It
was a vivid learning experience for everyone, somewhat frustrating, but a realistic example of what might occur when students are in the lab for the first time.

People need time to adjust to a new milieu. In the case where the attendee felt that it was too fast, one-on-one time was scheduled with one of the student experts to review the material at a more suitable pace. In the case of the workshop that was spent assigning passwords and accessing the network, the discussion focused on coping with and working through frustration and anxiety related to technology and how teachers adjust when equipment or procedures are not as they had planned. This illustrates the instructional focus on process rather than products of learning.

Returning to the notion of acting as facilitators for the learning, the three authors have further categorized (and sometimes caricatured) our roles within the faculty group. We each teach in a curriculum area and want to integrate technology into our work and the work of our students in a seamless and appropriate way. We bring complementary strengths to the process. Vi is the knowledgeable, listening, and enthusiastic leader and planner, Nancy is the supportive administrator (without a budget), Liz is often in the role of clown, adding lightness with humour when there was tension, asking hard and sometimes embarrassing questions. Vi asks, “What is the pedagogical foundation for this? Would something else work as well or better?” Nancy keeps things moving, saying, “I know how to get this started.” Liz asks “Who benefits from this? Who is excluded? Which children might be disadvantaged

In addition to Rogoff’s criteria we have identified what we call a “useful confusion” which supported our building a community of learners in a faculty of education. This useful confusion tolerates and validates a variety of definitions of expertise, a willingness to organize a wide range of learning experiences, including new ones where needed, and a willingness by those with great expertise to let those with less assume leadership functions where necessary. The useful confusion enhances our ability to work together co-operatively. However, as Rogoff suggests, cooperative learning does not imply smooth relationships; there are sometimes frustrations and in our case anger, when student experts could not get the access to memory and machines that were needed to prepare the workshops.

**Invisible Work**

We also were informed by past research which describes the “invisible work” of teacher education (Kapuscinski, Cooper, Krentz, Goulet, & Browne, 1997). Invisible work is the work which must be done to maintain a teacher education program and to ensure that it continues to develop. Invisible work includes conversation, collaboration, critique, and creativity. It is work which seldom receives visible recognition and so is not rewarded within the academic reward system. It may even bring criticism because it takes time which might be spent doing activities which are better rewarded.

In the case of this project, none of the initiators have faculty inservice or technology education as part of their job description. We teach curriculum and foundations. We volunteered to do this together when we understood the need in light of our provincial and institutional context. Organising the technology workshops, talking to faculty about attending sessions, hiring the students, planning the workshop content and schedule were all aspects of added (invisible) responsibility. Added to this was the necessity of attending the workshops to give support to learning, solving problems as they arose and facilitating the discussion on pedagogy. It was very time consuming. Many of the workshops were on Saturday mornings because of conflicting schedules Monday to Friday. For these sessions we would serve home-made muffins and coffee. We wanted to instil a sense of community in tangible as well as interpersonal ways—a community of people who gather as friends will usually serve coffee and home-made baking. Food contributed to the sociocultural comfort of the sessions. This invisible work was important to carrying out the sessions and to creating the sense of community of learners around this challenging topic.

The technology workshop also involved invisible work as the authors mediated between their vision and the realities of where individual faculty members were in terms of technology knowledge. Much of what takes place in pursuing the vision is conversation, that is voice. We participated in countless conversations planning, clarifying, re-reading, scheduling and so on. These are necessary parts
of a successful program, but they are often invisible to the dominant reward system. We continue to do them because they make us more effective.

**A Focus on Instruction**

**How to Use Technology Effectively**

We have come to understand how important it is to focus on instruction rather than on technology when doing faculty inservice. Initially, this may seem strange, it is certainly counter-intuitive. However, faculty do not want to learn technology skills for its own sake, they want to learn them to teach better, to teach student teachers to teach better, to communicate with colleagues and students, to do research more effectively, and to present projects and findings more effectively. Technology tools are highly sophisticated and what is suited to one situation may well be unsuited in another. The ongoing discussion around potential uses and what else might work better, kept the conversation changing focus between the specific skill being learned and application in various teaching and research situations. We determined that if we were going to use technology it was not because it existed, but rather because it was a superior tool to the ones we already had, or that we could see the possibility of doing something better with technology than without it.

We were also working to determine what aspects of a particular application might enable faculty members to apply and integrate technology in new ways of teaching and learning. Technology can be used in a direct teaching mode to enhance that teaching style, it can also enhance the teaching style of instructors teaching according to constructivist learning theory, and most important for our context, technology can be a catalyst in transforming an instructor's teaching style from objectivist to constructivist (see Fulton, Couros and Maeers, SITE 2000 for more information about teaching styles and technology use).

**Technology Anxiety and a Variety of Teaching Approaches**

The workshop organisers were not worried about the ability of the faculty to learn new technology skills. As experienced learners, faculty members are accustomed to learning. They have sophisticated strategies for learning new skills and connecting them with previous ideas and knowledge. We realized that some faculty members might be anxious about embarking on this personal technology journey because the content was outside their area of comfort. Shelia Tobias (1978) faced this same 'problem' when she worked with content area anxiety. She took experienced adult learners in one field (e.g., English) and put them into a completely novel situation (e.g., physics) and observed them exhibit the same characteristics of anxiety that physics specialists have in a new environment for them. She then worked with this anxiety and turned it into strength by using effective teaching strategies.

The authors worked with the student experts to develop a variety of approaches to the new content and ideas to be presented. A workshop would usually begin with an overview of the learning goals using presentation software. Thus, the participants saw how to use technology as a tool to present ideas about technology. The workshops included photocopied handouts with space to write personal notes. These handouts contained visual images of exactly what they would see on the computer screen. There were frequent short periods of intense hands-on activity interspersed with debriefing sessions for questions, problems, and extension ideas. Throughout the workshops it was considered essential that the participants see technology being used in effective ways in presentations and in the hands-on activities. We anticipated that this modeling of effective uses of technology would enable the participants to consider effective ways they could use technology.

Looking back, we see that the authors chose a diffuse model of knowledge production in providing this inservice. While this could have led to problems which accompany invisibility in the corporate structure, it also provided the possibility of instructional and political strength when the inservice was successful and felt comfortable to the faculty who were learning.
Recommendations

For others wanting to do faculty inservice around technology and WWW resources, we would recommend considering the following:

- Invite faculty to participate.
- Offer individual consultation with anyone unsure of what they want to know about IT.
- Circulate a questionnaire to gather data about what is wanted and needed. This also provides data which might be needed to gain funding from administrators.
- Keep the learning relaxed; recognise that each person has a unique technology learning path.
- Emphasise the focus on IT for curriculum purposes—to enhance teaching and learning with and through technology.
- Plan short workshops to teach some basic IT skills and discuss some appropriate ways to use technology.
- Provide a variety of teaching approaches in the workshops to enable faculty members to see many uses of technology. Provide opportunities for debriefing of questions and problems and also for discussion on how to use technology appropriately in the classroom.
- Ensure that everyone receives a handout summarising the content.
- Offer one-on-one assistance following the workshop.
- Hire students to teach faculty. They are an inexpensive and a creative alternative to hiring consultants. At a reasonable hourly rate, students might spend a couple of hours working with each faculty member to assist in designing a web site for a particular course or searching the web for sites suitable to particular curriculum topics.
- Muffins—treat your colleagues as you would your best friends—especially if they're coming out on a Saturday morning to learn new content.

Abstract: Faculty development serves as an important precursor to technology integration. There are several strategies that have proven successful in effecting changes in the use of technology. One strategy is mentoring or one-on-one tutoring. A technology mentorship program was designed to provide staff development for the teacher education faculty of a small liberal arts college. The program uses elementary and secondary education majors who are not specialists in educational technology to assist faculty with technology skills. The program is directed by the educational technology specialist and a regular faculty member. The model consists of four major stages: large group planning sessions, small group technical sessions, one-on-one mentoring sessions, and a final large group session for sharing projects designed and implemented. Faculty that have chosen to participate in the technology program decided on a specific technology integration project to implement in their classes this semester.

Introduction

Preparing teachers to use technology is a major area of concern for teacher education. If preservice teacher education is to make a difference in how teachers use technology then teacher educators must model effective technology use.

According to the Office of Technology Assessment (OTA) report Teachers and Technology (1995) too few faculty are modeling instructional methods that integrate computer technology into teacher education courses. As indicated by Ingram (1994), the missing ingredient is a college and university teacher education faculty that is sufficiently technologically literate to accomplish these goals. In a recent national survey of teacher education institutions, the best predictor of graduates' use of technology in the classroom was the actual use of technology during college training (Moursund, 1999). Although many schools reported a formal, stand-alone course in educational technology as a notable feature of their program, this design did not correlate well with technology skills and the ability to integrate technology into teaching. On the basis of these findings the report suggested that educational technology instruction should be integrated into methods courses rather than being limited to a stand-alone course.
Before faculty can model technology integration they must have the necessary technical skills. Faculty development serves as an important precursor to technology integration. There are several strategies that have proven successful in effecting changes in the use of technology. One strategy is mentoring or one-on-one tutoring. It has been used as a part of ongoing faculty development in both k-12 and higher educational settings.

Both Iowa State University (Thompson, Hanse, & Reinhart, 1996) and George Mason University (Sprague, Kopfman, & Dorsey, 1998) offer graduate courses in which instructional technology students mentor teacher education faculty in order to help the faculty members integrate technology into their teaching. Faculty in both programs report that the one-on-one approach was very effective in helping them increase their use of technology. Both projects began with a determination of faculty learning needs and goals, followed by one-on-one mentoring sessions with the graduate student and a faculty member. Thompson, Hansen, & Reinhart (1996) report the project forced the participants to devote time to learning technology. As a result of this required time the participating faculty members felt they made steady progress. Another strength of this project was the opportunity for the graduate students to address the specific needs of the faculty. In addition, Sprague, Kopfman & Dorsey (1998) report that participating faculty members enjoyed working one-on-one on their own computer where they felt more comfortable. The participating faculty members at George Mason University also reported that they felt they had made considerable progress in developing their technical skills.

On the basis of these models a technology mentorship program was designed to provide staff development for the teacher education faculty of a small liberal arts college (Milligan & Robinson, 1998). Unlike the Iowa State and George Mason University mentoring programs, this program used elementary and secondary education majors who were not specialists in educational technology. The program was directed by the educational technology specialist and a regular faculty member. Key elements of the technology mentorship program included one-on-one relationships between faculty and staff, the training of student mentors in mentoring techniques, communication with the program director in the form of meetings and e-mail journals, and a formal commitment for both faculty and students.

Model Description

The ISTE standards for preservice teachers were used to gauge the progress of faculty that participated in the original program. These standards include goals in three major areas: basic knowledge of computer operations and concepts, personal and professional use of technology, and integration of technology in instruction. During the first two years of the technology mentorship program the faculty developed skills in the first two areas of these goals. At the present time the technology mentorship program has been revised to focus on the third major area of the ISTE goals: integration of technology into instruction.

The new model consists of four major stages: large group planning sessions, small group technical sessions, one-on-one mentoring sessions, and a final large group session for sharing projects designed and implemented.
The key elements of the new mentorship program are similar to the previous model. As before, the one-on-one mentoring relationship is the primary feature of the model. In addition there are formal commitments for both faculty and students. Faculty commitments include time spent with mentors as well as time spent working on skills and projects between sessions, sharing their projects with other faculty, and participating in an evaluative interview at the end of the semester. For the students the formal commitment is in the form of a one-hour course. Course requirements include planning and implementing large and small group sessions. This will be part of the 35 hours of participation required. Other hours will be spent preparing for, and meeting in, one-on-one sessions with the faculty, developing their own technology skills, and attending mentor meetings throughout the semester. Mentors will provide updates between meetings through e-mail journals. Description of the four stages of the model follows.

Large Group Planning Sessions

There were three large group planning sessions. The program directors led the first session with an overview of the way technology has been used in instruction in the past, and a description of the new technology mentorship model. Emphasis was placed on the relationship between pedagogical beliefs and practices, and technology. The following ideas were presented for faculty consideration. Teaching with technology means we must think about both pedagogy and technical skills. Historically, technology has been used as a way to deliver instruction, as an aid to teaching, to enhance what the teacher is doing already. However, we propose another way to use technology, as it is used everyday in society, as a tool. We can use technology as a tool to challenge our beliefs about teaching and learning. Do we deliver information to students or help our students construct knowledge? Do we tell students what to do or do we facilitate their own ways of working and learning? It is time to make a decision about the way in which you will use technology in your teaching: to enhance what you already do, or to challenge you to do something different? As you focus on your pedagogical beliefs and goals you will develop the technical skills to support them.

The student mentors were the leaders of the second session because the primary purpose of that session was to inform the faculty of the abilities of their students. The mentors presented their own projects from the educational technology class that all education majors are required to take and from other educational technology courses and experiences. One technology mentor shared her web-based instruction on file management that she had created as a technology mentor during a previous semester. Others presented activities and lessons using spreadsheets, databases, HyperStudio, and PowerPoint. They also shared the departmental web page and the syllabus from the educational technology class, focusing on Internet sites for professional resources and organizations.

The final session focused on what other programs and institutions are doing to integrate technology into teaching. In addition to the review of the literature discussed earlier in this article, the project directors shared specific ideas from a variety of educational disciplines, including student assignments as well as faculty presentations. After this session, faculty were asked to consider a single course in which they wanted to
integrate technology. Planning sheets were provided to assist them in deciding what integration projects might be possible for them. The planning document included questions regarding the course in which they would use technology, ideas for use in instruction, ideas for use in student assignments, the software or technology they might use, and any additional needs they would have to implement their project. Faculty that chose to participate in the technology program decided on a specific technology integration project to undertake this semester.

Small Group Sessions

On the basis of the planning documents that were turned in by the faculty, three small groups were formed. The mentors led sessions for each small group. One mentor developed a session on using Netscape Composer, one mentor led two sessions on Internet searching skills, and another mentor worked with the faculty who wanted to learn PowerPoint.

Mentoring

Following the small group sessions, the mentors began working individually with faculty on their projects. Three faculty have chosen to develop web pages and put course syllabi and other teaching materials online. Three other faculty members have chosen to work with PowerPoint and develop electronic presentations for their courses. One faculty member has decided to learn about moderating listservs and will set up a listserv for a regional professional organization.

Project Sharing

We are currently planning the process by which faculty members will share their project with the department. This may be in a large group session or via special web pages. Evaluation of the program will be conducted using student journals, program director journals, and faculty and student interviews.

Conclusions

As you will see in the words of the students, they have started the program with enthusiasm. “We have some great opportunities in front of us. I am very excited about this.” They are already experiencing the benefits of sharing knowledge and learning about teaching. “I was extremely nervous about this presentation. I couldn’t sleep the night before. It was the most nervous, I have ever been, but then it was the least. It’s hard to explain – I think the fact that because I’m so comfortable with using technology helped me get through this presentation. I realized that I was there to provide information of which the faculty didn’t have knowledge. That gave me a confidence I don’t think I’ve ever experienced before.” Most importantly students and faculty are building
relationships from which they all will grow. "The part most beneficial to me is the relationships that are forming. In that area I am very pleased and learning a great deal. I knew that I was going to enjoy doing this, but it has gone beyond my expectations. That is very good." Professional development is ongoing, and it is going on here with this mentorship program to integrate technology into instruction.

TECHNOLOGY MENTORSHIPS IN HIGHER EDUCATION:
AN OPTIMAL MATCH FOR EXPANDING EDUCATIONAL
COMPUTING SKILLS

Dr. Sally R. Beisser, Ph.D.
Effective Teaching, Drake University
Des Moines, IA USA
sally.beisser@drake.edu

Abstract: Mentoring relationships to invite higher education faculty to learn educational computing skills on a one-to-one basis are an "optimal match". An optimal match involves a carefully constructed personal learning experience accommodating the inevitable differences in learning. An appropriate match builds connection with the circumstances that learners encounter and the schemata that they assimilate into their professional repertoire. Faculty technology mentorships build trust between participating individuals in order to implement new skills in non-threatening, meaningful ways to build personal knowledge and skills, to integrate new learning in a professional context, and to reflect on the learning process. Results from a specific technology mentoring experience are described in this paper including the perspective of both the mentor and the mentee.

Lack of University Education Faculty Leadership in Technology

An inadequate number of teacher education programs have faculty who are modeling instructional methods that integrate computer technology (Handler & Marshall, 1992; Office of Technology Assessment, 1995). Teacher training programs must recognize the need for training in technology, taught either in a specific class or across the curriculum. While scholars have advocated integrating technology in both methods and foundation courses (Berger & Carlson, 1988; Billings & Moursund, 1988; Bitter & Yohe, 1989) coursework needs to be redesigned to integrate technology in relevant contexts. Computer technology should facilitate content learning from carefully designed course goals and objectives which, then, can be developed using appropriate technology-based activities and practices (Todd, 1993).

New teachers learn to teach the curriculum using the technology they have already learned or have seen modeled in their college classrooms. Without faculty role models to observe in methods courses, preservice teachers are deprived of opportunities to witness models for teaching with computers (Bruder, 1989; Fulton, 1989, Beisser, et. al., 1997). According to Wetzel (1993), most college professors simply do not use it, in spite of adopted competencies that education majors should learn how to use computer productivity tools for effective instruction, and how to demonstrate those abilities.

The International Society for Technology in Education (ISTE) and the National Council for Accreditation for Teachers (NCATE) have established Foundation Standards requiring competencies to use and to evaluate computers and related technologies. Learners must operate software, multimedia and hypermedia, and telecommunications to support instruction. They must demonstrate skills in productivity tools for personal and professional use, understand equity, ethical, legal, and human issues related to technology; and stay current in educational applications of computers and related technologies. Despite ISTE/NCATE Standards first initiated in 1991, many universities have not adhered to these guidelines nor have they taken leadership role in this movement (Wilson, 1995).

This poor response to technology may be influenced by the fact that many college of education faculty, themselves, lack requisite skills or experience to model teaching techniques using computers in their areas of expertise. Therefore, it is necessary for them to receive personal assistance in learning how to use computers, as well as implementation of computer technology in their respective courses. Using graduate students to mentor college of education faculty has been shown to be an effective technique for integrating technology into the course work of preservice teachers (Brewer, 1995; DeWert & Cory, 1996; Thompson, Hanson, & Reinhart, 1996; Thompson & Schmidt, 1994; Zachariades, Jensen, & Thompson, 1995; Zachariades & Roberts, 1995, Beisser, Kurth, & Reinhart, 1997).
Background

A technology mentorship program developed at Iowa State University involves a one-to-one experience inviting faculty members to work with graduate student mentors as part of a long term department effort to improve faculty competencies and confidence (Thompson & Schmidt, 1994). Although mentorships last one semester, educators need much more time to fully implement goals and objectives using technology in the instructional process. Experienced computer-using teachers require five to six years to develop a framework for effective use of technology in teaching (Sheingold & Hadley, 1990). The paired mentoring experiences helps university faculty to learn and reinforce skills. University faculty members who volunteer for this semester-long experience are encouraged to introduce technology into their respective courses in a meaningful context.

A mentorship match begins with pairs of students and faculty assigned to work together. The mentorship involves weekly meetings and an established agenda. Crucial to the task, is the successful pairing of individuals willing interact regularly in order to develop technology skills and experiences in teacher education. Pairing should be an “optimal match” (Hunt, 1961), whereby both mentor and mentee are willing to engage in carefully constructed personal learning experiences reflecting the inevitable substantial differences in rates of learning. The appropriate technology-driven circumstances encountered by the mentee and mentor should match the schemata of the faculty member. The experiences assimilated into their professional repertoire must build trust between the two individuals in order to implement new technology skills in a non-threatening, meaningful way. The goal of the mentorship is to provide personal knowledge and skills, to integrate new learning in a professional context, and to reflect on the learning process.

Key Factors in Developing an Optimal Match

Learning is a sequential, developmental process. The development of skills, understanding in domains of knowledge, and strategies for solving problems are acquired gradually in sequences that are more or less predictable (Hilgard & Bower, 1974). Effective teaching involves a sensitive assessment of the individual’s status in the learning process, as well as a presentation of problems that slightly exceed the level already mastered. Tasks must be neither too-easy nor too-difficult to understand. Hunt (1961) describes this as the “problem of the match” which is based on the principle that learning occurs only when there is “an appropriate match between the circumstances that the learner encounters and the schemata already assimilated into his repertoire.” In other words, “teaching must start where the learner is (Hunt, 1961, p. 268).” The pace of educational programs must be adapted to the capacities and knowledge of individuals (Robinson, 1983). Mentorships provide an opportunity for starting with the learner’s experience and for progressing to exceedingly higher levels of complexity.

Elements of “joy” must be a part of an optimal learning match. Engaging, collaborative, complex, intellectually invigorating learning situations reflect elements of joy in order to sustain efforts (Csikszentmihalyi, 1990). Mentorships allow learners to confront tasks they need and want to complete together. A successful mentor pair must concentrate on mutually-determined regularly scheduled activities. The pair may establish clear goals for the tasks before and during each mentorship session or may freely explore ideas that emerge into an agenda. The intimacy of a private mentor learning experience allows immediate feedback through internalized criteria, trial and error, or explicit responses. They act with a deep yet effortless involvement, removing awareness of other worries and frustrations of everyday life. Both members exercise a sense of control over their actions. The concern for the self disappears, yet paradoxically, each member experiences a stronger emerging sense of self after the experience is over. For example, a scheduled hour of time seems to pass by in minutes (Csikszentmihalyi, 1990).

Mentorships, as an optimal match, account for the needs of the learner. Such a mentoring pairing program may facilitate the development of basic technological competencies, implementation of technology in college course goals and objectives, and reflection of the mentoring process. However, the success of any mentoring relationship is dependent upon several key factors. A successful mentor relationship is dependent upon a developmental, multidimensional relationship (Clemson, 1987). “Spontaneity and personal fit” invites mutual choice for mentor pairs to work together (Clemson, 1987, p. 86). Both participants in a mentoring program should have the freedom to choose one another. Both the mentor and protégé should benefit from the relationship (Clemson, 1985). Mutual respect and trust (MacArthur, et. al., 1995; Clemson, 1987) and mutual participation (Kay, 1990) are key factors. Open dialogue between mentor and protégé allow each participant to express their feelings, talents, knowledge and expectations (Gehrke, 1988). The more success factors present in a mentoring relationship, the more beneficial the relationship will be to each of the participants.
The Mentorship Experience

Carol M., an Iowa State University reading language arts instructor, volunteered for the semester mentoring experience. Her background included no formal training in technology, little experience using computers in personal or professional work, therefore utilizing the computer primarily as a word-processing tool. Her college teaching experiences included work in a small private college without much technical support or encouragement for using technology in teacher education. At a Midwestern public university she now has exposure to skilled faculty peers and eagerly sought a mentorship experience during her first semester. The following excerpts were from reflective journals maintained throughout the semester.

The Mentee's Perspective: Building Personal Knowledge and Skills

"On the first day, we made sure my e-mail was operating and set up my e-mail address book. I made a file folder called 'Sally' for communication with my mentor. We labeled [Eudora Pro 3.1.18] icons and changed them to labeled words. We switched them from the horizontal to vertical and reduced the size to be more accessible and practical. I also learned what they meant. Some I had known before this, but not all. I wanted all of my college classes to be on e-mail. I didn't know how to do that. I was thrilled today when I was able to send all my class an e-mail without highlighting each name separately. Sally had left a great message that enabled me to highlight by holding down the shift key. Hurrah!

We started Power Point®. My assignment for next time was to do several slides that I could actually use in class. Sally said she would show me how to "take them on the road" electronically. I am excited about this new aspect of computer technology application!

I felt very good as yesterday I accessed Power Point and started a presentation. I used the automatic method but still have a number of questions such as: How do I get to see what I've done? How do I change backgrounds? I am anxious meet with Sally today! I was very excited today when I was able to figure out how to add slides, pictures and text to those slides in Power Point®. I changed my printer port to a new printer, conveniently located in our office, and it worked! Sally left great instructions on how to do that. She also left me a message on how to access my class list and send a group e-mail.

So funny! Today I couldn't even remember what the shift key was called! The brain functions differently under pressure, especially when you feel inadequate about the content area - it doesn't work even with things that you know! When I struggled for the word, Sally whispered the word "shift key" to me. This was real HELP!

I am now up and running with e-mail to my classes. I have sent several whole class messages and a number of students are corresponding urgent needs via e-mail that could not have been taken care of otherwise. (This is using the media as it is intended - I love it! Real individualized attention too).

Next I learned about borders and shading, finding files, labeling disks, justification, alignment, and page preview. We started on templates, but will finish next time. Between now and then I will make sure I have the format just right for what I want made into a template. I usually hand out a paper to be filled in and handed back. Using a template will save paper and time. I will ask that the students access it and return the completed assignment through e-mail. No paper should be used. I will tinker with what I learned today.

My computer monitor quit today. After I had tried to re-start it, I asked my office mate for help. She couldn't diagnose the problem, so we called Lance, the technical specialist. Meantime she taught me the "paper clip trick," a "trick of the trade" to get my disk out of the computer. She bent a paper clip and inserted the straight end into the small hole just beneath the disk hole. The disk jumped right out! Hurrah! Lance responded within 15 minutes to my phone message. He determined that my monitor had died. He said not to worry as it was an old one and it happens. He went right down and got me another one and it was up and running immediately. What service! I was so relieved that I had not 'killed it.' Such thoughts promote computer phobia!"

Integrating new learning in a professional context

"Today was 'D' day because I decided to use Power Point in class. It was my first time using it to produce and present a lesson. In a relatively "safe" environment, I was able to think on my feet, process the steps to hook up the technology, and take it down while I was lecturing and interacting with my students. It went very well and I was amazed that I actually could do all of that at the same time.

I checked out the LCD panel, took the laptop, and went out into the real world ALONE! I went to my empty classroom before class and carefully set up everything by myself. I let the class know that this felt similar to their reading/language arts practicum. I, too, had butterflies and fear that things might not work. They asked me to
go back to one of the slides and I never had done that before, so I just pushed the back arrow and it worked! Yes!
Problem solving is always a big deal when under pressure. I honestly felt that I could have used regular overheads
with the same effect without all the hassle of toting heavy, very expensive equipment in a room so dark.

Fun time with Sally! I was able to make my Power Point scroll or change slides using various styles and
rates. It was so simple and I think it really improves the presentation by making it a bit unpredictable (nobody goes
to sleep). I will enjoy trying it in my class. I was reminded how to get rid of files, folders etc.

I also learned about a program called ‘Inspiration®’. I am so excited about it as it goes right along with
webbing and mapping that I am doing in my classes. It is a real graphic organizer that will certainly help us with
our work. Once I am familiar with it and feel “safe” I will reserve a computer lab to show my students. I accessed
theme units through the Internet search engine Alta Vista. I printed several pages and made overheads of them so
that I could show my two classes what was already done on themes. For beginners it would help to have such an
organizer. Some students already were very literate about this [Alta Vista], but most were not and were encouraged
and thought it helpful.

What a riot! Neither Sally or I could find how to shut off my computer. Even after we called the computer
guru’s office they only could say, pull the plug! I had to get on my stomach on the floor to get at the plug. I like
Sally’s ability to say ‘I don’t know’ and then seek to find a way or ask someone.”

Reflecting on the learning process

“I decided today that there wasn’t as much carry-over into the real world of usable technology as I’d
hoped. I was beginning to feel frustrated again. I am going to keep a little notebook next to me when Sally is
teaching me, so that I can write down exactly what steps were taken to produce the needed effect/product/site, date
them and then try the steps when Sally isn’t there.

I have concentrated on the goal of learning IN MY WAY. I learn best visually, then write ideas down and
try it from my notes. Under pressure I really “down-shift.” It takes me MUCH longer to learn (if I really ever do!).
Most of the time I just muddle my way through it and then finally somehow get an end result, but have no idea how
to replicate it. I am always just glad to be done and not to have looked like an absolute fool.”

Reflections of the computer technology mentorship

“I am not intimidated by the computer any more. I no longer feel I might ruin the computer, nor am I
afraid I will break something. I was worried I would display my ignorance to humanity. I felt the consequences of
not knowing were great...especially in the eyes of others—I felt I was losing information in the fast-growing
educational technology field at an alarming rate. The mentorship provided instruction and interpretation in a
meaningful way. This mentorship helped to bridge the gap. The mentorship was a match for my learning style. I
was able to take risks and pursue new ideas. This is very important. Sally was able to adapt to my learning style
and make technology important to me. In the absence of threat, I was able to reduce to a low level of stress and
engage in new learning that was of benefit to my teaching immediately!

The purpose of a mentorship is to scaffold—to build meaningful experience (Vygotsky, 1933). I liked
Sally’s role as mentor. She operated under, ‘I’ll be there for you...Your level of progress is your own. Your rate of
learning is OK...I have no expectations for you!’

I needed new skills in small increments. I needed time to process those skills. I needed hands-on
experiences. I don’t do well with “tell me.” I’ll lose it otherwise. The regularly scheduled weekly hour was
perfect. I knew this was my time to ask questions, to bring my concerns to Sally. It didn’t encroach on faculty
time. We agreed on “our time” together. There was a starting and ending time. This was a safe environment.

In summary, I’ve learned that just a little information to open up a vista of opportunities. There was so
much I didn’t know. It has been a great rapport builder with my students! They have thanked me for the personal
attention I have learned the power of Power Point®. I imagined uses and can now explore new uses for meaningful,
interactive presentations in class. It added ‘class’ to my presentations. It has given me vocabulary and new
language. Knowledge is power! You hear so many computer terms thrown around...file, folder, attachments, disk,
server, upload, download, etc. I can not only name but now use technology terms. I learned in privacy, not in a
class or a workshop. We had a chance to talk and to relate this to my personal and professional needs.”

The Mentor’s Perspective: Building Personal Knowledge and Skills
"Our mentorship began by establishing 'spontaneity and personal fit.' This was a mutual choice for us to work together as mentor pairs (Clemson, 1987). I provided Carol with the freedom to ask any question, figure things out on her own, and establish new skills with technology in her teaching and communication. Indeed, she has learned new skills in technology. In summary, she has learned specific functions of e-mail, word processing programs, files and folders, and management of information on disks and the hard drive. She learned about Power Point® software within the context of presenting content, not as a substitute for overhead transparencies. She practiced using a laptop and LCD panel to present her program to various audiences.

Using Inspiration 4.0® software for brainstorming, she increased the skillfulness of her students using graphic organizers. She searched the Internet for information, bookmarked valuable websites, ordered books from http://www.amazon.com, and learned about technical terms. She was introduced to Hyperstudio® as an authoring tool and has not only begun to experiment with it, but has a useful purpose to create a stack of book sharing slides from each of her students. Last but not least, she learned how to turn off her computer by crawling under her desk. Clearly, her reflective journaling describes not just what she learned, but the ways in which she learned. I see that she is figuring out solutions to problems on her own."

Integrating new learning in a professional context

"In the process of learning new skills, Carol acknowledged that autonomy and self-reliance were powerful learning tools. Her journaling gradually progressed from episodes of needing help, asking for assistance, and calling the department experts to making attempts to solve problems herself. She began using more specific technology vocabulary and credited herself with learning and using skills.

An "optimal match" is based on the principle that learning occurs when there is an appropriate match between the circumstances that the learner encounters and the schemata already assimilated into his repertoire (Hunt, 1961). Beginning with conversations about her experiences and needs in using computer technology in teaching and learning, we began with her level of interest and progressed gradually to exceedingly higher levels of complexity. The pace of Carol's technology mentorship was adapted to her capacity and knowledge. (Robinson, 1983). Carol did not learn skills in isolation. To learn Power Point®, she compared Vygotsky and Piaget to illustrate methods of teaching reading. To learn Internet search skills, she found thematic units and ordered literature online. To communicate with her students, she used e-mail, word processing, and various software programs."

Reflecting on the learning process

"Hawkridge (1983) summarizes that schools primarily adopt technology for social and vocational purposes to be sure learners are aware and unafraid of using technology. They know students should understand computers and their role in society. They want students to implement technical skills for employment in the twenty-first century. While Carol began the mentorship semester with social and vocational goals in order to overcome a perceived lack of skills, she finished the semester, using technology skills as teaching tools to influence the quality of learning in her classroom.

Hawkridge (1983) states that few schools implement technology with a pedagogical rationale in an effort to understand that there are known advantages to using computers in learning as compared to traditional methods. Fewer still use technology with catalytic rationale hoping to reform teaching practices or to make desired changes in student learning.

Carol's final product, a Technology How-To Notebook, archived her new technology skills and interesting ideas from our mentor experience. She has entered process steps in order to help her remember what she has accomplished. Next, she noted an application of each new skill to her Reading/Language Arts teaching and learning. Entries are dated in the order that she learned them during our mentoring sessions. They are for her, 'real life' experiences that fit her schemata of learning in an optimal learning match."

Conclusions

In reality many teacher preparation programs do not have sufficient faculty support in order to use technology in teacher education preparation. Encouraging teacher education faculty to use technology in teaching and learning is possible using effective mentoring as an optimal match to increase technological competencies. One-to-one mentorships can provide cost-effective, personally-rewarding experiences for faculty with motivation and freedom
to progress at their own pace. A mentorship team can explore and investigate responses to individual technological needs, address challenges of complex and open-ended problems, and rely on inquiry and invention.

As Harrington (1991) suggests, there is a difference between preparing teachers to use technology and using technology to prepare teachers. If we only prepare teachers to use technology, we limit the conception of the role of technology in education. University-level education faculty must be empowered to take more responsibility for both acquiring technological competencies in order to improve the capabilities of their preservice students.

Constructivistic Learning: Also for Faculty!

Simone Terwindt
Amsterdam Faculty of Education
s.m.m.terwindt@efa.nl

Abstract: The Amsterdam Faculty of Education is developing and implementing a new curriculum concept for professional education, for which it attained the status of “the experimental teacher education in the Netherlands” in 1997. This concept, fitting in the constructivistic learning paradigm, is nicknamed ‘learning through producing’. The concept does not only yield a vision on learning processes, but also an implementation strategy. By basing the professional development of the Faculty of the Institution on the same constructivistic principles one induces a transformation of both the curriculum and the organization. The result of this transformation should prepare both students and Faculty for the information age. ICT plays a role as catalyst in this complex transformation.

Introduction

This short paper will focus on the implementation strategy towards Faculty members and the Institution. The professional development on these levels uses the mirror principle of congruence: use the same concept of learning and education as the one you use for students.

Quality care in an institution is dependent on the way one succeeds in arranging learning processes for Faculty and Organization. Lifelong Learning is not only the future of a student, also the Institution must show the skill to keep developing itself using learning goals and learning action plans. At EFA we use the metaphor of "The Expedition" for this way of life in the Institution.

The mirror effect of congruence concerns the following central elements of the educational concept:
- constructivism (learning through producing; authentic learning tasks, resources of knowledge and skills)
- learning cycles: orientation, planning, execution and evaluation
- responsibility for one's own learning processes (integrative assessment, digital portfolio system)

The effect is also connected to some corollary elements:
- the teacher as coach
- collaborative learning
- information and communication technology

An extensive presentation of these basic ideas can be read in the SITE 2000 paper "Proving Competence: Integrative Assessment and Web-based Portfolio System in a Dynamic Curriculum", by Douwe Wielenga. We will not repeat that information here, but for the figure on the next page.

The mirror

We see the improvements in the quality of the programs' components as a learning process of the Amsterdam Faculty of Education itself, both on the level of the teacher educators and on the level of the institution. This makes it possible to mirror the model, concepts and facilities we use to facilitate the learning processes of the students on the learning processes of teacher educators and the institution!

We see the professional development of teacher educators as a continuous learning process, which follows the same phases as the learning cycle of the students. See figure 1 on the next page.

We are in the process of collaboratively describing the professional competencies that teacher educators need in the new concept of curriculum, we are using the same portfolio system for teacher educators that our students use, and we are thinking about possibilities to organize integrative moments of assessment where teacher edu-
cators have to show to their peers their growth on the desired competencies. In the last two years the development of new learning practices is already organized in a way that is both a process of development of new learning environments and learning materials and a learning process of the teacher educators that carry out this development. In this learning process experts are coaching Faculty on new learning technologies and peers are assisting them in formulating learning goals connected to their innovative productive work and connected to the desired competencies.

The same model can be used on the level of the institution. The expedition towards a more dynamic curriculum must be seen as a learning process. We have defined our learning goals as the main aims of the project. We use a portfolio to keep record of the development within the Faculty, of the results and experiences, and to prove our growth to the outside world. This portfolio registers products, reflections, and comments from people outside EFA. These reflections are often based on action research by Faculty and by academic research that is carried out by independent research institutions, commissioned by EFA. The management of EFA is coached by a group of experts on education and ICT, and we plan to organize external audits, which will act as integrative moments of assessment. In this way both the institution as a whole and the teacher educators individually will have to act as role models for the students.

Examples

During the SITE 2000 session the congruence on learning concepts will be shown using two examples of constructivistic learning by Faculty:

1.

The first example concerns an expertise center for curriculum development, where Faculty, relieved of their teaching duties, work on a specific curriculum development project and, at the same time, through this work acquire new knowledge and skills. As part of their development assignment Faculty heighten their expertise on subjects like the design of digital learning environments, self directed education, or collaborative learning. In this process another person is coaching them. This approach must result in a significant reduction of resistance to change. In the presentation we will show the details of this learning process and the dilemma’s that we encounter.
2. A second example is about the professional development of those members of Faculty who are responsible for the implementation of a brand new system of integrative competence assessment of students at the Amsterdam Faculty of Education. These persons develop their knowledge and skills in this area by producing innovative materials for assessment. Following questions that arise hereby they start research, consult experts or take part in demand driven training sessions that they think they need for their development work.

Information in the English language on the expedition of the Amsterdam Faculty of Education can be seen at the Publications part of the home site of EFA: http://www.efa.nl
Building a Vision for Technology Integration

Ann H. McCoy
School of Education
University of Alaska Anchorage
U.S.A.
afahm@uaa.alaska.edu

Abstract: Students have few opportunities to observe faculty using technology in courses and more rarely use a wide range of technologies in the classroom. This report examined data gathered to determine the state of faculty technology use for teaching and learning. Expectations of faculty for students to use technology, barriers and possible solutions to achieving technology integration in teaching and learning were examined. Three goals for further development of technology integration were established. 1) Preservice teacher education courses will be redesigned to reflect best practice and include the infusion of appropriate technology throughout. 2) Faculty will have the training they need to successfully integrate technology into their courses. 3) Students will have experiences that enable them to demonstrate effective and appropriate use of technology based on ISTE/NCATE standards. A plan was developed to build a vision for technology integration. Strategies for faculty development and program development were identified and implemented.

Introduction

The State of Alaska has been improving education through its Quality School Initiative. As part of this initiative, teacher education standards were developed and adopted as regulation (AK DOE, 1997). In September 1998, the State Board of Education adopted the National Council for Accreditation of Teacher Education (NCATE) standards and entered into a state partnership with NCATE. UAA is participating in the transition plan leading to required NCATE accreditation for approval of all Alaska teacher preparation programs by 2002. The University of Alaska Anchorage School of Education is reviewing and revising its teacher education program to meet these standards.

