In spite of these difficulties, the teacher participants reported increased comfort and interest in using Internet tools in the classroom. What methods were used to overcome the difficulties presented and assist teachers in increasing their confidence and skills? As most technology educators know, flexibility is one of the keys to success.

Instructors utilized different techniques for presenting materials: overhead projections for live demonstrations, handouts, instructor exchange at key moments in the syllabus, but gained the most success by offering a genuinely safe environment in which to experiment, make mistakes and correct those mistakes for optimum learning. The instructors presented themselves as life-long learners dedicated to sharing that philosophy with other adults; the tone for mutual sharing and open learning was established at the outset.

Being able to adapt the workshops even slightly to the abilities, interests, and needs of the participants helped them to understand that they have to be flexible in using technology in the classroom. For example, when it became apparent that most of the teachers in the workshops did not have e-mail addresses and had not used e-mail, an immediate shift was made to teach them how to set up and use Hotmail accounts. Less time was spent on Internet messaging, but a detailed handout was provided to the teachers to assist them when they went back to the classroom.

For many beginning Internet users, error messages are a constant source of frustration. Taking the time to explore and understand these error messages helped the teachers realize when problems were caused by their mistakes, and when they were caused by circumstances beyond their control.

The Utica School Web Project constituted one facet of the larger project described by this paper where modeling was most explicitly used to facilitate skill building and technology integration. The Web Project sought to engage teachers and students together in a learning process under the facilitation of SUNY instructors, where material was presented and interpreted by the instructors with the intent of teaching both content and instructional methodology to teachers. It was here that mentoring and modeling were most crucial to overcoming difficulties faced by the teachers. Attention is given to the details that made this portion of the project successful in influencing teachers’ attitudes toward the entirety of the Internet portion of the professional development project.

The Utica School Web Project benefited from the teacher group’s prior experience in learning to use Internet tools. Specific lesson plans for teaching teachers to design web pages began upon completion of the earlier project phase in which they learned to use the Internet and instant messaging. At this point, instructors knew where their skills were, had already experienced the way in which the group engaged in shared learning and were able to anticipate and plan for diverse reactions to new material.

Foremost in planning was the ensuing task of facilitating teachers back into their native teaching role with children. To that end, the instructor team planned for three outcomes:

1. Teachers will be comfortable using Netscape Composer to create a Web Page
2. Teachers will have ideas for a useful application of this skill in their classroom
3. Teachers will have an opportunity to give instruction to children under the guidance of SUNY instructors

At the end of their Web Design training session, teachers had expressed anxiety at the potential for ridicule by the students for being novices. Upon the teachers’ return with their students, the instructors were careful to leave authority with the teachers and concentrate on the syllabus. Everyone needed nurturing. The instructors included sensitivity to that need in all planning and presentation.

Syllabus

The instructor team produced a syllabus geared to logical, yet organic learning modules. These modules included:

* what is HTML
* creating a web page with HTML
• designing a web page with an HTML editor (Netscape Composer)
• searching for copyright-free material to enhance the web page
• saving and printing web material
• uploading material to a server, and
• possible scenarios for classroom application of the training.

Materials

Three distinct sets of materials supported the Utica School web project: a Master Packet, Teacher Packet, and a Student Packet. The Master Packet included all Teacher and Student handouts plus instructor notes for timing, suggested moments for reflection on real world application of the current training, and assorted ideas and tips for breaking up student training modules or customizing the student learning modules.

The Teacher Packet, designed to recall the classroom training in subsequent off-campus settings, also included all the children’s handouts. Particular handouts were specifically designated to be printed and used as lesson plans in the elementary classroom.

The Student Packets were the briefest. They consisted of several lessons:
• Looking at Web Pages
• Designing your own Web Page on Paper
• Use Netscape Composer to make your Web Page
• Find Clip Art for your Web Page
• Format your Web Page
• Make a Hyperlink
• Conclusion with summary

The teachers were encouraged to take the supporting materials and adapt them to their own teaching styles and settings. In this way, the SUNY instructors acknowledged that the teachers are the best arbiters of their own domains yet provided the support necessary for them to teach the new material.

Setting

Training took place on the SUNY Institute of Technology campus, a few miles north of the city of Utica, NY. The Continuing Professional Education lab, a state-of-the-art facility with Pentium class machines, Ethernet connections, large monitors and ergonomic chairs (a real plus when sitting for several hours at a time!) provided an ideal training lab. Its décor and large windows enhance the lab’s physical environment. In short, the setting encouraged comfort on the part of the trainees, which usually translates into decreased resistance to new ideas and greater willingness to learn. This particular factor in learning is hard to measure, but the teachers commented on the surroundings more than once! Incidental facilities, such as the computer laboratory building’s cafeteria, beautiful campus and access to phones, restrooms, etc. further increased the teachers’ comfort level.

Procedures

One session was devoted to designing web pages with each group of teachers. The teachers learned a little HTML to create a Web Page, created a Web Page with Netscape Composer, then saved and uploaded the file to the SUNY Institute of Technology server. Another training session followed the web design segment, this time with students. Teachers handpicked the students who accompanied them for training at this second session. These children presented a diverse group, culturally, in gender, in Internet experience outside of the classroom and in education level, including one special education student who experienced similar success to other students.
While the teachers had learned the basics of Web page design in their earlier training, the focus in the
teacher/student session was on assisting them in teaching the skills to their students. At each step of the way, time
was give to introspection of teaching technique, hands-on activity with students, and analysis of supporting
materials. Sample web pages were analyzed for both content and design, and templates were provided to assist in the
design of students’ own pages.

With two instructors in the lab, there was at least one instructor available to any teacher/student group in need of
further assistance. Discussions of security and privacy issues, copyright, and citing sources were imbedded into the
lessons. To preserve password security, the instructors uploaded the children’s pages to the SUNY Institute of
Technology server during a short break. Prior to the training session, the instructors created a home page for the
Utica School Web Project; the home page included a table of links to student pages, one table for each of the
training sessions. The students returned to class and discovered that the Instructor’s station was now able to see their
pages, their classmates’ pages and other student pages from the Utica School Web Project via the World Wide Web.
As certain pages still contained minor errors, the children also were able to witness some of the updating process.

Conclusion

Teachers considered these workshops an opportunity to see the potential for Internet tools in the classroom and gain
some initial skills to use in ongoing integration projects. Materials provided by the instructors and modeling of
techniques, particularly when teaching student/teacher teams, were both seen as important steps to success. Teachers
felt successful in guiding their students through this (now less threatening) process; students felt terrific about
creating a page for cyberspace.

The pre and post-test questionnaires used to determine the effectiveness of each of these three modules yielded
significant results (Mullick, Bauder, Sarner & Carr, in press). The results of the t-tests for dependent (paired)
samples showed that participants rated the modules significantly more favorably on the post-test compared with the
pre-test, indicating that they believed the modules to be effective. Open-ended responses further supported the
finding. When asked to indicate the single most valuable feature of the module participants said: “All the hands-on,
make and take, the resource materials and the Internet Web Page design”. “Having the children involved in the Web
Page construction.” “The Web Page Development”. When asked to indicate the single weakest feature of the
module, participants said: “We are not connected to the Internet in our classroom. The Internet ideas are great, if I
had access.” Until we have technical support to post our own Web Pages, this seems to have little merit for usage”.
“The time- too much information in too short a time”.

These comments support the observations made by the instructors during the workshop sessions. In spite of the
difficulties with time-frame, accessibility to resources, availability for training sessions, and insufficient prerequisite
skills, the workshops did provide the teachers with opportunities to explore and learn to use Internet tools in the
classroom.

Abstract: The Education Network of Ontario is a telecommunications corporation creating a network community for and by Ontario's elementary and secondary educators and funded with assistance from the Ontario Ministry of Education. ENO provides industry-standard ISP services, web-based Intranet services, professional development opportunities and model classroom projects. This paper describes the process and outcomes of a project to investigate a small group of teachers with a wide spectrum of experience in technology as they became content authors at a specific level of sophistication with a commercial content authoring company, watAGE Inc.

Introduction/Context

The initial stage of the Education Network of Ontario (ENO) was a UNIX-based, cross-platform, TCP/IP protocol distributed network application which provided bilingual (English and French) electronic mail, moderated conferencing (facilitated newsgroups), and database and Internet access across Ontario. It started with just eighteen members in 1993 and has grown to register more than seventy thousand teachers, administrators, trustees and education faculty, well over half of the K-12 education personnel of the province. The organization, a public sector Internet Service Provider has moved from project funding from the government to an independent not-for-profit corporation with an active and informed Board of Directors selling services to various levels of government.

The project has retained dial Internet access from any home or school location in Ontario and mail and conferencing services. However, ENO is fully retooled to enable browser-based moderated Intranet newsgroups, model classroom projects with interactive web creation scaled to suit the size of the province, and teacher development of industry-standard content. An industry-standard, no-cost, bilingual call centre supports all of the members and a web support site with automated tools for registration and access and service 'fixes'.

Teachers' Practices

Quantitative analysis tell us that our membership of 72,000 educators use the dial access an average of 9000 times a day with total connect time of 200,000 minutes a day in a summer or holiday month. The contention ratios on that access are the limits during the school year. In spite of that, a school month has statistics 50% greater to a total online time of nearly 9,000,000 minutes a month. However, the daily usage pattern changes from early morning through to midnight in the summer holiday to school times - late afternoon (after school) then throughout the night until leaving for school in the morning. Our servers handle as many as 100,000 messages a day. Some of our classroom activities sites register as many as 30,000 hits a day during peak activity times. This indicates a tremendous interest in and usage of the Internet and ENO resources; it also points out a real dearth of access equipment and time at the work site, at school.

Our anecdotal analysis and day-to-day experiences tell us a great deal about how educators use this suite of services. The major activity of the teachers continues to focus on the moderated conferences/newsgroups that they open to solve such endemic concerns as 'local' versus 'standardized' evaluation, reporting to parents, community work/learn programs, and general subject-based or level-based curriculum issues. A
second 'established' use occurs whenever a new provincial license for software is purchased. A conference is opened in which the technical support team from the vendor can discuss issues of use and technical implementation with teachers throughout the province. This 'mode' has expanded to include professionals from the Addiction Research Foundation who help teachers work positively with addicted students and the addiction resources regularly circulated to schools as a part of this agency's mandate.

Smaller groups of teachers voluntarily initiate a series of professional activities such as writing primary school curriculum units themed on ideas such as two-dimensions – measurement, journalling, drawing, electronic and snail mail. This arose from a typical and very successful example, the web-based project devoted to showing young students how to conceptualize two dimensions with a central fictional character called 'Flat Stanley' (http://www.enoreo.on.ca/flatstanley/). After the provincial collaboration, teachers mount the curriculum units on an ENO web site. Those who create the material then update and maintain it. The project is now international with hundreds of schools participating.

Administrators are creating a centralized resource of activities for teachers and administrators of northern schools who have no outside student recess for as long as six weeks in mid-winter. Teachers create a file of model parent letters and report cards for middle school students during a period of education reform. The network has a forum for school administrators in which teachers who wish to be administrators are mentored concerning effective career paths. Teachers, with education faculty and students, work on computer literacy curriculum units, plan professional development conferences, and hold meetings of subject-specific committee executives. One school of over two thousand students used the system for its internal electronic mail, information distribution and meeting scheduler. Another district's school custodians are working on practical identification and warnings about workplace issues and hazards.

Our largest project to date is an online environment to assist the Canadian National Marsville Program (http://mars99.enoreo.on.ca/index.en.htm), a project based on intermediate-level students creating a living environment for the pioneer astronauts and settlers of Mars. Students are uploading their air, water and food supply system drawings to their team's web pages. They access mentors' comments from Spar Aerospace and the Canadian Space Agency. They communicate with one another to prepare for the final 'link-up' day. Using this on-line environment prior to the main event enhances classroom learning activities.

Background for this Specific Research Project: Educating the Educators as Content Producers

In all of its activity, ENO enables personal, small group and even province-wide professional development. One of ENO's projects involved developing on an on-line course about telecommunications and writing for the technical environment for senior secondary students in English or Business Studies. ENO found that there are two distinct types of professionals at this time. The creation of even modules of a course requires a tremendous amount of design, content knowledge and technical skill. Many teachers could create small modules of engaging material. However, the ability to create usable modules for online and fact-to-face which would withstand scrutiny with respect to content objectives and be sufficiently technical to sustain students at a distance was not a part of every teacher's agenda. Those who had deep skills and interest were interested in markup standards such as SGML and XML that would produce a stable course, testing procedures that involved feedback from students, and Intranet applications such as newsgroups and chat to support 'classroom routines'. We engaged watAGE Inc whose content authoring model can be reviewed at http://www.online-learning.com/ptw

We began to focus on a smaller group, six teachers with varied experience and computing skills from a very advanced user with several years of programming in an insurance environment and a number of computer-based class initiatives underway, through members with some computer training and supervision of student projects to two neophytes with low key-boarding skills.

Because this was initiated as a research project, with a fixed set of objects, time frame and budget, the teachers involved were permitted to select their personal areas of lesson development and the depth and
scope of lesson materials. All projects run interactively in a Web browser, can be distributed via CD or server to students and other classes and all can be used in conjunction with other computer expressions within any parts of the Board’s curriculum.

The six secondary school teachers worked with the staff from ENO and watAGE to:

- learn how to author online courses using Web editors and course authoring tools – specifically SGML-based technology, using an SGML editor, InContext 2.1
- learned how to convert these documents to either HTML or RTF and append “options” files such as HTML headers and CSS style sheets using the watAGE Converter
- create Cascading Style Sheets for HTML
- learn how to create projects for students, link modules of learning for other teachers and use shared resources amongst a group of teachers.
- learn how to instruct other teachers in some of the fundamentals of online learning, using the materials the group designed and built together

The tools available to the project consisted of:

- ENO’s Conferencing site at server http://www.enoreo.on.ca. This includes all participants’ accounts, the project’s private conferencing area and the online basis for exchange of information, documents and access to each member’s project, as well as group files and activities
- The GEAC Incontext2 SGML editor for the creation of all project modules
- 4 watAGE DTDs and converters to produce both HTML and RTF versions of all authors’ SGML materials, including the CGI student questions for interactive surveys and online assessment of students
- watAGE’s Course Administration Tool (CAT) to enable teachers to create and supervise accounts and locate and receive online assignments within the course structure.
- The ‘Quiz’ SGML software to enable instructors to develop interactive short-answer questions directly inside lessons, with the answers for correct and incorrect student responses and the abilities for student self-checking of progress and for the distribution of student answers to course databases for analysis and grading.

Specific examples from the teacher projects will demonstrate their use of modularized and reusable components. We sought from the outset to initiate methods and subjects which seemed to encourage replication, both by their authors in related areas and potentially by other teachers and instruction groups.

**DM developed an SGML-based Calendar,** which converts into a simple HTML table with dates for the school year using the watAGE Converter. This Calendar feature, created by one individual, may be distributed easily and incorporated into any online course.

The Calendar, a portion of which is pictured on the left, enables teachers in any subject to outline
assignment due dates, important readings, and test dates for students in an easy to understand format.

In addition, students experience "just-in-time" learning through the live hyperlinks within the Calendar. For example, in the Calendar fragment pictured, a student may proceed directly to the "Log/Journal #1" assignment from the Calendar page. This prevents students from mishandling important information such as assignment and test dates.

watAGE has developed a Quiz facility that allows teachers to create interactive quizzes in SGML and render them as HTML through conversion. It enables instructors to generate interactive CGI scripts directly into lessons. These scripts allow a student to submit answers in a series of some eight short-answer formats—fill-in-the-blank, true/false, multiple choice, etc. The instructor combines these questions at any point in a lesson. The student's responses are displayed to the student for correction and support, used to initiate some remediation for the segment of the lesson if the results fall below a certain range and can be incorporated into the student's record for that segment of the lesson and course.

Teachers may select either "quiz" or "formal"; a "quiz" is marked on the desktop and the results are revealed only to the student for information (see the inset below for an example display). The "formal" test results are sent to the server to be marked, stored, and the results sent to a specified location such as the teacher's email address and the grade record.

This is an example of DD's History of Computers test using the Quiz software.

Quiz accepts questions of many kinds: multiple choice, matching, fill-in-the-blanks, true/false. The instructor can enter these questions and their ranges of answers or they can be easily modified from existing models to suit a particular lesson need or class. Students can be linked at the level of the performance display results directly to materials which explain the reasons for acceptance or rejection of their answers. In this way students can determine for themselves the levels of their understanding of particular information and they can choose the amount of additional study they wish to undertake to assure competency in that subject.

‘Quiz’ inquiries can also be adapted to elicit users’ reactions to issues and situations so instructors can incorporate evaluation into lessons at any point. These results can be used to determine learners’ satisfaction and perception of the effectiveness of the learning materials. These can then be adapted to better meet users’ desires and hopes. This point is often ignored or underestimated in teaching generally, but it is a major contribution to the success of online instruction in the system’s ability to identify and correct weaknesses and errors which can all too easily go undetected in the interchange and bustle of a classroom.
The BookShelf employs a familiar metaphor for the organization of course data. The modular units of the course, created by the teacher or many teachers, are stored behind a bitmapped image of a bookshelf. The books are colored according to thematic threads or functionality—assignments as light blue, reference materials as dark.

Information may be created and shared with little imposition on individual teachers while the ability to collaborate increases immensely. MD1 and MD2 collaborated on their Web site and created a very extensive outline of the new Introduction to Information Technology in Business course:

Welcome to our section of the Waterloo Online Learning Project. We have created a number of lessons dealing with the new Introduction to Information Technology in Business course. We thought that since most schools would begin implementing this course in September 1999 and that they would be able to utilize new software (Claris Home Page) that this would be a practical application of online learning.

To date we have concentrated on Unit IV: Electronic Communication and in particular Activity 4: Web Publishing.

They used the structure of SGML to modularize their course according to Ministry requirements and sound pedagogy. In the figure on the left is an example of how their lesson plans are organized according to Ministry requirements and delineated for students with active links to each of the lesson activities. Using SGML helped focus the organization of their Web site and render the material in a logical, usable form for students.
Conclusions

We used this company’s commercial content creation model as a research tool to ‘tease out’ the support necessary for a set of teachers to create sophisticated lesson and modular material. It was a great deal better and more productive than the HTML primer and training approach tried the first time. It was successful because the group was very hard working and compatible. However, the group required a great deal of time with highly technical personnel to move to a more sophisticated structure and content.

The process is not finished after three months with this level of support. This group will need to be supported and expanded over the next year to create and test online materials. To this point there is little or no board-level support for this steep learning curve and the resources to support it. This has proven to be a very expensive exercise that is not first on the funding list when so many educators need so many different kinds and levels of professional development.

Our deep concern is the ultimate cost to the public education system if teachers do not feel like ‘producers’ but are relegated as a group to the role of passive consumers of very expensive, dynamic web-based materials.

This research model should be created as a course and distributed to instructors and students via a CD which would include the course content on the BookShelf, all software in a program which installs it on the individual’s PC, and reference materials for online processes and information retrieval. Links could be made as needed from the individual’s machine to the course web server for the exchange of email, assignments and participation on group online activities. The CD could also contain instructions and tutorials in the authoring lessons and project modules. The resulting ‘course’ would provide a quite complete synthesis of teacher needs and course services. This professional development model works; it, or a similar model needs to be aggressively disseminated to foster Canadian educators as producers, not consumer of online materials.
Preparing Teachers to Investigate the Effects of Technology-Supported Instruction in Effective Partnership with Researchers

Abstract: This paper describes a procedural model aimed at forming teachers to conduct research in technology-supported instruction within a context where researcher and teacher work effectively together to promote knowledge advancement. First the steps of the model and the roles of the teacher and the researcher within each one of them is explained. A study conducted according to the model is then summarized. In its final section, the paper suggests a number of variables that may optimize researcher and teacher's inquiry efforts and attitudes within the model's framework.

Introduction

According to the document "NCATE 2000 Standards Revision" issued by the National Council for Accreditation of Teacher Education (NCATE, 1999) teacher candidates "should understand the importance of using research in their teaching" (p. 8). However, if teachers are to attain the Council's goal, they should be given the opportunity to actively construct such understanding through participation, as major players, in the research endeavor.