The University of Alaska Anchorage (UAA) is one of three state universities in Alaska. The University of Alaska system is aware of the importance of technology support for education. UAA implemented a system wide technology initiative and invested resources into developing an infrastructure of modern information technology that includes hardware, software, and training. The School of Education (SOE) continually upgrades its technology. All faculty offices and all computers in the SOE computer lab are networked into the campus backbone. All permanent faculty and staff members have multimedia-capable computer stations in their offices with 17” monitors and Ethernet connections. Grants have provided SOE faculty with professional development opportunities and support materials. School of Education has shared full time technician support (Macintosh and PC) with other departments within the College of Health, Education, and Social Welfare. To support the use of technology in the academic programs within the SOE, a student technology fee is assessed on any student taking any SOE course on the UAA campus. The implementation of this fee has resulted in the availability of modern technology resources and support for students. Students have access to multimedia computers, color scanners, color printers and other equipment in the SOE computer lab. A lab technician is always available while the lab is open to assist students. As part of a continuing effort to improve the integration of educational technology in teacher education, a needs assessment was conducted in the School of Education to determine the state of faculty technology use for teaching and learning.

The Study
Sixteen permanent SOE faculty members were interviewed in April 1999 to determine areas of strength and areas of need. Faculty were asked how they integrated technology in their teaching and their expectations for student use of technology in their classes. The Teacher Educator Integration of Technology Skills, Concepts, and Standards into K-12 Teacher Education Programs instrument (McCoy, 1998) was used to gather quantitative data. The questions were based on the ISTE/NCATE Foundation Standards (Thomas et al., 1997) and the types of integration as identified by Teachers and Technology Making the Connection (OTA, 1995) as supportive of technology integration. Quantitative data were analyzed with the Wilcoxon Matched-Pairs Signed-Ranks Test using SPSS. Areas of strength and areas of need were identified. Qualitative data were gathered as faculty defined the barriers and identified needs to be able to integrate technology in their teaching and learning. Data analysis was inductive. The results were presented to the administration in a SOE Education Technology Use Report.

Findings

All faculty members interviewed have used computers for a long period of time. Previous studies have shown that length of use does not necessarily lead to greater integration of technology in teaching. Other factors, including computers with Internet access, on-site technology support, time needed to use computers, training, access to adequate hardware and software, and opportunities for faculty to see multimedia computers used effectively to support teaching and learning are needed for that to occur (OTA, 1995).

The survey found that faculty expect students to use word processing and telecommunications. Most do not expect students to be able to operate multimedia computers or to use technology in learner centered classrooms. Only a few faculty use local, state, and national technology standards in their teaching.

Students have few opportunities to observe faculty using technology in courses. They rarely have the opportunity to use a wide range of technologies in the classroom. Lack of facilities, a smart classroom or laptop computers with a projector; limit the methods of technology use available to faculty.

All faculty members mentioned lack of time as a major barrier. On-site technology support, time needed to use computers, training, access to adequate hardware and software, and opportunities for faculty to see multimedia computers used effectively to support teaching and learning were all found to be significant areas of need. Most faculty stated that professional development opportunities have not been available at a time and in a manner that is appropriate for their learning. Many lack knowledge of how to use available hardware and software.

Expectations for Students to Use Technology

The needs assessment found faculty expectations for student use of word processing, communication and on-line resources, and computer-based technologies (including telecommunications) to access information (27% of survey items) to be areas of strength. Seven out of eight remaining items (64% of items), generally those skills needed to operate a multimedia computer, to use technology as a tool in a learner centered classrooms and those technologies which support different learning styles and needs were found to be significant areas of need. Faculty expectations for student use of technology do not prepare students to meet ISTE/NCATE Foundations in Technology for all Teachers nor the Alaska Teacher Standards. Faculty are not providing models of appropriate technology integration for their students.

Support for Use of Technology

School of Education faculty described the support they receive from the university. One item (17%), a computer with Internet access available at work, was found to be an area of strength. The other five items (83%): on-site technology support, time needed to use computers, training, access to adequate hardware and software and opportunities for faculty to see multimedia computers used effectively to support teaching and learning were all found to be significant areas of need. When universities provide these support items, faculty are more likely to integrate technology into their teaching (OTA, 1995).

Barriers to Integration of Technology into Teaching and Learning
Several themes emerged as faculty identified the barriers that kept them from integrating technology in their teaching and learning. They cited lack of time, lack of facilities, lack of technical support, and equipment issues as major reasons they do not use more technology in the classroom. Curriculum issues, as well as, administrative issues, training, and budget comprise other barriers. They also often found it difficult to coordinate work with other departments on campus.

Training needs are not currently being met for a variety of reasons. Faculty development classes are scheduled at an inconvenient time, are not on topics of interest to them, or are in formats they are uncomfortable with. Providing professional development in a variety of ways would serve them better. Many would like to learn "as needed" while others would like help with specific subjects. They asked for a faculty workroom where they could learn informally from each other, prepare materials, and learn in small groups. They would like to learn how to use the software that is available to students in the computer lab. They would like to know more about how to incorporate technology into the K-12 classroom and into their teaching.

Faculty Needs for Incorporation of Technology into Teaching and Learning

When asked what they needed to be able to use technology for teaching and learning about half of the faculty identified laptop (both Mac and PC) computers. Other items requested were high-end computers, color printers, access to digital equipment and the same software that students have. They would like readily available technical support for both hardware and software, for distance course development, and for development of web pages.

UAA SOE faculty report they have not seen technology being adequately and appropriately used in the K-12 schools that they visit. The status of technology in the Anchorage School District impacts this proposal because the UAA SOE places students in local schools for practicum and student teaching experiences. To meet NCATE standards preservice teachers need to use technology throughout their teaching experiences.

Hardware and Software

Faculty members developed individual lists of hardware, software or other support needed to facilitate incorporation technology into their teaching and learning. About half of the faculty identified laptop computers (combination of both Mac and PC), with mobile projection units to use in smart classrooms, as equipment they need to incorporate technology in their teaching. Some would like equipment for students to check out to use in the field. E-mates (no longer made) or something comparable that is practically indestructible.

Faculty asked for a variety of software applications. In addition, they felt is was important to have the same software that their students have. They would like to be able to read any documents they receive. They would also like to have technology support for whichever platform they choose. They would also like to be able to access their work computer at home.

Faculty Development

Training needs are not currently being met. There are a variety of ways to provide professional development. Many would like to learn "as needed" while others would like specific subjects. Some would like coaches to work with them. They would like low key demonstrations of capabilities of things we have available in the SOE. They would like training to use digital equipment. They would like training to learn to use a variety of different software applications.

They would like a faculty workroom where they could learn informally from each other. They would like the opportunity to meet with others in their field at regional and national meetings. They would like to know more about how computers and technology are being used in the K-12 classrooms as well as how to use elementary software and have time to practice.

Technical Support

Technical support is very important. They would like readily available support for both hardware and software that is accessible when needed. Faculty would like more ready access to technical person for help with
software problems on an as needed basis. They would like support for distance course development and for development of web pages. They need technician who comes in to office in a timely manner, to troubleshoot and stay until problem is fixed, and a choice of what is updated. They would like to define what they need and have technical services provide it.

Facilities

Many faculty are not aware of what is available to students in the SOE Computer Lab. They would like a tour of the lab and the opportunity to learn to use the hardware and software students have access to. The School of Education will be remodeled in the summer of 2000. The faculty are interested in developing classrooms that will promote the integration of technology in teaching and learning. When the new classroom is designed, faculty would like PowerPoint capable hardware in every classroom, video capability, a smart room with anything that is appropriate for the subject matter being taught, and videoconferencing capabilities.

Other Support

Everyone needed time for learning, for course development, and for technology related activities. There is also a need for a technician to assist with online course development, course revisions, and web page development. They would like help getting courses online and a secure spot (server with course management software) to house them. They would also like the technology funds to be allocated to the SOE to the same extent they have been allocated to other departments. The greatest need seemed to be TIME and assistance as needed.

Conclusions

The Office of Technology Assessment of the U.S. Congress published a report in 1995 called, Teachers & Technology: Making the Connection, which found: “To use new technologies well, teachers need more than just access to these resources, they also need opportunities to discover what the technologies can do, to learn how to operate them, and to experiment with ways to best apply them in their classrooms.” The report recommends avoiding the common approach of “short-term, one-shot training to familiarize teachers with a specific application or encourage general computer literacy” in favor of more long-term training that centers on the relationship between technology and the teacher’s role. “Helping teachers effectively incorporate technology into the teaching and learning process may not only help students become competent technology users, but may also help them become more accomplished learners overall, with skills necessary for the 21st Century Classroom (1997) that highlights the impact of technology on society and the importance of redesigning teacher education programs to prepare teachers for the new demands of the classroom.

Recommendations from the UAA SOE Faculty Technology Use Report included the need to provide adequate technical support; to involve faculty in technology planning and design issues; to provide a variety of training opportunities in several formats; to upgrade hardware and software, to provide equipment for classroom use of technology and to provide time and administrative support for the integration of technology into teaching and learning.

A plan was developed to help faculty build a vision for technology integration into teacher education. Strategies for faculty development and program development were identified and implemented. Three goals for further development of technology integration were established. They include: 1) Preservice teacher education courses will be redesigned to reflect best practice and include the infusion of appropriate technology throughout. 2) Faculty will have the training they need to successfully integrate technology into their courses. 3) Students will have experiences that enable them to demonstrate effective and appropriate use of technology based on ISTE/NCATE standards.

Models for faculty, and program development were designed. The models did not focus on the isolated acquisition of technology skills, but concentrated on the rationale and strategies for integrating technology across the curriculum. They were designed to provided faculty an opportunity to experience collaborative,
problem based learning. The models were incorporated into a successful Preparing Tomorrow's Teachers to Use Technology Capacity Building Grant. They also support technology integration in a successful Alaska Partnership for Teacher Enhancement Grant.

**Faculty Development Model**

Faculty will have the training they need to successfully integrate technology into their courses. A community of learners (COL) will be created to help all members of faculty realize the need to take responsibility for integration of technology and to help them acquire the skills and attitudes needed to infuse technology into the curriculum. The faculty will be invited to join the community of learners, as they are introduced to a new "work room" and provided information about faculty development opportunities. Faculty will become comfortable working in both an on site and an online collaborative environment. To meet the diverse development needs of the faculty, several types of learning opportunities will be developed, including online and CD ROM materials developed by our partners, as well as, one-on-one sessions provided by the ACT 3 methods faculty member. Apple Computer will provide online professional development opportunities that will allow the faculty to complete courses in applications and integration of technology on their own time schedule. Multimedia in the Classroom and Internet in the Classroom will give them specific examples of appropriate uses of technology in teaching and learning.

As the faculty become comfortable with applications the focus will move beyond basic technology skills to learning to use applications, such as the use of data bases and spreadsheets, to promote problem solving, higher order thinking skills, and effective communication in targeted student standards. Faculty will investigate strategies and techniques for the development of technology-integrated units that engage students in these processes and produce higher achievement, especially in under-achieving schools. They will have the opportunity to participate in ASD technology development activities. The "work" room will serve as a place for faculty to share learning, collaborate on joint projects, and to develop the community of learners. It can be used in conjunction with the ACT 3 methods classroom activities. Further opportunities for collaboration and professional development will be available through supporting attendance at national technology conferences.

**Program Development Model**

The Alaska Partnership for Teacher Enhancement Grant (APTE) is a five-year grant to redesign the teacher education program. Program Development Design Teams, composed of members of the SOE and CAS faculty, teachers, parents, and business partners, meet online and face to face, to restructure the School of Education and redesign courses. Activities will be provided to guide them as they develop and pilot methods for learning about best practice and integrating technology into the curriculum. They will develop a vision for teaching and learning which includes the use of technology and develop a model for redesign of preservice teacher education courses. The work groups will investigate larger technology issues that relate to parents and community as well as education. They will also have access to training in the Faculty Development sessions.

To help them develop the vision needed as they experiment with using technology in their current courses and model use of technology in the field, faculty members participating in this project will receive laptop computers with software comparable to what the students have in the SOE lab. A small projector and "smart cart" with student laptops will be available for check out. Apple Computer will conduct a workshop on mobile computing that is based on their work with other schools.

By the end of the 1999-2000 school year, members of both teams will have participated in three on site meetings and online collaboration. They will have developed the vision and skills needed to integrate technology into their teaching. Our goal is that by the end of the spring semester, UAA faculty will use the laptop computers and the "smart cart" in the classroom weekly. Evaluation of the project is ongoing. More faculty members were interviewed this fall. Their current syllabi were assessed for current technology integration strategies. Records are being kept for each activity and assessments and evaluations help guide the projects. At the end of the school year, activities will be evaluated for their effectiveness.

Teaching Well With Technology: An Educator's Guide to Wise and Time-
Efficient Use of Instructional Technology

Kevin Barry, OIT/Educational Technology Services, University of Notre Dame, United States, kbary2@nd.edu

Thomas Laughner, OIT/Educational Technology Services, University of Notre Dame, United States, laughner@nd.edu

Abstract. The Teaching Well With Technology workshop was created in an effort to provide faculty members with a systematic way of thinking about desired outcomes, use of time and space, and potential impact of technology for their classes. For the purpose of the workshop and our consultations with instructors, Educational Technology is defined as any human-made tool used to enhance the learning process. This session provides the rational for and an overview of "Teaching Well With Technology: An Educator's Guide to Wise and Time-Efficient Use of Instructional Technology" workshop. It is a full day workshop that resulted from a collaboration between the John A. Kaneb Center for Teaching and Learning and Educational Technology Services at the University of Notre Dame with support from AT&T.

Introduction

The Teaching Well With Technology workshop was created in an effort to provide faculty members with a systematic way of thinking about desired outcomes, use of time and space, and potential impact of technology for one of their classes. For the purpose of the workshop and our consultations with instructors, Educational Technology is defined as any human-made tool used to enhance the learning process.

The workshop is structured to provide the participants with an opportunity to select tools and strategies based on clearly identified learning goals that they define for one of their courses. Technology is demonstrated and discussed but there is no hands-on use of technology during the workshop. This format helps to avoid the tendency to find a problem to fit a "cool" technology solution. It also reduces the amount of time instructors spend learning technologies that are not viable solutions for their classes by helping them eliminate tools and strategies that are not likely to succeed before spending the time to learn how to use them.

The workshop is a result of collaboration between the John A. Kaneb Center for Teaching and Learning and Educational Technology Services (ETS) at the University of Notre Dame and has been underwritten by a grant from AT&T. The collaborative relationship between the Kaneb Center and ETS began when the center opened and has lead to the merging of some of the functions of the two groups and the appointment of two educational technology specialists as assistant directors of the Kaneb Center effective July 1, 2000. In addition to the workshop we consult with faculty and teaching assistants to assist them in the selection and implementation of technology tools that will help meet identified learning goals. A typical consultation with an instructor begins with the development of a mutual understanding of the goals for a course. When the goals have been clearly identified, tools or methods that may assist in achieving them are considered. These tools or methods may or may not be based on computer technology. The tools and methods identified are then evaluated to determine whether they fit with the instructor's style and to determine if they fit within time pressures and other external constraints (infrastructure, support, etc.).

The Workshop
The workshop consists of the following Seven Steps:

1. What Do I Want My Students to Learn
2. Identify the Best Teaching Approaches
3. Plan Major Assignments and Exams that Will Teach and Test the Learning that You Want
4. Plan Times and Spaces for Learning
5. What Technology Tools Can & Cannot Do
6. Choose the Technology
7. Implementation, Evaluation, Think Creatively

Step 1: What do I want My Students to Learn?

This first step of the workshop is used to focus the participants on the learning goals for a specific course that they teach. It is very important to take this step so that the decisions made later can always be tied back to the goals for the course. Basic instruction is given on the importance of defining clear measurable goals that will be useful for informing the choices made throughout the remainder of the day. The participants are encouraged to use specific terms such as describe, analyze, argue, solve, create and compare and avoid vague terms such as know, understand and be exposed to while listing their goals. At the end of this step, each participant has a list of goals that they will use to inform their choices throughout the remainder of the workshop.

Step 2: Identify the Best Teaching Approaches

In this portion of the workshop the best teaching strategies for undergraduate education are outlined and discussed. The focus of this section is the importance of increasing student involvement as a method to enhance the learning process, followed by the discussion of ten teaching strategies that may be used to attain the desired increase in student involvement.

Student Involvement is the Key to Learning

"The theory... Students learn by becoming involved... seems to explain most of the empirical knowledge gained over the years about environmental influences on student development... What I mean by involvement is neither mysterious nor esoteric. Quite simply, student involvement refers to the amount of physical and psychological energy that the student devotes to the academic experience." (Astin, 1985, pp. 133-51)

"Analysis of the research literature... suggests that students must do more than just listen: They must read, write, discuss, or be engaged in solving problems." (Bonwell & Eison, Executive Summary, n.p.)

"The body of research on the impacts of the college academic experience is extensive...The strongest general conclusion [is that] the greater the student's involvement or engagement in academic work or in the academic experience of college, the greater his or her level of knowledge acquisition and general cognitive development." (Pasquerilla & Terenzini, 1991, p. 616)

Ten Teaching Strategies Suggested by Research

1. Have students write about and discuss what they are learning.

"Learning is not a spectator sport. Students do not learn much just by sitting in class listening to teachers, memorizing prepackaged assignments, and spitting out answers. They must talk about what they are learning, write about it, relate it to past experiences, apply it to their daily lives. They must make what they learn part of themselves." (Chickering and Gamson, 1987, p. 3)

2. Encourage faculty-student contact, in and out of class.
"Frequent interaction with faculty members is more strongly related to satisfaction with college than any other type of involvement, or, indeed, any other student or institutional characteristic." (Astin, 1985, pp. 133-151)

3. Get students working with one another on substantive tasks, in and out of class.

"Students' academic performance and satisfaction at college are tied closely to involvement with faculty and other students around substantive work." (Light, 1992, p. 18)

4. Give prompt and frequent feedback to students about their progress.
5. Communicate high expectations.
6. Make standards and grading criteria explicit.
7. Help students to achieve those expectations and criteria.
8. Respect diverse talents and ways of learning.
9. Use problems, questions, or issues, not merely content coverage, as points of entry into the subject and as sources of motivation for sustained inquiry.

Step 3: Plan Major Assignments and Exams that Will Teach and Test the Learning that You Want

In this section of the workshop, we review the learning goals that the faculty members have identified and point out the frequent mismatch between these goals and the traditional coverage centered model of course planning. We do this by creating a course skeleton that shows using the coverage centered model and then creating a new skeleton using an assignment centered approach, identifying the major assignments and exams then inserting them in the week in which they are due. We then ask participants to ask these questions. Are the assignments likely to elicit the kind of learning you want? Consider what the assignment is called, will an assignment called a "Term Paper" get the same response as one called an "Argumentative Essay"? Consider the context in which students produce work (time frame, level of memorization required, and accessibility of help and likely work strategies). Are the assignments and exams manageable in terms of number, type, length, and spacing across the semester?

During this section we suggest to participants that it is better to concentrate on a few, well-chosen assignments and exams rather than to proliferate ill-conceived ones. Sometimes, "Less is more". We also discuss the importance of content. The assignment-centered approach does not excuse the students from learning the content but focuses the learning of content as needed for the completion of assignments.

Step 4: Plan Times and Spaces for Learning

In order to discuss times and spaces we first define three aspects of the learning process. These are first exposure, during which the student first hears/sees new information, concepts, procedures, etc. Process, during which the student applies, critiques, contrasts, synthesizes, argues, analyzes, etc. Process usually results in a product such as a test, exam, assignment, lab or clinic, performance, etc. The third aspect is response, during which the teacher, assistant, or peer responds to the product of student work.

The next step in the discussion of times and spaces is to look at how times and spaces are used to accommodate the three aspects of learning we have defined. To do this we compare the use of times and spaces in a traditional lecture vs. an interactive model for a class.
Traditional Lecture Method

<table>
<thead>
<tr>
<th>Students with Teacher (Class)</th>
<th>Student(s) &quot;Study&quot; Time</th>
<th>Teacher Alone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traditional Lecture Method</td>
<td>first exposure</td>
<td>process</td>
</tr>
<tr>
<td>Interactive Method</td>
<td>process, response</td>
<td>first exposure</td>
</tr>
</tbody>
</table>

Table 1: Aspects of Learning for Instructional Method vs. Times & Spaces

Notice that in the interactive method the teacher alone time is no longer spent responding to student work. This is positive in that the time can be used for other tasks and that response is moved to a time when it is much more likely to be effective for the students. Also, notice that by moving the first exposure to the student study time the more difficult task of process can be handled while the instructor is available to help with it. At this point in the workshop we discuss several cases of instructors that we have worked with and how they changed their courses to take advantage of these alternate ways of using time and space. To illustrate our point the Teacher alone time is left empty for the interactive method in this table. In the workshop we discuss the possibility that there will still be some amount of response to student work that happens in teacher alone time. At this time we also discuss alternate times and spaces such as lab, clinic, or recitation which may be used for first exposure, process, or response and office hours.

**Basic Principles for Using Times and Spaces**

1. Increase student time on task.
2. Involvement is the key to student learning.
3. Invest teacher time in the most difficult aspects of learning and/or aspects of technology that TA's or students cannot do alone.
4. Use peers or TA's appropriately; train and guide them for their tasks.
5. Make students responsible for first exposure in their own time or with TA's and peers.
6. Use technology to create, expand and enhance times/spaces and to accomplish all of the above.

**Times and Spaces Created/Enhanced by New Technologies:**

New technologies mean that the class, lab, clinic and recitation may be face-to-face or distributed and synchronous or asynchronous. Web pages, interactive software and multimedia are now available to students in their alone time and students' time with peers outside class, the instructor and TA's may be face-to-face or distributed and synchronous or asynchronous. Individual technologies that facilitate these changes are discussed in the next step of the workshop.

**Step 5: What Technology Tools Can & Cannot Do**

This section of the workshop is spent discussing various types of computer based technology tools and presenting cases that illustrate how they have been used successfully. In our cases we explicitly identify how the use of the technology ties in to the ten strategies suggested by the research and alters the potential uses of times and spaces. We do this by talking about a variety of categories of tools and providing examples of them to go along with the cases concerning their use. The tools that we cover are:

1) **Collaborative Writing Tools:** Tools in this category allow multiple authors and reviewers to interact with a document. The authors or reviewers are associated with the comments and or edits that they perform. This type of tool can be used by groups of students (or colleagues) to collaborate on a document. They also provide an excellent method to grade student work in a paperless environment. Examples of this type of tool include the reviewing features of Microsoft Word and Sixth Floor Media's CommonSpace.

2) **Presentation Software:** Facilitates the display of text, graphics, sound, video and other media and provides a relatively simple environment for the creation of presentations using these types of media. Also allows
for easy update and customization of presentations and for presentations to be made available for use outside of class. Microsoft PowerPoint is an example of this type of tool.

3) E-mail: Usually considered a one to one communication tool (may be one to many using aliases or nicknames). It is asynchronous (does not require the presence of both parties at the same time) and facilitates professor/student and student/student interaction. May reduce stress for those who don’t feel comfortable with verbal interaction.

4) Listserv/Bulletin Board
   a) Listserv List: This tool provides asynchronous group communication using e-mail. List subscribers are able to exchange e-mail with all other subscribers by sending mail to a single common address. Listserv facilitates professor/student and student/student interaction and may reduce stress for those who don’t feel comfortable with verbal interaction. Examples include Listserv and Listproc lists.
   b) Bulletin Board: This type of tool provides asynchronous group communication requiring login to Bulletin Board System (often web based). Facilitates professor/student and student/student interaction and may reduce stress for those who don’t feel comfortable with verbal interaction. Bulletin boards allow creation of a forum for each topic to be discussed and display messages organized by topic. Both of these features are advantages in online discussion of course topics. Examples include WebCT’s and Blackboard’s bulletin board systems.

5) Chat/Conferencing: These tools are designed to facilitate synchronous (all parties present at the same time) electronic discussions. They facilitate professor/student and student/student interaction and may reduce stress for those who don’t feel comfortable with verbal interaction. Text based systems do require keyboarding skills for full participation. Participants use chat software or other conferencing software to connect to a common server that allows them to interact as a group. The keyboard is the input device in simple forms with more complex forms including white board, audio, video and application sharing. Examples include IRC, WebCT, Blackboard and AOL Instant Messenger (text based and white board) and NetMeeting and CUSeeMe (video conferencing with text chat and whiteboard available).

6) Web Pages: Simple web pages facilitate display of and interaction with information that may be presented as text, graphics, sound, video and animation. They also allow linking of course materials to a larger body of information and can be used to "publish" student work. Simple web pages can be used to move first exposure outside of the class time. If students are the creators then they can also facilitate the increased involvement that leads to improved learning.

7) Integrated Course Delivery Systems: Products available allow the development of a one-stop location that provides the functionality of E-mail, Listserv and Chat along with presentation of information. These tools facilitate the creation of complex, interactive sites that may include on-line self-evaluation or testing, drill and practice, etc. Examples include WebCT and Blackboard CourseInfo.

8) Interactive Course Software: Applications that provide instruction and responses that may include multimedia elements. They could be web based (using one of the products above) or stand-alone applications and may be custom designed or commercial products. Examples include ADAM (anatomy and physiology), Progetto Italica (ND Italian language learning software).

9) Simulation: A presentation that attempts to model a real-world or theoretical process or event. Simulations may be used to show a simplified view of a real world event to facilitate understanding. They are most effective when they require student involvement/interaction. Examples include PCMolecule (Molecular Modeling), Orbital Motion simulation (http://www.nd.edu/~edtech/orbital).

Step 6: Choose the Technology

In step six we look at our sample course outline with major assignments and necessary steps mapped to the semester. Then considering the goals for that course we select technology tools that would help to achieve those goals and map them in the appropriate locations. Once they are mapped, we ask the following questions. Does it lead to learning/teaching improvements? Does it enhance community? Does the strategy fit with philosophies, priorities, and styles of teaching? Is it Feasible? Is the strategy consonant with time pressures and other constraints? The tools that pass these questions are then evaluated and one or more are selected for implementation in the course. Participants then go through the same process with their own courses.

Step 7: Implementation, Evaluation, Think Creatively
In step seven we discuss the methods to improve the likelihood and awareness of success. We suggest implementing in small steps when possible. Trying to use the new tool to do something you're already doing and to do something you've never done or to do something in a radically new way. We also discuss the importance of evaluation, even if informal. Finally, we talk about using this time of change as an opportunity to rethink in major ways by asking questions such as: What is teaching? What is my role as a teacher? What is learning? How do my students learn? What is "class"? How can I use times and spaces more effectively? What is the optimal relationship between students and teacher and students and students? And how can my time, TA and peer assistant time, and student time best be used?

Conclusion

This workshop works well because the focus is on teaching and learning. Technology tools are treated like other tools and methods and only selected when they will help meet learning goals and fit within the instructors style and other constraints.

References

Abstract: Assuring that education faculty members use educational technology effectively in their classes requires that they know and use technology themselves. This paper shares the experiences of a college of education’s 10 year effort to train faculty to use and infuse technology. The college has held an annual 1-3 week technology awareness and training session for the past 10 years, along with several other efforts to help prepare professors, instructors, and staff. Keys to success are included in this paper, as well as an effort to look at the future possibilities and challenges for education faculty development.

Introduction: The Challenge of Helping University Faculty Become Equipped to Prepare Preservice and Inservice Teachers to Use Technology

Preparing teachers to use educational technology in classrooms is an important and exciting challenge for the educational community, especially teacher preparation institutions. Teacher education is often criticized for the inadequate preparation of education majors concerning the use of educational technology in the teaching/learning process. In a 1995 study, Colon, Willis, Willis, and Austin (1995) reported that on a nation-wide survey, over one-half of the teachers who graduated within the last two years believed they were not well prepared to use educational technology in instruction. In a more recent study, first year teachers indicated that their preparation to teach with educational technology lagged behind their preparation for other instructional strategies (Strudler, McKinney, Jones, & Quinn 1999).

In addressing the issue of educational technology infusion in teacher education programs, several national and international organizations, such as the Society for Information Technology and Teacher Education (SITE), the International Society for Technology in Education (ISTE), and the National Council for Accreditation of Teacher Education (NCATE), have focused attention to the problem by holding conferences, publishing journals, and writing standards. In addition, many states, including Nebraska, have developed minimum technology competencies for educators. Changes in the amount of technology preparation in teacher education are a substantial challenge, but these changes are important to the future of education and its institutions. One of the most important factors in improving technology preparation of students is the increased use of technology by faculty, especially in the classroom setting (Persichitte 1998; Kent & McNerney 1999).

The faculty of the College of Education at the University of Nebraska at Omaha has developed a model for the integration of education technology into teacher preparation programs. This model was designed to adapt teaching methodology and curriculum in response to ever changing educational technology innovations. The need for infusion of education technology into the teaching/learning process was identified as a major goal by the college ten years ago. The goal was divided into teaching with educational technology, teaching about educational technology, integrating educational technology into the design and delivery of curriculum, and engaging in research regarding the use and impact of educational technology in the teaching/learning process.
The college established an Educational Technology Task Force, comprised of faculty, administrators, and support staff from all departments. This group was instrumental in providing operational direction to the educational technology vision of the college. This task force worked in concert with information provided by a similar group of educational technology personnel representing the Metropolitan Omaha Educational Consortium (MOEC) comprised of seven local school districts. Input from the two task forces provided input which resulted in:

- a formal College of Education mission statement for educational technology
- goals and objectives for the college in the area of educational technology
- educational technology competencies expected of all preservice and inservice teachers
- a coordinated plan for the purchase of all educational technology hardware and software for the college
- suggested research studies and topics reflecting the type and amount of educational technology utilized by the faculty of the college
- a formal advisory group to the dean of the college for feedback and future directions related to educational technology integration

Three Components for Increasing Faculty Use of Technology

Three general components were paramount for the increased faculty use of educational technology in the College of Education at the University of Nebraska at Omaha: 1) access to equipment, both in offices and classrooms, 2) expectation from the institution that effective educational technology be used, and 3) training and assistance to use technology, both personally and professionally.

Component 1: Access to Equipment, Both in Offices and Classrooms

During the past ten years, a concentrated effort has been underway within the College of Education to provide the technology necessary to prepare preservice and inservice teachers. Computers for offices and classrooms have been a priority. To equip faculty with current and appropriate desktop computers, two general guidelines were established, giving direction and rationale for these computer purchases. First, faculty members were allowed to choose either a PC (Windows) or a Macintosh for their office desktop computer. Second, high-end users would receive newer models, while trickling down their older computers to lower-end users. These guidelines provided general direction as the college moved ahead in giving basic microcomputer technology to each faculty and staff member in the college.

Early in the technology planning process, the college installed Ethernet connections in all faculty offices, instructional areas, computer laboratories, research laboratories, and support staff offices. The college local area network (LAN) is connected to the campus network, as well as the Internet. The room connections and the building wiring have been recently modernized to category 5 wiring and fiber optic space cabling. The file server for the college has been updated several times and is currently a Dell 300 MHz Dual Processor running Novell 4.11. The college will connect to Internet II soon.

Technology in classrooms and laboratories is important if faculty members are expected to infuse technology into their teaching/learning. The University of Nebraska at Omaha College of Education has developed, expanded, and updated this technology several times. Currently, several high-tech classrooms are available. These rooms have a computer, VCR, cassette deck, an audio board, an ELMO station, as well as a high quality ceiling-mounted projector. Several mobile carts, containing a computer, VCR, and projector are available for checkout to use in classrooms. A 30 station Mac lab, a 24 station Windows lab, and a 10 station Mac/Windows resource center are used for teaching, and other specialized research laboratories are also available to faculty and students.

Component 2: Expectation from the Institution that Effective Educational Technology Be Used

Many faculty are capable of believing that if educational technology is important enough for them to integrate it into their own classes, then technology is important enough to be an expectation for the institutional curriculum. In essence, it should be expected that all faculty will integrate technology into the
appropriate courses and situations. It is especially necessary for faculty to understand that they are not only supported in personal or office use, but also encouraged to use and model educational technology related teaching techniques. This support should be included in the merit, promotion, and tenure process.

Component 3: Training and Assistance in the Use of Technology, Both Personally and Professionally

The training and development efforts for the faculty of the college were designed around three levels: awareness, experience, and integration. On the awareness level, faculty members were provided with several opportunities merely to overview the vast uses of educational technology in the classroom. These sessions focused on getting faculty excited about, and aware of, the potential of educational technology use in the teaching/learning process. Also, it further provided faculty with a basic knowledge of several software programs. For the experience level, faculty members were given opportunities to experience some of the technology uses in a supportive and comfortable ‘hands-on’ environment, where knowledgeable individuals were available for assistance. For the integration level, the faculty participated in learning opportunities which focused on sharing how certain technologies might be used in instruction. This phase also permitted faculty to share with each other some of their integration projects and plans. Each of these training activities addressed improving instruction, expanding research, and increasing scholarship using the resources available through educational technology. This college-wide training of faculty and staff at each level has been addressed in various ways: summer intercession training, brown bag presentations, coaching/assistance teams, and the technology in education advancement model.

Summer Intercession Training

During the summer intercession the faculty had the opportunity to engage in hands-on training sessions in technology. These training sessions have typically been one to three weeks long. Initially, faculty was instructed in the basic use of a networked microcomputer laboratory along with its software. During the sessions, each faculty member developed projects that utilized educational technology relevant to their respective areas of expertise. From this beginning, the intercession summer training sessions became more individualized, focusing upon the specific needs and interests of participating faculty. More than twenty of the faculty per year has participated during the ten years this program has been in operation. In addition, the training format has been altered to provide large group instruction as well as one-on-one instruction and technical assistance.

The overall training during these intersession activities was designed to meet the needs of faculty members at their own level of expertise. The expertise of participating faculty ranged from those with very little knowledge of technology and no experience with its use in teaching, to those with some knowledge of technology who do not currently incorporate it into their teaching, to those currently using technology to some degree in their classroom instruction. All sessions encouraged faculty members to address their own specific needs and interests and to help be a resource to each other following the session. The following are examples of topics that have been addressed over the past ten years:

- productivity tools for curriculum integration (e.g. email, web browsers, ClarisWorks, MS Office, Hyperstudio, Persuasion, video editing, Harvard Graphics, and Micrograde)
- resource applications (e.g. instructional aspects of the Internet in support of the teaching/learning process, and authoring Internet-based materials using HTML, HomePage and Blackboard);
- experiential applications of integrated hardware and software resources available in high tech classrooms, mobile multimedia carts, and computer labs;
- integration of computer managed educational technology and media in the classroom; and
- restructuring teaching and learning applications using educational technology in a high-tech environment.

Brown Bag Presentations

In addition to the intersession training, the college also provided training throughout the academic year in a series of “brown bag” lunch hour presentations. The college’s Educational Technology Coordinator and several technology using faculty members offered the presentations. These presentations primarily
focused upon the use and integration of software programs resident on the college's file server, which is connected to every faculty member's office and all instructional classrooms in the buildings used by the College of Education, via a local area network (LAN). Topics for these workshops included a variety of software applications such as MS Works, Claris Works, Paradox for Windows, SPSS, e-mail, and Netscape, as well as other high interest topics such as the use of multimedia and the Internet. These content-specific sessions, usually one-hour in duration, were followed by coaching and encouragement from the instructors, as faculty and staff members implemented their newly learned skills.

Coaching/Assistance Teams

After several years of training, technology integration was on the increase, but still, several faculty members struggled with the issue. To address this concern, a coaching/assistance program was piloted in two teacher education methods courses: elementary language arts and elementary science. A team of five educators was assembled for each of the two content areas. Each team consisted of the subject-specific professor (the course instructor), an area K-12 teacher, a Teacher Education Department graduate assistant, an educational media professor, and an educational technology professor. Early in the semester, each team met weekly to discuss ways that educational technology could be infused into the methods courses. After these discussions, the methods professor chose appropriate strategies, and the team assisted with the implementation of those strategies. Software was reviewed, activities designed, and equipment reserved or acquired by the team. During class periods when technology was used, team members assisted the professor in any way needed, and in some cases, members of the team actually instructed the class. All the educators in this program were positive about the program. The educational technology integration increased greatly, not only in these two undergraduate methods courses, but also in all levels of the program and support team. Participants indicated that they had learned a great deal about technology, including various teaching techniques, curricular concepts, and collaboration approaches.

The Technology in Education Advancement Model (TEAM)

Project TEAM-Internet (Technology in Education Advancement Model), was an innovative Internet based inservice model, supported by the Helena Foundation. Project TEAM-Internet was directed by the University of Nebraska at Omaha together with the Metropolitan Omaha Education Consortium (MOEC). This most recent project was the third of a series of Project TEAM grants addressing educational technology.

The general goals of the project included building a community of learners/educators who were interested, involved and trained in the use of the Internet in classrooms, as well as development of cutting edge models of Internet use in the teaching/learning process. The project sought to enhance the use of the Internet by involving 25 educators (both K-12 teachers and College of Education professors) in a comprehensive and extensive one-year Internet training program. The project participants met over a 12-month period, with sessions being held on two Monday evenings and one Saturday morning each month. Sessions included training on specific topics related to Internet use and resources and were conducted by both participants and outside experts.

One of the requirements of Project TEAM-Internet was the development of an Internet based educational project by each participant. Because the educators worked with kindergartners to graduate students, the projects were varied in topic and complexity. Each participating educator presented her/his project in a large showcase at the end of the year, with area teachers, administrators, and professors invited to attend the presentation.

The participating institutions agreed that it is indeed more effective to approach technology inservice through a collaborative environment, where resources and expertise are shared. One of the most impressive aspects of this collaborative approach has been the emergence of a committed and energetic network of individuals who are continuing to share their expertise beyond the initial two projects. This network of knowledgeable individuals is now a substantial resource to all initial partners in the project. Many of the individual integration products developed by the project participants are truly remarkable, and several local districts adopted individual participant projects as part of their overall school or district curriculum.

The program labored to prepare the participating educators to assume a true leadership role in the effective integration of the Internet into education. The project attempted to take a very practical and
comprehensive approach to inservice training, by involving participants in extended and well planned instruction that was carefully focused on classroom impact. Perhaps what was most encouraging in the project, however, was the change in the individual participants themselves. At the conclusion of the project, most, if not all, of the participants were equipped with the technical skills, as well as the general enthusiasm, to help others use the Internet confidently and effectively in the classroom. It appears that collaboration is indeed a possible key to helping educators keep current with Internet related technology. In essence, we are adding additional evidence to support the old adage that sometimes all it takes for success is a little help from a friend, or in this case a TEAM of friends.

The Future

Predicting what the future holds for educational technology is extremely difficult. The commonplace of today was, in many instances, unheard of just a short time ago. The integration of educational technology into the design and delivery of instruction is definitely on a fast track. Faculty members are continually finding innovative ways to use technology in educational settings. Software and hardware manufacturers are moving ahead with new products that faculty will integrate into their teaching repertoire. Educators will see a tremendous increase in the development of teaching/learning models, which link technology developments with teacher preparation curriculum designed to better meet the learning styles of all students.