Two noteworthy efforts at providing such opportunity include practice-reflection and action research. A proponent of the former, Schon (1987) highlights the "need to create or revitalize a phenomenology of practice that includes, as a central component, reflection on the reflection-in-action of practitioners in their organizational settings." (321). Weighing the value of the practice-reflection stance, Bereiter (1999) contends that although individual teachers may benefit from taking a reflective stance their findings don't contribute to advancing the knowledge of the field and so achievements reside in the culture of practice.

The second effort is action research that aims at engaging teachers as reflective researchers of their own classroom decision-making processes, the learning of their students, or their interactions with them. In its early forms, practitioner-based research consisted of isolated cases of theory application to the specifics of a particular site and learning situation (Wallace, 1987). More recently, this type of research has been viewed as decisive for the generation, not just the application, of instructional theory (Miles & Darling-Hammond, 1998). Critics of the approach (Wells, 1994), however, contend that its possibilities to advancing knowledge are limited because, left in their role of researchers and in charge of identifying research topic and procedures, teachers are prone to address only their local needs and loose sight of the larger context of inquiry.

An alternative to the above efforts lies on what Bereiter labels a "hybrid culture" (1999, p. 4). A culture that demarcates the goal of the teachers, guiding students' learning about the world, from the goal of the educational researcher, understanding cognitive and social processes operating in classrooms. But, at the same time, a culture that encourages continuous dialogue between the school and research communities to promote symmetric knowledge advancement (Scardamalia, 1999).

How should teachers be prepared to contribute to research within the framework of this hybrid culture? For Bereiter, a possible answer resides in providing teachers with "intensive training in teaching for understanding" (1999, p. 32). However, the training that Bereiter suggests should encompass not only teaching for understanding but also researching for understanding research. It is through appropriate research practice that teachers may gain
insight to recognize and promote the type of classroom ideas and experiences that researchers can make to serve more principled kinds of knowledge integration.

This article takes a first step toward normalizing a way by which to provide teachers with that type of training. To this end, a research procedural model is presented first. A k-12 study developed according to the model is summarized next. Finally, a reflection on some of the variables that may improve teacher’s and researcher’s efforts within the model framework is provided.

The Procedural Model

Diagrammed in Figure 1 there is a six-step procedural model that contemplates the interest-, skill-based distribution between researcher and teacher of the variety of tasks involved in an educational research project.

![Figure 1. A six-step procedural model for educational inquiry](image-url)
In steps I and VI of the model, teacher and researcher work in the same tasks. Whereas in steps II through V they work in different but sequentially related tasks, the work being, as indicated by the dimmed horizontal arrows, mutually interactive.

In step I, teacher and researcher act collaboratively to identify the research issue. Through this shared responsibility, the model aims at generating a fruitful comparison and contrast between the researcher’s views on the issue and its theoretical and empirical contexts, and the teacher’s views on it derived from his/her practice.

In step II, the task of the researcher concentrates on processing and studying the theoretical literature relevant to the research issue(s) addressed in the project. The task also includes sharing with the teacher the selected literature and guiding the teacher’s own investigation of the practical literature pertinent to the study. Through sharing and mentoring, the model takes into account the fact that it is the impossibility of the demand, rather than the lack of interest (Wells, 1994, McGrath, 1999), what frequently prevents teachers from addressing this key component of any investigation. As Branson (1998) observes, “research duties be informed by a massive literature that cannot possibly be mastered by individual practitioners” (p. 3).

On the other hand, the main task of the teacher within this step is to situate the research issue(s) within the requisite curriculum and syllabus so as to satisfy his/her administrative and moral obligations. Indeed, the teacher has to figure out how to address the research issue through activities that satisfy in an optimal way the imperatives of the curriculum (Shulman & Tamir, 1973). From a moral standpoint, because research may consume a considerable amount of in-school time and because that time is designated for instruction, the teacher has to design classroom experiences that are relevant to the main research beneficiaries: the students (Wong, 1995).

In step III of the model, the task of the researcher is to fulfill two basic research requirements, which are careful design and systematic procedures. If research findings are to transcend the local practice and contribute to the advancement of knowledge those procedures should be handled by the researcher rather than by the teacher, as is often the case in action research.

The task of the teacher within this step is to design the experimental activities and supporting resources. Because of their practice-grounded views on curricular design, teachers are very well equipped to address the formal aspects of the design activity, including specification of activity’s objectives, delivery methods, and required classroom organization. More importantly, because of their first hand knowledge of their students, teachers are in a unique position to promote, if given the freedom and means to do so, activities that foster students’ beliefs in the power and value of their own ideas (Wong, 1995).

Within step IV of the model, the researcher chooses, or designs and field-test, the appropriate data collection instruments, whereas the teacher designs the technology-supported environment and chooses the software tools to be used in the study interventions. To effectively address his/her task at this step, the teacher should have a degree of technological literacy equivalent to the “ Appropriation” or “Invention” phases of Dwyer, Ringstaff, and Sandholz’s (1990) model of teachers’ adoption of technology. Indeed, according to that model, the computer expertise supposedly attained by teachers in those phases respectively enables them to experiment and to implement “fundamentally new forms of teaching and learning” (Gearhart, et al. 1990: 42).

In step V of the model, the researcher guides the teacher’s gathering of data and proceeds, or delegates to qualified personnel, with their computation. Conversely, the teacher implements the research activities and, with the appropriate coaching from the researcher, addresses the assessment procedures. The researcher’s coaching becomes crucial at a moment when, as Schön (1987) observes “there is a movement toward new ways of thinking about research and practice—ways that emphasize the merits of full, qualitative description of phenomena and the utility of well worked-out cases of intervention...” (p. 312). Since the procedures to assess such interventions are bound to be complex, training in their use should be provided to ensure reliability and replication.

Finally, in step VI, the researcher and the teacher team once again to analyze data from the study and to interpret the results. Collaboration at this level is particularly important if, adopting a contextualized perspective (Means et al. 1993), the study focuses on finding out specific outcomes as well as on understanding the relationships among various elements of the study and the ways that contributed to those outcomes.

Through its various steps the proposed procedural model may provide teachers with the amount of training and the degree of guidance they need to actively "feel" and appropriate the research practices, rather than just learning about them from “experts.” Indeed, the model, because of the extensive exposure to training it secures throughout its steps, may have a longer lasting impact on professional skill improvement than apparently do "nutshell" professional development activities (Fulfill & Stiegelbauer, 1991). Also, the model features "procedural specifications" of a developmental nature (van den Akker, & Plomp, 1993) that, by providing how-to-do-it advice, may help teachers elaborate on the what, when, how, and why of the incorporation of research into their teaching.
Application of the Model

The above model was applied to a study conducted by the presenters that assessed the effectiveness of a course for 9th bilingual graders,Españo 5/6. The course addressed San Diego City Schools District's (SDCS) mandatory standards for Language Arts through a literature-driven (Shehanan, 1997), technology-supported curriculum, and was grounded on social learning (Bandura, 1971) social development (Vygotsky's, 1978) and collaborative learning (Pea, 1994) principles. Effectiveness of the course was comprehensively evaluated through measuring its short- and long-term impact on the language performance, technological literacy, collaboration skills, and learning perceptions, of eighty-six students in three "low," "average," and "high" achieving classes.

The study featured a causal-comparative design (Cook & Campbell, 1979) and, to triangulate results (Yin, 1994), used data from thirteen quantitative and qualitative sources. Eight of the sources included the subject's scores on the course four partial exams, the pre- and post-course Spanish Placement Test (SPT), the final electronic portfolios, and the post-course activity and were aimed at verifying language comprehensive performance and growth. The portfolios and post-course activity sources also served to verify the level and evolution of subjects' technological skill.

The remaining four sources comprised the subjects' ratings on the pre-, post-, and delayed learning surveys, and the subjects' answers to the three open questions of the delayed Perceived Learning questionnaire. These sources aimed at unveiling subjects' perceptions of the learning gains (linguistic, literary, and technological) they derived from the course and the value of the course collaborative activities.

Data were collected using the SPT, four limited-response partial exams, the Portfolio Evaluation Criteria, the Post-Course Activity Evaluation Criteria, the Learning Interactions Recording Form, and the pre-, post-, and delayed Perceived Learning questionnaires.

Course activities were organized around four units, "Poesía," "Civismo," "El Cuento," and "La Novela," which drew on a series of fictional and non-fictional reading from different Chicano and Latin American writers. Students were guided in their use of the print and www resources, and the software tools including ClarisHomePage, ClarisWorks, Graphic Converter, HyperStudio, and Ofo, required to complete the activities. Course syllabus and reading materials were distributed via the World Wide Web.

Implementation of the course extended over a four-month period, from February 1st to May 31 of 1999. Using the web and the selected software tools, before, during, or after class time, and working mostly in pairs or groups, students completed the course activities and the end-of-course electronic portfolios. They also completed the SPT, the four partial exams, and the pre- and post-learning perception questionnaires. Six months after the experiment, and to assess the long-term effects of the course, students completed a web activity that required their use of the skills they had learned in the course and filled in the delayed Perceived Learning questionnaires.

Results, which can not be fully described here due to paper length restrictions, indicate that students in all course sections increased their linguistic, literary, cultural, and technological skills. Students also gained in learning confidence by participating in curricular experiences relevant to their socio-cultural background and mastering technology tools that would had been otherwise out of their reach. (A complete report of the study, including all descriptive statistics, will be published elsewhere).

Optimizing Variables

For the proposed model to generate that need for research that according to Bereiter (1999) should be "keenly felt by the practitioners as well as the researchers," (p. 24) a number of variables relevant to the researcher and the practitioner should be taken into consideration.

Regarding the researcher, a crucial variable is his or her true involvement in the research endeavor. Frequently, researchers are brought into a research project, or various ones, to ensure the project's allocation of
funds. Instead, the researcher should commit himself/herself to a research project in all its steps and in true partnership with the teacher.

A second variable relevant to the researcher is flexibility. Researchers should keep in mind that the complexity and unpredictability of classroom and school environments may affect the most sophisticated research design and that, consequently, they should learn how to readjust it if necessary. Learning first hand the constraints that teachers confront on their organizational settings and the ways they cope with them may be very instrumental in this respect.

The third researcher-related variable includes the acquisition, or cultivation, of negotiation skills. Indeed, researchers should be able, through a constructive process of listening and negotiation with teachers and school administrators, to conciliate potential conflicting views about a research project and to move teachers' interests on and solutions to local problems to a level where the solutions may have a more universal application.

On the other hand, if teachers are to participate in educational research projects in the ways suggested here, they should be given the appropriate recognition and incentives. Regarding recognition, teachers should feel that they are not viewed as subordinate research collaborators with a role often limited to the distribution to and collection from students of data gathering instruments. As pointed out elsewhere (van den Akker & Plomp, 1993), teachers should no longer be viewed by other education players "as 'gatekeepers' who should be overwhelmed or circumvented, but as partners in interactive and purposive learning processes" (p. 12).

With respect to incentives, appropriate mechanisms should be put in place to give teachers involved in research projects equitable release time so that they can devote to those projects the large amount of time and energy they require, particularly when they address issues pertaining to technology-supported instruction. However, reward mechanisms, particularly those in the form of release time or merit increase, should be designed very carefully to avoid professional rivalry that distorts and damages the collegiality that should inform the quest for effectiveness.

Finally, two incentives, of a more "ethereal" but very powerful nature, particularly for highly committed teachers, should be considered. One the assurance that teachers' research effort won't be an isolated one with little or no impact outside their classrooms. And the other, the assurance that teachers' understanding of the implications of a project is a worthwhile goal per se, independently of the research "success" or "failure" (Wong, 1995)

When occurring in combination, the above variables could help researchers and teachers to work toward resolving what Schön (1987) defines as "The Institutionalized Dilemma of Rigor or Relevance" (p. 309).

**Conclusion**

This article has highlighted the need for developing a research culture that, on a bi-directional and continual basis, draws from the knowledge and experience of both teachers and researcher to advance and integrate knowledge. More importantly, the article has proposed a procedure model, and summarized an illustration of its application, to prepare teachers to participate effectively in such culture. Both the research culture issue and the procedure model are topics for future discussion and testing.

Abstract: This paper identifies and defines the evolving concept of literacy with regard to Media Literacy and Digital Literacy. The importance of Media/Digital Literacy for teachers and students is explained. An outline of a course, EDTL 639 - Media Literacy for Teachers, recently introduced into an M.Ed. in Classroom Technology program for teachers, is offered. Examples of important resources are given and course participants' feedback is covered.

Introduction

In a now widely accepted definition stemming from the Aspen Institute's National Leadership Conference on Media Literacy Education, held in 1992, media literacy has been defined as the ability of a citizen to access, analyze, evaluate and produce communication in a variety of forms (Aufderheide & Firestone, 1993). While media literacy as part of the curriculum is well established in every other major English-speaking country in the world, it has been only recently that a growing movement in the U. S. has begun to integrate media literacy into the curriculum (Tyner, 1998; McBrien, 1999). Kubey and Baker (1999) report that in the last few years progress is finally being achieved, over a decade after Ernest Boyer, then president of the Carnegie Foundation for the Advancement of Teaching, stated, "It is no longer enough simply to read and write. Students must also become literate in the understanding of visual images. Our children must learn how to spot a stereotype, isolate a social cliché, and distinguish facts from propaganda, analysis from banter, and important news from coverage...." They report that media literacy concepts are now included in the curricular frameworks of 48 of the 50 states. They further report that, of the 50 states, media literacy concepts are included in English, Language Arts and Communication strands in 46 states; in Social Studies, History and Civics strands in 30 states; in Health and Consumer Skills strands in 30 states; and in a Media strand in 7 states. They also report that most state curriculum frameworks include media literacy concepts in at least 2 of the identified 4 strands. Additionally, Hobbs (1998) states that media literacy as a subject in teacher education programs is growing, as is involvement by health groups such as the American Academy of Pediatrics. Indeed, as Tyner (1998) has pointed out, literacy in the information...
age has expanded beyond traditional alphabetic literacy to include a variety of media which are, increasingly, digital (hence the term digital literacy). An ability to access, analyze, evaluate and produce communication in various forms has become essential to successfully functioning in society, both economically and as a citizen of a representative democracy.

Key Concepts

Regarding media messages, key concepts of media literacy have been identified as follows:

1. All messages are constructions.
2. Messages are representations of social reality.
3. Individuals negotiate meaning by interacting with messages.
4. Messages have economic, political, social and aesthetic purposes.
5. Each form of communication has unique characteristics.

(Hobbs, 1997)

Given these key concepts and the importance of media literacy, a graduate course, EDTL 639 - Media Literacy for Teachers was recently added to the Master of Education in Classroom Technology program at Bowling Green State University. The program follows the national guidelines in computer education developed by the International Society for Technology in Education (ISTE) and adopted by the National Council for Accreditation of Teacher Education (NCATE), (ISTE, 1992; NCATE, 1992; Thomas, 1993). The course provides a variety of experiences for students and helps to further implement Standard 2.4 of the NCATE/ISTE guidelines for the program:

"Candidates will use computers and other technologies in research, problem solving, and product development. Candidates use a variety of media, presentation, and authoring packages; plan and participate in team and collaborative projects that require critical analysis and evaluation; and present products developed." (ISTE, 1992)

Course Intent/Description

Constructed around the concepts identified above, the course involves several key components/approaches to the subject of media literacy. First, this offering combines material on media literacy concepts in relation to media such as web sites, television, video/film, still photography, advertising, and the news, with an appropriate hands-on component involving video. (In the past, some offerings of similar courses at other institutions have not included such hands-on experiences - this course is approximately 40% hands-on.) Second, the course approaches media literacy from an acquisition model (Desmond, 1997). This model goes beyond the protectionist model which tends to demonize media as something from which citizens need to be protected. Instead, the acquisition model presents media as a positive opportunity for learning activities. Such opportunities are focused on social artifacts whose meaning, use, and value can be questioned through access, analysis, evaluation and production. Third, the course investigates the value of media
literacy both as an understanding of various media constructions as art forms (television, websites, advertising, etc.), and as an understanding of the potential effects of various media products on citizens in a representative democracy (Tyner, 1998). In addition, the course builds on concepts from a previous course in the program, EDTL 611 - The Curriculum, where curriculum and the curriculum development process are presented as representations of numerous ideologies in society. These various ideologies continually vie for a voice in curriculum and instructional practice (including the integration of technology into the schools). As students analyze, evaluate and produce various media messages, they relate that work to the climate of the schools and their roles as teachers, technology users and change agents.

Additionally, the fact that we approach Media Literacy from a positive, acquisition model (mentioned above) as opposed to the more negative protectionist model, is strongly emphasized to students. The importance of analyzing, understanding, and producing media in our culture as a way to help produce good citizens in a democratic society and as a way to understand the highly developed art of producing (constructing) modern media are reiterated to students as important course themes. Also, three interwoven strands in the course are identified to, and experienced by, participants: 1) the in-depth, understanding of relevant theory and research strand, achieved partly through readings and discussion; 2) the hands-on strand, including analog camcorders, digital camcorders or hybrid digital/Hi-8 camcorders, editing video on the computer, web searches for resources and also web site analysis from a media literacy perspective etc.; and 3) the practical strand - including three assignments whereby students integrate media literacy into some aspect of the curriculum in their current professional position. The course catalog description follows.

EDTL 639 - Media Literacy for Teachers (3) Fall, and on demand. Introduction to media literacy and its place in the curriculum. Techniques for analyzing media products (e.g., ads, television, film, news, web sites, music videos) and application of media literacy to the curriculum. Introduction to video/camcorders as classroom tools including student-created video. Prerequisite: EDTL 611 - The Curriculum, or permission of instructor.

Course Objectives/Selected Materials

A listing of specific course objectives follows.

To provide student's with:

• an understanding of the importance of digital literacy/media literacy;

• experiences and skills to analyze the following from a media literacy perspective: Television; Video/Film; Music Videos; Advertising; News; Web Sites;

• an understanding of the importance of "reading," and "writing," various media in a democratic society;
an understanding of the importance of video and still photographic images and their potential integration across the curriculum as student-created and analyzed products;

• the skills and experience to use camcorders (analog) to create in-camera edited videos;

• the skills and experience to use digital camcorders to create videos;

• experiences using computer-based video editing software;

• the opportunity to create assignments (and analyze the products created) which integrate student-created video products into the current curriculum;

• the opportunity to examine, evaluate and recommend relevant web-based resources regarding media literacy;

• the opportunity to meaningfully integrate media literacy concepts and skills into a unit length, or longer, portion of the existing curriculum. regarding, but not limited to, one, or more of the following areas: Television, Video/Film, Music Videos, Advertising, News, Prevention Issues, and Web Sites;

• opportunities for reading/reflection and discussion of significant content in the area of media literacy theory, research and application

• an opportunity to learn about and apply The Partnership for Media Education’s (PME), stated goals for media educators: 1) We teach that listening to a variety of voices deepens our understanding of complexity: 2) We teach children not to accept facile interpretations of challenging issues, but to think critically about all aspects of a message: the content, the source, the motive in creating the message, its form, and more; 3) We ask them to probe more deeply beneath the surface so that they can uncover complex truths and come to their own conclusions; and 4) We invite those with different viewpoints to join with us and participate in the dialogue.