Although the future is uncertain as far as developments in software and hardware, there are some constants that are known. K-12 students have become visual learners, hence, preservice and inservice teacher preparation programs have adapted curriculum to effectively meet this learning style. The availability of computers, connectivity to the Internet, and on-going developments in educational technology will continue to strongly influence future teaching/learning environments. In addition, technological developments in the use of worldwide connectivity, broad band availability for distance education, lower costs for computers and related equipment, Internet II, software packages, and the adaptation of technology advancements from the area of information science and technology will fuel the use of educational technology in teacher preparation programs. Technological developments from the Jet Propulsion Laboratory and NASA are but two examples of scientific developments being adapted into teacher preparation programs. It is safe to say that the surface has just been scratched in the use of educational technology compared to where it will be in the next five to ten years and into the future.

College of education faculty will need to be on the cutting edge of educational technology, researching ways to better use current educational technology as well as how to infuse new developments into their curriculum. This small group of faculty will be a significant influence on colleagues, which will ultimately result in continued adoption of new instructional models.

Perhaps one of the greatest constants for the future is what has been learned in the past. There will be a need for new equipment, both software and hardware; training for faculty to assist in the integration of educational technology into the design and delivery of curriculum; and the continued expectation that faculty will indeed model the effective use of educational technology in teacher preparation programs. These three elements will be in constant flux. However, faculty in teacher preparation programs must continue to move forward in developing the very best teachers who can integrate educational technology into the design and delivery of instruction to all children.

Abstract: An efficient professional development program for teachers should be open, friendly, well-organized, capable of modifying, and self-contained. To satisfy these requirements, it must be built as a distance information and learning environment that offers access to various types of educational resources, to instructor-mediated independent and group training, communication and collaboration among all the participants in the program, and methodological support.

Introduction

Professional development (PD) programs for schoolteachers are of crucial importance as the quality of education depends heavily on teachers’ expertise. Although teachers have completed preservice teacher training programs, the nature of schooling changes through ongoing instructional reform efforts. Thus, teachers need to be continuously engaged in PD to keep up with advances in the field, update their competence in the subject area and pedagogy, and improve the efficiency of their teaching and quality of students' learning. Developing and maintaining a PD program is a complex undertaking for it embraces a wide spectrum of pedagogical, psychological, and content area aspects of teachers’ professional competence. It demands extensive time and funding commitments from the government, school and the teachers themselves. So, we, as teacher educators, must help teachers become life-long learners by developing efficient models for teachers’ PD.

Professional Development

PD is a planned, continuous, life-long process of dynamic personal development in a certain area or several related areas, a "constant process of reinvigoration and growth" (4, 22). It is, certainly, teacher’s own responsibility, yet, as his or her performance is evaluated by the outcome in the classroom, PD becomes a condition and an integral part of the teacher’s career. However, we cannot expect all teachers to volunteer for PD, or know exactly what they need and how to do it. So, we have to develop a permanently accessible (just-in-time) system that, together with rich resources that any teacher is free to use via a menu of options, offers some kind of organized training and management. We need to establish a "dynamic process which will be self-sustaining for a significant amount of time" (4, 26) with a structure, training facilities, efficient collaborative activities, counseling and consulting, and communication between teachers involved in the same program, and with the instructors and experts in subject matter and methodology of teaching.

Technology for Professional Development System

Such a system should include up-to-date and effective PD and training programs, all the necessary learning materials and an easy access to qualified methodological help in addressing everyday classroom
issues. These problems are particularly acute for teachers in rural schools. An efficient system of continuous professional development and support that would assist them in all aspects of their pedagogical activities can be built on a multimodal approach developed in our TSAT Model (Training based on Systemic Application of Educational Technology) [5, 310-319]. The technological basis for this kind of PD involving both group and individual work, independent or instructor-managed, is computer-based telecommunications via the Internet: e-mail, listservs, bulletin boards, chat rooms and videoconferencing. These tools allow multiple representation of information, communication and collaboration with other people, and are regarded not as merely delivery tools but as "mediators of learning interactions in educational settings" (1, 240). This distance learning approach to PD has such advantages as mass accessibility, economic benefits, convenience, flexibility and immediate feedback.

System Structure

A Distance Professional Development and Support (DPDS) System developed on our approach consists of 3 modules: training, communication and information [6].

The training module includes on-line courses, computer courses, telecourses, automated tests, workshops and teleconferences. These courses can be either planned credited courses or non-credit courses for general learning. The communication module allows participants of the PD program to interact with the instructors of the course. It also serves the function of providing access to peers, experts, teachers engaged in the same PD program and colleagues outside the program and is a tool for cooperative and collaborative activities in the group. The information module provides current information on the developments in the field, access to distributed educational resources like on-line libraries, university databases, educator web-pages, to various materials for self-study and teaching collected in the DPDS bank, etc. This module can also be localized to tie in with a particular training module or course. It may include an automated methodological expert subsystem for continuous online teachers’ support. There is overlap and intermingling of the modules’ functions to a certain degree, but each serves a unique role.

To be efficient, this DPDS system should satisfy a number of requirements, among them openness, friendliness, flexibility, and capability for modification and improvement. The system must also be self-contained.

Training Module

The training module is a central component of the DPDS. It includes 5 important elements that are presented in the Integrated Model of Professional Development (IMPD):

<table>
<thead>
<tr>
<th>Teacher</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web-based course</td>
</tr>
<tr>
<td>CMC/Videoconferencing</td>
</tr>
</tbody>
</table>

A key unit in the system is the Web-based course. It provides structure for the course, learning materials, assignments, quizzes, readings, and calendar. Communication in the web-based course is supported by two groups of technologies: Computer-Mediated-Communication (CMC) including email, chat, and discussion groups, and videoconferencing (CU-SeeMe and whiteboard). Independent study is based on both the materials offered through the Web-based course and on the more traditional materials like books, audio and videotapes, floppy and laser discs. The Support unit is a multifaceted subsystem that provides resources including an automated expert system, a bank of teaching and learning materials, tests and quizzes for self-evaluation, and reference materials (online and print-based).
It is clear that this model makes complex use of a variety of educational technologies. Among other technologies used in the DPDS system, "computer- and video-mediated conferencing are tools especially suited for continuing social arrangements that enable the joint construction of knowledge. Discourse created by these tools provides and opportunity for prospective teachers to relate everyday classroom teaching experiences to theoretical knowledge acquired in university courses, and, conversely, to use theoretical knowledge to make sense out of everyday classroom events" (1, 238).

Model of Training

Application of this approach can be seen in this model of a complete training session designed for one lesson of a PD course:

<table>
<thead>
<tr>
<th>Steps</th>
<th>Independent Activities</th>
<th>Small Group Activities (without instructor)</th>
<th>Whole Group Activities (instructor-mediated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Course outline study</td>
<td></td>
<td>Video lecture</td>
</tr>
<tr>
<td>2</td>
<td>1. Independent learning 2. Project design</td>
<td>Group collaborative work (classroom video assessment)</td>
<td>Workshop (video conference)</td>
</tr>
<tr>
<td>3</td>
<td>1. Independent learning 2. Lesson preparation</td>
<td>Teaching practice in the classroom (videotaped)</td>
<td>Analysis, discussion and evaluation by the group (video conference)</td>
</tr>
</tbody>
</table>

This model was developed from a number of experiences, in particular from our TSAT Model [5] and a corporate training scenario [2]. The 4-step lesson session that can take from 4 to 12 study days includes the types of activities necessary to provide efficient PD, starting with the new topic and material introduction (Step 1), offering various types of learning activities, both individual and group, that also includes a training classroom video assessment and every trainee's lesson analysis and evaluation (Steps 2 and 3), and ending with the project development, presentation and assessment (Step 4). It combines individual, small group and whole group collaborative work that may be either independent or instructor-mediated, and three kinds of assessment: self-evaluation with the help of automated tests, group evaluation and final overall instructor assessment. All the activities are supported through technology. Various types of feedback (general, selected group, individual) are possible depending on the students' needs.

It is worth noting that one of the main components of this model is practical lesson development and implementation by each teacher who is involved in a PD course. "Teachers develop as teachers through the process of teaching" (4, 24), or in the 'on-the-job' activities. Experience and PD come through research and practical performance in the real classroom (lesson preparation, implementation and self-evaluation) and training outside this classroom (lesson analysis, discussion and assessment by the peers and
instructors), besides regular learning. So, practice teaching or micro-teaching and team-teaching with observation or videotaping of each class given by one of the teachers with subsequent group analysis and discussion is an essential part of this model.

Communication and Information Modules

Two other modules support the main training module. The communication module allows communication and collaborative activities among the teacher who is in a PD program, and three categories of communicative partners: other teachers, instructor and experts:

<table>
<thead>
<tr>
<th>Teacher</th>
<th>Teachers</th>
<th>Instructor</th>
<th>Experts</th>
</tr>
</thead>
</table>

The information module provides access to several learning resources – system bank, distributed resources, educational web publications, and automated expert subsystem:

<table>
<thead>
<tr>
<th>Teacher</th>
<th>DPDS Bank</th>
<th>Distributed Resources</th>
<th>Educational Web-pages</th>
<th>Automated Expert Subsystem</th>
</tr>
</thead>
</table>

Face-to-face training

In addition to distance learning activities, live sessions are, in our view, a necessary part of PD and should be maintained wherever possible. Though they are not cost effective, they promote live, face-to-face interaction between the teachers participating in the PD course and their instructors thus allowing to preserve personal, human touch that is essential for educating people. Such a communication, undoubtedly, remains vital to education even in computer-based learning environments. To combine a distance, technology-based and traditional, live training, a "sandwich" approach to distance teacher training that involves periods of study alternating between on- and off-campus work can be very effective [3]. The main principle of the sandwich program is that it allows students to participate in face-to-face sessions periodically throughout the program. For example, students might begin the program with an intensive two-week summer session, then complete distant courses while working at their home schools, then return for another face-to-face session at the end of the program. Thus, they can continue both their careers and PD courses by alternating periods of intensive, group, instructor-supported study at the central location with periods of distance learning organized and mediated by a PD center while maintaining their regular teaching job.

Conclusion:

This DPDS model is actually teachers' informational and learning, social and technological environment that offers all the materials, tools, guidance and help needed to support their successful professional activity in the class throughout their careers. The strength of the model lies in the fact that the teachers' individual learning and PD is embedded in various social processes organized and supported via a system of educational technologies.

The DPDS system based on this model is designed to offer effective and cost-efficient teachers' PD. It can be expanded by adding intensive instructor-managed training sessions that help to preserve an optimal ratio between technology-based and live teaching/learning experiences. Students then engage in collaborative and individual work through both technology-mediated and face-to-face communication.

Abstract: Many universities recognize the need for additional training in the proper uses of technology for their faculty. Schools have invested in the infrastructure and hardware, yet find that many of their faculty need time, guidance and instruction on how to best use technology in their courses. Faculty members are being asked to teach distance learning courses, using either the Internet, videoconferencing facilities or both. As we are well aware, teaching a university course via the Internet or videoconferencing is not the same as standing in front of a group of twenty students. Many faculty need assistance and information on the best practices which can be incorporated into their teaching of these types of classes. Many faculty are including resources found on the Internet in their courses or are developing web sites for the Internet which are then used in their courses. Faculty requests ranging from developing PowerPoint presentations to learning how to program in Java are becoming commonplace. Yet where does the faculty member go who wishes to utilize these new technologies, but who does not have the training needed to incorporate them into their courses? Some universities are offering faculty development institutes on-campus which address these issues.

Introduction

As our university campuses become more technology-intensive and our courses use more technology-based sources of information, we are finding that many faculty require and request training in using various technologies. Many universities are addressing these needs through combinations of workshops, training sessions and one-on-one mentoring. These 'faculty development institutes' provide much needed skills which the faculty member can then take back into the classroom in order to provide additional resources for their students. Universities take varying approaches to these institutes, ranging from on-going workshops, work sessions which cover several weeks, to intensive one day programs which cover very specific needs of the faculty member. This article will discuss the programs at two universities, and the on-going evaluation of these programs.
The Faculty Development Institute at Auburn University Montgomery

Planning for the Faculty Development Institute at Auburn University Montgomery began Winter Quarter 1999, with the actual Institute conducted during Summer Quarter 1999. Several faculty members and the director of the Technology Center at Auburn University Montgomery began research into similar programs at other universities (primarily Florida State University and Virginia Tech) and quickly began planning to offer technology training at AUM. A committee was formed, consisting of faculty who were presently using technology in their classes and others who had expressed an interest in using technology to enhance their teaching. This committee dealt with two major tasks: defining how the institute would be conducted (the how, when, and what) and determining who would be the initial participants. The vice-chancellor at the university had provided funds for the Faculty Development Institute and participants were offered release time for one quarter for participating in the ten week institute. A call for proposals was delivered and the committee met to evaluate the requests and choose the participants. The range of the initial proposals was varied; some as little as a paragraph stating what the participant wished to learn, others, very detailed, covering how the participants would use the information learned in the institute in their classes. We learned from this that our call for proposals for the upcoming institutes would have to be very clear in detailing exactly the type of information we needed to better evaluate the proposals. As part of the initial proposal, faculty members were asked to rank their level of computer skills in several areas, ranging from software use to web page design. This information allowed the planning committee to determine which technology-based skills would best fit the selected participants. Skills requested by the program participants ranged from basic PowerPoint use, creating web pages to use as a supplement in the classroom, to creating web-based courses for use as a distance-learning class.

As a result of the proposal evaluation, twenty faculty members were selected to participate in the initial Faculty Development Institute. Ability levels, as noted by the participants themselves, ranged from very basic ("I only use my computer to do word processing and check e-mail"), to advanced ("I am presently teaching classes in JavaScript."). It was decided to run the institute in two tracks: one for the more basic skills (PowerPoint, creating a web page) and one advanced (JavaScript, developing streaming video for use on web sites). The classes were combined when topics such as copyright issues and paradigms used for evaluating Internet-based classes were discussed. It was decided, during the planning stages of the institute, to use WebCT as the basis for creating web-based Internet classes as well as web pages for use in other classes. Students were initially introduced to creating pages using HTML and then were provided instruction in WebCT. Classes were held once each week for two hours. This schedule was decided upon due to the rapid nature in which the institute was being developed and offered (basically developed over a five month period, and our teaching loads are set months ahead of time). We found this schedule provided time for the participants to cover the various tools that are available through WebCT. The original idea was to introduce the concepts during the class and allow the participants to work and practice using the concepts during the next week. This was a very good idea in theory that was much harder to put into practice. Future institutes will allow for more in-class time that will allow the participants to develop and refine their work in a more instructor-accessible setting. Future institutes will meet during a regular class periods so that
the participants will have adequate time to develop the skills needed to become more independent.

The Faculty Development Institute at Old Dominion University

The process of planning the faculty technology workshops began by outlining competencies in eight areas. The "blueprint" for technological literacy for faculty members was developed by the college of education instructional technology committee. The committee is comprised of members from each of the college departments.

1. Instructional personnel shall be able to demonstrate effective use of a computer system and utilize software.

2. Instructional personnel shall be able to apply knowledge of terms associated with educational computing and technology.

3. Instructional personnel shall be able to apply productivity tools for professional use.

4. Instructional personnel shall be able to use electronic technologies to access and exchange information.

5. Instructional personnel shall be able to identify, locate, evaluate, and use appropriate instructional hardware and software to support Virginia's Standards of Learning and other instructional objectives.

6. Instructional personnel shall be able to use educational technologies for data collection, information management, problem solving, decision making, communications, and presentations within the curriculum.

7. Instructional personnel shall be able to plan and implement lessons and strategies that integrate technology to meet the diverse needs of learners in a variety of educational settings.

8. Instructional personnel shall demonstrate knowledge of ethical and legal issues relating to the use of technology.

Following the adoption of competencies by the committee, enablers were created for each of the competencies. Topics for the faculty technology workshops were selected to support the competencies and enablers.

Classes Offered at the Faculty Development Institute at Old Dominion University

A smaller committee of four instructional technology faculty developed the topics for the faculty technology workshops. Workshops were held in the college of education computer labs every other Thursday from 12:30 to 1:25, which is the university-wide "activity time." Planning for the fall workshops was completed and advertised early in the summer to avoid conflicts with departmental meetings. Topics for the workshops included:
1. Using file servers and file maintenance
2. Using Lotus Email
3. Finding information with search engines
4. Creating a web site with Lotus Notes
5. A constructivist view of online interactions
6. Using scanners, digital cameras, and importing images into documents
7. PowerPoint and basic screen design principals
8. Using the Banner student information system

Based upon the topics, technology proficient faculty members were asked to conduct each of the workshops. Special care was taken to select faculty from each of the college's departments, not relying totally upon the instructional technology faculty. Workshop presenters were then asked to create a "fun" and "exciting" title for their workshop, such as: Clean up your mess! Using your server space for organizing, sharing and safekeeping your files. The title of each of the workshops, description, prerequisites, and what to bring were published in a six-page brochure and distributed to each of the faculty. Workshop presenters' e-mail addresses were included for workshop registration.

At the beginning-of-the-year meeting for the college of education, each of the workshop presenters gave a five-minute presentation highlighting his/her upcoming session. These light-hearted, yet technology and information-rich presentations created a high level of interest in the faculty, resulting in over-capacity attendance. During the workshop, attendees were presented with meaningful and relevant tasks which could be directly applied to their everyday duties.

Classes Offered at the FDI at Auburn University Montgomery

As noted, the classes that were offered at Auburn University Montgomery were based largely upon the perceived needs of the participants based upon the proposals submitted. The institute was held each Friday during Summer Quarter 1999. Classes were offered in PowerPoint, Basic HTML, WebCT (the majority of the institute was devoted to WebCT), copyright issues, using the distance learning classroom (two-way interactive audio/video), technology resources available on campus, educational issues related to the use of technology in the classroom, and, at the advanced level, JavaScript, developing streaming video content for web pages and mastering CD-ROMs. At the conclusion of the institute, a university-wide open session was held in which the participants could showcase the work they had accomplished during the summer. This mode of presentation allowed time for the participants to demonstrate what they had learned during the institute and provided additional advertisement for future institutes.
Problems Perceived and Overcome

At Auburn University Montgomery, during the initial planning stages, several faculty members commented that they had never, in the entire history of the university, seen the administration back so completely and so quickly the concept of the Faculty Development Institute. The initial funding, which included equipment to be used as servers, software licenses (primarily for both WebCT and Real Video), as well as monies to provide for the faculty release time, was quickly approved. Several committee members were allowed to visit and observe how other universities conducted similar faculty development programs. The quick turnaround time available from the initial call for proposals to the notification of the participants was a slight problem, which resulted, as noted above, a wide variety of the types of proposals submitted. The call for proposals for the Spring and Summer Quarter Faculty Development Institutes addressed that issue and provided a stronger guideline for prospective participants to follow and resulted in both a higher level of proposal and a much more consistent style of proposals from which to select the faculty participants. The reason all faculty who apply are not selected is primarily due to the funding needed for faculty release time. If funding is increased in the future, more faculty can be served. A primary problem that arose is one of equity of equipment across the campus. There were faculty who were using computers so old that they could not adequately access the Internet. We felt that we needed to show these faculty what they could do with adequate technology and attack the problem of finding this adequate technology at the same time. Fortunately, when the administration saw the level of enthusiasm and dedication from the participants of the institute, monies were found which allowed newer computers to be purchased for many of the faculty.

At Old Dominion University, although the workshops were endorsed by the dean of the college and were scheduled during the activity time well in advance, some meetings were scheduled which conflicted with workshop times. Interestingly, most of the conflicting meetings were scheduled by senior faculty members who had little or no interest in the technology workshops. In the future, ways must be found to ensure that such conflicts will not arise. The 55-minute time slot for the workshops was also problematic. Such a short time period was inadequate for most of the workshop topics. In the future, longer sessions will most likely be added, in addition to the 55-minute sessions.
Abstract: This paper is a report of recent research that included such areas as faculty perceptions towards technology and progress towards integration of technology into teaching. Encouraging faculty participation and ownership of technology integration had both rewards and revelations. Three categories of technology adoption and integration were identified. It was found that encouraging faculty to implement technology in their teaching by providing equipment, training, and release time proved more beneficial than costly.

Introduction
In fall of 1997, our college won a grant from a telecommunications and technology company that paid for some new desktop computers, software, projection machines, and most significantly, laptop computers for all faculty in the School of Education and Human Sciences. A crucial component of the grant was that faculty would integrate technology into their instruction in the classroom.

Design of Professional Development
Professional development opportunities were made available for all faculty members. The types of activities offered ranged from seminars to release time. Charter School faculty members have shown great resolve and initiative through their attendance at college-wide and school-wide seminars in technology that are offered by the Office of Academic Computing, Charter School, and Memorial Library. Charter School faculty are actively involved in researching the effects of technologically enhanced environments in the schools. Recent research has included such areas as faculty perceptions towards technology and the effects of multimedia technologies on the quality of classroom instruction. Several faculty were given release time to create technologically enriched environments for their classes.

Pitfalls and Epiphanies of Program Design
Encouraging faculty participation and ownership of technology integration had both rewards and revelations. The initial factor of access was addressed with assigning faculty members a notebook computer for their personal use. Notebook computer funding was grant based and therefore a one-time source of funds. The pitfall found here was related to funds to repair and replace equipment as well as provide notebook computers for new faculty positions. The rapid advances in technology itself also created a situation of functional obsolescence in the computers with no path (or funds) for upgrades. At the time of the initial purchase of notebook computers, the campus network infrastructure was rather fragile and would not easily support added devices nor allow any form of dialup access. This resulted in an appliance that faculty could not use for communication or research and therefore resulted in the notebook becoming a slideshow device. Network interfaces were eventually provided on a check-out basis for the notebook computers thus allowing email, network, and internet access.

Training opportunities were provided in operating system basics as well as application software basics. The initial training sessions were an addition to the existing teaching load and offered in lab environments. A technologist was also hired to work directly with faculty to learn and implement the new technology. In a campus-wide survey on technology, several faculty noted the additional time required to become adequately acquainted with the new toys, yet in every case, the faculty member noted that the time, effort, and "disequilibrium of learning a new way of thinking about learning" (as one professor put it), was worth the accrued benefits.

Following the initial training opportunities several faculty were given a reduction in teaching load to research and implement technology in their teaching. The research was guided by the question, "How does technology affect your area of expertise?" The participating faculty were asked to document their findings, integrate innovative technological applications in their courses, utilize technology in communications with students, and require students to use technological tools in fulfilling course requirements. Although reports from faculty varied widely, most agreed that the opportunity to focus upon technology for an entire semester gave them a chance to lay a foundation for future expansion of technologically-enriched teaching. On the negative side, faculty complaints centered upon equipment and specific software packages.

From an administrative viewpoint, encouraging faculty to implement technology in their teaching by providing a modicum of equipment, training, and release time proved both beneficial and costly. A grant was used to fund the initial technology and professional development. What occurred after the grant was a well justified demand for additional technology from the faculty. The notebook computer opened the classroom for technology integration and created a need for projection devices and network drops in all classrooms. Even though such expenditures were not initially anticipated, the momentum of the faculty made locating new funds absolutely essential. Although mining for dollars to fund projects is a tricky enterprise at best, the enthusiasm of faculty made the task tolerable.

Developments in Technology Uses
The faculty at the Charter School have enhanced many of their courses through technology so that prospective teachers systematically experience the power of digital and other technologies. A major focus of the ways that technology are integrated throughout the curriculum is to ensure that prospective teachers see these technologies being modeled by professors in the teacher education program. A second focus is to familiarize students with these technologies so that they are comfortable in using them in their own teaching. As evidenced by the high demand for projection devices in the building were education faculty teach, use of technology is a matter-of-course. In their assignments, faculty expect students to move beyond the "technology as toy" phase and become innovative producers and users of technology beyond the rudiments of course assignments. The faculty realize that students cannot create an effective cutting-edge lesson without first "seeing how it will fly" in a real classroom. Thus, through their progressively more intense field experiences, students learn to use what they have created in the computer lab in a classroom setting. In this manner, students move from learning about technologies to enhancing instruction through different kinds of technologies.

Categories of Technology Adoption
The levels of technology adoption and integration by the faculty can best be classified into three groups: Evangelist, Balanced, and Conscientious Objector. The evangelist group includes professors that have moved from little or no technology usage to full adoption, including many who insist on implementing some form of technological infusion in each class meeting. The following response in a recent survey of the faculty typifies this mode:

"I think students expect us to use technology as the main mode of instruction now. When we first were all using it, I think they were frustrated with us 'learning' on them! Now I feel funny if I don't use some form of technology in a class. The students appear to appreciate the note pages I hand out, so we can focus on the verbal information and interaction without having to worry about writing down every word. I'd like to infuse more technology with different types of software and applications that are used in the field."

Other "evangelists" have moved their course information to the web, taken technology leadership roles in national organizations, acted as technology consultants for international publications, and begun to share what they have discovered with other faculty. Some "evangelists" continue to seek new and innovative ways of utilizing technology by experimenting with technology as a matter of course in their teaching. For example, one professor who only two years ago pronounced himself a “neo-Luddite” has recently started an online magazine in his field and routinely requires students to read and report on breaking news via his personal message board.

The "balanced" group consists of professors who are comfortable with communicating with students and colleagues using email, searching various on-line databases for research, using some type of presentation software in their lectures, and feel that technology has helped improve their instruction. A survey response from this group stated that "even though the infusion of technology in upper-level classes required a great deal of time and energy, the benefits to the students outweighed the inconvenience."
The "conscientious objector" group was a small percentage of the faculty and could best be described as those that tried to incorporate technology and were not delighted with the time required to learn the new skills nor the results of their technological endeavors. Typical survey responses from this group were related to problems encountered with the equipment, how technology "distracted students," the lack of extended time for one-on-one training, and complaints related to technology services at the college. While the "conscientious objector" might rarely use technology, they did not actively attempt to dissuade other faculty from using technology. Like Bartleby the Scrivener, in regard to becoming technology users, they simply "preferred not to."

**Implications for Faculty Development**

To reach both the conscientious objector and the evangelist, a program of faculty development must be adaptable and appealing to a diverse group of professionals. Group instruction classes are the usual means for teaching new skills. This method may work well with the "balanced" group but is too limiting for the "evangelists" and too intimidating for the "conscientious objectors". A move to individualized instruction is currently under study. This method will utilize both web resources as well as CD-based media. Such individualization would combine access to the college’s central help desk with limited one-on-one personalized help from the school’s instructional technology staff.

Infusion of technology into teaching requires a different kind of commitment. Because no one-size-fits-all technique exists to enable a faculty member to comfortably plug technology into teaching, individual faculty must be allowed to research and observe exemplary teachers. While such programs can be found on campus, sometimes faculty are most comfortable leaving town for a few days to watch the different ways that faculty at other institutions employ technology in their teaching.

Perhaps the greatest epiphany of our three years of research is learning the importance of offering useful, welcoming, non-coercive faculty development. A serious commitment to ongoing faculty development is at least as critical to the integration of technology into instruction as providing the machines and the software.
PUZZLED BY TECHNOLOGY PROFESSIONAL DEVELOPMENT? WHICH PIECES FIT IN HIGHER EDUCATION?

Ellen Newcombe, School of Education, West Chester University, United States, enewcombe@wcupa.edu
John Kinslow, Department of Professional and Secondary Education, West Chester University, United States, jkinslow@wcupa.edu

Abstract: The USE Tech Partners Program at West Chester University is geared toward full-scale integration of educational technology in teacher preparation. This program, funded by the U.S. Department of Education's "Preparing Tomorrow's Teachers To Use Technology" grant aims to promote effective technology use in a University-K-12 school partnership. The presentation highlights strategies that have been effective, lessons learned through implementation, and next steps in the project.

Introduction
An important goal for teacher preparation institutions in the first years of the 21st Century is to graduate teachers who can meet national standards of technology integration. To achieve this objective, colleges and universities must insure that their own teachers (i.e. professors) can model the kind of technology integration they want their students to replicate in K-12 classrooms. For many teacher preparation schools, finding feasible ways to help faculty become role models will be a challenge: professional development resources are limited, faculty technology skills are just beginning to develop, technology integration at the university level is an unfamiliar concept, and personal incentives are uncertain.

However, driven by the realization that school districts will most quickly hire those candidates who are technology proficient and that the responsibility to educate students for a technological world cannot be ignored, higher education will find ways of addressing these professional development needs. Yet exactly how teacher preparation institutions can best provide the kind of professional development needed by faculty remains a puzzle. The USE Tech project is seeking to identify the pieces of that puzzle during its capacity building year.

Project Background
Undergraduate teacher education has been a primary mission of West Chester University (WCU) from its beginning in 1871. WCU now ranks as the third largest university in southeastern Pennsylvania and teacher education remains the most popular major for both undergraduate and graduate students. Over 600 teachers each year are graduated from WCU teacher-education programs. There are approximately 100 full-time and adjunct faculty members within the School of Education. Additional faculty from the College of Arts and Sciences (CAS), School of Health Administration and School of Music also help prepare teachers.

At the beginning of the project, only a few teacher education professors were integrating technology into their courses on a regular basis. WCU received a grant from the Preparing Tomorrow's Teachers to Use Technology program funded by the U.S. Department of Education. One of the major goals of the project funded by that grant, the Use Tech Partnership Program, is the modeling of technology integration by WCU faculty in both methods and content area courses. To achieve this objective 16 faculty have been awarded released time during Spring semester 2000. These faculty members, with technology skills ranging from novice to advanced, have written proposals describing their plans for technology integration. These plans range from basic ideas such as putting lectures on PowerPoint or using e-mail with their classes to complex schemes for capturing instructional video that will be made into CD-ROMs.
Professional Development Activities
West Chester University is addressing the professional development challenges presented by the needs of those faculty participating in the Use Tech project as well as other faculty who prepare teachers in several ways: by establishing a faculty technology center in the School of Education, as well as by providing skill training, assistance in integrating technology into specific courses, and supportive services.

Faculty Technology Center
Prior to the grant request for proposals, the WCU School of Education had established a Faculty Technology Center (FTC). The FTC loans equipment, provides a technology service, and conducts technology training. Knowledgeable staff from the FTC will assist professors in integrating technology in the specific courses they teach. Although there are other supportive technology services available from the university, the School of Education believes technology support available within their building and oriented toward the specific needs of an education faculty are integral to greater and timely technology integration in teacher preparation courses. The FTC maintains a room in which to conduct training and perform administrative functions.

Technology Skill Development
As part of the grant project, we plan ongoing professional development activities to prepare faculty to model technology integration in their own teaching. This will include both activities that develop technology skills and the ability to integrate technology into existing courses. Workshops and training sessions will be provided on the selection and use of software, the use of peripherals, the use of technology as a tool that focuses on extending thinking and learning skills in students, and the use of Internet resources. Additionally, faculty will explore the use of two-way video to increase connections to the K-12 community and to allow more opportunities for preservice teachers to practice teaching in an on-line environment.

Faculty will identify technology skill areas in which they need further development and training will be provided. Our initial plan is to feature the use of "just-in-time" support to address the immediate technology skill training needs of WCU faculty. Training activities will be ongoing throughout the project - - either one-on-one or in small groups.

Mentoring
Professional development research shows that peer coaching provides additional avenues for teachers to share expertise, perspectives and strategies with each other. Cohen, Talbert & McGlaughlin (1993) point out that "understanding how teachers respond to an ever-changing situation with knowledge that is contextual, interactive, and speculative." For this reason, we believe that faculty development programs should be structured around peer-coaching or mentoring in which the relationship between learner and coach is grounded in actual classroom practice. Learning new practices (such as technology integration), often involves changing old habits that have made teaching comfortable and predictable. A "buddy system" pairing a more experienced technology user with a novice will be established and should be especially helpful in the integration of technology in WCU classrooms.
Integration Strategies

In addition to on-going professional development offered through the FTC, a Technology Integration Institute is planned for the semester break between the Fall (1999) and the Spring (2000) semesters (January 10-14, 2000). During this time faculty members will be given time, training, and support in a "How to Infuse Your Course with Technology" workshop. Professors will be asked to attend the conference with their course materials in hand and will be given technical assistance to take the necessary steps forward in becoming technology-integration models for our preservice teachers. Project staff, WCU faculty, and consultants from other universities will lead the institute. Planned events for this workshop include clarification of goals, development of standards by which faculty will measure their technology integration activities and improvements, and workshops on web page basics, creating an online course, and K-12 technology integration.

The 16 participating faculty with released time during Spring semester 2000 will develop and test integration strategies in one or more of their courses. As a result of their activities, the project will detail a set of promising strategies and activities for technology integration in the WCU School of Education and College of Arts and Sciences. We expect the faculty to describe how they use e-mail, the Internet and web-based learning applications, content specific software, and common software productivity tools such as word-processing, spreadsheets, databases, presentation software, and video-conferencing to enhance the learning of preservice teachers. Faculty will explain what strategies best support learning with technology in their courses. By the end of the year, we will have a model of ongoing professional development for technology integration.

Visits to K-12 Classrooms

In order to become role models of technology integration for the teachers they prepare; university faculty must be knowledgeable regarding the use of technology in K-12 schools. After identifying master teachers who are able to serve as exemplary models for technology integration in K-12 schools, faculty will visit their classrooms either in person or via two-way video.

Communication of Successful Activities

A project web page will communicate project activities including preservice teacher technology competencies and strategies and activities for integrating technology into the teacher preparation program. This source of on-going development and communication will become important to the continued success of WCU technology integration as more of our work becomes web-enabled or web based for distance education purposes. By the end of the year, this project web site will post the work of this initiative to the participants or others interested in teacher preparation throughout the world. As a result of this activity, we expect to learn from colleagues who have common interests. Perhaps, through collaboration with others, we will identify enough of the pieces of the higher education professional development puzzle to realize our goal of enabling faculty to become technology-proficient role models.

Lessons Learned about Professional Development

The evaluation for this project will be a formative one. The purpose of the evaluation is to provide information that can help identify any problems and improve project design and management during our capacity building year. With such information in hand, we can adjust project plans for the implementation phase. Since we will focus during our capacity building year mainly on training faculty and developing integration strategies, the evaluation will focus on this emphasis. Key to the formative process will be a systematic effort to document and learn from the ongoing project activities to better understand faculty needs and identify the strategies, which meet them.

While the project is still in its initial stages we are beginning to receive feedback from working with the participants.

- Faculty members have different parts of a shared vision for technology integration and need time to share these ideas with one another. Hearing the same story from the same person in the same way can inspire not all.
- Released time from a course for the specific purpose of improving technology skills and integration of technology into their courses is a good incentive for faculty. Faculty appreciate the time allocated for their own development.
Faculty can become more interested in technology use when they see their own students modeling technology use in the course they teach. Making technology accessible to students for the purpose of class presentations enables their professors to see how technology might be used.

Easy access to technology when and where it is needed is very important for higher education faculty. Requirements for advanced planning, complicated sign out systems or movement of equipment from floor to floor creates barrier to use.

Next Steps for the USE Tech Partners Program
We are still in the early stages of our project and much remains to be done. During Spring semester, 16 faculty members with reduced course loads will have the time to integrate technology into their courses. The project will support efforts at continuous improvement as they use ISTE/NCATE standards as a guide for their technology integration. Future plans include a scaled-up effort with additional faculty becoming involved and additional activities with K-12 schools that will include both preservice and inservice teachers.
Aids and Cautions for Developers of Web Pages to Supplement Courses in Higher Education

Cleborne D. Maddux
Department of Counseling and Educational Psychology
University of Nevada, Reno
United States
maddux@unr.edu

Abstract: This paper presents a number of problems commonly found in web pages intended to supplement traditional courses in higher education. These technical and content problems limit the usefulness of such pages, and frustrate both students and instructors. The solutions to these problems are simple and can be implemented by any instructor. Some require an elementary knowledge of hypertext markup language (HTML), while others require only an awareness of how common pitfalls can be avoided.

Introduction

The World Wide Web has become ubiquitous in nearly every walk of modern life. An index of the unprecedented growth in size and popularity of the web is the fact that there were fewer than 50 web pages in existence when President Clinton took office. Today, of course, there are literally hundreds of millions of pages, and an early study of popular use patterns revealed that in the first three months of 1995, Internet users spent more time surfing the web than the total combined playback time of all rented videos in the United States and Canada (Masotto 1995)!

Not surprisingly, the web is transforming diverse elements of our culture, including education. One of the earliest educational movements to be affected was distance education. Only a few years ago, distance education around the world was centered on audio signals, closed circuit television, and videotape. Today, colleges and universities around the world are offering web-based undergraduate and graduate degrees of all types and descriptions. In the future, as web-based, multimedia technologies evolve and improve, distance education will continue to expand its involvement with the web.

Perhaps in the future, there will be web style and design standards that are well-thought-out and widely-accepted. However, no such standards exist today. Consequently, the quality of web pages varies greatly, and the state of the art in education related web pages could justifiably be termed chaotic. This is true for pages of all types, including (or especially) those associated with higher education courses.

There are two general types of web pages associated with higher education. The first type is more highly developed than the second type, and consists of those pages that are part of higher education courses that are delivered to students completely electronically. These pages are, in general, of higher quality than those associated with the second type, which are those intended to be supplementary to traditional courses.

The reason that many pages for use in totally distance-delivered courses are superior to those that are supplementary to traditional classes, is that many institutions employ both technical and pedagogical experts to help develop such pages. Although such experts do not
always produce excellent pages, either technical or pedagogical, they do often avoid some of the more obvious problems that novice developers frequently make. Individual professors, on the other hand, frequently do not have either the time or the expertise needed to produce even minimally competent pages, and their institutions often provide little if any technical support to help them do so. Consequently, many supplementary web pages are of such poor quality that they are of little use to students, and some are so crudely done that they represent student liabilities rather than assets.

The purpose of the present paper is to present a variety of aids and cautions for developers of web pages that are intended to be supplementary to traditional courses.

Some Common Web Problems and Some Easy Solutions

The widespread availability of HTML editors and translators, together with the lack of institutional support to help instructors develop supplementary pages has resulted in many pages that have been designed and developed without even cursory expertise in HTML (hypertext markup language). Consequently, there are serious technical problems with many web pages.

Many pages lack TITLE tags (a descriptive title located between <TITLE> and </TITLE> in the code for the page). This omission results in popular search engines and directories listing these pages as "UNTITLED" or with titles that are incorrect or misleading.

Other pages lack META tags (tags containing a brief narrative description and list of keywords for use by search engines and directories). This may cause search engines and directories to list such pages in the wrong categories, or to provide descriptions that are not accurate.

Much of the growth and popularity of the web is probably due to the ability of modern browsers to display graphics. However, many pages do not make judicious use of graphics. Developers should remember that many students are equipped with slow, obsolete modems, and even up-to-date, fast modems will be slowed unacceptably by the overuse of graphics. However, good HTML and a little common sense in the choice of graphics can overcome the problem of pages that load too slowly due to graphics problems.

Developers should keep in mind that once an an image has been loaded into a user's browser, it can be used again on that page without reloading time. Therefore, horizontal divider bars and other incidental graphics should be reused whenever possible.

Developers should also take care to include the pixel height and width of all graphics in the image source tag for the page (An example using a graphics file named "bar.gif" might be <IMG SRC="bar.gif" HEIGHT=10 WIDTH=200>). Defining the height and width in this manner will allow each graphic to display as it is loaded, thus providing something for users to see immediately. A lack of height and width specifications will cause the browser to display a blank page until all graphics are loaded.