A wealth of material is available regarding media literacy, including numerous informational, advocacy and commercial web-sites. Key organizations/projects such as: The Center for Media Literacy, The Media Education Foundation, The Just Think Foundation, The New Mexico Media Literacy Project, The Center for Media Literacy, The Media Literacy On-line Project, etc., provide gateways to relevant, helpful material and opportunities for communicating with university and K-12 instructors as well as students with an interest in media literacy. The major conference, Summit 2000, to be held in Toronto May 13 to 17, 2000 (http://www.summit2000.net) will build on last year's exceptional National Media Education Conference held in St. Paul, Minnesota as a source of information, networking and inspiration. A sample of videos currently used in various ways within the course include: Tuning In to Media (Center for Media Literacy), Teach the Children (California Newsreel), Production Notes: Food for Thought (Video Data Bank: The Art Institute of Chicago), and The Ad and the Ego (California Newsreel).
Participant Feedback/Conclusion

Student response to the idea of such a course as well as to the course experience itself, has been extremely positive. Participants understand the rationale for this offering and welcome the opportunity to explore the topics in the course, gain more skills in the use of technology, reflect on where media literacy fits into their curriculum, and then implement projects in the schools. In the near future the course will be available as an elective to students in another program within our division, a Master of Education in Curriculum and Teaching degree. While adjustments may need to be made to the hands-on portion of the course depending on students' prior experience (or lack of prior experience) with technology, the hands-on component will remain in the course. In such an instance, students will still gain all aspects of the experience, as they access, analyze, evaluate and produce media in a variety of forms. In both programs, such experiences are timely, important and highly valued by teachers and K-12 students alike.

Empowering Minds by Taking Control:
Developing Teachers' Technological Fluency with LEGO Mindstorms

Abstract: This paper documents "Empowering Minds," a project that has established a partnership between St. Patrick's College (Education faculty of Dublin City University), the Irish National Centre for Technology in Education (NCTE), the Media Lab at the Massachusetts Institute of Technology (MIT), and selected Irish primary schools. In this project, we are collaboratively designing and implementing a program for the use of control technology with primary school children, which it is hoped will open the gateways to new ways of learning in schools.

Background

Funding for this project is provided under the NCTE's (www.ncte.ie) Schools Integration Projects (SIP) initiative. This initiative is funding a wide diversity of Information and Communications Technology (ICT) based projects across the first and second (elementary through high school) levels of the educational system in an attempt to identify good practice which can serve as models to be replicated across the educational system. All Irish schools were invited to respond to the SIP initiative in October 1998. The four schools selected are loosely representative of the main school types prevailing in Ireland (large middle class suburban; inner city disadvantaged; medium semi-rural; two teacher rural). The participating teachers within each school volunteered their involvement in the project. The experience level with ICT among the teachers would range from complete beginner to experienced. The project builds on previous research on educational applications of control technology developed at the MIT Media Laboratory. We are using the commercial version of the MIT "programmable brick"—the LEGO Mindstorms Robotics Invention System (Martin, 1988; Martin et al, 2000 [in press]). We are also working with teachers/researchers who participated in early programmable brick research (Martin, 1996; Hayward, 1995).

Rationale

Across the globe there is an urgent need to develop and use educational frameworks for integrating ICT into the school curriculum. These frameworks needs to be informed by sound educational theories and practices, as technology of itself does not directly change teaching or learning. Therefore, we must encourage a careful and intelligent meshing of educational and technological agendas. Much prior research has focused predominantly on the child in the educational environment. We believe a change of focus is required; the key to successful implementation of technology is the teacher.

Attention, therefore, needs to be directed at the 'chief agents of change'—the teachers—and how they view not only technology, but more importantly themselves, the learner, and what is to be learned. Assumptions about the nature of the learner and the teacher in the process of learning will have implications for not only how technology will be used in education, but also for everything that happens within the classroom. The most common uses of technologies in schools today generally reflect instructionist educational philosophies, which view students as recipients of information dispensed by the teacher or by the technology. Rather than the acquisition of specific skills or knowledge, "the real potential of technology lies in its capacity to support pedagogical approaches that encourage students to become active participants in their own learning and to acquire critical thinking skills and more complex understandings" (O.T.A., 1995, p. 126).
Teachers’ assumptions about the nature of learning need to be challenged. Primarily, we would hope that the project would act as a catalyst to challenge the perceptions and assumptions about learning which it is hoped will result in a major change in classroom practice at primary level. Teacher education needs the same conditions as good classroom learning. Teachers need time to experiment, reflect and discuss with others in a supportive learning environment before a shift in their thinking can occur. We believe that the “real promise of technology in education lies in its potential to facilitate (these) fundamental, qualitative changes in the nature of teaching and learning” (President’s Report 1997). Technology, in the proper context and a supportive learning environment, can facilitate the teacher as a learner. Therefore the design of an effective computational learning environment should “....emphasise the importance of constructivism and the learner’s activity in building mental models of .... knowledge. The environment should ... support conversational and collaborative learning ...give sufficient feedback and be able to adapt to the needs of various learners.”(Ruokamo-Sari & Pohjolainen, 1997, p.82) It was with this premise in mind that the project was organised from a constructivist perspective.

According to the constructivist’s learning theories, knowledge is individually constructed in a social setting. Consequently each individual must be active in the learning situation and be responsible for their own learning. If the learners are actively involved in the learning process, the experience is ‘meaningful’ and motivation levels will rise accordingly (Ruopp, 1993; Thompson et al, 1992, pp.11, 68; Thornburg, 1994, pp.24-25). If teachers see themselves as learners along with their students, they will be inspired to implement change both in their classrooms and in schools in general.

Project Design

In the proposal to the Schools Integration Project, we presented the following plan as ‘Phase One’ of our larger goal to bring meaningful technology design projects to the Irish first level schools in a large-scale way. As of this writing, we are midway through the 1999–2000 academic year.

Table 1: Phase One of Empowering Minds Project

Materials and Concepts

For the technology basis, our project uses the LEGO Mindstorms set of robotic design materials. This set of materials includes the “RCX Microcomputer” (a hand-held computerised LEGO brick that can be built into LEGO models), electronic sensors, LEGO Technic components (motors, gears, axles, and wheels), and the standard set of LEGO building bricks. These materials allow children and teachers to have rich and in-depth explorations of key ideas in control technology, including (but not limited to!) mechanical design, power, speed, gearing, friction, sensing, feedback, software design, and project management.

A significant part of the design experience in working with the Mindstorms system is the programming of one’s model. We evaluated two different software packages for this purpose: RoboLab, marketed by LEGO Dacta (the school division of the LEGO Group), and RCX Code, part of the retail package. Most of our teachers gravitated toward the RCX Code software because it is adequately powerful and substantially easier to use.

The Initial Workshop, April 1999

After the teachers were selected, the initial workshop was conducted at St. Patrick’s College of Education, in Drumcondra (a suburb of Dublin). The workshop ran for five days over the Easter holidays. For the first two days, we had invited participation from two parents and four children from each of the four selected...
schools. The final three days were spent working exclusively with the teachers chosen for the project. This format was an interesting innovation; an infectious enthusiasm from the children greatly contributed to the excitement of all, and built a great base for subsequent parental involvement. The days with the small group of teachers were focused and productive. In this workshop, teachers were asked to design their own projects, a novel experience for many. They all engaged wholeheartedly with the materials and were so immersed they were reluctant to leave even for lunch. There were times of frustration as they struggled to achieve their goal. Ultimately, however, they achieved success and the sense of accomplishment was palpable. These experiences opened up many conversations about how to implement this approach in the classroom and how to get the children started—whole class at once or sub-groups? From the beginning, it was apparent to all that we would be relying on the intuitions and expertise of the teachers to implement classroom models effective for their own particular situations.

Exploratory Work in Classrooms, May - June 1999

After some problems, material was procured and delivered to the schools, with approximately four weeks left in the school year. This was just enough for teachers to bring the materials to their children in a limited scale, and themselves obtain this practical experience which would serve as the basis for subsequent reflection in the summer workshop. The exploration with the materials before the second workshop proved valuable in many respects not only for the direction taken in the second workshop, but also for the teachers' implementation approach for the autumn term. The teachers made specific requests for the workshop content as they realised the need to develop their own understandings of the principles of building solid structures, how gears worked, etc. These inputs were acted upon and the second workshop was designed to accommodate the teachers' expressed needs.

As an example of 'lessons learned', one of the teachers working with the inner city children before the summer quickly realised that the majority of these children had no prior experience of building with LEGO. They had major difficulty trying to follow even the simplest of building plans, and this combined with their social background made it very difficult for them to share materials. Consequently, attempting to use the materials with the whole class simultaneously was a recipe for disaster. The teacher tackled these issues by enlisting the help of the support teacher and the infant teacher in the school. Withdrawing a small group of six children each time, she slowly worked through constructing simple models, with and without plans. In this way, she was able to give each child the attention he or she required. The teacher also worked on developing the children's ability to work together. As the children became more experienced, she began withdrawing two groups at a time and has now progressed to having the whole class working on their own models at the same time. This approach combined with the time spent organising the materials has been the key to progress. This teacher plans to have weekly whole-class building sessions and begin to withdraw the small groups again when the children are ready for programming.

The Second Workshop, August 1999

We were fortunate to be able to bring in John Bilotta, a district technology co-ordinator with over twenty years of primary classroom experience, who had participated in previous MIT research on programmable bricks. We used a substantially more structured format in this second workshop, providing teachers with focused half-day experiences rather than a multi-day open design process. These half-day focused activities proved invaluable for helping the teachers gain some important insights. For example:

The Silent Game: In this activity one person improvises a model, another responds by adding on to it, and a third observes. Although less than 20 minutes was spent on producing the models, many of the builders had a strong sense of it being 'theirs' and had mixed feelings about the Responders adding on to them. The Observers' presence highlights the different possible interpretations of builders' intentions. For the teachers, this crystallised the need to respect children's sense of ownership, and made them realise that it is hard to tell children's intentions from only seeing snapshots. This was brought into relief for the group by Joan's response to John's model. He hadn't intended to make a pattern, but she replicated his model, taking something that he intended as 'random' and making it a clear pattern.

Slow-car Building Challenge (Build the slowest car possible that still moves): This challenge drove home the theory and practice of gear reduction, and pointed out the complexity of designing successful models. One group had lots of trouble building the supporting frame around the gears and didn't finish until the next day. Another group's car fell on the floor and smashed to a thousand bits. They
commented that it was the best thing that could have happened: they needed a full redesign, but had not been prepared to take their model apart!

Building a Learning Community

Other people are the greatest source of alternative views (von Glasersfeld, 1989) that stimulates new learning. A key feature of this project is that the teachers and children are externalising their thinking and reflecting on what they are doing and how they are learning i.e. thinking about how they think. All the children are keeping a log into which they record the models they have built illustrating it with diagrams and pictures. Each teacher is keeping a journal in which they record how the project is developing in their classroom, problems they have encountered, things that have worked particularly well for them, etc. Reflecting on how they are learning and discussing it with the children in the classroom and within the group is providing the opportunity for them to realise that everyone has their own way of understanding. As they work together they are realising the importance of dialogue and the interactions among group members, as they struggle to solve their problem collaboratively. Two things are happening simultaneously: teachers are engaging in a learning environment, and are reflecting on the process of how they are learning. They are learning with technology, not about technology. Technology if harnessed in this way could provide the vehicle for lasting change and for improving learning.

The importance of a learning community where ideas are discussed and understanding enriched is critical to the design of an effective learning environment. “Teaching, more than many other occupations, is practised in isolation, an isolation that is at times crushing in its separateness.” (Maeroff, 1988, p.3). But “increased communications is one of the biggest changes technology offers …to …transcend the walls of isolation” (O.T.A., 1995, p. 2). Therefore, if this power of technology is harnessed and used in a collaborative environment, an effective learning community can be established among educators. Current problems of isolation will be reduced, the community of learners widened, and classroom walls, as they exist at present, broken down. To this end, a mailing list was set up for all participants in the project. Initially, use of this was confined to the more experienced users of the group. However, one of the teachers suggested that we mark Netd@ys (www.netdaysireland.ie) by getting the children emailing to the group a sample of some of models they had been working on. This was the springboard that was needed and it provided the context for children to begin to communicate with one another. It has generated excitement among the children who, inspired by what others had been working on, began to incorporate or adapt some of the ideas they had seen in the emails into their own models. The emails also sparked off interesting discussion as children pondered design issues e.g. how a particular gear train had been structured and what effect it had on the movement of the model. We hope to develop these links with other schools and institutions nationally and internationally. This will provide teachers and children with a relevant and meaningful context to make use of the internet and email as valid communication tools for accessing information and ‘comparing notes’ about their designs and the problems they are experiencing.

Removing Barriers

Other research has identified potential barriers for teachers’ effective use and integration of ICT within the curriculum. We have minimised these by providing:
- adequate and appropriate hardware (e.g. computers and digital cameras)
- support structures
- appropriate professional development (cf. workshop descriptions and support structures)

Adequate and Appropriate Hardware

The majority of teachers chose to have their schools augment the grant provided, and purchase laptop computers rather than desktop machines. This has been significant in the teachers’ development of computer skills and the subsequent integration of their newly acquired ICT expertise into the curriculum. All of the teachers claim that without the opportunity to bring the computer home, to “tinker around and play with”, they would not have achieved such a computational fluency. Neither would they have had the confidence to use it so widely in their everyday classroom work, e.g. writing up their journals, sending
email, finding resources on the Internet, programming the models, etc. To the teachers, the value of having the computer at home to use on their own time, rather than having to stay behind after a tiring day in school cannot be overemphasised. This was especially true for the complete beginners, who could try things out at their own pace, in their own time and without the pressure of time constraints and other people's eyes.

A digital camera that recorded pictures on floppy disks (the Sony Mavica- MVC-FD73) was provided for each school to aid in the recording of the models the children created. The deciding factors on which camera to purchase were simplicity and ease-of-use. This has paid enormous dividends as all teachers and children are using the cameras confidently and effectively on a daily basis. Their use has not been restricted to the project only as the cameras are being used for a myriad of purposes—e.g. school events (sporting occasions / concerts) and projects (insects, flowers, trees).

Support structures

A variety of support structures was put in place to provide the teachers with scaffolding as they embarked on the project and their journey into “learning with the children”.

Within the classroom—constructivist teaching approach: All of the teachers agree that they have never learned so much since beginning to work with the children in building their models and helping them solve the problems they encounter.

Within each school—two teachers were involved from each school: A buddy system operated as one of the teachers was more experienced with using technology. Having the supportive environment means teachers can take risks in safety as they know if something goes wrong a helping hand is always available to provide advice and support. As one of the teachers remarked “having someone in the school or at the other end of the phone takes the fear out of trying out things. I’m no longer afraid to get myself into a mess because I know if I can’t sort it out one of the others will give me a hand.”

Across schools: A small number of schools was selected for the initial phase of the project and good relations and a sense of rapport was built up among them over the course of the workshops. Email communication is strengthening this sense of identity and will continue to do so. The cluster of schools act as a source of ideas and inspiration for one another, as well as providing advise about issues as they arise e.g. classroom management and organisation of materials.

The project co-ordinator: The regular school visits and meetings with teachers by the project co-ordinator (Deirdre Butler) provide an opportunity for appropriate skills to be introduced as the need arises. This is the embodiment of what Vygotsky meant by the “zone of proximal development” as we were able to respond to the needs of these children and their teachers and facilitate their development of ICT skills in response to an expressed desire and need.

Resource Team: These provide expertise and advice to the group as they have had prior experience of working with the materials in a variety of settings.

Conclusions

Inspired by both the enthusiasm of their students and the response of the community, the teachers have developed a great strength of belief in the work they are engaged in. They have been invited to give hands-on workshops, present at conferences, and host visits from other interested teachers. This has had the
effect of reaffirming for the teachers the validity of their work, has increased their confidence, and has heightened their awareness of the use of technology in education.

Evidence of improved home/school links has begun to emerge which, we hope, will lead to the development of a more relevant and meaningful approach to learning, both in school and at home. For example, parents have been visiting the schools to see the children’s work, and in some cases have volunteered to help out during class and after school. The children also have renewed their interest in building with LEGO materials at home.

As the project unfolds in each individual classroom, we expect that there will be an opportunity for wide-ranging cross-curricular integration, including the development of mathematical skills, problem solving abilities, and opportunities for art, music, drama, writing, and poetry. When teachers incorporate these new technologies and a more constructivist way of learning into their classrooms, they are more able to connect their unique backgrounds with the curriculum and the interests of their students.

Acknowledgements

This project would not have been possible without the generous support of the Irish Dept. of Education & Science through the N.C.T.E. and Eircom. We would also like to thank John Bilotta from the South Kingstown school district in Rhode Island, and all of the wonderful contributions of the Irish teachers involved in the project.
PRACTICAL WAYS TO IMPROVE INSTRUCTIONAL EFFECTIVENESS USING INTERNET-BASED COURSE SUPPLEMENTS

Abstract: This paper documents methods to increase the effectiveness of conventional lecture/discussion/demonstration classes through the addition of internet-based supplements to those face-to-face classes. Types of websites discussed include informational and interactive sites. The authors share practical experience and student comments on personal websites, listservs and email, and integrated web-based learning packages. Suggestions for instructors who want to begin including web-based components in their instruction are included.

Introduction

While striving to make their classes more understandable to their students, teachers are continually changing course content or activities, reallocating time allotted to certain activities, or increasing student participation through various means. Internet-based course supplements fall into two different categories, informational and interactive. They are used to fulfill very different needs in instruction. Informational supplements provide additional data to the students while interactive supplements help students to transform and internalize information that has already been accumulated. Interactions can be either synchronous or asynchronous.

Boettcher (1999) has described four distinct levels of “Course Webness” (p. 50) to consider: web presence, web-enhanced, web-centric, and web courses. A web presence has all the information included in the traditional course catalog. But this level is more about marketing than pedagogy. A web-enhanced course is a step away from the traditional classroom model. These courses support the distribution of course materials and communication via web-based resources. Web-centric courses differ from web-enhanced courses not in the types of web resources used or even in the way the resources are used, but in the amount of emphasis given to the web resources. True web courses are designed to be 100% available 100% of the time via the internet and a web browser. Three approaches for supplementing courses are exemplified in this paper: personal websites, listserves and email, and integrated web-based learning packages. They exemplify Boettcher’s web-enhanced and web-centric courses.

Approaches for Supplementing Courses

Personal Websites
Personal websites are primarily informational and can be used to post supplemental course materials such as syllabi, documents authored by the instructor or others that the instructor has copyright for, and links to other websites with information available. They provide the teacher the opportunity to present information on the instructional issues in a variety of formats. Using the relatively simple programming language, hypertext markup language (html), basic, functional web pages can be produced by relatively inexperienced programmers. Using a web-authoring program such as PageMill, FrontPage, or Composer (included with your free copy of Netscape), exciting designs including graphics can be produced quickly, with minimal effort. An added plus is that html is system independent, reducing translation problems that often surface in distance environments. We use our web pages (see http://www2.gasou.edu/eltr/tech/rcarlson/frame.html and http://www2.gasou.edu/eltr/tech/jrepman/repmanhome.html) to provide direction on the course (syllabi, daily lessons, or activities associated with specific classes), course documents to be downloaded, or links to various websites that provide amplification to the instruction. These websites also become a point of access to begin searching for other web-based documents related to the lesson - a pointer page for the lesson.

The personal web page helps to foster a sense of community. Students can look at other courses that the teacher has conducted/is conducting and gain a sense of course flow. We also publish our vitas and some writings along with some personal information so that the students can get to know us better. With the students' permission, publishing the students' pictures and email addresses on a class page can extend this sense of community.

Listservs and Email

Listservs and email comprise a type of course supplement that provides students and instructors a way to conduct course discussions. Experts can sometimes be used to anchor these discussions. Additionally, an informational function can be addressed (albeit inefficiently), when documents containing course materials are attached to electronic messages.

Hara and Kling (1999) looked at email interactions from a student perspective. They found that frustration centered around three areas: technological problems, minimal or untimely instructor feedback, and ambiguous communication. Students they observed frequently felt isolated and believed the experiences that they had were unique and not shared. This was especially true when they were frustrated with a technical problem. The students felt as if they were the only ones who experienced a problem. Feedback problems from the instructor's perspective had to do with both the nature of the communication (asynchronous) and the amount of time it took for the instructor to respond to each query. Ambiguity is frequently encountered in situations where there is not the ability to immediately question and clarify instructions or responses. This seems to be the case in this study.