Then too, the HTML code should make use of the ALT attribute to specify a text description of each graphic for display in case the user views the page with a browser that is not capable of displaying graphics, or in case the user has turned off the browser's graphics display capability in order to speed loading. (The example above might be <IMG SRC="bar.gif" HEIGHT=10 WIDTH=200 ALT="Blue dividing line">)

Large images can take several minutes to load, especially by outdated modems. Therefore, large images should always be preceded by small, "thumbnail" images that will
load quickly because of their small size. Then, users who wish to view the large image can click on the thumbnail, and other users are spared the necessity to wait for these images to load. Developers should display the size of the full image below the thumbnail link, so that potential viewers can decide for themselves whether or not the full image is worth the wait.

Web pages should never make use of graphics that must be loaded from another site. Instead, all graphics should be copied and stored in the same place as the files that make use of them. Loading graphics from a different site slows loading unacceptably. Then too, the owner of the site from which the graphic must be downloaded will not appreciate a "hit" on that site every time anyone on the web views any page containing the image. Many graphics sites on the web have been removed or a password system instituted because repeated hits caused by this practice have brought the server down or slowed it unacceptably. (Of course, before copying and displaying any image, developers should make sure that the image is in the public domain, or that the owner has given permission for its use.)

"Imagemaps" (special areas of a graphic that function as links) should be used sparingly, and there should always be alternative, text-based links available. Developers should keep in mind that many students are not highly skilled web users, and some may not realize that areas of graphics can be made to function as links.

Developers should avoid the use of "frames" (an HTML strategy for dividing the browser window into separate displays or windows.) Frames present a number of user problems that can be highly frustrating to students who are web novices. Such students often do not understand that bookmarking a page located in a frame merely stores the frame definition page, rather than the page to which they wish to return. Thus, they may find themselves searching repeatedly for pages they erroneously believe they have already bookmarked. Then too, incompetent HTML frames code can cause any page viewed subsequent to viewing a frames page to appear in a frame within a frame. Novice users are often frustrated by this problem. (Developers should consider the use of HTML tables rather than frames for most uses that require distinct areas featuring separate displays.) If frames are used, the HTML should be written to provide a link to the same material in nonframes format.

Every page should contain a link to the e-mail address of the person or persons to whom problems and suggestions should be reported. Such links should display the full e-mail address, in case users do not have browsers that are properly configured to automatically open blank e-mail messages when such links are chosen. Such users can then copy the e-mail address for use later when they have opened their chosen e-mail application. (An example of code to display a link to the author's e-mail is: &lt;mailto:maddux@unr.edu&gt;maddux@unr.edu&lt;/A&gt;.)

Every page should contain a link at the bottom that will return the user to the top of that page, and to the site "home page." (The home page is the first page that the developer wishes users to view.) A link to the top of the current page saves the user from the necessity to scroll to the top of the page. A link to the home page is necessary to avoid another surprisingly common and frustrating problem - the problem of failing to fully and properly identify pages. It is essential that developers take care to identify institutional and departmental sponsorship of pages. Such identification of sponsorship should be complete and should not involve abbreviations or acronyms of any kind. However, an almost unbelievable number of higher education (and other) web pages contain no identification whatsoever! This often happens because the developer of a given page erroneously assumes
that the page will be found only by those who follow a link found on one of the developer's other pages. However, most pages are not found by "surfing." Instead, most are found by users who type a search string into one of the many popular web search engines or directories. (Search engines are large, automated databases that attempt to include all pages on the web, while directories are smaller databases that include only those pages that have been viewed and categorized by human workers.) Consequently, all pages should be self-contained with respect to identification of institutional and departmental sponsorship. The full names of all institutions and departments should be spelled out at the top of the page, and complete addresses provided. More and more institutions have developed style manuals for use on all official pages, and developers should check to see if such a manual is available. In the absence of an institutional requirement, developers should also include a "footer" at the bottom of every page. This footer should contain an identifier, a link to the institution's home page, a statement as to when the page was last revised, the full URL of the page, and a link to the e-mail of the developer of the page.

Many course pages do not contain a link back to the home page (the "home page" is the first page of a series of pages at a web site). Pages with no link back to the home page are web "dead ends." Viewers of such pages are often unable to locate the home page for the site, particularly if the site does not contain proper identifiers. Again, this problem may be due to web page developers incorrectly assuming that all users will arrive at each of their pages by choosing links located on one of their other pages. Such users who have chosen a link on the site home page can return to that page by clicking on the "back" button of their web browser. However, users who found the page through use of a search engine or directory, and who wish to view the site home page, will be able to do so only if the developer has placed a link to the home page on every one of the site pages.

Many supplementary course pages contain lists of links to other sites that deal with course content. Such links can be extremely helpful to students who wish to view more complex information on a topic, or who need a different approach to the same material. However, many course pages contain links that are no longer active and that produce error messages when they are chosen. This can be highly frustrating to students and may cause many of them to ignore all links provided by their instructor. All links should be checked frequently - probably at least weekly to make sure that they are still functional. "Dead links" should be removed or brought up to date.

Every page at a site should begin with a short statement of the purpose of that page. This will assist the developer in keeping the proper focus as the page is developed. Then too, it will assist students who are looking for the page on the site that contains specific information.

Pages should not be too lengthy. At most, there should be two to three screens of information. If more lengthy information needs to be included, it should be broken into smaller "chunks" and placed on one or more linked pages.

The content of supplementary web pages is also of obvious importance. A recent informal survey of several hundred students in the author's department revealed that students most want lecture notes to be available on the web. Such notes need to appear soon after each lecture, ideally within 24 hours. Students also want full syllabi including grading policies and criteria, a course calendar, and the ability to download all handouts given during class.
Many course pages show inadequate attention to the mechanics of writing. Spelling, punctuation, and grammar should be meticulously checked for accuracy. There is no excuse for educational pages that provide poor models of such mechanics.

Developers should also take care to view their pages in more than one browser. At a minimum, Netscape and Internet Explorer should be used to preview pages. Every browser is slightly different in the way it displays certain elements of HTML. Therefore, developers need to ensure that the page is acceptable when viewed with these two browsers.

Conclusions

Web pages that are supplementary to traditional courses can be highly beneficial to both students and instructors. However, the web is full of pages with serious problems that limit their usefulness. Many of these problems are easy to rectify. This paper has provided a discussion of some of these common problems together with some suggested solutions. For a complete discussion of these and other recommendations, readers are referred to Maddux and Johnson (1997).

Abstract: Examination of new search tools and techniques that teacher educators can use to improve the efficiency and effectiveness of their own web searching. Techniques to be presented include use of metasearch tools, improving search relevance with search engines, backwards searching, searching the invisible web, and use of kids’ search tools.

Introduction

Showing students great curriculum-related web resources is a popular activity in many teacher education courses at both the graduate and undergraduate level. Not only does this allow faculty to model the integration of technology into the curriculum, it also gets students excited about the new kinds of resources available. But is it enough? As E.M. Forster said, “Spoon feeding in the long run teaches us nothing but the shape of the spoon.” Knowing how to search for web-based information is the critical skill. Unfortunately, searching for web-based information can be a frustrating and time-consuming experience. This paper identifies new search tools and techniques that can be demonstrated to students to improve the efficiency and effectiveness of their searches. Five specific techniques will be highlighted: using metasearch tools to improve the comprehensiveness of web searches, improving search relevance with search engines, backward searching, searching the “invisible web”, and using kids’ search tools to identify developmentally appropriate resources.
Comprehensive searching with metasearch tools

A recent article in *Nature* (July 8, 1999) by Steve Lawrence and C. Lee Giles received wide attention in the press. Lawrence and Giles examined the World Wide Web in February 1999 and found that publicly indexed web pages had increased to 800 million (up from an estimated 320 million in December 1997). Their article analyzed how well eleven search engines/directories performed in accessing the information contained in those 800 million pages. Lawrence and Giles estimated that the combined coverage of the 11 tools was only 42% of the total web and that the overlap among the search engines was surprisingly low. This research implies that using multiple search engines is a necessity today. Metasearch tools allow us to do just that -- quickly and effectively. Metasearch tools that will be demonstrated include ProFusion (http://www.profusion.com), Metacrawler (http://www.metacrawler.com) and SavvySearch (http://www.savvysearch.com).

Improving search relevance with search engines

Most of us probably have a favorite search tool, such as Yahoo!, Infoseek, or Excite, and there is certainly something to be said for developing a high degree of familiarity with the search features of a single search engine or directory. However, in the rapidly changing world of the web, it is important to be aware of new search tools and the features that they use to try to improve the relevance of results. New search algorithms are developed regularly, usually in conjunction with a new search service.

Google (http://www.google.com) is one of the most exciting search tools available today. Google’s search algorithm is based on an approach called PageRank. The FAQ states that, “PageRank capitalizes on the uniquely democratic characteristic of the web by using its vast link structure as an organizational tool. In essence, Google interprets a link from page A to page B as a vote, by page A, for page B. Google assesses a page's importance by the votes it receives. But Google looks at more than sheer volume of votes, or links; it also analyzes the page that casts the vote. Votes cast by pages that are themselves "important" weigh more heavily and help to make other pages "important" (available online at http://www.google.com/why_use.html). Google allows users to capitalize on this by choosing an "I’m feeling lucky" button. When this button is chosen the user is directly linked to the page Google identifies as the most relevant. A search limited to United States government sites is also available through Google.

While Surf Fast (http://www.surffast.com) isn’t based on a new searching algorithm, it does provide “one stop shopping” for web searchers. This well organized page provides keyword searching for all of the major search engines, plus quick access to major news organizations and other useful web resources such as Mapquest and Travelocity. Surf Fast can help students understand how important it is to match the
Backward searching

Chris Sherman suggests the term “backward searching” for the technique of using the “link” operator to identify pages linked to the URL that you have entered (http://websearch.about.com/library/weekly/aa082499.htm). The basic idea is that people only add links to sites that they consider highly relevant, although searchers still need to determine whether or not popularity actually equals quality. Backward searching is done using a link operator. Queries are usually structured like this: +link:URL. To assess quality, look over the list of “linking” URLs. Are all of the links from individual pages or are the links from well respected sites like Kathy Schrock’s Guide for Educators (http://school.discovery.com/schrockguide/index.html) or the Librarian’s Index to the Internet (http://sunsite.berkeley.edu/InternetIndex/)? If you find a promising page and you follow these “backward” links, you get a sense of whether others find the page so useful that they link to it. Backward searching is just one of the many power search tools educators can utilize once they become aware of the advanced search features included in different search engines. Unfortunately it can be a challenge to locate information about using advanced search features. At Infoseek you have to choose advanced search then choose help before you come to this information (http://infoseek.go.com/find?pg=advanced www.html&ud9=advanced www).

Searching the “invisible web”

Many resources that are very useful and relevant to teacher education cannot be retrieved using standard web search tools. ERIC, online library catalogs, and archival resources, are examples of resources that are simply not retrieved by the spiders and bots used to build search engine databases. If you have ever spent hours fruitlessly searching for information you’re sure is accessible electronically, the information is probably “hidden” on the invisible web. And if students tell you that they couldn’t find even one article on a common educational topic, they have probably been doing a web search, not searching in a specialized database. Students often do not understand the difference between information on web pages and information found in databases and indexes. Identifying places to search for these “invisible” resources is one step toward developing this understanding.

Direct Search (http://gwis2.circ.gwu.edu/~gprice/direct.htm) is a comprehensive index maintained by Gary Price at George Washington University. Direct Search provides links to a variety of education
specific resources, plus general interest resources including Your Nation (which uses data from the CIA World Fact Book to create customized, comparative statistical profiles for different countries), Termium Plus (billed as the definitive French-English dictionary), and the Writer's Guidelines Database. Lycos provides access to over 300 searchable education databases at http://dir.lycos.com/Reference/Searchable Databases/Education/. Infomine (http://infomine.ucr.edu/) permits multiple database searching, which is a significant time saver, and it also has two long lists of instructional resource databases (for K-12 and for higher education).

Using kids’ search tools

Another common task for teachers and teacher educators is to locate developmentally appropriate resources on curriculum-related topics. One strategy is to design a Boolean query such as “lesson plans AND nutrition AND third grade” and then to try the search with a general search engine. It may be far more efficient to search using kids’ search tools. These search tools are directories of resources that have been carefully reviewed and evaluated for accuracy and age-appropriateness. Three examples will be demonstrated: ALFY (http://www.alfy.com), a totally icon-driven search tool designed for pre-readers, Searchopolis (http://www.searchopolis.com), an excellent search tool for elementary and middle grades students, and the Britannica Internet Guide (http://www.britannica.com), which is very useful for high school students. These well organized sites almost always identify relevant sites on the topics commonly taught in K-12 schools. As an added benefit, when students become comfortable with these specialized search tools they will be more inclined to let their own students begin to search the web.

Web searching is a complex activity that requires a considerable amount of knowledge and critical thinking. Learning about new search tools and search strategies that allow teachers to focus on the task and not the tool are important skills.
Interactive PowerPoint for Teachers and Students

Abstract: PowerPoint has become more than a linear presentation tool. The later versions of PowerPoint support branching navigation, custom buttons and menus. These features make a powerful and flexible product for creating custom lessons. In addition, a PowerPoint show can include Web links, and a variety of files created in other programs. PowerPoint has also streamlined the process of designing for the Web. When using presentation software in the classroom it can be applied for education in three general formats: Teacher to Audience; Teacher to Individual; Student to Audience, depending on the structure of the presentation. Additional two types of interactivity that can be included in any PowerPoint presentation are navigation and feedback. When creating PowerPoint presentation, design considerations should be followed concerning number of items/points, font size, and color applications. Additional the use of multimedia (such as sound, images, and video) is an excellent way to enhance a presentation.

The Presentation

PowerPoint has become much more than a linear presentation tool. The 97 and later versions of PowerPoint support branching navigation, including custom buttons and menus. These features make PowerPoint a powerful and flexible product for creating custom lessons. This tool is useful as an automated kiosk, or as an individualized tutor. It is easier than ever to incorporate multimedia elements such as sound, graphics, animation, photos, and movies into the show. In addition, a PowerPoint show can include Web links, and a variety of files created in other programs. Databases, spreadsheets, and charts are a few examples. Now PowerPoint streamlines the process of designing for the Web, when presentations are saved as HTML files.

Presentation software, such as PowerPoint, can be used for education in three general formats:
1. Teacher to Audience
2. Teacher to Individual
3. Student to Audience

Teacher to Audience presentations involve the teacher, as presenter, sharing information with a class or group, in the classroom or even across the web. A presentation can be used to do more than just transmit information. Other applications include brainstorming, organizing, and reviewing. Benefits of interactive presentations include sensory engagement through multimedia, and easy reuse and updating of saved files.

Teacher to Individual presentations are often delivered by way of a hands-on computer station. Here students or small groups can work on tutorials, interactive lessons with feedback, review, and even testing. Using this approach students, can work at their own pace, and can experience individual remediation or enrichment. This type of program can be run in a computer lab, through a school's network, or via the World Wide Web.

Student to Audience presentations allow a student or group of students to share their learning with their class, their parents, their community, and even the world. By developing a
presentation, students gain extensive experience with organizing information, and they experience the real-world task of communicating knowledge to others.

Design Basics
When creating PowerPoint shows, some design considerations should be kept in mind. These characteristics will make presentations easier to comprehend and make the presenter appear more professional. First, on any slide it's best to use a maximum of six text items as phrases or bullet points. Any more than will cause the text to be too small and to present so many points that it is hard for the audience to keep in mind. With more than five or six points, consider grouping them into subtopics, then present the list for each subtopic as its own side. For purposes of presentation, it is recommended to use clean fonts and large font sizes. Avoid using decorative letter fonts, and instead use the classic Arial or Roman font types. When presenting, a 20-36 point font size is effective for distance reading. Avoid writing in all upper case, even for titles. The shape of a word can make it much easier to decode, and all caps cause all of the words to have the same block shape. Also, since web use has become very common, be sparing in your use of the underline and limit it to URLs and references only. Always choose a few high-contrast colors for the presentation: too many colors can become confusing, and a lack of contrast between the text and background can render the presentation unreadable. While people prefer to read dark text on a light background, light text and dark backgrounds are also acceptable. Ensure that the contrast is sufficient. Finally, consistently test the display of the presentation, along with testing microphones, speakers or any other associated equipment that is needed.

Multimedia
Visual media are extremely effective in education, and their proponents claim that they have great potential for further affecting learning. Many consider that visual media (including audiovisual) hold the greatest hope for the future of education. Regarding the use of multimedia including visual based media Barron and Orwig (1993) discussed reports that the use of multisensory delivery methods are more appropriate than single sense methods as some learners learn better under specific modalities. Since the use of multimedia provides instruction that is delivered to the student through numerous sensory channels, it allows for students of various learning styles to benefit. Others also support this viewpoint by suggesting that the educational setting should be providing a multi-disciplinary approach. In a large review summarizing methods for improving interest in the classroom, Bonwell and Eison (1991), state that the use of visual-based instruction, coupled with opportunities for responses from students, produced significant positive changes in students' attitudes. A multimedia presentation approach can involve the use of a variety of technological components such as video, audio, imaging, and other such materials. Use of multi-sensory multimedia approaches in the classroom has been shown to improve student learning. Studies also seem to indicate that the use of images and video in a presentation presents material within a framework that promotes better recall (Beaver, 1995).

The use of multimedia is an excellent way to enhance a presentation. Use graphics, sound, video, animation, and charts to emphasize the message. Whenever possible, keep multimedia files small, since they will have to load into the presentation computer's RAM before being displayed, and therefore may cause delays or pauses in the presentation. Don't include picture or sounds without purpose. An image or sound that has no bearing on the presentation can often be confusing or distracting. Avoid using repetitive sounds. A short tone is usually acceptable, but something longer that repeats often can be disruptive and distracting.

Multimedia Examples for Inclusion
- Virtual field trips

• Vocabulary pronunciation

Interactive Presentations

Educators such as Chickering and Gamson (1987) have stated that “learning is not a spectator sport. Students do not learn much just by sitting in class listening to teachers, memorizing prepackaged assignments, and spitting out answers.” In active learning, students must talk, write, and relate to what they are learning. Overall, a need exists for a modification to the lecture, which has been the historic standard for instruction. Bonwell and Eison (1991) made the point, in their monograph summary of active learning at the higher level, that a major failing point of the traditional lecture is that students remember material presented at the beginning of a lecture better than information presented at the middle or the end. This result means that large amounts of information presented to the students are being lost. To overcome this loss and make instruction better, many are suggesting a shift from the basic lecture to a presentation that is more interactive in its approach. Meyers (1993) considered that active learning derives from two basic assumptions: (1) that learning is by nature an active endeavor, and (2) that different people learn in different ways. Others consider that, simply put, active learning is more likely to take place when students are not only listening; but are also engaged in activities. Students must do more than just listen in active learning: they must be engaged. According to Sims (1985), activities requiring active participation were found to be associated with higher levels of attention than were more passive types of activities. All of these results lend credence to the inclusion of interactivity into presentations.

A method that has been found to be effective in teaching is to shift from a lecture format to one of active learning, where the student has some level of interactivity with the material being presented. Two very easy types of interactivity that can be included in any PowerPoint presentation are navigation and feedback. For navigation, use onscreen buttons and hypertext for a branching structure, allowing the user to visit the sections as they wish or to provide the option to gain more information on topics of interest. For feedback, slides can present questions and offer choices of answers. With proper scripting, when students make choices they are either given feedback on the slide or are taken to new slides that provide information. Benefits for the user of this structure include increased engagement, control, and interest along with immediate response.

A teacher can go even further with interactivity with the use of Visual Basic for Applications (VBA). With VBA, it is possible for a PowerPoint presentation to not only ask and evaluate questions, but also track responses, store information, provide feedback, and generate reports.

How to add interactivity with buttons for navigation or answers:
4. From the Slide Show Menu choose Action Buttons
5. Select button appearance
6. Then choose the action for the button
7. Locate and size button on slide
8. Double-click button to change color
9. Right-click on the button to add text or change action

How to add interactivity through hypertext for menus and links:
10. Highlight text
11. Right-click the selected text to choose Action Settings
12. Select an action for the text, such as:
   - link to another slide
   - link to another PowerPoint
   - open a file
open a specific web page (URL)
run a program
run a macro (or VBA application)
play a sound or video

PowerPoint is capable of more than a linear presentation. By including branching, relative navigation, custom buttons and menus, you can make PowerPoint become so much more than just a presentation application. Understanding how and when to incorporate multimedia elements (sound, graphics, animation, photos, and movies) creates a more interesting and effective presentation. Through the application of Web links, and files created in other programs, information presented in PowerPoint becomes much more dynamic and current.

Abstract: We have developed a searchable on-line database of staff development material relating to electronic teaching resources, which operates across the University network. The database is searchable via a simple interface and offers staff with little experience of computing the ability to locate general or subject specific information and then use the resource directly using a simple point and click procedure. This facilitates the distribution of information via a one to many approach and eliminates the redundancy inherent in personalized data mining. The database contains a pool of local resource material, which can be shared between teaching staff. Each item of material is catalogued according to predefined search terms, and single database field allows web links, shortcuts, images and program links to be "dropped" into it. Such an approach makes the database a more personalized information delivery mechanism.

Introduction

The major reasons why the use of computers to deliver teaching material is not more common in university education are well documented but have not yet been fully addressed at least within the United Kingdom. There is a significant lack of knowledge on the part of academic staff as to the pedagogical and technological changes which computers bring to higher education. There is an urgent need at least within the UK for staff development programs that can provide information on this subject and can hasten the management of these changes. Information on, and access to such programs must in our opinion be available from the user's desktop and must take cognizance of an individual's computer skills, teaching style and lecture content.

While the WWW is in theory the obvious delivery mechanism for such information, in its current state it has three restrictions when considered for this task. Firstly the teacher entering this field for the first time will need to acquire information on topics relating to both the teaching/pedagogical role of computers and then to his or her subject specific material. The organization, grouping and indexing of this material can be done in a limited way using the “bookmark” approach, but rapid retrieval of such relatively unstructured information demands some skill and commitment from staff. Secondly, many examples of for example interactive software need to be demonstrated locally and in a manner which allows a high degree of user interactivity. To convince staff that for example a simulator program may be a useful teaching tool needs more than an interactive web page demanding a plugin the user may not have or may not understand how to use. Finally the web approach does not facilitate the sharing of resources and information in the same immediate manner as for example a LAN based application. The situation is changing rapidly and the wider introduction of databases using the web as a query and delivery mechanism will improve information flow. However, we feel there is still a place for a computer program which presents a structured, user friendly approach to the dissemination of validated resources and allows their immediate on-line execution.

We have developed software which combines what we feel is the best of these two approaches. We use a server-based database to collate/index/ and present a simple search interface to staff. The database stores web links, links to server based demonstrations of interactive CAL, non-copyright images, sound and video files, rich text formatted information and links to examples of spreadsheet, presentation and database material. This allows any member of staff to profit from the data mining of another and to share resources.
The program is essentially a word processor/database into which active links can be pasted, grouped where required and indexed. Formatted text on a particular subject can be displayed within a record together with “shortcut links” to relevant web sites, documents, images, etc. As a staff development tool this allows us to deliver a coherent collection of several information resources relating to information on a single subject. Random browsing of the web by staff is reduced since if for example they require information on for example “Computer Adaptive Assessment” they simply key in the phrase and ALL the material which ourselves AND their colleagues have previously researched and entered into the database is available to them.

Operating across the network, staff can either run or download the material. Image files, presentations etc. can be linked to the staff member who produced them and thus staff can communicate with colleagues if they wish to borrow material for teaching.

We feel that until the use of web–driven database’s are common and more staff have a higher degree of skill at downloading and installing software, the opportunity for them to browse or search through a comprehensive database of information will be a valuable asset to our staff development program.
Teacher Educators’ Reflections on Using Group Response Technology

Abstract: The study reported in this paper explored the use of group response technology (GRT) by teacher educators and their reflections on the use of the system with preservice teachers. Five teacher educators used GRT with undergraduate students and then reflected on how the system impacted student participation, class discussions, and instructional planning. Data for the study consisted of instructor interviews. The results suggest that GRT was an efficient means for all students to participate in class and for the instructor to monitor student progress during instruction.

Background

Recent federal initiatives call for the development of teachers who can meaningfully use technology to help students learn (U.S. Department of Education, 1999). Unlike instructional technology diffusion efforts of the past, the focus of the current initiatives is to prepare teachers who understand both the technology and pedagogy and can effectively integrate the two to create learning environments where K-12 students use technology to make meaning. Toward this aim, current initiatives integrally involve teacher educators from all disciplines and not just those in instructional technology. Moreover, current initiatives call for the regular integration of the technology into the teaching and learning activities of all aspects of teacher preparation (U.S. Department of Education, 1999).

In our efforts to move beyond using technology primarily to supplement instruction, we need to develop technology applications that help solve current challenges in teacher education. One challenge in teacher education is the need to enable active student participation across large groups of students and provide efficient instructor access to student knowledge during instruction. The typical mode of instruction for large groups is lecture (Benjamin, 1991). Although lecturing may be an efficient means of information
dissemination, student participation is passive, at best. Another challenge is the absence of efficient means for instructors to monitor student progress during instruction. Instructors' questions in large classes generally are rhetorical or answered by only a few students. Even if the instructor receives input from some students, it is still difficult to efficiently monitor all students' progress during instruction.

In teacher education, the challenge of creating participatory learning environments and facilitating instructor monitoring is greater because the implications of not doing so are far reaching. Because teachers tend to teach the way they were taught (Lortie, 1975), it is imperative that preservice teachers learn about teaching in cognitively engaging environments where they are active participants.

Group Response Technology

To more fully engage all students during group instruction and provide an efficient means for instructors to monitor student progress, we explored the potential of group response technology (GRT) to support teacher education. GRT is one form of groupware that has potential to enhance the effectiveness of lecture-based instruction (Foegen & Hargrave, 1999). GRT supports efficient communication within a group by collecting input simultaneously from each group member; furthermore, that input can be accessed and reviewed by a single user (Foegen & Hargrave, 1999). Common examples of GRT include audience response systems used in the marketing and entertainment industries.

The GRT system used in our investigation was Discourse®. Discourse, which consists of individual student terminals networked to a teacher's workstation, is a text-based response system that allows students to respond in phrases, complete sentences or even paragraphs. Discourse enables the instructor to obtain feedback during instruction from each student in the class about course content (see Foegen & Hargrave, 1997; Robinson, 1994). The purpose of this article is to describe how teacher education faculty used GRT and their reflections on their use of the system.

Method

Our study examined the perceptions of instructors at a large, Midwestern university as they learned to use Discourse and incorporate it into an undergraduate course. This system was housed in a model "technology classroom" and was supported by a quarter time graduate assistant. During the 1998 fall semester, we recruited seven instructors to participate in the project. Interview data for five of these instructors formed the data set for this study. These instructors (four females, one male) taught a variety of courses ranging from a sophomore level introduction to teaching strategies course to a senior level student teaching seminar. All had graduate degrees (2 doctorates, 3 masters degrees), and each had taught their respective courses during previous semesters. Additional information about the instructors' courses and use of the GRT are presented in Table 1.

Late in the 1998 fall semester, the instructors participated in a Discourse training session. During this 90-minute session, instructors experienced (from the student perspective) several different models for integrating GRT into instruction (e.g., large group discussion, independent practice activities, cooperative group learning). At the close of this
session, the instructors brainstormed ways in which they might incorporate the technology into their 1999 spring semester courses. Each instructor was asked to use GRT a minimum of two times with at least one of his or her undergraduate classes.

During the first few weeks of the 1999 spring semester, the graduate research assistant met individually with the instructors to assist them as they prepared to use GRT with their classes. These activities included practice in operating the system, preparing specific lessons or questions to be pre-programmed into the system for use during class, and basic trouble shooting of the system. Each instructor taught his/her class using GRT at least twice during the semester. Within two weeks of the second use of GRT, data were collected on instructor perceptions.

We gathered data on instructor perceptions using semi-structured interviews. The interviews were conducted by a graduate student (not associated with the group response technology), who used a 17-question protocol to elicit the instructors’ reflections. The questions were designed to elicit information regarding instructional purposes, instructional planning and preparation for using GRT, difficulties related to GRT use, and other instructional issues. Sample questions used in the interviews included: What were your expectations for using GRT? What instructional issues did GRT cause you to address when planning your lesson?, and What effects did GRT have on the flow and focus of class discussions? Each interview was 40 to 60 minutes in duration. At the end of the semester, each of the interviews was transcribed.

The purpose of our inquiry was to describe how teacher education faculty used GRT in their courses and explore their reflections on the use of this technology as an instructional tool. More specifically, we wanted to explore their expectations for GRT use, comfort in using GRT, and evaluation of the GRT system. To accomplish this task, we carefully reviewed each instructor’s interview, noting instances in which their comments related to the three topics of interest.

Findings

We began our analysis of the data by examining the frequency and manner in which the instructors chose to use GRT. Four instructors used the system two times during the semester; the fifth instructor used GRT three times. A review of interview transcripts indicated that the instructors used the system most often for whole group discussions (N = 4), followed by demonstrations of the system and multiple uses (N = 2 each). Multiple uses referred to class sessions during which the instructor used the system in more than one manner during a single session (e.g., whole group discussion and individual work). The instructors, who used the GRT system in multiple ways, each reported that they used GRT for small group activities and individual student work.

Most commonly, the instructors chose to use GRT to introduce new material. In two cases (Instructors B and C), this was new content related to the methods course; in two other cases (D and E), the “content” of the instructional session was the technology itself. Instructor A chose to use GRT to reinforce previously taught content in preparation for an exam.

**Expectations and Instructional Purposes:**

Prior to their use of the system, the instructors possessed expectations for the GRT. That is, they expected the technology to contain certain features that would allow them to access and manipulate input gathered from students. Based, in part, on these expectations, the instructors had specific instructional purposes they wanted to achieve through the use of GRT.

Four of the instructors reported that they expected the GRT system to alter class discussions by allowing more students to participate. Instructor A noted, “...I thought this might be a good way to better hear from those students in my classroom ... who don’t speak up regularly in whole class discussions.” Instructor C concurred, “...I thought the [conversational mode of Discourse] would really assist me in reach[ing] those silent students. Because they tend to be there in our courses.” Instructor E anticipated GRT might alter class discussions because students would read other students’ responses as opposed to hearing them. She hypothesized that students might generate higher quality answers when responding in written form, and that this, in turn, would alter class discussions. “What I was hoping would happen later is students’ responses would be more thought out because there
was that forced automatic wait time. ... so I was hoping it would slow some of those students down to really think of well thought out answers instead of quick answers” (Instructor E).

In addition to altering class discussions, several instructors reported that they wanted to demonstrate new technology to their students and model how the technology can be integrated into regular teaching and learning. As an example, Instructor C remarked, “I want students to experience technology as a natural part of whatever we’re studying.”

Comfort

Of particulate interest to us was the degree of comfort the instructors experienced in preparing for and using GRT for group instruction. For the most part, the instructors reported that they were comfortable using GRT with their students. The greatest source of discomfort stemmed from technical or structural issues with the system. Instructor C reported that her biggest challenge in using Discourse® was remembering specific system commands and to switch between various modes in the system.

Two instructors indicated that the physical structure of the classroom with the GRT system was somewhat awkward and required them to adjust their instructional style. Instructor A commented, “I felt I had my back or side to the class too much. Because I’m looking at the screen... with more practice I think it would be seamless between me changing the question and talking to my class.” Similarly, Instructor B noted, “I might be in the back of the room talking and I want to change what’s on the screen, so I have to quick run back up to the front of the room... That alters my style a bit.”

Two instructors indicated that using the GRT changed their planning or preparation for class. Instructor A noted, “The active participation of students was something I was cognizant of as I was... thinking about how... I should be using [the study.com] in a way that helps student learn the most they can.” Instructor B also experienced changes in her preparations: “It impacted the way I presented directions and tasks and information.”

Three of the instructors indicated that use of the GRT in class did impact the pacing and focus in their classes. In the student teaching seminar course, Instructor E was surprised to find that using GRT caused students to focus more on the mechanics of their writing. “When we have worked on these questions before it was a very intimate close conversation and a lot of positive reinforcement between students. ...the focus changed from being a very cooperative learning and sharing to one of individual thought. ...The students become much more focused on their writing than on each other.” Two instructors reported that the pacing in the course changed because of GRT use. Instructor C found the pace of her class slowed: “The pacing ... was affected because my students weren’t using Discourse on a regular basis. ...they’re not all very fast keyboard users. They are really careful about how they say what they say... So they need more think time before I expect them to start typing.”

Evaluation

Consistent with every type of technology used in the classroom, each of the instructors stated that s/he experienced minor technical problems with the GRT system. The majority of the difficulties stemmed from a lack of familiarity with the system. Other limitations cited by the instructors included becoming proficient in teaching with GRT and
the physical layout of the classroom. Instructor A noted, "It's hard to practice [teaching with GRT] without an audience unless I'm hitting a study com and also working at the

Instructor B found GRT required changes in her usual patterns of movement within the classroom: "It's a little bit cumbersome to have to go over to the computer. ...it takes you away from wandering around the desks. ...[Discourse] pretty much glues you to the front of the room so you can manipulate the computer." The difficulties with the physical layout of the room were also noted by Instructor A, who commented, "I felt I had my back or side to the class too much."

Other challenges identified by the instructors included a shift away from focus on content and limited flexibility. Two instructors reported that when using GRT the students began to focus on minor writing concerns and not major subject matter issues. Instructor E indicated that GRT changed class discussions and "brought out a lot of students' insecurities [about] their writings." Instructor A pointed out that the GRT system limits spontaneity in the classroom: "If students come up with a divergent idea, ... [GRT] didn't let us explore an option that could have lead to more learning."

The instructors cited several positive aspects of using GRT, including monitoring students’ responses to instruction and engaging a larger number of students. Instructor A noted, "It's just a real easy way to scan, see who answered and who was off track, and see who I might have to do so teaching with later." Instructor B also found the monitoring features to be beneficial: "When I was able to put up samples of students' comments, ... it allowed me to focus on specific things that were said and build off of them and make connections and have the comments visually in front of the students... it provided an accurate representation of what the students said rather than me trying to rephrase it and may be putting my own twist on it unintentionally. I think it influenced [my ability to lead discussions] in a positive way." In addition, Instructor B found the ability to include all students’ responses to be significant: "...Everyone got to have a say. Whether everybody's [comment] got up on the board or not, I got to see that everybody was things and what they were thinking."

Conclusions

The purpose of this study was to describe how teacher educators used GRT with undergraduate students and their reflections on their use of the system. Consistent with their expectations, the instructors reported that the use of GRT effected class discussions by increasing the number of students actively involved in class. Two instructors stated that using GRT allowed them to hear from all students and monitor their thinking during class sessions. In addition, two instructors reported that their pacing was slowed due to GRT use.

The instructors stated that, for the most part, they were comfortable using GRT, although it did cause them to alter their instructional style slightly. In their evaluation of the system, the instructors cited several limitations of the GRT system that impacted their instruction. It should be noted that some of the technical limitations cited by the instructors were due to the instructors' lack of experience or fluency in using GRT. As the instructors become more experienced, their perceptions of system limitations may change.

It is clear from the data that the instructors were generally positive about the use of GRT. It is relevant to note, however, that the instructors who participated in this study were first-time users of GRT. Thus, the researchers are cautious regarding implications of the study. In this exploratory study, GRT appeared to meet the challenges of teacher education by providing a participatory learning environment where instructors can efficiently monitor student progress during instruction. To more fully understand the potential of GRT for group
instruction, faculty will need to become more familiar with GRT systems and make them a more natural part of the classroom structure.

Understanding Graphics for Effective Communication

Jerry P. Galloway
Division of Education
Indiana University Northwest
United States
IUN@jerrygalloway.com

Abstract: The use of graphics in screen design by students and teachers alike often fails to achieve real communication. Today's authoring tools allow designers to randomly select and place graphic imagery virtually anywhere in presentations, tutorials, etc. Some graphics are useful and important, others are basically neutral in their effect while others can detract or interfere with messages and ideas being presented. It is important to better understand graphics and how graphics affect screen design in order to improve communication. This paper reports recent research on teachers' use of graphics in HyperStudio screen displays. Graphic displays are analyzed and the use and application of graphic imagery is categorized into discrete levels based on their level of communication.

Introduction

Advancements in computer graphics technology, especially hypermedia, are changing the language of visual communication and defining multidimensional communication models that require new perspectives in information design (Search, 1993). Virtually any screen presentation is now considered passé poorly designed if lacking icons, graphics or other visual imagery. Icons can be used to represent information, concepts and ideas (Borg & Staufenbiel, 1992) and linkages (hotspots) to other information sites. Graphic symbols may only decorate screen displays yet can be used to convey or identify information, summaries or overviews, supplying instructions, and indicate position, size, representation, and more (Pettersson, 1993).

It has been said that a picture is worth a thousand words. In fact, graphics have been described as so information-rich that it is difficult to fully account for the content. Structured or systematic classifications of the communication, information or effectiveness of graphics is even more difficult. Tiemens (1993) provides seven categories to account for visual imagery: (a) duration, (b) transition, (c) framing, (d) view angle, (e) orientation, (f) motion, and (g) content. While this classification system might be useful, Tiemens calls for the need to organize or classify the use and application of graphics and visual imagery to better analyze their value. Communication value, the conveyance of ideas through visual representations, is difficult to analyze and catalog without rules and codes for the application of graphic imagery. Misanchuk and Schwier (1995) further attest to the problem of lacking protocols for guiding the design of graphics and screen imagery for instructional purposes.

Graphics are among numerous important components of screen displays (Schaefermeyer, 1990) from text style to scrolling effects and graphic line design (Aspillaga, 1992). Overall screen design and graphic appearance are also important variables in effective communication and user-interface for hypermedia of all types including web page design (Descy, 1995; Van Brakel, 1995). Research has shown that computer screen displays can affect learning (Costello, 1995; Hathaway, 1984) and retention (Aspillaga, 1991). Even the early years of computer technology in education called for software that would more fully utilize the visual versatility of the medium. Graphics and graphic imagery do affect the learner's understanding of material and provide additional meaning to text displays. But, the role that graphic symbols play in screen design of educational products should also account for the needs of specific audiences (Emery, 1993).

Graphic Appearance

Ready-to-use clip art is available in many software packages and respectable graphics are easily created with drawing tools available on virtually any machine. Yet, graphics can be poorly applied and reduced to achieving a mere decoration or, in worse cases, even distraction from the primary content. There is a need to
actually think visually in spite of current limitations of the medium (Gibbs & Fewell, 1997). Graphics can be abstract lines and figures, or pictures, logos, etc. any of may be intended as realistic or merely representational (Eugenio, 1994).

Philleo (1993) looked at using graphics on buttons and hotspots in HyperCard with middle school kids. He looked at (a) graphic appearance, (b) user curiosity and attention to buttons with graphics, and (c) the relationship between graphic and content. However, the research yielded no significant conclusions other than the general usefulness of the hyper-medium. It left many questions yet to be explored.

Graphics can provide clues to trails and pathways through instructional hypermedia and help to structure the information presented. Graphics may be considered in terms of their design and appearance as well as how well they may be understood (Keasley, 1988). The cognitive impact of icon design (Lee, 1996) addresses issues of color, size, placement and the inclusion of text in terms of how these elements actually affect understanding. The complete setting, including the background, can affect the recognizability or retrievability (meaningful understanding) of graphic imagery (McNair, 1996).

While graphics can be analyzed intrinsically, it is a common concern of computerized presentations that graphics be considered in terms of the human-computer interface. That is, looking at graphics beyond their mere physical characteristics and considering attention value versus learning and recall, the relationship between packaging and content, and therefore the overall effectiveness of communication (McFarland, 1995). Knupfer (1997) examined the use of graphics and icons in web page design as tools for communication, including aesthetics and functionality. Educational and school web sites tended to use text rather than images to present information; sometimes overuse of backgrounds interfered with the overall message. Non-educational sites were similar except that professionally developed commercial sites contained a greater use of animations and more sophisticated graphics.

A system for understanding graphics in terms of their communication value is needed. The study below outlines a structured approach in which graphic imagery is categorized into 6 levels of communication from meaningless abstractions to conveying conceptual relationships and compound notions.

The Study

The Course

In-service teachers (n=30) participated in a summer workshop on using HyperStudio. While approximately three-quarters were beginners in using computers, all were new to using HyperStudio and hypermedia in general. The teachers were to create three stacks (hypermedia presentations) during the 6 week course. They were (a) a linear presentation, (b) a virtual tour, and (c) an instructional stack. No specific topics were assigned and no specific parameters were assigned about the percentage of graphic imagery versus text in screen design. The communication value of graphics with examples across all levels described below was presented as well as other communicative aspects of overall screen design.

The linear presentation project called for students to design a relatively brief presentation of 5 to 7 cards (hypermedia screen views) arranged linearly with no hyper-jumps included. This “slide-show” concept was to be consistent with making a presentation to a passive audience in a lecture format. The sophistication of screen design was completely up to the ingenuity of the teachers. Other than small, one-card activities to review tool use and other functions, this was to be the first actual assignment to be completed early in the course.

The virtual tour project (second in the course) called for teachers to create a virtual world of some geographical spatial area that could be toured by the reader. The virtual world was to provide information and a realistic sense of being in that place in terms of geographic locations (forward, back, left, right, in, out, etc.). For example, one might enter the door of an art museum and walk through the rooms or halls to view the exhibits contained inside. This project did not call for an animation component for creating the actual sensation of movement. In other words, this was not to be a simulation of motion and travel. It was instead to be an exploration or expedition through both a topic and a geographical space in which that topic might normally be found. Another example, might be a walk along the boardwalk next to the beach. One might move forward or back, left or right to move from one shop or attraction to the next. Depending on the map or physical orientation involved, one might turn and see the beach as well. The goal of their project was to present information about the sites, attractions and points of interest in that virtual area. Whether that information was to be primarily graphic or textual was left to the teacher.

The instructional stack was intended as a self-guided tutorial or instructional presentation, but in any event, to serve in the process of teaching. Too, it was not to be merely linear as in the first assignment and would thus
need a multidirectional, hyper-linked layout. This assignment was to be more substantial overall, communicate more and better than the first because this was their final work in the course.

Exclusions and Limitations

Many issues are faced in the development of effective screen display: too much or too little, black and white or color, clip-art or hand-drawn, scanned or downloaded, and more. The term graphics is often used to refer to everything from buttons to full-motion video. For this report, the term graphics is meant to include geometric shapes, clip art, drawn or imported images, including black and white, color and even animated graphic images. Furthermore, the term "graphics" addresses generally discrete images as separate entities and thus ignores the potential of combining graphics into a composite or a choreographed symphony of interaction for a combination design or communication effect. Sound, while often an issue in screen design, was not considered except to the extent that a graphic symbol or image may be associated with that sound. Video per se is considered categorically separate from the graphics drawings, images, pictures and icons of this study.

Certainly there are different types of graphics. The distinctions between object-oriented, vector or bit-mapped graphics is irrelevant in this study and more appropriately relates to how such graphics are created than the role they play in screen appearance. Various methods of drawing and creating graphics have both merit and limitations depending on the application and one's personal skills. Sources of graphic imagery are basically irrelevant in this study as the focus is instead on its use and on-screen role and communication value. Distinctions between drawing original images versus using commercial clip-art or downloading imagery from the Internet also have no bearing on display uses and more appropriately relate to issues of availability, ease of acquisition and such.

This paper does not address the operational function of graphic images as programmed objects to perform tasks or as mapped hotspots to execute actions. It is the role of the graphic object and its application to the screen design and communication value that is of interest here. Certainly, programmed functionality can be applied, depending on the software used, to any graphic or portion of a graphic at virtually any level of screen application. For example, a simple 3x5 card frame or picture frame line or image that might be used to contain text or another graphic image, low in communication value, can itself be programmed as a hot-spot in HyperStudio, in HTML Web-page programming and other software packages. Also, an image of gears or pulleys for a display about industry (higher in communication value) might be programmed to execute specific actions, again depending on the software. Nevertheless, the functionality is irrelevant to the role of the graphic design and communication value.

There are many important issues about programming functionality into hyper-media applications for graphics as well as text. These issues are better left to another discussion and have little or no real bearing on the levels of graphic use outlined in this paper.

Graphic Communication System

The system involves six levels of use or application of graphic imagery in screen design and communication. These levels represent a hierarchy of sophistication and complexity in the graphic's communication value in screen design. These levels do not rate the sophistication or complexity of the graphic images themselves. Graphics are identified and classified into one of the 6 levels with the notion that higher is better in terms of conveying and representing clear and useful ideas.

It may be that more complex graphic designs would serve better or might be more functional at any of the various levels to achieve the prescribed purpose while the role in communication remains the same. For example, a simple black box frame (level 1) might be sufficient to delimit text from the surrounding screen area. However, a box with gradient color and varied line thickness might somehow serve better in the aesthetics or general appeal of the screen appearance. Another example, a simple, two-dimensional triangular shape (level 5) might be sufficient and effective in instruction, where as, a three-dimensional triangular object with shadow effects might be preferred. In each case the use or application of the graphic object - the role the graphic image plays in the display - would be the same: level 1 versus level 5.

The six levels are detailed below and include a description of examples to assist in evaluating screen designs. Of course, different observers might interpret these descriptions differently.

**Level - 1**

Includes the most basic, abstract geometric shapes such as boxes, lines, circles, arrows, etc. These graphics are used primarily to establish abstract separations, to delimit screen areas, to create borders, separate text, provide some color, etc. These graphics have no particular appearance other than general geometric shapes and may often decorate screen appearance or focus attention on other screen components.
Level - 2
Includes shapes, clip art and images for purposes similar to level 1 above. These graphics would more likely be specifically designed for the role they play in the screen design. It may be that they're commercially designed (clip art) and thus, their quality may more clearly establish their role and purpose. For example, a picture of a notebook, window or stage, courtyard or patio, etc., which might be used to delimit screen areas, to create borders, provide some color or provide on-screen containers for text or other material.

Level - 3
Includes shapes, clip art and images, drawn or commercial, provided for purposes of decorating the screen. The decorative effect is likely limited to random, ambiguous or very general purposes. For example, the inclusion of a smiley face, stick figure, a star or the sun, etc., all of which serve no specific communication purpose.

Level - 4
Again, this level includes shapes, clip art and images, drawn or commercial. These graphics would be used to decorate a screen display consistent with or to establish a theme. The primary difference from level 3 above is that these graphics seem to focus attention on a particular or specific idea and thereby serve to further that notion. For example, an apple or school house on a screen for teachers, a car or stop light on screen for drivers, a compass or sextant on a screen about explorers, etc.

Level - 5
Again, this level includes shapes, clip art and images, drawn or commercial. But, more than merely establishing a theme, these graphics tend to convey ideas and are often objects used in instruction. That is, they may instruct or be referenced in instruction. The images themselves are not mere decoration and are intended as the focus of the display. For example, triangles referenced in instruction on geometry, a clock image for telling time, component parts for constructing machines, etc.

Level - 6
Again, this level includes shapes, clip art and images, drawn or commercial. This highest form of graphic imagery is used to communicate specific and more complex ideas and concepts important in the communication. The notion that a picture is worth a 1000 words. Such graphics might include conceptual relationships conveyed in the imagery itself but somewhat more sophisticated than level 5 above. For example, a turning earth used to illustrate planetary rotation, etc.

Results and Discussion

In general, most projects were under developed and involved fewer cards than expected. Hand-drawn graphics were poor in appearance as skills with tools and mouse control were weak. The virtual tour project was somewhat misunderstood and many of the instructional projects were little more than linear presentations and thus lacked sufficient multidirectional linkage. However, these findings were incidental to the graphical classification system being employed in this study.

Graphics were tallied and classified while observing presentations of their completed projects. Figure 1 illustrates that teachers make frequent use of simple shapes like lines and boxes in their screen displays an average of 4.31 times per student across their three projects. This is an interesting comparison with the significantly less average of 1.31 occurrences of level 2 graphics, which can achieve a more or less similar purpose but at a higher quality.

</tbody>
</table>

Figure 1: Average occurrences of graphic levels in student HyperStudio projects.
Levels 3 and 4 proved to be the highest occurrences of 4.62 and 5.23 respectively indicating that graphic imagery was typically used for purposes of decorating the screen. There seems to have been a balance between the general or random application of miscellaneous graphics and those used to emphasize or support a theme or topic.

Much more infrequent were level 5 graphics (2.92) that might have been referenced in instruction or been used to convey actual ideas. Of course, at 0.28 level 6 graphics were practically nonexistent and the least used out of all categories.

As shown in Figure 2, the quantity of teachers who designed and used graphics of the various types (at least one instance across the three projects) is quite similar across the categories to the averages per student. With 100 percent of the students using type 4 graphics they all thought in terms of using graphics to support a theme or topic. Of course, a low 31 percent of teachers used any graphics that conveyed actual concepts and notions intrinsic to the graphic itself. It is encouraging that 77 percent of teachers had at least one instance of level 5 graphics - imagery used to instruct or assist with instruction.

This study of course provides no standardization or inter-rater reliability and different observers might judge the same screen displays differently. The judgments made in this study, while consistently applied from a single observer, are nevertheless subjective and debatable. This largest form of graphic use from these teachers - levels 3 and 4, decorative graphics - is still considered weak in communication value. Graphic use generally failed to make the shift to becoming functional tools of communication.

The notion that graphics can intrinsically convey complex notions and ideas seems lost on most amateur designers. Teachers almost presume that the very purpose and intent of graphic imagery is merely to decorate in support of a general theme. It may be that these teachers tend to seek a comfortable balance, a kind of moderation, between text and graphics without much effort toward communicating with graphics. Text is readily available and easily applied to virtually any screen area and thus tends to become the preferred method of communicating ideas. As most of these teachers were beginners with computing and hypermedia, a simpler explanation might simply be that their history of communication was predominantly words.

There are of course many interesting questions that can be examined using this categorization method. For example, how do art teachers, who may be comfortable with and experienced in designing graphic and pictorial imagery, compare with language arts or literature teachers in designing hypermedia presentations? Of course, it would be important to examine how teachers can be directed or influenced to think in terms of graphic communication. Virtually any prompt or treatment can be examined with control groups using this system of classifying and understanding how graphics can be made to communicate ideas.

A Study of Two Online Learning Innovations: Implications for Teacher Education and Professional Development

Herbert H. Wideman, Ronald D. Owston
Centre for the Study of Computers in Education
York University
Canada
herb@yorku.ca

Abstract: This paper reports on a study of the implementation of two telelearning projects based on different pedagogical models and using different delivery systems. One of these projects was perceived to be more successfully implemented than the other. By means of a comparative analysis of teachers' reported experiences with the two programs, we illustrate what factors beyond training and support contributed to their relative success and failure, and to describe how these factors interacted with the traditional elements of implementation. A theoretical model of telelearning implementation is then articulated and related to traditional views of program implementation. The paper concludes by considering the implications of the analysis for effective teacher training and professional development in the use of online learning environments in schools.

Introduction

When planning the implementation of technologically innovative classroom projects in schools, administrators and project leaders tend to believe that a project will be successful if teachers are provided with enough training and support for the innovation. Yet, the process of implementing such projects is often not as straightforward as proponents of the technology thought it would be. As Kerr (1996) notes:

[C]ontrary to the expectations of some pro-technology advocates, the process of adopting new devices and the approaches they make possible is neither rapid nor easy, nor does it automatically lead to the sort of revolutionary restructuring of teaching that proponents have predicted (pp.115-116).

While studies do indicate that traditional support for teachers in the form of training and in situ coaching are crucial to a project's success, another consideration has been found to be equally important—the educational practices and contexts within which the use of the technology is embedded. According to Therese Laferrière and her colleagues at Canada's SchoolNet: "effective use of the technology is embedded within practices and activities that realize its functionality for specific purposes and situations...[T]he potential of new technologies is immense, but many conditions are required for this potential to become a reality in classrooms and schools" Bracewell, and Laferrière, 1996). Similarly, Plomp, Brummelhuis and Pelgrum (1997) claim, "...the integration of technology in education depends upon not one factor, but on interconnected elements that will vary according to the level of implementation of technology" (p. 468).

Without consideration of the many interrelated factors associated with the implementation of a new technology, there can be no significant impact on students' learning. As The U.S. Office of Technology Assessment states, "it is becoming increasingly clear that technology in and of itself, does not directly change teaching or learning. Rather, the critical element is how technology is incorporated into instruction" (U.S. Congress Office of Technology Assessment, 1995, p. 57).
The Study

We investigated teachers’ perspectives on the implementation of two telelearning projects based on different pedagogical models and using different delivery systems. One of these projects was perceived to be more successfully implemented than the other. By means of a comparative analysis of the two programs, we illustrate what factors beyond training and support contributed to their relative success and failure, and describe how these factors interacted with these two traditional elements of implementation. A theoretical model of telelearning implementation is then articulated and related to traditional views of program implementation. Finally, the implications of this analysis for effective teacher training and professional development in the use of online learning environments in schools are discussed.

The two telelearning programs studied were the Satellite Network Schools (SNS) and Writers in Electronic Residence (WIER). The SNS company links schools via digital satellite to a commercial curriculum content provider headquartered in the United States and offers a collection of over 12,000 videos indexed to the K-12 curriculum. The service included a two-way interactive television channel, development of “custom curriculum”, printed curriculum resources, and a selection of interactive software. Only three Canadian schools were connected to SNS and all were studied during their first and second year of program implementation. A company consultant trained teachers on-site via one and two day workshops on the technical, operational, and (to some extent) pedagogical aspects of the system, and several options were made available for resolving technical problems and providing curriculum selection and development assistance.

WIER, a university-based telelearning project at a mature stage of development (it has been in operation for about ten years), involves up to 120 classes from all across Canada ranging in level from junior elementary to senior high. It uses a network conferencing system to link writing and language arts students to Canadian authors, teachers, and each other for the exchange and discussion of original work. Students “post” drafts, an assigned author reads and responds with comments and revision suggestions, and students also read and respond to work posted by other schools. Teachers are encouraged to do the same.

Training for WIER use consists of an initial two-week online orientation for teachers. Only online and written materials are made available—no in-person training or support is provided. Experienced teachers act as teacher-moderators through an online forum WIER provides for trouble-shooting on technical and program issues.

Method

Semi-structured interviews with school staff were conducted to glean information on the process of program implementation, and its effects, from the teachers’ perspectives. For SNS, interviews were held at the beginning of the project and followed up one year later (n=38). For WIER, teachers using the program from eleven participating schools were interviewed. All interviews were audio taped, transcribed, qualitatively coded and analyzed. The focus of analysis for this study was on the teacher-related dimensions of attitude and behavior that contributed to the success or failure of the online program.

Findings

SNS was perceived by most of the interviewees to have had very limited success. In sharp contrast, WIER was praised as having been a very effective online learning experience. Two key factors beyond training and support emerged from our analysis as central in determining a project’s perceived outcome: (1) the teachers’ perceptions of the value of the program, and (2) the congruence between the pedagogy implicit in the program’s design and operation and the teacher’s own practices. Our contention is that these two dimensions, together with training and support, played the major role in determining the ultimate success and sustainability of the program.

Initially, SNS appeared highly attractive to most teachers. In practice, the system was complicated to learn, technologically overwhelming, appeared to make too many time demands on teachers relative to the results obtained, and was lacking in quality. The content was often irrelevant, too diluted for the level requested, and often contained errors. The service support staff, although described as friendly and helpful, did not always call back or answer the phone, did not acknowledge or correct errors, had difficulty fulfilling
custom video requests, and were found wanting in subject area expertise. All in all, SNS seemed burdensome to incorporate into the curriculum and practice.

As for WIER, teachers found that the training material and two-week orientation proved sufficient to access and use the conferencing system. Technical support provided by computer teachers or technicians and WIER’s forum for questions and issues filled in gaps experienced by teachers. Uploading and downloading material was time intensive; teachers preferred to undertake or closely supervise this task to ensure the appropriateness of all material being posted to conferences. The fit of the WIER timetable to school schedules sometimes made posting difficult and limited extended dialogue between authors and students over several revisions. Also, these posting deadlines or class priorities set by teachers limited time available for reading other students’ posted stories.

The perceived value of SNS and WIER also differed. Regarding SNS, teachers felt that the investment of time and effort made to use its resources was generally not worthwhile. Occasionally, the system was useful for the teaching of typically difficult or boring topics but it was mainly employed for learning reinforcement purposes. Lack of Canadian content (accents, metric, word spellings, terms and definitions, law and history, and authors) and grade appropriate material proved significant concerns. The perceived educational value of WIER, however, outweighed the difficulties and limitations it presented. According to the teachers, students of all levels demonstrated an increased motivation to write. The WIER program was seen as offering students a broader and more meaningful audience for their work, heightening the authenticity of the writing process. It was also perceived as allowing students to learn the value of giving and receiving constructive criticism and to absorb new approaches to considering their work on the basis of the comments made by professional authors.

The degree of congruence in pedagogical approach between the teachers’ own teaching style and that of the programs also played an instrumental role in the teachers’ willingness to incorporate SNS and WIER into their classroom activities. In the case of SNS, senior school board personnel made the decision to adopt the program, and teachers, particularly those teaching mathematics and science, were expected to make use of the service. This pressure coupled with the problems encountered that were discussed earlier, produced frustration—especially since teachers simply were not happy with the fit of the materials to their curriculum and teaching styles. SNS did allow for varied learning opportunities, concept repetition, and support and practice in learning concepts taught by the teacher, but the resources was consistently noted as being pedagogically and curricularly weak. Conversely, the perceived program worth of WIER outweighed the burden it imposed by its rigid scheduling and time demands. The process-writing orientation and professional development it offered was in harmony with ongoing teacher practice—teachers saw that it supported, augmented and increased the efficacy of their pedagogy. Comments by the professional authors validated the teachers’ own responses to student work, and teachers appreciated the greater opportunity WIER afforded them to assume more frequently the role of writing facilitator (as opposed to writing grader).

Discussion

Implementation success—or the lack of it—could be attributed to the dialectic relationship amongst the following teacher factors: (1) training and support, (2) the perceived value of the telelearning network in promoting desired educational outcomes, and (3) the congruence of the network with teachers’ pedagogical practices. WIER offered educational depth and meaning to both teachers and students. SNS offered some student motivational value but its educational merit was perceived to be lacking and its pedagogical approach was seen as divergent from those practices considered desirable by teachers. A sequence of events appeared to influence the success of implementation: at first, teachers’ initial perceptions of the program determined the amount of time and effort initially devoted to its use. Following the initial experiences with the program in the classroom, continuing use was dependent upon (1) whether the program did or did not match what were considered desirable teaching practices and (2) whether the perceived program value was high or low. The pivotal issue surrounding the extent to which teachers were willing to put the time and effort into developing a mastery of the technology appeared to be the opportunities the program offered for new possibilities for learning and teaching in a manner that the teacher found pedagogically acceptable and practicable.

Our analysis suggests several implications for teacher education and ongoing professional development. First, teachers must be active participants in any decision to participate in online learning initiatives.
Without their active and willing support, implementation is bound to fail, regardless of what support structures and processes are in place. But teachers cannot be expected to make considered decisions without being given the opportunity to develop a thorough understanding of the basic principles, potentials, and limitations that these new learning media present. Both pre-service and in-service teacher education programs need to provide teachers with opportunities to study about and learn with these technologies. Prior acquisition of operational competency can significantly reduce the learning curve for teaching staff when such new learning resources are introduced, decreasing their resistance to innovation. And successful experiences with online learning in conjunction with exposure to a range of potential in-class applications during pre- or in-service education will allow teachers to make more informed decisions about online learning implementation. Teachers will be better prepared to both contribute to the deliberations when a district or school considers acquiring a new online technology and to make effective use of these new resources. Recent research reviews make it clear out that teachers must have a significant level of knowledge and skill to effectively use online learning environments (Grégoire et al., 1996; Bracewell et al., 1998).

Another implication of this study is that the pedagogy associated with a telelearning network should be largely congruent with that of the vast majority of teachers who will use it, since the degree of congruence appears to be related to implementation success. Significant divergence in pedagogical perspectives can seriously impede implementation. As the Schoolnet review points out, technology infusion "does not diminish the controversies and conflicts that pertain to school improvement efforts. On the contrary, it illuminates existing debates from new positions. It acts as a debate catalyst, as individuals bring to the debate their own perceptions of what technology can do or not, and of what school is about" (Bracewell et al., 1998, p. 22). If (as is often the case) the implementation of online learning is being used as a "Trojan horse" to foster the adoption of a more constructivist or knowledge-building pedagogy, our results indicate that even a well-supported program is unlikely to succeed unless the culture of teaching and learning in the institution is first addressed. Formal and informal teacher education can play a major role in helping teachers become aware of the value of these new perspectives on practice prior to the introduction of new technologies and programs, fostering their willingness to try new approaches and providing them with the more general pedagogical skills that are the necessary foundation for online program success.

A final, related implication is that providing teacher support and assistance is a necessary but not a sufficient condition for implementation success. The necessity of such support is not in question; it has been found in numerous studies to be critical in fostering innovation (Maddin, 1997; Benton Foundation, 1997). But regardless of the amount of support available to teachers, they need to see that a distinct advantage for their students will accrue for the implementation to proceed smoothly. In the present study, we saw that SNS teachers had an abundance of support, yet they were loath to take advantage of it because they did not see sufficient benefit in network use for their students. On the other hand, WIER teachers had a modest level of support, however they took it upon themselves to learn the system because they felt that their students would profit. Therefore, when a telelearning network is implemented, a wise strategy would be to structure network activities so that teachers obtain perceived educational successes with their students early on during the implementation process. This approach would encourage teachers to learn more about the network, either from taking advantage of formal support services or from collegial discussion and sharing. And it would provide a window of opportunity for professional development, by providing staff with the knowledge, experience, and motivation to gradually begin experimenting with variations in their traditional practices and roles.

U. S. A.

Abstract: Previous research into classroom life exposes the difficulty of integrating new technologies into teaching. Professors of teacher education courses should prepare students for technologically advanced classroom expectations, but often these professors do not model the requisite new behaviors. By exploring the relationship between teacher beliefs and teacher resistance to change, a teacher education professor examines her own practice. An action research methodology provides a self case study of a teacher education professor who investigates how to reconcile beliefs about classroom life with the implementation of technology. Teacher beliefs about the nature of the student-teacher relationship, the importance of particular learning experiences, and the context of the classroom impact technology implementation. In the final analysis, the professor-researcher models to students her beliefs, hoping to shape the students' beliefs as future teachers confronted by innovative practice.

Introduction to the Question

Research into life in the classroom exposes deeply traditional dynamics (Lortie, 1975; Lieberman & Miller, 1984; Rosenholtz, 1989). The university classroom is seldom an exception (Schuttloffel, 1998b). Occasionally undergraduate teacher education students who arrive steeped in traditional classroom culture may resist or feel threatened by technology, but more often technological resistance comes from the professor (Cummings, 1995; Schuttloffel, 1998a, 1998b). Professors who have little teaching experience with newer technologies, or have not attempted to explore their usage in their courses, personify this reluctance. This paper presents my latest investigation into how to reconcile teacher beliefs about life in the classroom with the implementation of technology (Robinson, 1995; Schuttloffel, 1994, 1998a, 1998b; Zachariades & Killingsworth, 1995). And, in the final analysis, this teacher education professor recognizes a need to model to students transformed practice, thus shaping the student's beliefs as future teachers working in an era of innovation (Smith et al 1986; 1987; 1988).

Over the last ten years my investigations into the contributing factors of successful school reform, the acceptance of innovative practice, and change in classroom practice consistently reverts to the beliefs teachers and school leaders treasure as integral to their practice and their being. Beliefs are those undergirding values and philosophical dispositions that provide the basis for decision making about practice (Sergiovanni, 1992). The beliefs of teachers and school leaders either facilitate changes in practice, or by comparison, those beliefs may impede innovation. Mindful decision making is what teachers and school leaders do (Zumwalt, 1989; Schuttloffel, 1999). During the decision-making process, teachers and school leaders who choose to incorporate an innovation into their practice connect the innovation to their belief system. Also, teachers and school leaders may choose to reject an innovation if a change in practice contradicts their fundamental beliefs.

The proposed purpose for technology implementation takes several forms. First, technology provides educators another tool to reach students and serve their needs. Or the integration of technology proposes to expand educational possibilities by transforming learning from the teacher-dominated classroom to a more student-centered environment (Dwyer, 1991; Nickerson, 1988; Perelman, 1988). Next, reminiscent of the earlier futurist promises (Papert, 1980), technology serves as a vehicle for the visionary reform of educational institutions at all levels. Lastly, business leaders suggest that by increasing technical knowledge schools graduate a more productive worker for the marketplace. If today's technology promise centers around utilitarian motives, without ever questioning how technology confronts substantive teacher beliefs, how will its successful implementation be determined? The university classroom is an example of this struggle with the purpose for technology implementation.
Pressure for increased integration of technology is an example of an innovation pushing for change in university classroom practice. Sophisticated web technologies challenge the core of traditional teaching practice, including the very concept of a classroom. Uncovering those teacher beliefs that support, or impede, the integration of technology are key to successful change in practice. Numerous studies of innovative practice focus on the technical elements of implementing new methodological approaches evidencing new classroom practice. Often overlooked are the more subtle reasons for the failure of reform efforts, such as teacher beliefs. Could beliefs about the role of teacher and learner, the worthiness of content knowledge, and the ideal of the student product impact a teacher’s willingness to undergo the inconveniences demanded by changing their teaching practice? Seeking an answer to this question led me to scrutinize my own beliefs and practice. I recognized that I was doing little to model a change in practice for my teacher-education students. My case study documents my adventure with an innovative technology as an example of connecting my teacher beliefs with my teaching practice.

Methodology: Action Research and a Case Study

Action research bases its methodology on the premise that teachers investigate problems that arise from their classroom practice (Kemmis, & McTaggart, 1982). The question of changing my teaching practice due to new available technology emerged from my own university classroom. Since the education department’s teacher-preparation program incorporates numerous action research strategies, this methodology seemed a logical choice. It also facilitated discussion with students and other faculty about what I was attempting to accomplish in my class. Standard qualitative data collection methods (Wolcott, 1995; Eisner, 1985) were used in the study. For nearly one year I kept a journal account of my experiences including: the development of the course, the problems encountered, solutions or potential solutions, and interactions with assisting individuals. This article shares my self-case study as a teacher education professor with no prior experience with web-based instruction, who seeks to implement a new technology into an undergraduate course.

The Case of Dr. Mimi

The Catholic University of America is a medium size university set in northeast Washington, D.C. The most notable historical fact about the university is that it was created by the United States Catholic Bishops as a research university to provide scholarship for the Church and the nation. Although there exists today a thriving undergraduate college, research is the dominant identity of the institution. Recently there is clear direction from within and without the university to integrate technology into courses and to expand various courses into a web-based medium. Within this environment remarkably little has actually been done within most departments. My suspicion is that while some professors feel inadequate in using more complex technology, others experience an inherent conflict. These professors perceive that technology interferes with their deeply held beliefs about the role of teacher, the teaching-learning dynamic, and the meaning of attending a university.

An apparent dilemma for teacher education professors is the positive endorsement of new technologies for teacher education students while maintaining fairly traditional practice within the teacher-education program. The importance of preparing beginning teachers with a belief system that incorporates a critique of the available technologies seems obvious. This approach is consistent with a reflective framework which underpins the department’s teacher-education program (Van Manen, 1977). Providing students model experiences in how one confronts these technologies within their teaching practice has been less readily achieved.

Beliefs. Providing the framework for my case study analysis are five core beliefs about teaching and learning. This list is not exhaustive, but its broad shape comes from my experiences as a student, those of my children, and my diversified teaching career. My twenty-five years in education cross the continuum from preschool to graduate doctoral students, public and parochial schools, as a teacher, school counselor, principal, and professor.

First, I believe students need teachers. Teachers bring knowledge to the context of learning both from their life experience and from advanced study. This rule generally applies to all levels of schooling and in all content areas. In other words, teachers are necessary to help students learn what, when, and how to learn.
My second belief is that students and teachers need to interact with each other. My own teacher training took place during a surge in student-centered classroom practice. Long before constructionism was identified, I learned its substance. For me then, teaching is not just relating information, but creating a learning environment that develops the whole person. Teachers guide students in their search for knowledge by providing maps, directions, and markers. It is fair to say that required undergraduate survey courses are not typically a hot-bed of student-centered learning. Often these classes are too large and impersonal for holistic student growth.

Thirdly, I believe knowledge is both eternal and changing. I accept that there are classics in literature, art, and music that are timeless in their ability to portray the human condition. I also recognize the growing body of biological, geophysical, and psychological knowledge available for exploration today. Even the topics of history and political theory, which might appear as constant, challenges a discussion to questions previously thought to be settled. Consider only the effect of the concept of human rights and how it has evolved and impacted the world in the twentieth century.

Fourth, I believe that students learn from each other. Students often have the ability to clarify concepts so that classmates comprehend. Students working together learn to compliment each other and learn to respect what each person contributes to the learning endeavor. Collaboration is key to problem solving in most settings.

Finally, I believe teaching and learning may take place in a variety of contexts. K-12 teachers readily admit the importance of explorations that take students outside the classroom. Curricular goals are often met in parks, museums, and historical sites. Practicum and student teaching experiences in teacher education programs are typically where students begin to connect theory to practice.

Events. My case study began with my introduction to the potential of web-based technology through a faculty orientation session. I was intrigued with the possibility of making my undergraduate course more user-friendly and supportive of student learning. From my experiences with the nature of sophomore behavior, outside classroom supports seemed like a practical way to meet their many needs. A web-based system of teaching was offered as a tool to meet my needs.

My experiences with learning the web-based technology had five phases: 1) great enthusiasm for what I potentially could accomplish with the web-course, 2) the belief that if I had enough information I could accomplish the task, 3) the bitter realization that even with assistance the task would be time consuming, 4) qualified hope that more time and assistance would allow me to take on a realistic form of the task, and 5) a sense of satisfaction that something had been accomplished and learned

Great Enthusiasm. I first contacted the Center for Planning and Information Technology in February of 1999. Those professionals are in charge of moving campus personnel toward total technological literacy. The director was enthusiastic to assist me in whatever way possible. He assured me that the process was very simple and that after an introductory lesson to the template program, I would be ready to go. I was given a password and my new course was entered into the system. After my discussion with the technology center I was extremely confident. I decided to jump right in and begin putting together my course.

Information is the Key. After I spent an afternoon trying to figure out the directions for beginning the web course I was both annoyed and humiliated. I decided that I needed some tutoring on the process. George was assigned to me. He is a veteran of the university and an experienced technology expert with numerous areas of expertise that more than qualified him for the task of helping me.

Our first session began with my explanation of the unproductive “loop” that I had been caught in while trying to begin the first task in the program. Two and one half hours later George resigned himself to our failure. He admitted that the program was new to him and he thought it would be easier. He apologized profusely about the difficulty of the task and assured me that he would help me get this course up and running by fall.

In April George focused on helping me set up my “welcome page” for the course. More work on the course made it increasingly clear that this was not going to be an easy task, even with George’s help. My biggest setback was realizing that I could not simply enter information into the web-course, each file had to be translated
into a programming language. Then once they were uploaded, these files were not easily changed. To prepare for this process, I returned to my office with a more new information about the program and a 500 page manual.

No Easy Solutions. May arrived and I went to see George in a computer lab where he had an office. I had brought one copy of my syllabus that I had saved in HTML. When I opened the file, there were numerous formatting errors. George also pointed out that I should adjust all the material exactly how I wanted it to appear, (scheduling changes, assignments) as changes were difficult after the information files are on the website. George also told me that he was pretty sure that I could not use my test bank without a means to translate it to HTML.

I met with George in early June with all my files sorted and changed to HTML. I believed that it would be a simple process from then on and I would finally see some results from all the work. George was showing me how to upload the files when we came to a roadblock. He worked on it for a long time and then in frustration sent me home. He informed me that he would find out the answer and upload the files. The next time I heard from George, he was very pleased to tell me to look at my web course. He had loaded all my files. The site looked rather impressive to a novice. George assured me that he would be able to teach me how to upload files for myself.

At our next session in late July I brought the rest of the files to complete my course. George admitted that it would be harder than anticipated to upload the files. But, in spite of the loss of three key people, he would be available to do so. He also informed me that it would be helpful to continue to learn more about HTML to assist myself in this project. I then asked George about my other looming concern, the test bank. He informed me that there would be no way to upload the test bank into the template system. Questions would have to be individually entered. George suggested that I convert the files to HTML and circumvent the program’s testing module. The new link would not be as efficient, nor have all the features, but it would be simpler at this stage of the project. I had to take George’s advice.

Qualified Hope. When I went to see George in August, I had good news. My old test bank files would not convert, but I had received from my textbook publisher a new test bank that could be converted to RFT and then to HTML. I was very excited. George was now convinced that I would be better off to construct the quiz with this system and by-pass the template program’s own testing process.

My Foundations of Education class met in late August in a “smart” classroom. I went through the usual introductions, but I added that I was trying to learn more about web-based technology. I pointed out that I would be experimenting with various elements of the process during their course. I wanted them to be aware that this was a learning process for me. They were intrigued by the idea of a web-site with support for the course.

In early September I forwarded my first quiz for George to post on the web-site. I told my class that we would not assemble in the classroom for the quiz. They would take the quiz off the web-site within a set period of time. Students seemed enthusiastic about the freedom. I urged them to use their textbook and notes to thoroughly complete the quiz. George posted the quiz on a Thursday morning.

On Thursday afternoon I received an email from a distraught student. He was concerned because I had posted the answers to the quiz as well as the questions. I contacted George that I needed to make a correction on the quiz upload. Fortunately, he was available to make the correction very quickly.

Learning and Satisfaction Shared. The next time my class met I informed them that the first quiz had answers posted for the first day. I also chided them for procrastinating and missing this golden opportunity! Then I shifted my discussion to my own difficulties with trying out new technology that I was not completely familiar with. My intention was to raise in students’ consciousness the belief that teachers continue to learn by investigating new knowledge throughout their careers.

Throughout the remainder of the semester there were no more startling events with the quizzes. Students learn to use the information I provided, but more importantly I learned how to communicate any difficulties I was having with the web-course or the other available technical equipment.
Reflections on the Case Study

Reflection is a key element in action research (Ross, Bondy, & Kyle, 1993). Building upon Van Manen’s three levels of reflection (1977) as a framework, I encourage my teacher education students to investigate inherent dilemmas in teaching practice. In the same manner, by reflecting critically on my teaching beliefs, the influence of values and educational philosophy reveals its impact on decision making that affect my teaching practice. The connection between beliefs as isolated theory or ideals and daily practice takes place at the interpretive level of reflection. My case study experiences exhibit my desire to communicate a clear message to students about the role of teacher and the teaching profession. I wanted my students to see teachers as persons who grow throughout their careers by exploring new knowledge and practice. At a technical level of reflection, I wanted my students to see teaching as a profession that requires continual updating and renewal in order to give students the benefits of current research and technological advancements, for example, my learning how to use web-based technology. My actions characterized my beliefs, sent messages, and attempted to create a particular meaning for teaching. My beliefs also required me to do something that was new, difficult, and ultimately changed my teaching practice.

An analysis of my introductory experiences with web-based technology provides some insights into how the web-based technology interfaced with my five beliefs about teaching and learning. First, I believe that teachers are necessary. This belief was exemplified in two ways during the case experiences. I desperately needed George as my teacher. He made it possible for me to leave the safe haven of my known terrain in teaching and move into a less familiar landscape which required new information. I also believed that my students needed me to teach them about life long learning as a role model learning a new methodology. I wanted the students to be aware of my experiences as a vehicle of my beliefs. I hoped that my actions would assist my students in identifying with me as a learner.

My second belief, that of the importance of teacher-student interactions, was given a boost by my emphasis in the usage of the course bulletin board and my own email address. I encouraged and received numerous communications from students. I was forced to consider the possibility that some students preferred the anonymity of email to visiting with me face to face. Interactions were supported through this experience and I was comforted.

My belief in the nature of knowledge as both eternal and changing, was less challenged by this experience than the methodological choices that determine how that knowledge is taught. The content of the course remained substantially the same, but the focus of attention shifted more accurately to reflect my curricular priorities. I believe further refinement of the web-based course will reinforce my efforts to arrive at the core material for this course.

I do not believe that I fully explored how to better create an environment within the classroom or within the web to facilitate peer learning. I think there are many possibilities and students are eager to consider them.

By allowing the students to take their quizzes out of the classroom I hoped to communicate my belief that learning takes place in many settings. The school site visits supported this belief. Again I think there is much room for growth in this area and it requires some imagination on my part to expand the classroom even further.

This case study points to the importance of continuing research on teaching and learning in technology-rich environments, the implications of transforming the traditional university, and the impact of professorial beliefs on such a transformation. A more thorough reflection on these complex issues is required before making university-wide decisions about technology implementation.

It is possible to teach an old dog new tricks, with care and treats.

Abstract: In this paper we describe a research project in progress about IT use in education. Today educators feel frustrated about the way IT is adopted. In the paper we suggest how to initiate a discussion among educators to facilitate the start of a more substantial adoption of IT in educational practice.

Introduction and Background

An information society is emerging and information technology (IT) is an important part in this new society. The importance of IT is of course recognized in the Swedish education system. Community leaders, school boards, legislators, parents, etc., proclaim the value of this technology. Therefore, a large number of schools have an advanced infrastructure of computers and networks. By this, schools ensure that students are exposed to information technology since it will be a major part of their future lives. However, many teachers have no chance to assimilate and explore the technology on their own terms, and as a result of this, the use of IT in Swedish schools is limited. This is a problem.

We have a tough economy to deal with within the comprehensive schools, in Sweden. The resources allocated to schools depend on how many pupils there are and if the school has a need for extra money due to different kind of problems, e.g., dyslexia. Despite the advanced infrastructure it is a fact that each school still has to deal with choosing whether to buy new books to the pupils, or see to that there are enough pencils.