We used email communication as a tool to extend our capabilities. Our students typically are full-time teachers, so they have difficulty communicating with us during the week. One of us seems always to be in class when the other tries to communicate. We impress on our students the importance of using email as an asynchronous communication tool. We insist that all of our students have functional email systems. Early in the semester, we test the systems, usually requiring some small project to be completed and handed in using email. Part of the assignment is to attach a document. This tests the system and the technical sophistication of the user and allows us to provide timely tutoring to those who need it. Later in the semester, students can take advantage of those capabilities by asking questions of the teacher or conducting asynchronous discussions with the teacher or other students. Similarly, a listserv can be used to foster class-wide discussions. We found that free web-based listservs such as OneList (http://www.onelist.com) are easy to use. Of course, almost any college/university information technology department has that service to offer to its instructors, as well. We tried to focus the listserv discussion by breaking it down into small groups and found it was not as helpful as the synchronous chat-type discussions.

Integrated Web-based Learning Packages

Finally, integrated web-based learning packages provide integrated information management for both the instructor and the student. Included in these packages are calendars, asynchronous threaded discussions, course documents, whiteboards, and synchronous discussion (chat) groups. Integrated web-based learning packages
such as Learning Space, Web Course in a Box, or WebCT are particularly useful to augment our instruction. For a better comparison of these competing products, see Sharon Gray’s article in the January 1999 Syllabus or access David Wooley’s site at http://www.thinkofit.com/webconf.

Dabbaugh, Bannan-Ritland, and Silc (1999) evaluated the pedagogical implications of courses which used integrated web-based learning packages using Kahn’s Framework for Web-Based Learning (1998), a comprehensive framework that includes eight dimensions and over sixty sub-components. They found that web courses provide ample opportunity to use appropriate pedagogical strategies – either objectivist or constructivist. Strengths of web courses included clear organization and presentation formats, well directed objectives, exceptional guidance for learners, and the use of collaborative, shared workspace. Weaknesses observed centered around interface design and lack of flexibility. They recommend that course authors focus on the use of collaboration tools such as Learning Space.

Rittschof (1999) summarized the pros and cons of a course that used WebCT as the learning package. This course was a graduate-level course in educational psychology which involved higher-level thinking skills and discussions about theoretical issues. When compared to a traditional classroom setting, students reported that they shared more personal insights, voiced their true opinion more, and interacted with others more. This should encourage instructors who want to generate more discussion and include all class members. However, problems with technical aspects (the chat feature was unreliable) and the feeling of isolation (not knowing the instructor or other students) persisted throughout the course.

We chose Blackboard (www.blackboard.com) as our standard, because it offered comparable features to commercially available products, was easy to use for our students and ourselves to use, and it was free. We particularly liked the communications section, which featured email, threaded discussion, and a whiteboard/chat feature. The email provided all of the features addressed earlier. Threaded discussion provided the teachers and students an opportunity to carry on multiple asynchronous discussions throughout the week. Hot topics flourished while others died. We found that it was necessary to carefully guide the discussions so we might not unduly influence the students, while at the same time helping them to remain on track. The chat/synchronous discussion was the most challenging from a teacher’s viewpoint. First, the chats could easily become schizophrenic quite rapidly because a large number of participants deteriorated into multiple conversations. This could be alleviated somewhat by breaking down the chat groups into smaller units (nominally 8 maximum). Technical problems included students with slow modems, slow computers, or inadequate keyboarding skills who subsequently experienced trouble keeping up with conversations. We never found a good way to rectify situations such as those – except for the obvious. The course documents section of the integrated packages allows the publication of course documents such as syllabi, presentations, and text and graphics documents. These were distributed in a fashion similar to those distributed via web pages, but were more convenient.

Student Comments

In order to gather student comments about the course supplements, a survey was emailed to the students of the classes who used the methodology. There were a total of 35 responses, a 67% return rate. The survey asked:

1. How did the materials posted on the web (on Blackboard or on a personal/class web page) aid your learning?
2. What communication tool worked best for you - Blackboard threaded discussion, email (listserv included), or chat? What made them helpful or not helpful for learning?
3. Did the fact that you were physically located at a different site from the instructor for at least part of the course affect the usefulness of the tools mentioned in questions 1 and 2? Why?

Materials

Almost universally, the students liked to have the class materials available on the web. Every class had a component that used PowerPoint as a presentation tool or class notes prepared on a word processor. These documents were made available through the instructor’s web page or through the integrated web-based learning
package (BlackBoard). Students were able to use the documents as advance organizers, allowed them to focus on the lesson, and saved time copying notes. They also appreciated the cost savings over printed notes that instructors have previously made available at the bookstore. The following statements are typical.

"...the ppt slides were a great reinforcement to my readings."
"By looking at these slides before class, I was able to focus on the important parts of the reading assignment."
"I had them before class and was able to add important in formation to them instead of concentrating on writing everything down." (italics added)
"I spent more time listening and less time copying notes."
"...established an anticipatory set..."
"...helped to review the lesson."

Problems tended to be technical and avoidable. The following are examples.
"...problems are many. It was VERY slow."
"The only problem I had was that if they were not posted the night before class, I have a hard time getting them."
"...problems getting the notes off BlackBoard."
"...server down..."

Communication Tool

When asked to name the communication tool that worked best, students split between email and threaded discussions. But the reasons that they liked the tools were surprisingly similar. First was convenience in both time and location. Students liked being able to adapt their learning to their lifestyle.

"...time was not an issue..."
"...without driving 3 1/2 hours round trip..."
"...communicate in our own time frame..."
"...could ask my questions when they were fresh in my mind..."
"...immediate feedback..."

They also liked having a written record of the discussion.
"...good for documenting the responses..."
"You could see the development of the discussion..."
"...You could see all the posts..."

Students thought that the discussions provided new ideas.
"...thoughtful comments..."
"...can be very thought provoking..."
"...made me look at things in a different way..."

Being able to prepare a response was important, also.
"...believe it or not, I like to think before I answer!"

Problems centered around access.
"...couldn't use group chat due to access problems..."
"...couldn't schedule a time for chatting (among the group)..."
"...chats never work..."

Training on how to use the various tools was another issue.
"More instruction on how to use the various BB components would be helpful."
"...have to get into the habit of checking BB..."
"...probably 'how to use' instruction would have been helpful."

Timeliness also was frustrating.
"...not everyone responds as quickly..."
"I don't think everyone understands how it (threaded response) is supposed to work..."
"...makes everything too drawn out."
"Email is more immediate..."

Physical Location

Being physically located away from the instructor for much of the course was not a problem as long as there was some prior contact.
"...helped me with personal questions that may not apply to the whole group."
"...I felt in-touch without having to travel 4 hours every week."
"...sense of connectedness..."
"...should have met physically at least once..."
"If I had not met the people, I would have had a much harder time..."
"...have a mental picture of who I was talking to...

But students didn't like to work with one another on projects.
"...problems with different sites on the group project..."
"...only bothered me during group projects..."

Recommendations

From our experience, we would make the following suggestions to instructors who want to begin including web-based components in their instruction.

- Start small. Begin at Boettcher's first stage and work your way up. It is a gigantic leap from a web presence to a full web course.
- Make sure that you provide for training on the applications to be used. Not everyone is as sophisticated as you. Most students overestimate their technical ability.
- Make sure that the students understand that they must have access to appropriate hardware and what that hardware is. If their access is limited (to either school or home) they are going to make their course interaction more challenging.
- Have at least one face to face session. This allows the students to build a mental image of the person to whom they are talking and makes communication easier and better. If that is not possible, post pictures, biographies, and audio files on the web so that this information can be used to acquaint the class with each other and the instructor.
- Post materials in a timely manner. They should be up on the web at least two full days before the class. This also helps to bypass unavoidable technical problems.
- Have a way to help students work through technical problems.
- Provide digests or written records of chats to those who request them.
- Discuss strategies for group work at a distance.

Following a logical progression will help you enhance your course by using tools that are available and easy to use.

Reflective Judgment and Cognitive Interaction in an Electronically Distributed Astronomy Course For Educators

Kevin Carr
Department of Teacher Education
George Fox University
United States
kcarr@georgefox.edu

Abstract: An Introductory Astronomy for Educators course was delivered over the Internet using mostly-asynchronous communication tools, as well as interactive Java simulation and data-sharing applets. The on-line environment was teacher-designed to provide a platform for rich interaction and critical thinking, while providing for maximum time and space flexibility for students and instructors. The purpose of this inquiry is to evaluate the efficacy of the course in meeting the goals of flexibility, science literacy through critical thinking and cognitive interaction. Data were collected in the form of student coursework, electronic records, fieldnotes, and student learning journals. Findings indicate that critical thinking and cognitive interaction were uniquely facilitated in ways that are problematic in the traditional classroom setting. Issues raised include the need for technical preparation, varying readiness for critical thinking, and the high demands placed on the instructor.

The landmark document *Benchmarks for Science Literacy* (AAAS Project 2061, 1993) set in place specific goals for science literacy. Development of critical thinking in science is suggested by *Benchmarks* as a primary component of science literacy throughout schooling. One important means of helping all students reach this goal is to provide in-service teacher training in science, featuring methods that promote critical thinking. Can the internet be used to deliver flexible, interactive in-service science education in a way that successfully models and fosters critical thinking? This study examines the delivery of a summer in-service course entitled *Astronomy for Educators* using a teacher-developed internet environment.

Structuring For Flexibility and Collaboration, and Critical Thinking

Overcoming learner isolation is a primary goal of in-service teacher education. Cognitive interaction in *Astronomy for Educators* (AFE) was facilitated using a variety of networking tools, each having different temporal and access features:

Table 1: Interactive Features of AFE

AFE is designed to foster a complex network of flexible, cognitive interaction. The rich interactive structure of the AFE course was interpreted using Granott's Interaction Framework (Fig. 1), a model in which cognitive interactions are classified in a two dimensional model (Granott, 1993). Using this model, the various electronic conversations that took place in AFE can be classified, forming a composite profile of the interactivity of the environment as a whole.
One dimension of the model describes the degree of collaboration in the interaction. Collaboration can involve high mutuality, with a common focus of attention (Rogoff, 1990). Such collaboration is highly interconnected and non-local in nature. Other interactions, though, involve minimal two-way exchange of ideas and common focus.