This is hardly anything unique for Sweden, but Sweden has come quite far when it comes to using IT in education. This means that the schools now also have to deal with how to afford to use the existing infrastructure with their already limited budget.

Schools receive funding to ensure that computers and networks are installed at the schools. However if the educators do not know how to use the new technology, it might even happen that the computers remain unpacked. Too often computers are used in the same way as typewriters.

The problem

The form of schools and education has remained fairly unchanged over hundreds of years, and so has the technology used in teaching, despite both pedagogical and technological influences. Today the culture of the educational system and its technology is challenged. IT is here the main vehicle for implementing change and may help bring about some important reforms (Barker and Dickson, 1996). Just providing schools with an infrastructure, of computers and networks, will not have the desired effect.

It is not only IT itself that makes the chances. Educators need to know how to use IT, in a pedagogical well-grounded way. With the rapid development of IT this is certainly a dilemma and it is a growing
frustration among the educators. Those who are very enthusiastic about using IT also have to convince those who are skeptical about IT.

The educators are also instructed by the government to use IT, but the government does not say anything about how to find the time needed for reflecting upon this. Today, with the already heavy burdens for educators, there is certainly not enough time.

**What has been done?**

Below we give four examples what has been done in schools, about this undesired situation.

- There are several successful pilot projects that are working very well. Unfortunately they tend to be only pilot projects, not having a broad impact on the regular educational practice.
- Often the educators at a school are requested to take a course in the basic use of a computer, like word processing. Even though the educators learn something themselves, it is difficult to find that course relevant, compared to how you want to use IT as a pedagogical tool with your pupils. There are few courses made for educators with a pedagogical aspect on how to use IT with the pupils.
- Commonly one person at the school is appointed to be responsible for IT. This person is to be the link between IT, the field of applications and the educators. Normally that person has very limited education about IT and the support is therefore often quite poor. There is also a lack of time for working with these issues, even though it is well known that this area is very time wasting working with.
- Outsiders have tried to introduce IT into schools. After proclaiming its potential in the classroom, the educators use IT only slightly, if they do not really burn for using IT as a pedagogical tool. If they have not much knowledge about IT, it is reasonable to think that they find it time-consuming trying to understand IT while they have to do the daily work to. Above that they have to find out the pedagogical possibilities with IT.

**What should be done?**

With a situation as described above we claim that awareness of the problems with information technology in schools is necessary and that a structured interaction among teachers is a fruitful starting point. To gain commitment and firmly establish a constructive climate, all decisions must come from the educators themselves.

Therefore we suggest PIER (Nuldén and Scheepers, 1999a, 1999b) as an appropriate methodology to approach the problem. PIER is based on four concepts: Problem based learning, Interactive multimedia, Experiential learning and Role-playing.

1. In problem based learning (PBL) the starting point of learning is a real world phenomenon or problem the learner wishes to understand or learn more about.
2. A great deal of attention has been focused on interactive multimedia, especially within the educational domain. Many educational institutions have produced different types of educational interactive multimedia courseware to replace or enhance educational activities.
3. Experiential learning refers to an encounter that the learner experiences and from this encounter learning is initiated.
4. By role-playing the participants use their own experiences and their assigned roles, while understanding problematic situations.

PIER follows four phases as outlined below. How PIER is applied in this research is described in the next section.
<table>
<thead>
<tr>
<th>Phase one.</th>
<th>Experience. A group of people experiences a problematic situation through role-playing in a multimedia scenario. The duration of this activity is three hours.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase two.</td>
<td>Individual reflection. Duration one week.</td>
</tr>
<tr>
<td>Phase three.</td>
<td>Debriefing and discussion. The group meets together with the facilitator and discusses the situation presented in the scenario and further action is outlined. Duration two hours.</td>
</tr>
<tr>
<td>Phase four.</td>
<td>Using their experiences from phase 1 to 3, to start creating a change of the phenomenon or problem the learner wished to understand or learn more about e.g. how to use IT in the pedagogical best way at their school. A continuous learning-process.</td>
</tr>
</tbody>
</table>

Table 1: The framework of PIER.

Reflection is an important aspect of the framework for PIER. There are three different types of reflections that apply to the PIER methodology. First there is reflection-in-action, reflection that is made during the enacting of the scenario in activity one. Reflection on what happened during activity one, i.e. reflection-on-action, is done during activity two and is discussed at the seminar in action three. Reflection-for-action, i.e. thoughts about how to use the knowledge gained by the experience in a future situation are initiated during activity three.

**PIER – in this research**

PIER can be used to get the educators to engage in constructive discussions about IT use. In this section, we describe how PIER will be used with educators in Swedish schools.

**Phase one - Experience**

Between five and eight persons are role-playing guided by a multimedia-scenario. The participants can choose whether they want to play themselves in the scenario, if they want to hide behind their role character or a combination of those. The scenario is created specially for this group of participants, with their problematic situation about IT use, as a background.

The scenario begins with giving the group some information about where they are, what time it is and their role-character in this scenario; e.g. you are in your school where you work as the headmaster. It is in the beginning of the term and your school has been given 20 computers. Now you should use them in the best way. How?

The entire situation is similar to the reality at the participants’ work place and by that the participants have to discuss together and try to find solutions about the same questions, as they have to confront every day. They also have to make a lot of choices during the scenario. For instance if they should use IT in every classroom or in a certain room? Who are allowed to use IT and what purposes should IT be used for?

During the scenario, multimedia is used to make things clearer; e.g. a video to show more information and guidance, virtual persons are saying controversial things and photos are shown to create a certain feeling in the group.

The scenario does not give the participants any solutions and it ends in a cliffhanger, abruptly, with more questions than answers.

**Phase two – Individual Reflection**

After the scenario the participants are left by their own, for about a week, to reflect on their experiences.
Phase three - Debriefing and Discussion

After a week the participants meet again to discuss the scenario – how they felt during the role-play and what happened. They also talk about their own daily situation at work and what can be done to change it. After the scenario the participants have got many ideas how to continue, and a plan for the future can easily be made.

Phase four - The Evolution of the Experiences Based on the Earlier Activities.

Further on, the plan for the future is the starting-point for using their experiences in their daily life.

How to continue

The scenario is not a solution by itself. It is a starting point for further discussions. When the questions the participants might have been thinking about for a long time, are raised during a three hours scenario, new questions are evolved and probably the further discussions will help them to find alternative solutions of the problems.

The effects continue to develop further discussions and less frustrated educators, but also that the participants have found new areas where IT is very useful as a pedagogical instrument.

Future work

The motivation for our research project is the fact that a large number of schools in Sweden have an advanced infrastructure of computers and networks, but the use is limited. In this paper it is suggested how to initiate a discussion among educators to facilitate the start of a more substantial adoption of IT in educational practice and by that making the educators less frustrated about IT use.

The Impact of Information and Communication Technology (ICT) on Job Characteristics of South African University Academics

Igonor, A. and Soul, Y.
University Library
University of Fort Hare
Alice, South Africa

Abstract: A study was recently carried out on the use of Information and Communication Technology (ICT) by South African University Academics. The impact of ICT on job characteristics of academics - teaching, research and to a lesser extent, administrative duties was investigated. Academics at the University of Fort Hare, South Africa's oldest and first historically black institution (HBI) were tested in this exercise. Realizing that South Africa's HBIs exhibit a lot of commonalities in structure, operation and management, no doubt, this study strongly reflects the general situation with this country's HBIs. Academics across all disciplines and hierarchy were included in this questionnaire survey supplemented by interviews. Results indicate an established need for ICTs, a general lack of adequate computer facilities, low level of computer literacy among academics, a need for training in ICTs, high level of unreliability in networking allowing access to the use of the INTERNET, and the non-existence of ICT policies for computer equipment upgrades, hardware and software purchases and training. Albeit, it was evident from the study that academics with adequate knowledge of the use and application of ICT in their jobs did record significant improvement in the discharge of duties.

Introduction

The organisational world has over the past twenty years witnessed a revolution in work practices, brought about by developments in Information Technology (IT). Drucker (1986) describes present organisations as "information based" and those who work in them as "knowledge workers". The new IT, either computer-based, computer-related, or computer-influenced - today reaches into all kinds and sizes of enterprises, in every conceivable industry and specialized activity and with a multiplicity of options from which a user can choose whatever suits his particular needs. For many years, it has been quite clear that technology not only changes the structure and nature of organisations but also change the way people do their jobs and to some extent the way individuals in organisations view themselves in the context of the society (Irving and Higgins, 1991). Irving and Higgins (1991) went further to affirm that IT affects the nature, quality and perhaps the frequency of communication in an organisation. They explain that as more people become oriented toward terminals, communications may tend to be more impersonal through the use of the electronic mail.

Universities have been major users of computing since the latter first appeared. In recent years, they have also become leading users of networking. In the UK for example, the creation of JANET (Joint Academic Network) in the latter part of the 1980s encouraged a diversity of networking activities. At the end of the 1980s, a discussion of the "electronic campus" in the UK found no difficulty in reaching the conclusion that information technology (meaning especially the combination of computers and networks) would have an increasing impact on all the main strands of higher education - teaching, research and administration - during the 1990s (Brindley, 1989).

Several studies have been carried out in the past decade to look at the role ICT plays on University campuses. The way academics react to their institutions’ ICT changing environment and the role this technology plays generally in University affairs have been issues researched in the past and still receiving attention. In developing countries, however,
the obvious problem of insufficient finances for the purchase of computer equipment cannot be overlooked. Many institutions cannot afford to provide either the equipment or the infrastructural support, nor do they usually command the necessary resources of skilled manpower. However, some developing countries (sometimes distinguished as “third world”, rather than the “fourth world”) do have the potential for overcoming these obstacles in the foreseeable future (Bukhari and Meadows, 1992). Like Universities in developed countries of the world, many South African Universities are making the same kind of transition to ICT. The present paper investigates the impact ICT has on academics’ job functions - teaching, research and administration - in South Africa’s Historically Black Institutions (HBIs).

The Method

A survey was carried out at the University of Fort Hare with the use of questionnaires supplemented where necessary by interviews to determine a number of issues relating basically the University of Fort Hare academic, his/her job characteristics and role ICT plays in this regard. Specifically, the study determined:

- the level of accessibility of academics to ICT in the form of computers and internet connectivity;
- the level of use of ICTs;
- know-how regarding the use of ICTs;
- to what extent (if at all) ICTs influence their job functions - teaching, research and administrative.

This study we believe couldn’t have been better timed, especially considering the financial state of tertiary institutions in South Africa, especially the HBIs. Its interesting to know also that donor agencies: the European Union, Cannon Collins Educational Foundation of the UK, Community H.E.A.R.T foundation of the UK, America’s Andrew Mellon Foundation are among those actively contributing computer hardware among others products towards the development of tertiary institutions in South Africa. The significance of these technologies in the South African educational sector cannot therefore be over-emphasized. The questionnaire survey carried out by Igonor and Makalima (1999) involved the distribution of 40 questionnaires with a 95% response rate. Academics ranking from Professors down to Junior lecturers and tutors were surveyed in the exercise. The questionnaire tested areas such as -

- Information Technology available, in use and the extent of use;
- Information Needs of University Academics;
- Computer Literacy among academics;
- Relevance of Information Technology (computers and networks) in academics’ operations and its impact on teaching, research and the performance of administrative duties.

The University of Fort Hare - South Africa’s First Historical Black Institution (HBI)

The University of Fort Hare has a strong missionary background. In 1878, there was a proposal by James Stewart of the Lovedale Institute for the establishment of a college of higher education for South Africa’s black students. Due to the Anglo-Boer and World wars, the formation of this college was not until 1914. The college was taken over in 1946 by the Rhodes University in Grahamstown and was named the University College of Fort Hare. After the 1948 elections, Bantu education was extended to tertiary level and the college was
placed under the supervision of the University of South Africa. In 1970, the University College became autonomous and then named the University of Fort Hare. The institution is located in the rural town of Alice, in the Eastern Cape province of South Africa.

University Academics’ Job Characteristics and ICT

Job functions of University Academics involve basically teaching, research and the performance of administrative duties. It is important that academics not only keep abreast of developments and current trends in their various fields, but also facilitate qualitative and up-to-date learning processes and produce lifelong independent fully baked graduates.

It is a cliché to say that university academics are by nature information-oriented. The quest for information is not new, it is characteristic of all people whether the need be articulated or not. In the words of Coggin (1979), access to information can be a matter of life or death for an individual. Information needs do not arise in a vacuum, they are constant, persistent by-products of life in modern society. Day-to-day need for information is always the child of a specific situation. With a changing, complex society, formerly simple solutions to information need become more complicated. Where to turn for expert information and how to determine which expert advice are questions facing many people today - academics inclusive. Saying that every society needs a basic minimum stock of usable information to survive will be understated. Every society needs to acquire, store and exchange this basic stock of information to allow it to survive. Similarly for the academic to carry out its obligations - teaching, research and administrative - access to reliable information is not negotiable. The means to getting access to this information is yet another challenge. Access knowledge and use of ICT in developed countries is seen as part of normal scenario in almost of every societal sector. In developing countries, including South Africa, the situation presents itself differently. Of particular interest is the case with South African black institutions that have suffered from apartheid government. Many Universities in developing countries, including these South African HBIs cannot afford to provide either computer equipment, or the infrastructure support; nor do they usually command the necessary resources of skilled manpower. However, coupled with the growing quantity of information are the development of technologies which enable the storage, retrieval and delivery of more information with greater speed to more locations than has ever been possible. Computer technology makes it possible to store vast amounts of data in machine-readable files and to program computers to locate specific information within data files. Telecommunications developments enable the sending of messages via tv, radio e-mail to bombard people with multitudes of messages. The Internet, a vast storehouse of information covering various subjects is also a by-product of this computer technology. Universities have in fact been users of this technology for a long time now. In fact, Woodworths (1991) argues that academic departments in colleges and universities have diminishing needs for typists and filing clerks as Local Area Networks, universal access to word processing, electronic mail and desktop publishing are introduced. In the words of Jungk (1972): In this world of change and complexity where the need for information upon which to base personal decisions is of greatest importance; in this world of huge amounts of information and sophisticated technology to help in retrieving and delivering the exact information needed; in this world which is entering a post-industrial age or knowledge-based era; in this world of the 1980s, “information, its lack and availability, its use and misuses, its treatment and transfer and last but not the least, its possession may well be a crucial factor in our evolutionary crisis”.
The importance of information for the survival of the university academic cannot truly be over-emphasized and the means to having access and succeeding in this regard very well depends on the capabilities of information and communication technologies. Those people who have accurate, reliable and up-to-date information to solve day-to-day problems, the critical problems of their business, social and family life, not to mention academics' need for research and teaching, will indeed survive and succeed. "Knowledge is Power" - the truest saying of the 80s may well be true for the 90s, and access to information (thanks to ICTs) may be the most critical requirement of all people.

**Result**

**IT available and in use**

The available IT tools and in use from the result of the survey is summarised in table 1 below:

<table>
<thead>
<tr>
<th>IT Tools available</th>
<th>Number of users</th>
<th>%</th>
<th>Number of non-users</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computers</td>
<td>31</td>
<td>81.6</td>
<td>7</td>
<td>18.4</td>
</tr>
<tr>
<td>Telephone</td>

<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Mobile phone</td>
<td>32</td>
<td>84.2</td>
<td>6</td>
<td>15.8</td>
</tr>
</tbody>
</table>

Table 1: IT available and rate of use.

While the above table reveals IT tools available, the state of these technologies is yet another issue which might just not be part of the scope of this report. 81.6% of academic staff members make use of computers in their jobs. The percentage of non-users (18.4%) may be due to a number of reasons; notably - no access to computers, or that they possess their personal computers and would rather prefer to work from them, or do not possess sufficient knowledge to use computers and are therefore not bothered. No doubt, academics need computers in order to function effectively and efficiently. Eraut (1991) well supports this arguing that IT has several effects on teaching, because of the availability of vast amount of data and also increasing need for proper education in putting the information to intelligent use.

The computers available to academics are used for a variety of purposes. The survey revealed that academics need computers

- for teaching purposes; word processing lecture notes, calculating student scores and administrative purposes;
- for Internet connection; the Internet is indeed rich in a lot of information and academics need access to this fastest growing database. Information on research done in various parts of the world and teaching methods can all be accessed here;
- to link library online public access catalogues via telnet;
- access CD-ROMs and also other online journal databases;
- to communicate with the use of the electronic mail system. Electronic mails are used for exchanging information between colleagues, friends and families within and outside the institutions;
Computers linked to the Internet provide a fast and easy access to reliable and up-to-date information.

Mwawenda (1997) clearly states that research, publication, teaching and administration are some of the functions of academics, with research being the most important. Atkin (1991) further stresses this, arguing that research has been identified as not only a primary function of a university but also an integral aspect of the work of academics. In a world where research and publications are used as criteria for promotion and the determination of the best academics, the potential of the computer in making available information tappable cannot therefore be over-emphasized. The table below quickly indicates the proportion of work done by academics using computers.

<table>
<thead>
<tr>
<th>Task</th>
<th>No.</th>

<td>68.4</td>
</tr>
<tr>
<td>Searching online databases</td>
<td>21</td>
<td>55.3</td>
</tr>
</tbody>
</table>

Table 2: Proportion of work done on computers and the rate of usage.

The value of the e-mail to the academic is most reflected in the following ways:

- an enhancement of the freedom of expression among employers and employees;
- saves time;
- saves costs;
- fosters communication between staff and students;
- unlimited in potential audience size;
- breakdown of bureaucracies associated with communication.

**Computer Literacy among Academics**

Table 3 below gives an indication of computer literacy among academics surveyed in this study.

<table>
<thead>
<tr>

Table 3: Level of computer literacy among academics

The table above indicates that academics have a slightly above average knowledge level of computers and their use. Basic knowledge in this case refers to performing of basic tasks such as word processing with Ms-word and Word-perfect, use of e-mail and very little knowledge of information searching and retrieval form the World Wide Web. As already mentioned, most developing nations lack the required capacity to train and develop adequate human resources. Computer literacy training among academics is a necessity otherwise they'd be left behind as new computer technologies evolve. Computer literacy skills are essential skills for academics especially as the society has come to depend on electronic text. Skills such as finding, manipulating and scanning electronic documents as well as word processing, Internet use and typing are basic training components to be covered here.

**ICT and its relevance in teaching, research and the performance of administrative duties**

The relevance of ICT in the operations of academics is manifest in a number of ways. ICT has made it possible for academics to have access to online journals, the online public access catalogues (OPAC) of libraries, the world wide web and also CD-ROM accessible databases. Some of the questions we sought answers for relating this section of the study included:

- In what ways has ICT influenced individual access to information?
- Does ICT in any way influence academic-related decision-making issues?
- How does ICT then impact on academic performance in terms of job efficiency and effectiveness?

Questions of this nature are quite unlimited, but we do know that it’s an established fact that academics’ do need information to survive. The relevance of the World Wide Web in meeting the needs of academics cannot be totally explored. The Internet which was initially developed by the United States Military, has now grown from a tool of small group of scientific researchers to development of substantive sites covering a breadth of topics useful for teaching, research, entertainment, to mention a few. Types of materials covered include secondary, teaching, and reference and news sources. With the availability of scientific journals, online, several functions or observations could be emphasized -

- it makes it possible to build a knowledge base. Journals serve the most basic functions of science; the creation of published core of knowledge for public availability.
- easy communication of information. Everyone publishes his or her work to be read, confirmed, praised, cited, analysed and commented on in future works. By so doing, the functions of building a knowledge base and communicating information become a part and parcel of one whole function.
- helps in the validating of quality and the distribution of rewards.
Without ICT, the academic does not have access to all these. Academics generally accept and identify with electronic journals due to their credibility, accessibility and permanence made possible by the wonders of ICT. The evolution of new ICTs has led to the development of web-based teaching, the emergence of fully dedicated web courses and course homepages that provide links to supplementary materials.

Conclusion

The relevance of ICT in academic teaching, research and the performance of administrative duties is no longer an issue of debate. Major problems facing developing countries include the lack of adequate funds to acquire these technologies, a shortage of skilled manpower to run and train people in this technology and poor maintenance of existing technology.

Abstract: Funded through the U.S. Department of Education, Project PICT (Preservice Infusion of Computer Technology) was developed to enable preservice teachers to fully utilize modern technology for improved learning and achievement in their future classrooms. To achieve this goal, the Bowling Green State University (BGSU) Technology Consortium developed a model grounded in the collaboration between teacher education faculty, arts and sciences faculty, and K-6 teachers. Primary project outcomes are: revised teacher education curriculum that reflects the ISTE technology standards; faculty Technology Training Model that prepares faculty to infuse technology in their teaching, model effective technology uses, and provide opportunities to observe technology-rich K-6 classrooms; Teacher Education Technology Infusion Model that systematically integrates technology in teacher preparation courses; system for assessing preservice teacher technology competencies; evaluative data on the impact of the pilot programs; collaboration with technology-rich K-6 schools, expansion of consortium partners; and grant proposals for future funding.

Introduction

A mission of the College of Education and Human Development at Bowling Green State University (BGSU) is to prepare reflective, creative and competent teachers for the new millennium. Essential to this mission is the development of preservice teachers who are not only technology literate but able to integrate technology into their instruction so their students will develop the ability to use technology throughout their lives. Currently BGSU teacher education programs produce approximately 750-800 graduates per year, many of whom are from rural Ohio and often return to the same rural areas to begin their teaching careers.

For the past decade, Bowling Green State University has struggled to educate the preservice teachers so that they will gain the competence needed to utilize technology in their classrooms. Due to the rapid advance of technological changes and limited financial resources, for many years, the major effort to achieve this goal has been restricted to a required technology methods course typically taken during the junior year. This course has most often been taken in isolation of any clinical experience that would provide the opportunity for students to utilize the skills being learned in an instructional setting with children. Additionally, most preservice teachers have not experienced technology integration in their other education courses and have not had the opportunity to observe and teach in technology-rich K-12 classrooms. Barriers that have impeded such technology infusion include: inadequate resources to purchase hardware and software for university classrooms and surrounding K-12 schools; lack of technology competency and professional development opportunities among teacher educators and classroom teachers; and lack of programmatic alignment with the International Society for Technology in Education (ISTE) standards across the curriculum, both at the university and elementary/secondary school levels. Another issue that has complicated the matter is the lack of technology experiences that many of BGSU’s teacher education students bring to college as many of these preservice
teachers are from technology-poor rural/low income areas in Northwest Ohio. Since many of these same students return to these areas for teaching positions, BGSU has a unique opportunity to impact these rural/low-income schools by returning these students as technology-using educators.

Recently, the lack of hardware in K-12 classrooms has been addressed by the Ohio SchoolNet Initiative while BGSU is investing in more equipment on the university campus. Ohio SchoolNet has installed typically three to four computers in most elementary classrooms throughout Northwest Ohio with plans to expand installation to secondary classrooms in the near future. BGSU recently has committed to installing three permanent and one portable electronic classrooms to promote faculty infusion of technology. These classrooms will be located in the College of Education and Human Development and will serve as models for the university. Unfortunately, while technology access has increased for education faculty, most instructors lack the skills and understanding to adequately infuse technology into their teacher preparation courses. In addition, the current teacher education programs do not facilitate the systematic infusion of technology throughout the curriculum. Consequently, both program restructuring and professional development training have been needed to facilitate technology infusion throughout the preservice teacher experience. The BGSU Technology Consortium is currently implementing Project PICT (Preservice Infusion in Computer Technology) that will address these needs by restructuring the current teacher education programs, piloting a faculty technology training program, and piloting a technology infusion program.

Project Design

The overall goal of Project PICT is to enable preservice teachers to fully utilize modern technology for improved learning and achievement in their future classrooms. To achieve this goal, the BGSU Technology Consortium proposed a model grounded in the collaboration between teacher education faculty, arts and sciences faculty, and K-6 teachers. (Note: First year implementation has focused on the elementary education program since equipment acquisition for Ohio K-12 schools has been primarily limited to elementary schools). Consequently, representatives from these three entities have worked in teams to restructure the current teacher education programs and begin implementation of a technology-rich teacher preparation curriculum. Participants for this first year included: six (6) university methods faculty, ten (10) K-6 teachers, and two (2) arts and sciences faculty. Participating faculty and K-6 teachers were required to attend the following: 1 day workshop on ISTE standards, 2 day workshop on technology planning and infusion, team meetings, and 5 training sessions. Participants were also expected to create team and individual technology plans, revise curriculum, and implement at least 2 technology lessons/units in the Spring 2000 semester.

Objectives that guided Project PICT include:
1. Conduct a needs assessment of faculty technology competencies and level of integration;
2. Restructure existing teacher preparation curriculum to systematically fulfill ISTE/NCATE technology standards for all teachers;
3. Develop a system for assessing preservice teacher competencies of ISTE/NCATE standards;
4. Establish consortium partners that will enable BGSU to fully implement its technology integration program;
5. Facilitate cross-disciplinary collaboration between BGSU faculty and K-6 schools;
6. Pilot technology training program:
   a. Create teams of instructional and clinical education faculty;
   b. Provide educational (instructional and clinical) and arts & sciences faculty with training on ISTE/NCATE technology standards for all teachers;
   c. Provide educational (instructional and clinical) and arts & sciences faculty with training on how to integrate technology in course instruction and model effective technology use;
7. Pilot technology infusion program:
   d. Provide preservice teachers with opportunities to observe and experience technology rich K-12 classrooms that represent a variety of socio-economic and population levels through video-conferencing and field placements;
   e. Provide preservice teachers with opportunities to observe, experience, and use technology within their college courses;
   f. Provide preservice teachers with technology mentors in their K-12 field placements (clinical faculty/participating K-12 teachers will serve as technology mentors).
Evaluation

Project PICT has been subjected to rigorous formative and summative evaluation in order to establish clear benchmarks for documenting impact of pilot implementation and future improvements. Quantitative and qualitative methods have been conducted to permit periodic assessment of progress toward achieving outcomes. Specific variables to be measured among teacher education faculty, both instructional and clinical, are: technology competency, level of technology integration (frequency, type, and quality), perceived barriers of technology integration, training preferences, impact of training program, perceived impact of Technology Infusion Model on preservice teachers. Specific variables to be measured among participating preservice teachers are: technology competency, experiences with technology in courses and field placements (frequency, type, and quality), perceived barriers of technology integration, training preferences, impact of Technology Infusion Model on preservice teachers, and changes in one's vision of a technology-rich classroom. Measurement of these variables will occur through the following data collection methods: pre/post surveys for faculty and preservice teachers, focus group interviews with faculty and preservice teachers, observation of technology-rich lessons in the education and K-6 classroom, content analysis of preservice teachers' products (course assignments, lesson plans, unit plans), content analysis of faculty products (revised curriculum, course syllabi, lesson plans). Control groups have been developed to allow for comparison between participating and non-participating preservice teachers as well as participating and non-participating faculty.
Abstract: Recognizing that changing teacher education is a key requirement for changing K-12 teacher practices, Apple Computer developed the Apple Summer Institute for Teacher Education, more commonly referred to as "Camp Apple" by the 42 participants who represented faculty teams from 17 universities. This panel discussion is focused on the results of this novel program in promoting institutional change within participating universities, including results of the project-based learning sessions, reports on how the training influenced classroom practice and institutional change by participants, and recommendations for improving faculty development programs based on evaluation of this first-year effort.

I: From Camp Apple to Classroom Practice: A New Model for Staff Development

Recent studies have indicated that the best predictor of the skills that teacher education graduates have in infusing information technology (IT) into instruction is IT use in coursework throughout their preservice program. As a result, these studies have included strong recommendations to ensure that technology is a key part of methods classes so that future teachers understand and are able to integrate technology within the disciplines that they will teach (Cooper & Bull, 1997; International Society for Technology in Education, 1999; National Center for Education Statistics, 1999; National Council for Accreditation of Teacher Education, 1997; Willis & Mehlinger, 1996). Meeting this challenge requires new models of faculty development that deal with the barriers which have been identified as inhibiting past efforts in changing practice through training: motivation, resource access, and time.
Recognizing that changing teacher education is a key requirement for changing K-12 teacher practices, Apple Computer developed the Apple Summer Institute for Teacher Education, more commonly referred to as "Camp Apple." In July 1999 Apple Computer conducted a one week, residential professional development institute for teacher educators which attempted to address this challenge. Deans from schools and colleges of education had advised Apple that the professional development of their faculty, particularly of the methods faculty, was a primary concern. "Camp Apple" was designed in conjunction with 17 teachers' colleges in the U.S. and Canada to meet this need. While Apple has provided a camp experience for K-12 teachers, administrators, and technology support professionals in previous years, this was the first camp program that was aimed at higher education faculty.

The goals of Camp Apple were (1) to develop technology skills among faculty who rated themselves as novice computer-users, (2) to provide opportunities for them to consider how technology might enable more constructivist methods for their own courses, and (3) to give them time to reflect, share, and apply their new learning with colleagues from across North America.

Camp Apple was conducted in a rich technology environment. Participants had access to cutting-edge technologies like high speed Internet connections, three full labs of iMacs and G3 computers along with printers, digital cameras, scanners, authoring and educational software, and a wide variety of peripheral devices which are used in specialized disciplines for teaching and learning. The staff at Camp Apple were Apple employees and IT directors from Colleges of Education who had previously been recognized as "Apple Distinguished Educators."

Attendance at Camp Apple was "by invitation only." The deans on the Apple Advisory Board were invited to send teams of methods faculty from each of the four core curriculum areas (social studies, English/Language Arts, Science, and Math) to Camp. Each institution was responsible for the travel expenses of their participants; Apple paid for the training costs, room, and board. Forty-two methods faculty from 17 different institutions attended. Three deans also attended.

Apple's corporate goals for sponsoring this program were (1) to better understand the elements of successful professional development for teacher educators, (2) to cultivate a cadre of faculty who would apply the kinds of constructivist methodologies which are best supported by technology in their courses, and (3) to create a professional development model which could be easily replicated by other teachers' colleges at their own sites.

The Camp Apple Model

Several of the professional development strategies implemented at Camp Apple seemed to have combined to create a unique experience: a residential program in a scenic and secluded location with "24/7" access to cutting-edge technology; a reliance on collegial teams; and a focus on pedagogy. Finally, the longer-term effect of Camp Apple, as measured by the various dissemination activities of its participants, seems to have come from the "partnership" premise established between Apple and the participating institutions.

Location, Location, Location: Located in the Marin foothills just north of San Francisco, Camp Apple was conducted at Walker Creek Ranch. The ranch is an outdoor environmental education facility owned by the Marin County Board of Education. Cell phones cannot reach this canyon location and Walker Creek has no television. The residential aspect of the program promotes collegiality amongst participants in a way that "commuter" experiences cannot. Anyone who ever went to summer camp knows how powerful a "24/7" communal environment is on developing new friendships.

Focus on the Pedagogy, Not the Technology: The primary goal (and the greatest challenge) of Camp Apple was to focus on pedagogy, not on technology. While it is necessary for faculty to develop competence in the technology, it is more important for them to investigate the pedagogical relevance of these resources for teacher education. With access to expanded technology resources, faculty were free to experiment, explore new possibilities, and reflect on their teaching. Using the "Unit of Practice" (a curriculum development framework created by the ACOT research team), participants spent the week learning new technology skills, discussing teaching issues with colleagues, and developing a new teaching module for their methods courses. Finding the balance between these competing demands—developing the skills, considering the implications (of the technology), and creating a meaningful implementation was challenging and at times frustrating for both participants and staff. Further research will reveal whether these three ob-
jectives can be reached simultaneously or whether there is an evolution of thought and practice which is sequential.

The Importance of Teams: Drawing from our professional development research in the ACOT schools, we knew that teams were critical to the success of the program, both in the short and long term. Teams were used in two ways to achieve our goals. First, faculty worked in curriculum-area teams during the week on their curriculum development projects. Consequently, new collegial relationships formed around the common goals of learning and creating new materials for their courses. Participants were able to learn from new friends and share this learning with the team from their own institution. In order to insure participants would apply what they learned when the Camp concluded, individuals met as university teams before they left to plan follow up activities for the fall. Participants were asked to extend their learning to their students, to others at their schools, and to the broader teacher education community through new publications and research based on their Camp Apple experience.

Partnership: Apple’s explicit goals for sponsoring this program relied heavily on the commitment of the participants to apply what they had learned at Camp to their teaching. It relied on their interest in continuing the conversation with others—in their own institutions and beyond. To achieve this, each participant committed to creating two more Units of Practice for their courses during the Fall semester and publishing them on Apple’s online teacher network, the Apple Learning Interchange. They also committed to at least one dissemination activity. This could be new research, a publication, a conference presentation, or other leadership activity which would further the discussion of technology in teacher education.

Unlike many professional development experiences which are soon left behind in the wake of everyday demands, the follow up activities of these teams have been extensive. In addition to the individual work by faculty back on their own campuses, local teams have been able to draw on Apple resources for continued support. As a result, the Camp Apple program continues to produce ongoing change. Two of these are explored in the following sections by Joyce Morris of the University of Vermont and Christy Faison of Rowan University.

II. How I Spent My Summer Vacation and Ended Up Changing the World

Journey of a Thousand Miles

To many higher education faculty the prospect of learning new technology is a journey of a thousand miles. They are expected to use and integrate technology to increase their own efficiency and model it for future teachers even though these technologies were non-existent when they were students. Experts in their respected fields, they are often novices when it comes to using new technology, yet government and public mandates are calling for the infusion of technology in all preservice coursework (International Society for Technology in Education, 1999; National Council for Accreditation of Teacher Education, 1997; Thompson, 1999). In their national survey on information technology in teacher education, The Milken Exchange reported, “...the technology infrastructure of education has increased more quickly than the incorporation of IT tools into teaching and learning,” and that “many faculty do not model technology use...” (International Society for Technology in Education, 1999, p. 2). There is a growing consensus that the integration of information technology into the teaching/learning environment can best be addressed through advocating and role modeling (Office of Technology Assessment, U.S. Congress, 1995). Advocacy implies showing others how technology can be applied to advantage in their teaching by role modeling the use of technology to achieve this objective as well as demonstrate the personal and professional benefit to be derived from its use (Wright, 1993).

People adapt to innovations in different stages (Hall, Louckes, Rutherford, & Newlove, 1975). Each level is characterized by observably different behaviors related to the user’s development in acquiring these new skills and level of using the innovation. Research by ACOT discovered levels of use are also characteristic of adaptation of computer technologies by teachers in their classroom (Sandholtz, Ringstaff, & Dwyer, 1990). The Milken Exchange has aggregated these into five stages—(1) entry, (2) adoption, (3) adaptation, (4) appropriation, and (5) transformation—in a Professional Development Continuum (http://www.milkenexchange.org/pdc/pdcdocs/pdcll.pdf). To model technology fluency one must feel comfortable with basic computer skills, the focus of the entry stage. At the adoption and adaptation level, technology is somewhat integrated into existing practices. In the final stages, appropriation and transformation,
technological tools are used as a catalyst for significant changes in learning practices. At the adaptation level, technology is thoroughly integrated into existing practices. The final stage, transformation, uses technological tools as a catalyst for significant changes in learning practices. One advances to another stage through practicing skills, using the technology in a supported environment, professional development, and networking with colleagues to determine best practices.

To enable faculty to use technology at an adaptive and transformative level requires reallocating resources and providing time and support to learn the technology that will enable them to systematically redesign programs, curriculum, and field experiences that capitalize on the power of these tools. We know what to do, the problem lies in how to pragmatically implement a retooling of our faculty while we teach, research, and serve our local communities. We face many of the same problems the K-12 community has been facing—how do you redesign a machine without ever shutting it off?

From Camp Apple to Campus

When the opportunity for four elementary education faculty to attend Camp Apple was extended to our program at the University of Vermont in summer 1999, faculty jumped at the offer. They would give up a week of their summer vacation to learn, explore, and play with technological tools and think about how they could infuse technology into their teaching.

Faculty returned to Vermont energized with visions of ways to infuse technology into their teaching, assignments, activities, and presentations. Depending on their level of comfort in using technological resources, faculty are using their learned skills. One professor who coordinates the elementary education program and teaches a reading course to preservice teachers was the most insecure about her technological competence. Since her visit to Camp Apple, she has set up a listserv for our program that she is managing and facilitating, and for the first time, has prepared a presentation for a National Reading Conference using PowerPoint. She is in the process of designing a telecommunication project with her third year preservice students and Vermont elementary school children as an extension of the WEB project, a preexisting program connecting public school children with mentors. Next semester her preservice students and a group of elementary students will read selected children's stories and use a web board to discuss different issues surrounding the stories.

A second professor teaches a literacy course for third year students and a portfolio development course for seniors. In 1995 the State of Vermont implemented a results-oriented program approval process for teacher certification—evaluation by portfolio to be initiated at institutions of higher education that serve those preservice students (VISMT, 1995). In this professor's literacy and portfolio courses he has introduced Inspiration, a concept mapping program, to his students to help them visually and textually organize their portfolios through themes of practice. At the University of Vermont, professional portfolios must be organized as a text, via themes, with student selected documentation that describe the emerging teacher. State and Program criteria are located in appendices and cross-referenced with their documentation. Students collect, select, and connect their artifacts and caption the pieces to explain the context and relevance of evidence. Preservice students are expected to relate educational theory to practice, drawing upon their coursework, fieldwork, and community experiences to create personal profiles. Students are encouraged to use the power of multimedia to construct electronic portfolios to document this portion of their certification. It is anticipated that with increased resources, all students will establish their portfolios electronically.

The third professor to attend Camp Apple is a partner in the literacy team and had a fairly good level of computer literacy before her summer experience. She previously connected with a fourth grade teacher in one of our field sites and arranged a telecommunication project, where through e-mail, preservice students read and discussed multicultural stories in common with fourth graders. For her camp project she created a model for adapting literacy portfolios that preservice students create in their third year, to an electronic format. Through a local network, students document and critique elementary student work and share feedback with each other. In our fully networked transformable classroom, laptop computers are delivered to allow students to upload their files, practice file sharing, and create running records of student work that they examine in their field experiences. These are critiqued and shared by groups of students and incorporated into literacy portfolios.

The fourth professor is introducing a HyperStudio assignment for third year students into the Inquiry Block, an integrated science, social studies, and art methodology course in which she teaches. Our preservice students have previously used HyperStudio in a first year required computer course. In this assign-
ment students develop multimedia hypertext stacks that teach a science concept to accompany a science center that all inquiry block students build and leave in their field placement classrooms for two weeks. Science Centers must be self-sufficient with activities and assessments about science content and processes. Creating a multimedia based resource helps preservice students demonstrate their ability to develop grade-appropriate content, organize information in a logical interesting way, and use technology tools to present this to an elementary audience. Many of our neighborhood schools already use HyperStudio and for those that do not, the stacks will be uploaded to the Internet for viewing.

The Impact

The impact of Camp Apple far exceeds its effect on these four faculty. At the beginning of the semester thirty-two faculty throughout the college attended a set of three conversations about the Camp Apple experience and how we move forward with technology. Two of these meetings were attended by the College Dean and Vice Provost of Information Technology at the University. Faculty voiced their concerns about adequate resources and the lack of a clearly articulated vision and plan. This has resulted in a newly formed technology task force of faculty widely representing the college and being facilitated by a respected K-12 technology educator. The task force is taking a serious look at a number of issues and for the first time we are working together to define what it means to be a teacher of twenty-first century teachers. We are working together to define how this new literacy in technology and learning will help us develop practitioners that know how to use all the tools available to them and will be prepared to teach children brought up in the net generation.

Camp Apple provided the impetus for a number of changes we are already beginning to see in our college classrooms and administrative attention. This experience carved out the time to learn how to use new technology, to explore technology in a richly supported environment, and to think about what and how we teach and how technology could and should change that. There was structure to provide focus with flexibility to accommodate our special needs and interests. Our summer experience encompassed a definition of professional development that goes beyond the term "training" with its implications of learning skills, and incorporates a definition that includes formal and informal means of helping faculty not only learn new skills, but also develop new insights into pedagogy and their own practice. Camp Apple helped faculty see where their thousand mile journey could end and took us a few hundred miles towards our destination in a week.

III. Replicating Camp Apple Locally: A Professional Development Model

Starting with Camp Apple

Ongoing professional development for faculty in teacher education has been and continues to be an integral part of the climate and culture of Rowan University’s College of Education. In the past five years, efforts have focused mainly on improving technological literacy and more recently, on the integration and modeling of instructional technology in the professional component of our programs. Past activities have included workshops on the use of productivity tools, specific software packages, and presentation programs. These activities have met with moderate success. However, those workshops/experiences that provided little or no follow-up, were ‘demonstration only,’ and/or involved technology that was not accessible or reliable were more frustrating than helpful. In a continued effort to enhance the technological abilities of teacher education faculty and keeping those concerns in mind, the associate dean attended the week-long summer institute for teacher educators known as Camp Apple during the summer of 1999. Using the ‘Camp’ model as a turnkey, professional development activities were planned that could be replicated for

Back at Rowan University

Many challenges had to be faced in replicating the Camp Apple model. These included: a) finding an appropriate time during the semester that was convenient for the majority of faculty, b) ensuring that facili-
ties/hardware were adequate to accommodate the number of attendees and types of activities to be undertaken, c) determining a topic that would be useful across various education departments (elementary, secondary, special education, health & exercise science, reading, and educational leadership), and d) motivating faculty to participate. We faced two additional challenges in planning an activity. First, an existing computer lab in the College of Education was to be upgraded during the summer of 1999, but as of the start of the semester, no action had been taken. The second was that the College was slated for an upcoming NCATE continuing accreditation review in the fall and all attention and effort was focused on the visit.

Given these concerns and circumstances, the associate dean met with the instructional technology specialist several times during the semester to determine an appropriate course of action.

Fortunately, the computer lab in the College of Education was renovated and upgraded during the first week in October, and the NCATE visit followed two weeks later. Those two challenges being met, planning for the professional development activity continued. The January intersession was chosen as the time for Camp Apple since no classes would be in session, yet faculty would be returning to campus for registration and to prepare for the spring semester. The Camp Apple theme (i.e., casual attire, bag lunches, technology counselors, and give-aways) would be used as a motivator to attract participation. The focus of the professional development activity would be to introduce education faculty to WebQuests—inquiry-oriented activities in which some or all of the information that learners interact with comes from resources on the Internet (B. Dodge cited in Schrock, 1999). This activity was chosen because it could be used across all education departments by professors, and in turn, incorporated by education candidates for use with K-12 students.

In addition to the overall camp theme, other components of the week-long institute would be incorporated into the campus-based professional development component. One positive aspect of Camp Apple was the ready access to technology specialists during the hands-on workshops. This would be accomplished by having "technology counselors" available during the workshop to provide assistance as needed. As in the Camp Apple model, faculty members would be encouraged to work in teams on projects using their existing course syllabi. Faculty would be introduced to a modified Unit of Practice (UOP) as a model for incorporating technology into their education courses. The session would be divided into two components—a "minds-on" session where faculty would be introduced to, and discuss the value of WebQuests, and a hands-on session where faculty would develop WebQuests appropriate for their courses. Follow-up would be an important component to the success of the professional development activity. To that end, the instructional technology specialist will develop a web site where education faculty can share their WebQuests, and seek support and/or assistance in the integration of this technology strategy. The site will also be a resource for links to other WebQuest sites. In addition, the technology specialist who authored the text used by all of our teacher education candidates (Orlando & Levy, 1998) will add a new chapter on WebQuests to the revised text to encourage preservice candidate use with K-12 students.

In order to promote participation, flyers were distributed to all education faculty and announcements were posted on the College of Education web site. The Dean of the College of Education agreed to supply funding for refreshments and give-aways. The college instructional technology specialist, and a university instructional technology specialist (with an education background) volunteered to be technology counselors. The only perceived obstacle to success was the timing of the workshop. Although classes would not be in session, faculty would be on "holiday," so participation might be limited by those who already had plans for this particular timeframe.

The goal of the workshop, which is to be held January 10, 2000, is to explore with faculty meaningful ways to integrate technology into professional education courses using hands-on experiences. The specific objectives include the ability to: a) define and construct WebQuests, and b) evaluate existing WebQuests and Internet sites. The intended outcome is to increase the likelihood that education faculty would incorporate and model the use of technology in their education courses using the WebQuest activity as an instructional strategy. If this particular strategy is successful, participation in future workshops would be expanded to include all university faculty, so that the modeling of technology use would be evident campus-wide. Another potential strategy would be to replicate the Camp Apple experience for inservice teachers at our partnership and PDS schools.

Our education faculty have shown a consistent interest in enhancing their professional skills. Likewise, a culture exists which promotes and supports faculty professional development. Rowan University's Camp Apple will be another wonderful opportunity to assist the College of Education in the preparation of excellent teacher candidates, ready for the classrooms of today and tomorrow. Teacher education is touted as a
major factor in improving K-12 education. Skilled and talented teacher educators can be the catalysts in meeting this necessary goal.

IV. Evaluation: What did We Learn?

Participants were asked to provide Apple with a written reflection evaluating their experience at Camp at the end of the week. In addition, a follow-up survey was done three months later with plans for continuing evaluation in the future. Remarkably, evaluations were very consistent. Where the program succeeded, participants acclaimed its success. Where the program required more work, participants' comments were consistently critical.

Technology Integration: It's Not What You Think It Is: The most significant learning from the week was the realization that technology integration means different things to different people. It is really two issues.

When faculty think about “technology integration” in their teaching, they are usually thinking about things like using email to communicate with students, moving their lecture notes to electronic slides with software like PowerPoint, or putting their syllabus on the web. When educators talk about “preparing tomorrow’s teachers to integrate technology” for K12 instructional use, they are talking about instructional strategies which use technology to promote critical learning processes in children. We discovered that one has to separate the use of technology for professional productivity by the faculty member and modeling instruction to promote new learning outcomes which employ technology. That a faculty member puts his or her syllabus on the web as a way to “model” technology usage for preservice students will not help those preservice teachers teach more effectively in their future classrooms.

Bringing Effective Practices to Teacher Education: There is a great opportunity for teacher educators to explore effective practices for their own teaching. Many of these effective practices are constructivist in nature, and require technology in order to make them most effective. While we erred at Camp Apple by presenting effective practices in the context of K12 instruction, it became immediately clear that faculty were very interested in exploring the potential of strategies like simulation, project-based learning, collaborative learning, and group learning within the context of their courses. Professional development for teacher educators should provide participants with the opportunities to explore these possibilities. If preservice teachers have these kind of first-hand learning experiences, they will come to implicitly understand the power of technology in teaching. This is the kind of “modeling” that needs to take place in teacher education when we talk about “technology integration.”

Follow-Up Survey

A follow-up survey of all participants three months after the program asked them to assess how their Camp Apple experience was making a difference in their current teaching and practice, and what activities they had engaged in to fulfill their commitment to disseminate what they had learned. We received 23 responses to this survey (51% return rate). In their retrospectives, participants uniformly praised several aspects of the Camp Apple model, including the residential, secluded location, the outstanding staff, and the availability of cutting-edge technology.

Residential, Secluded Location: In their evaluations of Camp Apple, we learned that the residential aspect of the program was the most powerful strategy employed. Participants also reported that the secluded and scenic location created a wonderfully relaxing environment in which they were able to focus intensely on the subjects at hand. Faculty were unanimous in their evaluation of Camp Apple for giving them the opportunity to spend such a long period of time in the company of colleagues to discuss issues and share ideas.

The Right Staff: Camp Apple was staffed by Apple employees and instructional technology directors who had previously been designated “Apple Distinguished Educators” from several Colleges of Education. They were all experts in a particular technology or in a particular implementation of a technology for teaching, like simulation, multimedia authoring, or process-learning. Evaluations from participants ranked the staff as the single most significant factor in the success of Camp. We tried to provide both direct instruction as well as just-in-time learning. The broad technical expertise of each staff member made this possible.
Technology Immersion: Participants remarked that the technology-rich environment at Walker Creek made them feel like they were "kids in a candy shop." There were technologies and software products available to them that they did not know existed. The ability to have round-the-clock access to these resources combined with the expertise of the staff was one of the key points of feedback in favor of the program.

Teams At Work: Participants who attended in teams of three or more had a significantly different experience than those who came by themselves or even in a pair. Of the 42 participants, 40 reported that they would recommend Camp Apple to a colleague. The two who said they would not have attended came as "solo" participants, without a team. Of the 17 participating campuses, 11 were represented by three or more people.

More importantly, responses to this survey indicate that a wide range of activities have been implemented on campuses as a result of the Camp program. Three months later, the schools which sent more than two people are exhibiting more activity in preparing for and using technology. Of the 11 schools which sent teams of three or more, six have planned new faculty development activities for the current school year. Two have commissioned new technology planning committees, and three have asked Apple to help them run their own Camp Apples next summer. Two of these eleven schools have not had any kind of significant follow up. Of the 42 attendees, four papers/research/presentations proposals have been prepared in the four months following the experience. Eighteen faculty have indicated that they would like to return to staff Camp Apple 2000. Additional follow-up is planned at the end of the academic year to further examine the ongoing effects.

Camp Apple was a model professional development experience for many reasons. But perhaps the most significant one is that it truly represents a partnership. Apple provided the resources and opportunities for learning, and in return, many faculty members have followed up with outstanding activities which have extended their learning to students, other professors, and to other institutions.

The Unified Elementary ProTeach Program: Impacting UF and Beyond

Colleen Swain
University of Florida
United States
cswain@coe.ufl.edu

Abstract: The Unified Elementary ProTeach program at the University of Florida is a new teacher education program with the potential to positively impact future teachers, public school children in the state of Florida, the UF community and beyond. The explicit and implicit use of technology is one of the program highlights dramatically affecting the teaching and learning environment for students and faculty in the College of Education. Several examples of changes in faculty and students are explored. Another major component of the program is the integrated teaching block students are experiencing. Faculties from the Colleges of Education and Liberal Arts and Sciences will team-teach academic areas and teaching methodologies. As the faculties of both colleges work together to improve the educational experience of teacher education students, the College of Education faculty have the potential to influence the teaching methodologies of the faculty from the College of Liberal Arts and Sciences.

Introduction

Walk through the halls of the College of Education at the University of Florida and you will hear conversations ranging from the use of electronic portfolios to how special populations benefit from a specific teaching strategy. The event triggering all this excitement is the beginning of the Unified Elementary ProTeach program for elementary and special education majors, which is a restructuring and revision of the original ProTeach program.

In the early 1980s, the College of Education faculty recognized that teacher preparation needed to drastically change. Classroom conditions faced by teachers are more complex and stressful than those in the past and teaching continues to become more difficult. Hence, faculty members developed a program to prepare teachers in elementary education, special education, early childhood, and secondary education titled ProTeach (from PROfessional TEACHer). This rigorous 5-year program was designed to culminate in a Master of Education degree. Since the implementation of ProTeach in 1984, hundreds of new teachers have been produced and hired in the state of Florida.

The Unified Elementary ProTeach Program

Regardless of the success of the ProTeach program, the teacher education faculty again recognized the need for a new conception of teacher education to meet the challenges posed by an increasingly diverse student population. The reexamination and revision of the preservice teacher education programs in elementary education and special education was prompted by factors such as the changing character of the U.S. population of school children (New Faces at School, 1991), the number of students with disabilities served primarily in general education classrooms (U.S. Department of Education, 1994), and the potential of inclusive education policy (Will, 1986). The College of Education has unified and restructured the special education and elementary education programs into a Unified Elementary ProTeach program which is designed to prepare teachers with a dual emphasis in elementary education and mild disabilities. Students who successfully complete the 5-year program will receive a recommendation for certification in elementary education, an ESOL endorsement, and an option for special education certification.

The Unified Elementary ProTeach program accepted its first cohorts of students in the fall of 1999. Although the program is successfully underway, there are still implementation issues needing
discussion and planning. One of the components of the Unified Elementary ProTeach program requiring considerable work is the integration of technology into the program. The faculty has made the explicit and implicit use of technology a program highlight. Faculty are focusing on the best ways to use technology in each course and to insure that students are observing effective methods of teaching and learning with technology. A second major component of the program is the integrated teaching blocks students will experience. Faculties from the Colleges of Education and Liberal Arts and Sciences will team-teach academic areas and teaching methodologies. These two innovative components have the potential to positively impact ProTeach students, the school population in the state of Florida, and the faculties in the Colleges of Education and Liberal Arts and Sciences. This paper will chronicle the process of the faculty as they strive to become outstanding models of integrating technology into their teaching, the changes in the students as they incorporate technology into their learning experiences as well as their teaching, and the impact the infusion of technology into the Unified Elementary ProTeach Program is having on the rest of the University of Florida.

Faculty Development with Technology

Data from over a decade of research from the Apple Classroom of Tomorrow (ACOT) research project indicates that teachers progress through five stages (entry, adoption, adaptation, appropriation, and invention) in their pursuit of integrating technology into their teaching (Sandholtz, Ringstaff, & Dwyer, 1997). While other stages have been identified (Becker, 1994; Berson, 1996), it is indisputable that it takes time for teachers to become effective technology users in the classroom. Hence the College of Education is using a variety of techniques to facilitate the learning process for all college faculty, and specifically, the faculty involved in the Unified Elementary ProTeach program. The Office of the Dean, educational technology faculty, College of Education technology committee, and the Office of Instructional Resources at University of Florida are using numerous strategies to provide the needed training. Brown bag lunches, workshops, individual consulting, and partnering with educational technology graduate students are just a few ways faculty are learning new technology skills and experimenting with previously learned skills in their teaching. The diverse methods of faculty development allow individuals to progress at a rate that is comfortable for their movement towards effective use of technology in teaching. The goal is for the faculty in the College of Education to be technologically fluent so that effective and appropriate modeling of the use of technology during instruction can take place. Being computer literate is not enough since there are additional issues involved in the use of technology in instruction. As a result, conversations are taking place about how to integrate the use of technology into teaching and how the role of the instructor and student changes.

The use of electronic portfolios is another area where faculty are becoming acquainted with technology in the learning environment. In order to comply with the Florida Department of Education documentation requirement for the state Accomplished Practices and to assist ProTeach students with developing a richer understanding of learning and assessment, the faculty has adopted the standard of students creating electronic portfolios. This also requires considerable conceptual and technical training for the faculty.

For a majority of faculty in the teacher education program, the first step in the implementation of electronic portfolios was to consider the various methods in which students could present their materials for documentation purposes. For example, to document that students have performed certain teaching strategies in a classroom, students were previously videotaped. Now students could using digital recorders or digitize videotape as another technique to include in their portfolio. The faculty must make sure students are aware of the wide array of methods to demonstrate the Florida Accomplished Practices and then provide instruction on how to accomplish the task. Faculty agreed that everyone could not learn how to implement each task due to factors such as time constraints and lack of equipment. Hence, instructors are primarily relying on educational technology graduate students to provide student instruction. Still, faculty members are learning to create various electronic portfolio elements. The College of Education faculty are adamant that we demonstrate to students that we are life-long learners just as they should be. Students can see that learning how to use different types of technology and that incorporating technology into teaching takes time and is a long-term commitment. By observing their peers and the College of Education faculty, students are seeing Rogers’ (1995) diffusion theory in action.
The Impact of Integrated Technology on Students

As faculty are incorporating more technology into the classroom activities and are modeling teaching with technology, students' expectations for faculty and themselves are changing. The Unified Elementary ProTeach students have become accustomed to a great deal of electronic communication among the instructor and their peers. The use of email, bulletin boards, and web pages for dissemination of information and discussion of course materials and issues are commonplace and expected by students in a majority of their classes. Students are also requesting easy access to class instructional and activity materials, such as Power Point presentations, web sites, AppleWorks projects, HyperStudio stacks, and MicroWorlds projects. We are seeing this reciprocated when students give presentation and create lessons for their assignments and field placements. Students are discovering that when giving a presentation or teaching a lesson to a class reserving a traveling computer cart for a room that is not technology-equipped can be problematic. We have so many faculty and students requesting mobile computing carts for their classrooms that the college runs out of equipment. This will continue to be problematic until the renovation of the College of Education is completed.

Another change for students in the College of Education is their creation and use of electronic portfolios. We know from literature (Fogerty, 1996; Porter & Cleland, 1995) that portfolios allow students and faculty to express their strengths and understanding of concepts in a richer way along with encouraging reflection and collaboration among peers. Electronic portfolios are also a method students can provide districts with proof of mastery of Florida's Accomplished Practices as well as developing various products demonstrating their preparedness to teach.

Before a full-scale implementation plan was established, a pilot study using electronic portfolios was conducted. During this study, students were allowed to present his or her understanding of a task and proof of mastery for a Florida Accomplish Practice using on-traditional methods. Students in the pilot study had vastly different technical skills allowing novice and advanced computer users to be challenged. As students began to share ideas with each other and specific faculty members, the work of the students improved. Novice computer users began to learn from the advanced computer users and became excited at the potential of the electronic portfolio. Advanced computer users were constantly trying to find new computer techniques to implement their ideas. Several students incorporated videos into their portfolios. Frequently, students went beyond the scope of the assignment to add scanned pictures, animation, and reflection pieces to their assignment. In addition, the conceptual quality of the work improved as students began to demonstrate a deeper and richer understanding of the content. This finding is supported by literature (Kent, 1997). The instructor of the class noted that students expressed satisfaction in creating a product that would continue throughout their college career and beyond. This excitement is now spreading to faculty and students who were not involved in the pilot study.

Faculty members are discussing with students how to present evidence of mastery on the Florida Accomplished Practices. As mentioned earlier, it is critical that students learn from faculty that electronic portfolios allow multiple methods of expression. One concern for students is answering the question "Who will assist me in this process?" To provide assistance and instruction for students, a graduate student in the educational technology program developed a series of workshops and a help center web site for ProTeach students. Students were provided with three multiple-hour long seminars to create their initial web pages. As seen with the faculty, there was a wide array of ability levels among the students. Students also were given web sites to see samples of various methods of documenting each of the Accomplished Practices. These examples are separated by academic specialization area since a mathematics specialist might want to document a requirement differently than an English specialist. In addition, the doctoral student holds substantial office hours so students can have individual consulting when they encounter difficulties.

Faculty members are noticing differences in our students as they expand the integration of technology into their educational experience. First, students are beginning to view course content with a different perspective. Students consider the assignments in classes as more significant since they can see how this task truly relates to a valued teacher preparation experience. In the past, there was a tendency for some students to naively think that these assignments could be done with a half-hearted approach since it was just a college activity. Now, students are looking at how each assignment will impact their future job opportunities and experience. The idea of placing as many artifacts into the electronic portfolio as possible to demonstrate mastery of an Accomplished Practice is important to many of the students. Second, students are beginning to develop lessons that are becoming more technology-rich than the lessons of the past. Third, students are starting to recognize that the role of the teacher changes as technology is
It is encouraging to hear discussion in the hallways dealing with how technology-rich lessons could be implemented and the most effective strategy and role for the teacher in the lesson.

**Impacting the University of Florida Community and Beyond**

The University of Florida teacher education faculty realizes that the diffusion process occurring with respect to technology is not unique. Teacher education programs across the United States and globe are increasingly integrating the use of technology into the curriculum. However, the senior year experience in the Unified Elementary ProTeach program is distinctive and innovative. ProTeach students will have two semesters where their academic content classes and curriculum and methodologies classes are team-taught with faculty members from the Colleges of Education and Liberal Arts and Sciences. ProTeach students will take an integrated block of science, mathematics, and technology during the fall semester and an integrated block of language arts, social studies, and special education during the spring. Each semester, students will have a field placement experience in surrounding schools. As the faculties of both colleges work together to improve the educational experience of the ProTeach students, the College of Education faculty have the potential to influence the teaching in the College of Liberal Arts and Sciences. It is hoped that best practices in teaching will be seen throughout the University of Florida. In addition, it is hoped that these experiences will dramatically impact the public schools where the ProTeach students are placed. Conversations are taking place with the deans of the two colleges, department chairs, and the professors teaching the courses dealing with the content needed by the Unified Elementary ProTeach students and the modeling of effective teaching techniques for these students. We desire our students to constantly have best practices modeled to them and for them to acquire a strong foundation in content areas. A major element of these discussions involves the effective use of technology into daily teaching. Currently, the fall semester schedule allows for the team teaching of the science, mathematics, and technology areas. This structure has been established so professors from the Colleges of Education and Liberal Arts and Sciences can participate in all the classes. In addition, if one professor needs additional time for a lesson or series of lessons the block schedule allows for this. Another benefit of this scheduling is that students have extended time for their field placement experiences. The spring semester is similarly developed but contains a separate course devoted entirely to a field placement. This course has students in a public school classroom throughout the semester. This differs from the fall term where the field placement is a component of the semester block courses.

These two semesters of team-teaching and integrated academic subjects allow for faculty members within the Colleges of Liberal Arts and Sciences to see exactly what types of teaching methodologies are needed by teacher education students. In addition, as these professors have the opportunity to visit schools where students are doing their field placements, they can experience how critical it is for teachers to be well-versed in content and the ability to effectively and appropriately relay information about the subject area. College of Education faculty members benefit from working with experts in the subject matter areas to increase their knowledge and in developing curriculum materials needed in the public schools. The Unified Elementary ProTeach Program is truly allowing faculty from across the University of Florida to grow in new ways.

It is hoped that we will see change in the public school classrooms from the senior year experience. As the ProTeach students go into the classrooms for their field experience, ideas for teaching can be discussed with experienced classroom teachers. As the students and teachers critique lessons together, determine the appropriateness and effectiveness for that particular classroom, classroom learning environments could change. The College of Education faculty hope that this will allow some experienced teachers to gain ideas on implementing technology-rich lessons for their students.

**Conclusions**

The Unified Elementary ProTeach program has the potential to positively impact the University of Florida community and beyond. As faculty and students increase the integration of technology into the curricula, the learning environment of classrooms at all levels will change. ProTeach students will benefit
from seeing the use of technology modeled in daily teaching. College faculty will increase their knowledge with respect to using technology and in various subject areas as well as gain a greater appreciation and understanding of what colleagues from various parts of the University of Florida are doing. As the Unified Elementary ProTeach program continues, College of Education faculty desire to gain data and knowledge dealing with the changes in student work related to the infusion of technology into their work, how the Unified Elementary students will act as change agents throughout the state of Florida, and how team-teaching with the College of Liberal Arts and Sciences will impact the teaching across the University of Florida system. We look forward to great things!

Introduction

Recent state legislation in Virginia requires teacher licensure programs to guarantee that graduating teachers are computer literate. Future teachers must demonstrate the ability to operate and integrate technology into the classroom. In an effort to accommodate this mandate, faculty within the School of Education at Virginia Commonwealth University are analyzing the use of technology in courses required for certification. Through this process, faculty recognize a need to enhance their own technology skills, and also acknowledge the importance of modeling effective uses of technology in their own methods courses. However, faculty report obstacles in integrating technology throughout the teacher education curriculum. Reasons include lack of time, lack of knowledge in the operation of hardware and software, and lack of clarity about how to infuse technology into the curriculum. Faculty also realize that infusing technology into courses is not enough; prospective teachers need to practice delivering instruction which incorporates technology into “real-life” experiences with K-12 students.

While there is a call for new teachers who are computer literate, there is also considerable demand to provide avenues for existing teachers to learn about technology. School of Education faculty maintain close contact with practicing teachers by supervising preservice teachers’ field-based experiences. Practicing teachers report an increased demand to incorporate computer literacy skills into their everyday teaching, and they are turning to institutions of higher education for assistance. Thus the School of Education is faced with two challenges: to prepare technology literate preservice teachers and to provide technology training and assistance to teachers already in the field.

Grant Implementation

In an effort to assist university faculty with the tasks of incorporating technology into methods courses and modeling effective uses of technology for preservice teachers, a grant was awarded by the US Department of Education. The grant provides 1) funding for additional personnel to provide technology training programs for university faculty, 2) course release time to allow university faculty time to incorporate technology into their current methods classes, 3) portable equipment (laptops) which allow preservice teachers to practice newly acquired computer skills, and 4) a support system for faculty to prepare preservice teachers as “agents of change.” As university faculty increase the use of technology in methods courses, a pilot group of preservice teachers are applying this knowledge during practicum and student teaching placements. These experiences provide preservice teachers the opportunity to share their
knowledge with practicing teachers in the field. Additionally, faculty and preservice teachers are working together to design learning activities that address curriculum objectives. This process allows the School of Education to provide technology training to students obtaining initial certification and practicing teachers.

University faculty participating in the grant are charging their students to implement practical, field-based technology experiences. One science education professor is training his students on the use of a computer-based laboratory system and the associated scientific probeware to engage students in investigative science. A national manufacturer, PASCO Scientific has donated teacher's guides, software, and probes. These materials are being used to equip five computer-based laboratory stations in each of two middle schools. There is a faculty liaison with each school who receives load credit for working with the teachers of the school. The teachers hold clinical faculty rank and serve as cooperating teachers for practicum and student teaching placements. A science educator and four secondary science students are working with the science faculty of both schools to infuse this computer based technology into the existing science curriculum in grades 6-8. The preservice teachers are studying the existing curriculum and the computer based activities to determine matches between the two. In addition, they are making suggestions on how to modify current labs to use the probeware to collect, graph, and analyze data. A correlation of the computer-based laboratory activities to the Virginia Science Standards of Learning for grades 6-8 has already been completed.

A Social Studies education professor is having students learn about digital imagery in order to create virtual field trips which can be accessed via the World Wide Web. The instructor's modeling of virtual field trips in a social studies methods class demonstrates the uses of multimedia, hypermedia, digital photography, and scanning devices. His "trip" through an exhibit at a local history museum was posted on a Web site. Students later visited the exhibit allowing them to understand both his decision making and the technical aspects of designing the "trip". The grant funded a technology specialist within the School of Education to assist with this project. During an introductory class session, the technology specialist showed numerous virtual tours of exhibits (dreamscape.com/frankvad/museums.exhibits.html), provided individual assistance for students, and demonstrated how to post trips to a Web site. Students were required to develop their own virtual field trips (http://www.vcu.edu/eduweb/newhomepage/proj.html), and reflect in writing about the following questions:

- How could you effectively use a virtual field trip in your curriculum to expand the walls of the classroom?
- What is the function of your virtual field trip, and how can it enhance social studies instruction?

The objective of this assignment for pre-service teachers is to engage children in activities that stimulate them to imagine realistically a museum exhibit, historical site, or portrayal of a historical event. Students are creating virtual field trips during their field-based experiences, and in particular, with inner-city children who have limited resources and opportunities. Based on an informal student survey, the instructor has decided to implement this project next semester with two classes.

Conclusion

It is a challenge to modify a teacher education program by encouraging university faculty to develop technology skills and devote adequate time, effort, and resources to infuse technology into the curriculum. It is a major task to ensure that preservice teachers graduate technology literate. Receiving a federal grant has provided much needed equipment and resources. The School of Education looks forward to expanding its efforts with more faculty and students.
Faculty Development in Technology
For Teachers of English For Specific Purposes (ESP)

Tatiana Slobodina
Department of Foreign Languages
Northern International University
Russia
tatiana_slobodina@hotmail.com

Abstract:
Entering the global market in the age of information, Russia is in desperate need for experts in all areas of economy, highly qualified, competent, and capable of using foreign languages for handling professionally valid information, solving problems, and making reasonable decisions. To produce such graduates, Russian universities must reconsider their foreign language teaching concept. Constructivist university-level ESP teaching requires the instructors to possess certain specific competencies as a part of their technological literacy. These can be acquired through the system of on-site ESP faculty development. The paper considers the current practices of faculty development in technology in Russia=s universities and suggests ways of restructuring it to provide a high quality of university education in the new millennium.

Introduction
The link between faculty development and the quality of higher education makes the former a prerequisite for the latter. Today, while the tasks of the faculty remain basically unchanged and, on top of instructing students, embrace consuming and generating ideas and information, the tools used to fulfil these have changed dramatically. Tons of necessary and useful information simply cannot be produced, stored, retrieved, manipulated, and disseminated without electronic devices: New technologies . . . are guiding the information flow (Hyerle 1996). The capability to operate these, or tech-literacy (Baratta 1990), has become an integral part of literacy in the electronic age. Therefore, Afaculty and students must become literate in the skills of electronic information processing, both to accomplish the tasks of education better (Johnston 1986). The main task of Russia=s higher education is to train literate specialists for the national economy that is now entering the free market system; it is based on the revised concept of literacy.

Tech-Literacy in the University Curriculum
In the modern world, literacy is much more than just the skills of reading and writing as it has been traditionally understood:
1. reading should also embrace the skills of referencing and scanning for information;
2. writing is not only fixing what has been said on paper (or on a computer screen) but also engaging certain authoring and presentation skills;
3. such enhanced literacy cannot be exercised today without the skills of using certain types of computer software;
4. literacy in one=s mother tongue is far from sufficient today, when academic and economic success and social mobility greatly depend on one=s literacy in one or more world languages (Goodman 1987);
5. a university graduate should also be able to disseminate the texts he/she has produced not only as hard copies but also - and rather - through the electronic network which also requires certain specific skills, including such sophisticated abilities as using hypertext and multimedia authoring systems.

These activities can be included in the curriculum in two ways: first, as a part of the General Professional and Special Subjects cycle and, second, as a part of the General Humanities cycle. In the first, they either take the format of specific, professionally oriented courses or are integrated into the courses on the core subject. Meanwhile, the enormous potential of the second has virtually been neglected - because of the insufficient technological facilities as well as because of tech-illiteracy of the Humanities faculty, including foreign language instructors. This can be changed only through the successful system of faculty development in which the instructors should learn to understand the technology, practice designing and developing technology-based materials, and generate new concepts and ideas.
on using technology in class.

The purpose of this paper is to consider the faults of the system of ESP faculty development in the area of technology in Russia and to suggest ways to bring it to concordance with the today's needs.

Technology in the Constructivist ESP Classroom

Foreign Language Courses in Russian Higher Education

According to the State Educational Standards of the Russian Federation, a sufficient command of a foreign language is a graduation requirement for majors in any area (other than linguistics) and, as such, is mandatorily included into the curricula of Russian universities. Normally, it is one of the basic European languages, but English that occupies a special position on the world's market of languages (Coulmas 1992) dominates in the non-linguist curricula. The majority of students planning to take up occupations in international business, economics, management, or engineering consider English a good investment and a prerequisite for getting a good job after graduation. Therefore, they take courses in English for Specific Purposes (ESP).

The whole system of ESP instruction at Russian universities has undergone dramatic changes since the drop of the iron curtain; the major transformation was that of students' attitude: from just a graduation prerequisite of no actual importance, ESP became instrumental literally overnight. The wide involvement of computers and the introduction of joint ventures also contributed to motivating students' interest in learning ESP. However, it brought about problems, as well. First, the focus of ESP courses should be switched from passive language skills (e.g., translating scientific texts) on to active communication and information search which required great amounts of linguistic and extralinguistic information to be consumed; second, there was the lack of time, both in and out of class, which definitely limited the learning process and impacted results. The search for effective, efficient, and time-saving ESP teaching/learning techniques made the faculty turn to Intensive Language Teaching methods; so the advent of modern technology into the ESP classroom was predetermined, and the computer, an excellent learning device (Bork 1982), joined such old-timers as audio, TV, and even video; moreover, it managed to bundle these up in the format of multimedia.

Multimedia Technology in Teaching ESP

The State Standards require that the Russian higher school graduate be able to use a foreign language to converse both in professional and informal settings as well as derive significant and handy information from any source, including printed materials, electronic networks, and other speakers. This actually implies two groups of skills that must be taught on the university level: first, language (linguistic) skills based on the knowledge of the language structure and how it should be used for communication and information exchange; and, second, specific (extra-linguistic) skills based on the knowledge of the core subject and other areas to be communicated on. Therefore, ESP classes have to be specifically arranged: they are built on the use of professionally significant information which is retrieved from foreign sources and communicated in the foreign language. To be successful, they depend heavily on modern technologies specially designed for language learning.

The multimedia language-learning software has been incorporated into the ESP curriculum for several reasons. Multimedia as the blend of text, video, and audio provides sense-supported introduction of enormous amounts of information. Its interactive form not only stipulates presentation, as in video, but also simulates life-like communication engaging the learner as an active participant. The non-linear structure of presentations (hypermedia) facilitates multiple return to the information. These result in highly effective and time-saving multimedia-based classes. Besides, a student-oriented mode allows customization of learning regimes according to the needs of each student. Finally, its fragmented format supports incorporating multimedia into course units which also enhances the capabilities of constructivist ESP teaching.

Constructivist ESP Classroom

The search for successful ways to teach foreign languages, in general, and ESP, in particular, has been one of the constantly burning problems of Russia's higher education system. Direct instruction, that results in having students acquire and reproduce factual knowledge and well-defined skills, has its limitations when it comes to
teaching high-level thinking skills (Zahorik 1995). Since the aim of university-level ESP teaching is the active and creative skills of using English in professional settings, the constructivist approach to teaching and learning appears to be of critical importance for securing the high-quality output from the higher education system.

The purpose of ESP teaching is to support acquiring declarative and procedural knowledge of both linguistic and extra-linguistic character: *declarative linguistic knowledge* embraces knowledge of the language structure (grammar rules, vocabulary, etc.) while *procedural linguistic knowledge* includes the skills essential for using the language structure for extraction, verbalization, and communication of ideas (listening, speaking, reading, and writing skills); *declarative extralinguistic knowledge* implies knowledge about professional communication venues, topics, and etiquette as well as of formats and tools used to present professionally valuable information (e.g. knowledge of a company structure, staffing policy, and workplace ethics plus knowledge of the format of a resume and what tools can be used to generate it) while *procedural extra-linguistic knowledge* comprises the skills of using technology for professional communication, information search, and idea presentation (e.g., the skills of generating various documents using special software, the skills of browsing the Internet for some information, etc.)

So, the use of language-learning multimedia supports only one, *the linguistic*, side of ESP classes. The *extra-linguistic* side needs the involvement of electronic sources of information, such as CD-ROM references and the World Wide Web, as well as special types of software capable of manipulating professionally significant information. This software includes word processors with document templates; computer dictionaries; speech recognition systems; machine translation systems; spreadsheets; computer presentation and desktop publishing programs for generating flyers, posters, leaflets, booklets, and slide shows; specific task software, e.g. business card makers, business planners, marketing campaign planners, accounting and finance software, web page generators, etc. To be productively integrated into the constructivist ESP classroom, this requires some sort of specific competence from the ESP faculty.

**ESP Faculty Development**

**Faculty Specific Competence for a Technologically Enhanced ESP Classroom**

Understood holistically, Acompetencies are complex combinations of personal attributes enabling the performance of a variety of tasks@ (Preston & Walker 1993). To perform the task of facilitating a highly successful, technologically enhanced, constructivist ESP class, an instructor should actually possess both general and specific attributes: the first comprise the command of English and of language teaching methods as well as of technology and instructional design basics; the second imply a knowledge of the core subject area basics and metalanguage, i.e. the specific terms used, as well as the command of specific software used in the area.

**Russian Practice of Faculty Development in Technology**

On-site language-teaching faculty development in Russian universities is arranged around one of three focal points: language, teaching methods, or technology. Each course is delivered by experts in the corresponding area, but the courses in technology appear to be the least successful, with the real outcome much lower than planned: the only skills acquired are typing, fundamentals of Microsoft Word and basics of Excel which is obviously insufficient for facilitating technology-enhanced ESP classes. There are several factors that account for this weakness:

1. The primary cause of development course failure is ignoring the needs of ESP faculty in the course curriculum, though the monolithic approach, that assumes supplying the same material for all teachers, irrespective of their particular areas and interests, has proved to be unsatisfactory.

2. Another drawback of the development programs is the inflexibility of technology instructors: having strong engineering background, they unconsciously assume that their faculty students have the innate knowledge of computer basics. This results in sophisticated explanations which are extremely hard for humanities faculty to understand.
The last but not the least fault of faculty development in technology is the coaches’ ignorance of the specific needs of ESP instructors and of the specific software to be used at the ESP classes. As has been previously mentioned, the result is limited skills. Generally, faculty can do little more than prepare handouts for classes.

Thus, to rectify the current situation and to significantly improve the ESP faculty development system, it is vital to consider the three weaknesses when designing the course in technology for the ESP faculty.

Constructivist ESP Faculty Development

Constructivist faculty development suggests two basic approaches. The first, classified as psychological (Piagetian), focuses on individualization of the development programs; the second, situational (social), assumes that situated cognition and group interaction (Richardson 1997) is important. Considering these as well as the faults of the current faculty development system, one can conclude that successful on-site ESP faculty development in technology should be focus-oriented, which implies arranging the small groups according to the specific area of teaching ESP (e.g. technology in teaching Business English, Geological English, Automotive English, etc.); task-oriented, that is providing the faculty learners with the knowledge and skills to be used for doing their specific teaching practice tasks (e.g. how to use a Business Planner in class); learner-oriented, i.e. presented in the format that can be easily understood by humanitarians; and outcome-oriented, which is helping generate original technology-based course materials, from hard copies to interactive network assignments, etc. that faculty will use.

New ESP Faculty Development Course in Technology

Assuming that the new course should model the manner of involving technology in teaching ESP and thus help the faculty understand its functions and capacities as well as the conceptional foundations of its use, I would suggest that the course be structured as is shown on (Fig. 1).

Since the course is focus- and task-oriented, it should be delivered by technologically competent ESP instructors assisted by technology and/or field experts. Based on solving the real classroom problems and elaborating usable ESP-teaching materials, the course should offer the faculty learners a wide array of learning opportunities (Liberman 1995), combining individual experiences and creativity with group collaboration and support.

The Concept of Life-Long ESP Faculty Development
Tech-literacy of the ESP faculty is not a once-and-forever competence: the acquisition of tech-literacy, as any other knowledge-accretion process, takes long time (Nickerson 1986). New advances in technology that finally enter university classrooms are never ending: to keep pace with technological progress and benefit from it, ESP faculty should enjoy a system of life-long development. This might be shaped as lectures on advanced technologies, such as fiber optics connections and digital TV, demo classes (e.g., in distance education), consultations on new software, and material-development workshops, as well as brainstorming sessions, round-table discussions, new ideas presentations, and journal publishing. The concept of life-long faculty development in technology should therefore become the basis for the ESP Department seminars.

Conclusion

Providing high quality ESP courses today is totally impossible without the wide involvement of modern technologies used both to support language learning and to bring the instruction as close as possible to the realm of students' future profession. This can be accomplished through the implementation of the new concept of ESP faculty development, essentially constructivist, life-long, focus-, task-, learner-, and output- oriented, and flexible in the sense of content. In Russia, such restructuring of the current system of ESP faculty development in technology is vital because it might significantly improve the quality of higher education through teaching students how to use the English language in their professional practices most efficiently and effectively.

Abstract: A recent ISTE report provides persuasive evidence explaining the shortcomings of older models of technology education in preparing tomorrow’s teachers. New methods and models are needed to successfully prepare teachers to integrate technology in the classroom. The purpose of this interactive panel session is to highlight the models followed by four Colleges of Education at varying stages of the integration process. The Universities represented are: University of Illinois at Chicago, University of Nevada at Las Vegas, Utah State University, and the University of Connecticut.

The rapid influx of hardware and software into public and private school systems has placed sharp demands on teachers to know how to use and how to teach with technology. Yet, year after year, Colleges of Education (COEs) are sending new teachers out under-prepared for this task. As such, COEs are being challenged to re-examine the methods that they use to infuse technology into teacher preparation curricula to provide more information and practice for tomorrow’s teachers before they enter the classroom. This is a particularly burning issue for those colleges wishing to maintain their NCATE certification.

The traditional model for technology education centers on a single technology competency course or multiple competency modules. A recent research study put out by the International Society for Technology in Education (ISTE) (Moursund & Bielefeldt, 1999) examined this model of technology integration and found it inadequate. The report clearly states no correlation between formal instructional technology courses and instructional technology utilization by K-12 classroom teachers. Instead the report supports the notion that infusion of technology throughout the entire teacher preparation is the key to classroom technology integration. As such, COEs are scrambling to find space and expertise among classes and faculty to facilitate the transition.

While all COEs are different in some respects regarding technology integration, some types of planning for technology are common across institutions. Technology planning includes equipment acquisition and maintenance as well as professional development activities that guide the integration of technology into teaching and learning. While COE technology plans run the gamut from formal to informal, the same key issues must be addressed by each university planning for the integration of technology into teacher education programs. These issues include but are not limited to:
Type of Coursework: Coursework issues include how to accommodate for core competencies, modeling problem solving and critical thinking using technology, mediating learning/teaching through technology.

Technology Teaching Responsibility: Whose responsibility is it to teach with/about technology? As we ask such questions, we become forced to address a serious issue: Are we asking methods teachers to introduce applications or technology teachers to teach methods?

University support: For technology integration to occur, university support structures must exist. Administration and faculty in colleges of education must collaborate in order to identify and nurture administrative support and commitment to faculty and facilities.

Faculty Support: This issue includes providing faculty with technical support, professional development and compensation for the added workload that they can incur through the technology integration process.

Student Support: Students must also be supported as they use technology in course projects as well as within their practicum experiences.

In-service/professional development: As graduates enter the workforce, the technology support that they received as students must be maintained.

While the ISTE report (1999) provides persuasive evidence explaining the shortcomings of older models of technology education in preparing tomorrow's teachers, the report fails to give guidance to colleges of education on methods or models that will lead to increased integration of technology in the classroom. Instead the report advocates that educators share and disseminate their successful models and lessons they have learned along the way.

The purpose of this interactive panel session is to highlight the models followed by four Colleges of Education at varying stages of the integration process. The Universities represented are: University of Illinois at Chicago, University of Nevada at Las Vegas, Utah State University, and the University of Connecticut.

University of Nevada, Las Vegas
Neal Strudler, Department of Curriculum and Instruction

Project THREAD (Technology: Helping Restructure Educational Access and Delivery) was funded by the U.S. Office of Education's Preparing Tomorrow's Teachers to Use Technology grant program for Fall 1999. It was designed to build upon and expand the work done in previous years through the integration of technology into teacher education courses and field experiences for preservice teachers (Handler and Strudler, 1997; Strudler, Handler and Falba, 1998). The consortium for this project includes UNLV's College of Education (COE) and the Clark County School District (CCSD). In addition, it involves a new collaboration among various entities at UNLV, the project's lead organization, and a continuing collaboration with a K-8 private school, St. Viator's. The consortium's overarching goal is to build the capacity of individuals and institutional structures to support the infusion of technology throughout UNLV's teacher preparation program. This is being done through: (a) a series of inservice workshops for university faculty, administrators, field supervisors and mentor teachers; (b) one-on-one follow-up support provided by project staff and advanced undergraduate students; (c) a "mini-grant" program in collaboration with the UNLV's Teaching and Learning Center to support the development of technology-based modules for teacher education courses; and (d) expanded opportunities for students to apply technology in their courses and field experiences.

Project THREAD staff have been working with COE faculty to plan for the integration of technology based on the ISTE/NCATE foundation standards for preservice teachers. A critical component of those standards involves the application of technology in practica and student teaching. The project is addressing this need by beginning to implement a system in which students can request technology-rich field placements. In addition an advanced undergraduate educational technology course will be created to include a field placement with exemplary technology-using mentor teachers.

While Project THREAD's main focus is on professional development, it has enhanced the COE's technology resources via: (a) the purchase of a mobile laboratory of laptop computers for use in courses; (b) the development of an online version of our undergraduate educational computing survey classes; and (c) the availability of CD-ROM based software for checkout for students and faculty.

Overall, Project THREAD is attempting to weave together a mixture of new and existing learning opportunities to prepare preservice teachers for tomorrow's technology-rich classrooms. It seeks to move from "pockets" of
technology integration toward widespread infusion in all aspects of our teacher preparation program. While the proposed initiatives are designed to be carried out within the one-year time frame of the grant, the interventions described mark beginning efforts in what we plan to expand via a further infusion of resources.

University of Illinois at Chicago
Kim Lawless, Department of Curriculum and Instruction
Louanne Smolin, Department of Curriculum and Instruction

In addition to NCATE/ISTE Standards for Technology Competencies, the Board of Education in the State of Illinois has developed additional guidelines for teacher certification programs in the state. These guidelines focus on in context technology application that move beyond technical skill to classroom integration. Challenges presented to UIC were great and included minimal technology infrastructure. Efforts to infuse technology into the education curriculum had to start from scratch.

Initial efforts focused upon the development of a framework that served as a guide for the infusion of technology within teacher certification programs, the acquisition of equipment and professional development. This model was created specifically to accommodate the set sequence of activities that all teacher candidates experience as a part of their program of study. Therefore, it places minimal additional burdens on students, faculty and technology staff.

Since most certification programs at UIC are two year sequences technology integration occurs across four semesters, the students junior and senior years. The model is as follows:

A. Mandatory general competencies: General competencies include such applications as e-mail, file systems, etc. This could be a course for as many as three credits or a series of competencies that must be met by all COE students prior to entry into the Junior year of coursework.

B. Content/domain specific software integrated (Junior and Senior Years): The methods teachers, facilitated by the technology faculty would model in context use of technology and subject related software applications. This would illustrate a sampling of what technologies are available within specific domains as well as demonstrate appropriate uses of technology.

C. Culminating experiences (First Semester Senior Year): Students develop and build a portfolio highlighting technology applications. For example, they can develop webpages, multimedia modules, or webquests. These applications become a part of a portfolio.

D. Classroom integration project (Second Semester Senior Year): Students take what they have learned and develop a classroom based project in which technology is seamlessly integrated. They will run this project with their students through their practicum experience.

University of Connecticut
Scott W. Brown, Department of Educational Psychology

The University of Connecticut's Neag School of Education is taking an integrative approach to addressing the standards and guidelines proposed by NCATE/ISTE and the Connecticut State Department of Education as we prepare teachers for the 21st century and provide professional development for inservice educators. The multiple guidelines and standards within an extremely dynamic field have led us to take a dynamic approach to address this challenge.

In addition to the national standards, the Governor of Connecticut has declared that all children will be technology competent by the sixth-grade in the year 2004. He further delineated a three-tier progression through which he expects Connecticut teachers to pass through, reaching the highest level of proficiency, also by 2004. At UConn we are involved in the training of future teachers and the development of inservice training and assessment for Connecticut's current educators. To this end, the United Technologies Corporation has awarded a significant contract to the Neag School of Education to develop training for inservice teachers, develop an opportunity for an on-site MA program in Instructional Media and Technology, and to develop an assessment system for measuring the success of this project. The UTC project specifically focuses on the Hartford Public Schools. Additionally, the new superintendent of schools for Hartford has started "the lap top program" in which 400 laptops were distributed to
selected 9th grade classes across the city. Many of our students will be working with these classes in their practicum and internship activities.

The assessment component of the UTC project involves three levels of the educational technology use. The first level is skill-based but the later two levels employ a problem-based format and portfolio format respectively. Our current students are involved in the development, field-testing and implementation of the assessment protocols. This has been an opportunity to integrate our students in a real problem involving educational technology.

The Teacher Preparation Program at UConn is a five-year program within which students are admitted to the Neag School as juniors and graduate with a B.A. at the end of four years and an MA at the end of five years. Prior to being admitted to the Neag School, juniors will have competed general education requirements, which include a limited number of technology, related courses, designated as C courses. Therefore, as juniors they take an educational technology course in the fall, but this course is integrated across several other courses during the fall semester: two courses in learning, a course in special education, and a seminar that is designed to specifically link the activities that students engage in will in their clinical placements with the course content presented in the above stated courses. These activities are specifically designed to emphasize the education in educational technology. Students engage in activities and projects that focus on the educational impact of technology across the content of the fall courses and provides the basis for further integration across the remainder of their program. As juniors, seniors and MA students, they continue to integrate their educational activities and experiences in a technology rich environment. Our courses and programs stress the integration of education and technology to solve problems and address the challenges and issues of providing the optimal educational environment for all students.

In order to achieve our goals, we have instituted professional development for all Neag faculty and staff involved in teacher preparation, we have raised the expectations of integration of educational technology in our own educational activities, and we have formed a school-wide advisory committee to develop the support structures necessary to meet our goals and provided them a funding basis to reach these goals. We have initiated an electronic portfolio process for our MA students in which their materials will be pressed on a CD for review by a faculty committee and also used to demonstrate proficiency as a teacher and as a proficient user of educational technology. The portfolio system is modeled after the national and State standards. Current plans include the expansion of the professional development to all Neag faculty and staff.

Utah State University
Steve Soulier, Department of Instructional Technology

The Department of Instructional Technology at Utah State University has been recognized as a leader in the field of instructional design for over 25 years. More recently however, the department has had to adopt a new mission, that of facilitating the use of technology in teaching throughout the College of Education. This has not been an easy task, but changing state and national technology initiatives have made it a must.

In an effort to prepare outstanding teachers to use technology in mostly rural setting, the department has faced many logistical problems. Time and location constraints have made the delivery of instruction to many willing students difficult at best. As such, USU had to move to a distance-based model of teacher/technology training. Full distance education programs in educational technology and media endorsements were implemented in the fall of 1996. The programs are a mix of two-way interactive video, satellite broadcast and web delivery systems. Students meet in cohort groups around the state weekly to work on class projects and receive instruction.

The first cohort group within these programs has now graduated and students are now working throughout the state in technology related teaching positions. While the program can certainly be considered a success, a number of lessons were learned from the first technology cohort. First, the lack of standard equipment at the various sites made some of the more technical coursework difficult at best. Future cohorts will need to purchase personal equipment at program onset. Additionally, management over a number of the sites through the Internet proved challenging with server failures and lack of student support at the sites. These concerns and others will be discussed as part of the presentation.

Research within the areas of graduate and inservice remain a predominant area of importance concerning the appropriate integration of technology into today's learning environment. Graduate and inservice learners have come to insist upon learning environments in which the sound understanding of appropriate technology understanding and integration is expressed; as a representation of this necessity, the outstanding articles within this section attest to the latest innovations and discussions pertaining to graduate and inservice learning environments. The authors offer the latest research and theoretical issues through which the future of appropriate technology integration will appear. For ease of discernment, the following research paper summaries are presented in alphabetical order by the author's surname.

Abate explores the relationship between numerous classroom learning activities and tools; specifically the integration of technology into the learning environment. Within Abate's paper the initial findings, based upon ethnographic field data and survey administration, is presented. Specific aspects of the survey data that is addressed are three points: middle school facilitator's classroom activities; technological level of such activities; and, any impediments that may occur to the integration of technology into the learning environment.

Bauder, Rossi and Mullick offer a discussion surrounding the integration of a supportive modeling technique and mentoring aspects within Internet inservice workshops. The integration of these aspects is meant to facilitate the integration of instructional technology into learning environments. As a reward for their efforts, the teachers reported an increased level of comfort when integrating the Internet and subsequent Internet tools into the learning environment.

Beam and Beam present a process and outcome description of a project that was focused upon the investigation of classroom instructors with a wide spectrum of technological experience who were shifting career goals. The learning the challenges faced during their learning curve as content authors within a commercial content authoring company are addressed.

Borras and Manriquez describe a procedural model through which teachers learn to conduct research studies through the integration of technology-supported instruction. The context through which this model is facilitated lies within the model's working relationship between the researcher and teacher. In conclusion, Borras and Manriquez offer a number of aspects that may positively affect the inquiry efforts and attitudes of the research and teacher.

Brownell and Brownell discuss the evolving concept of media literacy and digital literacy within a classroom technology masters-level degree program. Examples of resources are offered, the course participants' feedback is presented and an outline of the specific course under discussion is offered.

Butler, Martin and Gleason present a project wherein a collaboratively designed and implemented program pertaining to control technology for use with primary-level students is outlined. The project design, project implementation and the development of a learning community wherein support structures are enhanced are discussed.

Carlson, Repman, Downs and Clark document the methods implemented to increase the traditional face-to-face learning environment discourse effectiveness through the integration of Internet-based interactive activities. Suggestions for future instructors are presented.

Carr focuses upon an Introductory Astronomy for Educators course wherein the evaluation of the course efficacy towards meeting the predetermined goals of flexibility, critical thinking and cognitive interaction are addressed. Research-based findings and issues raised are included.

Cotugno and Kahn examine the theoretical implications and realistic pathways through which the appropriate integration of technology into classrooms is examined. Of interest is the overarching focus of Cotugno and Kahn upon the instructional process within the instructional unit, rather than at a classroom-by-classroom focus level.

Cox discusses strategies that instructors can implement to offer students the ability to locate necessary statistical information on the Internet. The efficient capture of statistical information and the ability to critically evaluate an Internet site, as well as the statistical information presented within the Internet site, are primary focuses.
FitzGibbon, Drury, Oldham and Tangney reflect upon the introduction of a modular inservice program, entitled Hero's Journey. The focus of this modular inservice program is pedagogical and curricular issues and, therefore, relies upon the contribution of experienced classroom instructors.

Gallagher offers an alternative model for inservice teachers wherein technological training is provided within a classroom-based environment. The success of the alternative technological training model is apparent; however, the monetary amount necessary to sustain such an innovative program is also addressed.

Gibson and Kear analyze the importance of appropriate technological integration into a graduate teacher education program. The focus of this integration is to attempt a transformation of teaching practices towards a more student-oriented learning environment model.

Glatz presents information pertaining to the integration of technology into learner-centered foreign and second language teacher training programs. A discussion surrounding background information, important developments and problematic issues pertaining to the teacher training are addressed.

Headley and Carr offer a grass-roots alternative to traditionally designed and developed online course presentation and delivery models. The effectiveness of the grass-roots model is discussed, as well as early lessons within the process and recommendations for future grass-roots initiatives.

Heath describes the design and development issues pertaining to active learning environments for professional development sessions. Such innovative aspects presented within this paper are instructional strategies, classroom management models and the successful integration of technology into the learning environment.

Hegwer-Di Vita presents a summarization as well as a discussion of appropriately integrated technological modeling techniques within special education teacher training program coursework. A primary concern of Hegwer-Di Vita is the possible discrepancy between the level of technology that is available within the university systems and the availability of technology within the P-12 systems.

Hollon, McIntyre and Majdalani document an effective model for professional development wherein the appropriate integration of technology into classroom situations is imperative for the active engagement and use of existing and emerging technologies. The support structure within their collaborative technology professional development model for P-12 students, P-12 teachers, university preservice teachers, university faculty and instructional technology professionals is addressed.

Hutchinson, Verkler and Delius present a case study within the efforts of instructors towards an improved communication between fellow instructors are described. Of interest is the constantly shifting desires and needs of the instructors are being addressed due to the knowledge acquisition and expertise gained by the instructors.

Keefe and Tsantis present a work-in-progress report on a metaphorical scaffolding. The use of digital video techniques aid in the reduction the teacher apprehension levels pertaining to innovative approaches to learning.

Larsen, Barry and Staud provide an overview of the creative initiative regarding the integration of technology into a holistic teacher education program. Further, Larsen, Barry and Staud offer an exploration of the role of technology within the current program, a description of recent adjustments within the initiative and the development of technology surveys. A needs-analysis report will be presented at the SITE conference.

Levin and Waddoups discuss the integration of a different, highly interactive online learning environment model. An in-depth effectiveness evaluation is reported.

Maeers examines the use of WebCT, an online course development tool, in two graduate-level technology courses. Data is presented and interpreted so as to address WebCT's effect and responsibility towards the enhanced learning of the students within the course.

Mullick, Bauder, Sarner and Carr offer successful results pertaining to an instructional staff development project. The goal of the project was to facilitate the appropriate integration of technology into the learning environment.

Odenthal and Voogt emphasize the design of learning practices as appropriate professional development activities for teacher educators. Of interest are the specifications for the design model and a description of the initial prototype is presented.

Plumer discusses a masters program that successfully prepares inservice teachers to appropriately integrate technology into the instructional environment. A focus of this paper is the use of information technology to its full potential.

Rhodes explores the impact of online interactive World Wide Web sites as integrated into graduate pre-service literacy education courses. A qualitative research aspect is chosen due to the key themes that emerged and which revolved around issues of teaching and learning. The responsibility of the university to appropriately prepare teachers is addressed.

Rodriguez, Perez, Garcia and Mompo describe an Intranet that has been developed for a teacher's lifelong learning international project. The focus is upon developing and interactive environment through which a supportive, fostering community environment may emerge.

Stephen, Gammon and Podleski describe a project that attempts to address barriers surrounding the integration of
technology into the school curriculums and thematic units. The authors emphasize curricular areas that necessitate strengthening, as identified by the United States of America’s Department of Education.

Topp, Eshleman and Hirschfeld focus upon a successful model of inservice teacher training, which is designed to support teachers to enhance lessons through appropriately integrated technology. The focus of the inservice teacher training model is to engage the learner in the learning environment through teacher training in the areas of technology integration, lesson design and brain research.

Wildner-Bassett summarizes a retrospective ethnographic and pedagogical theory analysis pertaining to key features of a computer mediated communication (CMC) environment within a course structure environment. The collaborative efforts pertaining to knowing, teaching and learning are emphasized.

Wilson, Phillips, Spence and Gibbons utilize a constructivist theoretical model approach towards the implementation of a professional development situation. The enhancement of learner-centered opportunities pertaining to information integration and conceptual frameworking develop a knowledge base and aid in the development of higher order thinking skills.

Yang, Shindler and Keen examine the bilinear problem-solving instructional strategy that was designed, developed and implemented within a graduate applied technology course. The authors provide conclusions and recommendations regarding the problem-based learning strategy model.

Zhang and Stacks present an article that documents the integration of a task-oriented training model in a Midwestern city within the United States of America. The task-oriented training significantly contributed to the technological competency and theoretical understanding of the learners.

Graduate and inservice research and discussions surrounding pertinent theoretical issues are imperative as the technological hardware becomes available to all levels within the educational environment. Only through the thoughtful reflection and rigorous research that the authors within this section have presented will the appropriate integration of technology into all levels of learning environments become a reality.

Cleveland State University, USA
r.abate@csuohio.edu

Abstract: This paper explores the relationship among classroom teaching and learning activities, the design of technological tools, and technology integration in the classroom. Ethnographic field methods were employed to represent and understand the teaching and learning activities of a middle school community. Surveys were administered. Descriptive accounts of classroom interactions were recorded as field notes and follow-up interviews were conducted in order to develop a preliminary understanding of classroom/technology interactions. The preliminary study examined the teaching/learning activities across four content areas; Science, Mathematics, Social Studies and Language Arts. A suburban middle school participated in the study. This paper will present initial findings based on the survey data regarding the 1. types of learning activities employed by the middle school teachers, 2. level of technology use related to those activities and 3. perceived impediments to technology integration.

Teachers who integrate technology into their teaching on a regular basis still represent the minority of classroom teachers. (OTA, 1995) Despite considerable cost and effort the potential of technology has by and large remained unfulfilled in the classroom. This unfulfilled potential of technology represents a major problem for advocates of technology integration as questions regarding the efficacy of educational technology intensify (Stoll, 1995). What makes the current situation increasing untenable is that over twenty years of inquiry into the barriers to technology integration have led to an understanding of many of the key obstacles to integration. However, despite increased knowledge of the obstacles, widespread adoption of technology remains elusive.

Dias (1999) has identified resources, teacher time, training, and support as critical to technology integration. As more districts equip schools with computers, software and internet access issues regarding resources; hardware, software, and accessibility to technology have given way to questions regarding the nature and quality of professional development; teacher time, training and support (Ohio SchoolNet, 1999). Further, in spite of the adjustments in research focus, the integration of technology remains as challenging a problem today as it did twenty years ago. Research has identified other significant impediments to implementation. Prominent among these are attitudinal issues such as teacher beliefs (Ertmer, Addison, Land, Ross & Woods, 1999) and adoption of instructional reforms (Neiderhauser, Salem, & Fields, 1999). Neiderhauser et al have commented that traditional beliefs about schooling remain strong and stable and that dissatisfaction must occur in order for teachers to change their beliefs. Technology integration as a component of instructional reform requires that teachers change beliefs and practices. The question remains for many teachers whether the level of dissatisfaction is sufficient to institute technology reforms.

All of these documented obstacles are critical to the acceptance and widespread integration of technology into teaching. Underlying the analysis of these obstacles is the assumption that the technological tools currently available to teachers support classroom activities of teaching and learning. Although this paper recognizes the importance of the documented obstacles, it deviates from current lines of inquiry by revisiting the assumption that technological tools currently available to teachers are appropriate. The assumption of appropriateness is explored from a design perspective. Are the technological tools designed for teachers' work environment? This study considers this question in light of how currently available technological tools are implemented by teachers and students in a middle school setting.

Issues of usability
Interest in the usability of technological tools is a relatively recent phenomenon. This interest is an outgrowth of a technology market that has matured from one consisting primarily of individuals with technical orientations such as engineers, scientists, and mathematicians to a wider population representing all occupations. How the change in user audience has influenced computer usability is a significant attribute in assessing if current technological tools meet the needs of teachers.

Cooper (1999) has identified two categories of computer users. One category experiences frustration for failing at attempts to use technology while the other category feels powerful at overcoming the difficulty imposed by technological hardware and software. These two extreme emotions polarize people into being either a “survivor” or an “apologist”. According to Cooper an apologist is synonymous with a power user. Someone who regardless of how hard or useful an interaction is will ignore the difficulty and use it. Video cassette recorders (VCR) provide a good example for an apologist. Most VCRs require a manual to program, the directions are typically poorly written, and the VCR does not respond gracefully when the user enters an inaccurate key press. The apologist will point out to a novice user that the VCR is really not all that difficult to operate. Simply enter an arcane list of commands in the appropriate order and you can record a program.

At the other end of the spectrum are the survivors. In most occupations the survivor cannot abandon technology. It is not that the survivor fails to grasp the difference between hard and easy but rather that the technology is required for their work. For example, a marketing executive’s initial efforts at using a spreadsheet to create graphs may not be perceived as easy. However, the job requires the use of hardware and software, so the survivor learns to use enough of the operating system and the spreadsheet program functions to create a finished product. In the workplace the survivor is not in a position to choose whether to use technology or not.

Despite attempts to integrate technology into the curriculum, many teachers do not perceive technology as supportive of their goals (Abate & Jin, 1999). The majority population, the teachers that would be survivors in other occupations do not have a job imposed requirement to use technology so their level of technology integration is low. To simply require the use of technology in education as it has been required in other work setting assumes that the work of education is commensurate with the work of business.

Historical Perspective

Sutherland’s Sketchpad a graphical design program was one of the first programs to make it possible for users to implement a direct manipulation programming environment. It was twenty years later that Sutherland’s ideas became refined, elaborated, and widespread with the introduction of graphical user interfaces (Hutchins, Hollan, & Norman, 1986). The underlying principle behind the graphical user interface was to make computational media available to a wider audience by making it more intuitive to the casual user. The idea was to make technology user friendly. The graphical user interface was a significant step from the command line orientation of early computer systems.

Ease of use reflects a dynamic construct. What made the original Macintosh interface successful was the perception that it was easy to use. This ease of use was based on consistency of the graphic user interface across applications. (Winograd, 1996) Guidelines were created for developers to insure that standardization of the interface was maintained. (Apple Computer, 1987). Standardizing simplified use. When something can’t be designed without arbitrary mappings and difficulties, the option remaining is standardization (Norman,1983). A standardized system only needs to be learned once but the conditions of standardization still require training. If the standard is set while the technology is still primitive problems inherent in the mappings and difficulties become locked into the design. Based on the rapid advances in hardware, software, and networking, current technological tools though powerful appear primitive at least in regard to usability. This issue is born out by personal experience. The Windows and Macintosh OS interfaces are based on pull down menus and windows but the mappings across the two systems are different and so are the standards. When instructing students familiar with one system, it is quite common to hear the complaint that whichever system was learned first is better than the one learned second. (Abate, 1999). Neither operating system is intuitive to the novice user. Currently, ease of use is based more on user familiarity with a standard than on natural mappings.

Work and Technological Tools
The effect of technological tools on people at work is linked to assumptions about the work they undertake. How well those assumptions correspond to the reality of what those individuals do on the job influences the individual's productivity and job satisfaction (Kuhn, 1996). The considerations that must be made in building technological tools for professionals in a business setting require a different set of design requirements than those made for teachers who employ the tools in a setting for learning and teaching (Nicol, 1990). This connection of design to work task speaks directly to the assumption of the appropriateness of the technological tools currently available to teachers. Have design principles been applied to the creation of educational hardware and software? An argument supportive of software specifically designed for education can be made solely on the basis of the hundreds of software titles currently available in K-12 education. Regardless of the quality of these titles, they are marketed directly for classroom use. The same argument cannot be advanced for hardware. With minor exceptions, hardware tools have historically been designed for the business or home markets and then adapted as tools for education.

Survey
Limitations

The procedures and methods adopted and implemented in this design emerged from a non-standard view of why the integration of technology into K-12 teaching falls below the standards promoted for educational technology. The research problem from this viewpoint proposes that factors other than professional development and accessibility to technological equipment are influencing the levels of technology integration in the classroom. This viewpoint is supported by prior experiences with professional development in the integration of technology (Abate, Atkins, Hannah, Benghiet, & Settlage 1996). Instead, the technology integration problem is considered with respect to the design of technological tools. This viewpoint of a tool design problem evolved from a pilot study that suggested that many of the technological tools currently available to teachers may not match the learning activities commonly implemented in their classrooms (Abate & Jin, 1999). The tool mismatch problem presumably influences technology integration by teachers regardless of their level of expertise. As such, the problem considered in the study was the role of technological tools and the classroom environment on the integration of technology in teaching.

In explaining the specification of the problem, after analysis, it is tempting to make the research approach appear purposeful and conscious. However at the outset there was not a well formulated rationale for the approach. Rather, while in the field the 1. environment of the classroom and 2. functionality of the tools made explicit a rationale for concentrating on certain kinds of phenomena. An assumption was made early in the inquiry that matters of importance to these two key issues would reveal basic understandings regarding the integration of technology.

Not all participants in the study were considered equally. The classroom teacher, the technological tools and the aspects of the classroom environment as they impinged on the teacher were of central concern. Emphasis was placed on studying issues that mattered most to teachers regarding the implementation of technological tools with students.

Method

The method of investigation involved a form of participant observer employing three methods—participant observation, interviews, and enumeration/sampling. For participant observation the author directly observed classroom teachers in a middle school setting and played a quasi participant role by providing technology workshops for the teaching staff. Interviewing occurred following observations of classroom teaching. Since field observations are still underway, this preliminary analysis considers only the survey data.

A four part survey consisting of 47 items was distributed to 44 teachers at a suburban middle school. The first section consisted of six questions that contributed background information on the respondents. Included in this section were questions on teaching experience, grade level, subjects taught, technology expertise, and student expertise in technology.

The second section provided a list of eighteen possible learning activities along with a four-point scale indicating the anticipated frequency of the learning activity. Traditional and technology based methods for implementing the activity were listed below each learning activity. The teachers were directed to rate all items...
that applied. The eighteen activities represented a range of learning activities including; writing, collecting data, organizing data, analyzing data, presenting information, classroom discussions, reviewing instruction, and developing projects. Ideas for the learning activities were based on sample activities included in assignments submitted by teachers enrolled in a graduate level instructional development course during the past ten years.

Fifteen different technologies were presented in the third section. The teachers were presented with a four-point scale to indicate how often they modeled or directed their students in the use of the fifteen technologies. Included in the technologies were: Internet, email, word processors, spreadsheet, databases, statistical software, video tapes, simulations, graphics, hypermedia, drill and practice, teacher utilities, presentation packages, overhead projectors, and other.

The fourth section of the survey included eight questions pertaining to students use of computer based tools. These statements were also scored using the four-point scale. In addition, the teachers were asked to select the reason(s) for the score. Twenty-four reasons were provided. The teachers were encouraged to select all reasons that applied or to choose "Other" and explain this choice. The respondents were informed that this was a pilot survey and that comments were welcomed.

Results

 Approximately ninety-five percent (42 of 44) teachers returned the surveys. Section one focused on general background information. Of the forty-two, twenty-nine respondents taught one or more of the four content areas; Language Arts, Social Studies, Mathematics, and Science. The median years of teaching experience for this group was in the ten to twenty year range with grade levels five through seven represented. Nineteen of twenty-nine teachers taught more than one content area. Less than one-third of the content area teachers (8 out of 29) considered themselves to be experienced with technology.

Section two of the survey was included to ascertain what learning activities are commonly implemented in the classroom and to discover what if any technologies the teachers employ with the learning activities. A four-point scale; 1-never, 2-rarely, 3-occasionally, and 4-frequently was employed. Seventeen of the eighteen learning activities had a median score for one or more methods of implementation at or above the "occasionally" level suggesting that the learning activities listed for analysis did occur in these classrooms. The exception was "writing correspondence" whose median score was "rarely". In retrospect this category could have been incorporated into one of the other writing categories.

Section three considered the teachers' modeling of technology. Again a four-point scale was employed. Of the fifteen items listed only word processing and use of the overhead projectors received scores of 3 signifying occasional modeling by the teachers. Video tapes received a median score of 2 or rarely. Other was never selected. The median score of the eleven other technological tools (spreadsheets, E-mail, Internet, databases, statistical software, presentation software, simulations, graphics, teacher utilities, hypermedia, and tutorial software) was 1 (never) with a mean score of 1.40 across the items.

Section four posed eight questions regarding students' current use of computer based instructional tools. The four point scale was used and respondents were encouraged to identify the reason for their selection from a list of twenty-four possibilities. The median score across the 8 questions was 1-never with two items word processors, occasionally and calculators, frequently. The most common reasons for calculator use was that they were inexpensive, useful, and easy to use. Common reasons for using word processors included "easy to use" and "professional looking".

Conclusion

The survey portion of this study provided a snapshot of the learning and computer integration activities of the middle school teachers who teach Language Arts, Science, Mathematics and Social Studies. The distribution of technology skills reported by the teachers may be unique to this middle school.

The responses confirmed that the learning activities listed in the survey were representative of the learning activities that occur in middle school classrooms. As such, the activities offer a starting point for examining an activity-oriented view of middle school teachers and students as technology users. In particular, it advances a framework for further examination of the field data currently being collected at the school site.
What remains open to question are the reasons influencing the use and non-use of technologies in learning activities? Several variables proved confounding. Lack of equipment was identified as a key reason for student non-use of tools. Yet, two computer labs were available, several of the science classrooms were equipped with ten computers, and most classrooms have one or more computers available. Comparing the results of the science teachers who have access to ten computers in the classroom with the entire group there were differences. Whereas the eleven technological integration items averaged 1.4 for the entire group, they averaged 1.8 for the six instructors who taught science. The science teachers were less likely to list "not enough equipment" but listed "not useful" as a a reason for not employing computer based instructional tools. Also, presentation packages received a median score of three from this group so questions regarding technology access will require further consideration during the collection of field data. Lack of student training, and time needed for student use was also noted as a problem by several teachers.

The primary arguments listed against tool use were "not enough equipment" and "lack of training". As such the survey results mirror the concerns identified earlier. (Dias, 1999 & Ohio SchoolNet, 1999) The studies concern regarding the assumption of the match of tool design to tool use remains open to question. The only locations where a response of "useful" appeared were with word processing and calculators. Why wasn't useful listed with other tools? This result is somewhat confusing as learning activities that might benefit from computer tools such as the activities of drawing maps, collecting data, and organizing data all recorded the relatively high median scores of three "occasionally" or four "frequently" as learning activities. Yet, databases, the Internet, and spreadsheets, technology integration tools that support the collection and organization of data averaged 1.28 with 1 signifying a use of never. This result reveals a more complex relationship between learning activities and technology than simply access to equipment. Based on the results of the science teachers, even when technology is available it is not perceived to be easy to implement.

The survey data provided a starting point for analyzing the connection between technology tool design and technology tool use at this middle school site. Without question, the issues already identified in the literature as pertinent to technology integration are evident as impediments to integration at this school site. Additional work is required to establish an understanding of how the teachers perceive the technology available to them and whether this technology supports the learning activities they employ in their teaching. The survey results suggest preliminary questions regarding technological tool design and tool use. However, ongoing collection of field data is required to establish if the design of technological tools is a key factor influencing the use of technology by this group of teachers and students.

Abstract While most Internet inservice workshops include hands-on activities and opportunities for exploration, not all also offer the support found by modeling techniques and mentoring new users. The Targeted Instructional Staff Development Project was designed as a professional development project to facilitate the integration of instructional technology in the classroom. While the project consisted of nine separate workshop modules, the Internet modules focused on Web search strategies, Web page design, and instant messaging. In addition to teaching these skills to teachers, the Web design module also included a session with students and teachers so that teaching strategies could be modeled. Although the modules were designed with careful scope and sequencing, unforeseen difficulties presented challenges to success. In spite of the difficulties, the teacher participants reported increased comfort and interest in using Internet tools in the classroom. Materials provided by the instructors and modeling of techniques, particularly when teaching student/teacher teams, both were seen as important steps to success.

Introduction

While most Internet inservice workshops include hands-on activities and opportunities for exploration, not all also offer the support found by modeling techniques and mentoring new users. Modeling the behaviors expected in integrating technology into the classroom has been found to be an effective means of reinforcing skills taught (LeBlanc & Oates, 1997). Mentoring can be accomplished by training lead teachers, through telecommunications, development of mutually supportive cohort groups or faculty-student interaction (Planow, Bauder, Carr, & Sarner, 1993), (Bauder & Sarner, 1996).

The Targeted Instructional Staff Development Project was designed as a professional development project to facilitate the integration of instructional technology in the classroom. The ultimate goals of the project were to empower students to use technology in all phases of their education, to facilitate teachers as learners, and to achieve the New York State Learning Standards by developing interdisciplinary thematic units focusing on Mathematics, Science and Technology and English Language Arts and at the same time fully integrating technology into the curriculum. The Project involved a consortium of four local districts in a metropolitan area in Central New York.

The participants were 25 teachers in grades 3-5 from nine different schools within these districts. While the project consisted of nine separate workshop modules, the Internet modules focused on Web search strategies, Web page design, and instant messaging. In addition to teaching these skills to teachers, the Web design module also included a session with students and teachers so that teaching strategies could be modeled. The instant messenger service was
to be deployed for mentoring between workshop instructors and teacher participants and between college and elementary school students. The Internet modules were attended entirely by teachers from the Utica City School district and held at SUNY Institute of Technology at Utica/Rome.

This paper describes only the Internet portion of the comprehensive professional development program and the methods used to ameliorate difficulties faced by participants and instructors. At the time of grant writing, some assumptions were made concerning the audience, timeline, and scope of Internet modules. Teachers were to be chosen from grades 3 – 5, have some experience with computers and the Internet, and have access to the Internet on at least one computer in the classroom. They were expected to be teachers who had already been using the Internet in classroom activities and for professional development, but who wanted assistance in being more efficient in doing so.

Over the course of several months, teachers would attend, in groups of 12 – 14, a full-day session on Web searching and instant messaging. The Utica School Web Project portion consisted of a full-day session for these groups on Web page design followed by one more full-day attended by 4 – 6 teachers with two students each. Two instructors from SUNY shared the teaching load and team taught the session on Web design with students. As soon as the instant messaging was taught, teachers were expected to use it and email to keep in touch with each other and the instructors, and to teach their students to use instant messaging to communicate with mentor students from SUNY's Learning Center.

Challenges

Although the modules were designed with careful scope and sequencing, unforeseen difficulties presented challenges to success. The sponsor's timeline compressed the workshop schedule into a near impossible timeframe. The total time available for the entire project was six months, rather than one year and for the Internet modules was six weeks rather than 12 weeks. As a result of the teachers reported that there was too much to learn into short a time frame, and when combined with all of their of their responsibilities, they could not into internalize all of the information. Shortages in substitute teacher availability made participation difficult at times. Some teachers are arrived at the training sessions only to be greeted by a message that they had to return to school because there was no substitute teacher for them. To miss one session of the total of three with no opportunity to make up for the session because of the tight time frame only added to the teachers' and instructor' frustrations.

Teacher participants did not necessarily have the skill or comfort level nor access to Internet resources that had been expected. During the web search course, the instructor found that she had to teach Internet basics before she could teach Internet search strategies. Although it had been expected that the teachers would not only have access to e-mail but would use it, neither of these true it proved to be true for the teachers. Unfortunately the tight time frame did not allow for a reorganization of the course to teach the use of e-mail to a degree that would have been optimal for the students. Adding a brief introduction to e-mail before teaching the Internet messaging, meant that the messaging portion of the course was shortchanged. Teaching Internet messaging was further hampered by the messaging service being accessible at the time of one of the classes.

Back in the classroom, it appeared that the technical services were not what either the teachers or workshop instructors had been promised. In some classrooms computers did not yet have Internet access, instant messaging had not been installed, and in many cases the teachers had no access to e-mail other than signing up for a free e-mail service on the web. Technical support was so slow in coming that some teachers never did have access to the instant messaging service in the classroom before the end of the spring semester. Only one or two teachers were able to establish the service and usage for the student mentoring portion of the project.

Although the web page design portion of the project progressed more smoothly, it turned out to that the school had no web hosting capability for the teachers. For some teachers the incentive to learn web page development was diminished by the inability to host and maintain their own pages. Fortunately the Continuing Professional Education department at SUNY and was able to provide web hosting on at least a temporary basis.
Overcoming obstacles