The second dimension describes the participant’s relative knowledge or and expertise in the content of the interaction. A peer-peer interaction is termed symmetric, while an expert-novice interaction is termed asymmetric. These aspects of interaction can be presented visually as a 2-dimensional space, in which each dimension is considered to assume a continuum of values (Fig. 1).

Figure 1: Interaction Framework (adapted from Granott, 1993, p.187)

Structuring For Critical Thinking: Constructing Personal Knowledge

Critically thinking students do not simply learn about astronomy, they practice being astronomers. To facilitate being astronomers, the course was structured as a sequence of problem-centered activities in which students construct an increasingly powerful personal cosmology based on actual observations and data. This structure is supported through the use of interactive, data-sharing modules, some delivered using JAVA programming language, in which students make astronomical observations, post and share data, and draw conclusions using the on-line environment. Such activities require critical thinking and reflection at a level comparable to scientists in the field.

The Reflective Judgment Framework (RJF) is a powerful tool for assessing the use of, critical thinking (King & Kitchener, 1994). Analysis of over 2000 intensive interviews of college students (using a wide variety of ill-defined problems) gave rise to the construction of a three-level developmental model based on the different way in which knowledge and justification were viewed. Pre-Reflective, Quasi-Reflective, and Reflective levels of reasoning, characterized by distinct views of knowledge and justification, provide a framework by which the developmental nature of reflective thinking may be understood.

<table>
<thead>
<tr>
<th>Stage</th>

<td>Outcome of process of evaluation.</td>
<td>Weight of the evidence, value of interpretations</td>
</tr>
</tbody>
</table>

Table 2: Overview of Reflective Judgment Framework (Adapted from King & Kitchener, 1994, p. 44-74)
Using the RJF, growth in critical thinking during AFE can be understood in terms of three broad developmental stages. Using the model, students work can be both evaluated qualitatively, and understood developmentally.

The Study

Distributed learning de-localizes school in both social and cognitive ways. Social/cognitive interaction and critical thinking are key components in a professional development science course for educators. The purpose of this study is to evaluate and analyze the implementation of on-line Astronomy for Educators in meeting the goals of time/space flexibility, critical thinking, and cognitive interaction. Results indicate that AFE was effective in blending maximum learner flexibility with strong intellectual development and social interaction. Caveats about AFE include technological and cognitive readiness, and the time demands of instructor involvement and interaction.

Data Sources

The electronic nature of AFE provides a unique and powerful opportunity for data recording and analysis. Data were collected electronically and automatically, giving the researcher more powerful and direct access to the content of both student work and student interaction. In this study, three separate instances of course implementation were analyzed, consisting of a total of 40 students over three different semesters. The data collected was analyzed according to grounded theory, a researcher-driven, qualitative methodology often used in teacher research (Strauss & Corbin, 1994). The data were generated from a variety of sources:

- **Synchronous Meeting Transcripts**
  Several synchronous on-line meetings were conducted. Attendance at these on-line "chat" sessions was optional. Text transcripts of these hour-long meetings were saved and analyzed. Approximately 100 pages of on-line meeting transcripts were collected.

- **Study Group Transcripts**
  Each student was assigned to a four-student electronic study group, which consisted of a message board with access restricted to group members. Approximately 200 electronic study group interactions were archived in text form for later analysis and interpretation.

- **Idea Container Transcripts**
  Each activity included an electronic message board to which all students and instructors were provided access. Approximately 500 electronic idea container postings were archived in text form for later analysis and interpretation.

- **Reflective Learning Journals**
  Thirty-five students wrote entries in an electronic learning journal in which access was limited to the individual students and instructors. Journal content of approximately 150 pages of text was parsed and passages relevant to cognitive interaction and growth in reflective judgment were extracted, forming a reduced record.

- **Reflective Essays and Other Student Work**
  A series of reflective essays, activities, and exams were administered. The first asked students to reflect on the meaning of distributed education; the second asked students to reflect on the evaluation of critical thinking after completing midterm exams. The third asked students to reflect on the impact of cognitive interaction in the course. The final essay asked students to summarize how individual cosmology changed as a result of the course. Essays and content of other student work (approximately 1000 pages of text) was parsed and passages relevant to cognitive interaction and growth in reflective judgment were extracted, forming a reduced record.

- **Structured Interviews**
  Two extensive structured interviews of approximately one hour each in length were carried out with off-campus students. The interview content was videotaped for analysis. Interview content was transcribed, and the resulting text recorded.
Profiling Electronic Interaction

Figure 3 displays the way the learning environment was used for various types of interaction in Granott's framework. The idea containers were used for the broadest range and amount of interaction.

<table>
<thead>
<tr>

<tr>
<td>Collaborative</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Figure 3. Distribution of Interaction Types in the Granott Framework

Imitation and “parallel play”

Imitation is an independent, roughly asymmetric interaction in which a novice learns from an expert through direct modeling, with limited two-way interaction. Idea containers were extensively used for imitation. It was reported that it was useful to “see others ideas when I was stuck” (Student Evaluation, 3/98). The perception that others' ideas were worth reading and evaluating indicates an open and critical sharing of work and ideas.

Different from imitation is the notion of “parallel play,” a non-collaborative, symmetric interaction. Parallel play differs from imitation in that “partners” perceive each other as having equal expertise in the activity. The perception of equality is evident in reports that “I liked compare my ideas to others to see if I was on the right track.” The idea containers facilitated the imitation—parallel play continuum in a very flexible and effective way.

Guidance and Counterpoint

More collaborative than imitation or parallel play, guidance and counterpoint were also evident in idea container interactions, as well as in study group communication and in live meetings. Counterpoint consisted of short periods of interaction interspersed through independent activity, taking the form of “question-answer” (asymmetric) or “point-counterpoint” (symmetric) dialogue. Often, counterpoints were separated by days or even weeks in time.

Collaboration and Apprenticeship

Collaboration is characterized by a highly interaction between peers of equal expertise (Granott, 1993). Collaboration is reciprocal and symmetric, with quick shifts of dominance from one to another. The participants are engaged in common activity, with common goals, sharing materials. “The participants co-construct their knowledge by continuously sharing their ways of understanding. Their knowledge structures, therefore evolve simultaneously” (Granott, 1993, p.189).

High levels of collaboration were rarely, if ever, observed in asynchronous idea container or study group interaction. Some counterpoint interactions were extended into “counter-arguments” but the central features of collaboration such as common goals and synchronous learning was not evident. To observe collaboration in the AFE we must turn to synchronous communication. The meeting room interactions demonstrated Granott’s criteria for mutual collaboration (symmetric) and apprenticeship (asymmetric collaboration).
Development of Reflective Judgment

About 70% of the in-service teachers, many of whom had limited background in science, initially held a pre-reflective view of knowledge and justification in astronomy. The remaining students began with at least a quasi-reflective view, with a few demonstrating “expert”, reflective understanding of the nature of astronomy knowledge. Most students experienced some initial and understandable discomfort with applying reflective thinking skills in an astronomy course. Many students were able to integrate higher level skills as the course progressed, and reported that the interactivity of the course was an important factor in growth:

“I really enjoy taking control of my learning, but it does take a while to get going with such a new concept...I do enjoy this type of approach, though because it gives me the chance to be responsible for getting done and to what extent. It gives me the sense of initiative needed to gain the knowledge that is required to pass this course. It also gives a self-confidence as a learner because I am also a teacher. I like the on-line chat program where we can go with questions and comments to get help or to help other students (Student Evaluation, 12/97).”

“I learned a great deal. I enjoyed finding the planets in the evening sky. I enjoyed plotting the sunrise and sunset and moon phases. It was fun creating a sun dial and finally understanding how they work. Working through the units in determining the size and mass of things allowed me to discover things beyond this solar system...I have been out of complicated math for so long that I was frustrated a bit at times...I liked the flexibility of working when I found the time. It was a great experience completing things at any hour and submitting it. I appreciate the flexibility that you had with me, especially when my computer was not being user friendly. I appreciated the help that you gave when needed. In the beginning there was more student to student interaction...I enjoyed reading what comments people submitted. I could see myself doing even better the next on-line class I take... It was really cool being able to look up information on the internet. It was also fun going to sites set up in the various units. It is amazing how much information I could access. I felt that this class provided many opportunities to have the student interact with the subject through the idea tank (sic), physically viewing the sky, creating sundials etc. I think I have spent more time on this subject than any others - It was fun...I have come away from this class with a great deal and you have furthered my love of science. I will be able to use many of the things I learned with my family and my Second Grade Class” (Student Evaluation, 8/99)

“I have really enjoyed taking this astronomy class. I have learned a lot. This is not just book knowledge, but I was able to see (both literally and figuratively) these facts for myself. This course did encourage me to think critically... Being able to talk to others taking the class definitely helped. There were times when I got stuck on an activity and reading what they had done put me in the right direction to solve my problem. There were also times when I was able to help others. As a teacher I really enjoyed that” (Student Evaluation, 8/99)

Discussion

Along with the enthusiasm of a predominantly successful experience with AFE comes awareness of a number of challenges for future implementation. By addressing these caveats on an on-going basis during future development I believe that AFE has the potential to facilitate powerful, robust learning for in-service teachers.

Student Technological Readiness

About half of the students began the astronomy course with skills inadequate for independent utilization of the technology. As one student put it, "I feel as like this should be a nine-credit class. I work on it constantly." It turned out that the student was engaged in two simultaneous tasks. He was not only engaged in the problem-solving tasks intended by the course designers, but was spending a great deal of time learning basic computer and internet
skills as well. The student suggested that perhaps a separate training course with instruction in the necessary technological skills would meet his needs.

Providing a course “on-ramp” which is technically negotiable for as many students as possible is one of the most challenging facets of AFE implementation. Many tasks that seem transparent to course designers such as habitually saving work to disk, using hyperlinks, efficiently arranging the computer desktop, sending email from a variety of environments, and even finding and connecting to an internet service provider can prove to be a great consumer of time and cause of frustration for students. It is recommend that future AFE course designs include optional training modules for those who are unfamiliar with the network technology.

Student Cognitive Readiness

A few students were challenged by both the independent nature of the course and the critical nature of the activities, becoming at times angry and regretful at having enrolled in the course. In two instances, students were unable to meet the demands on the on-line environment, reporting that they needed “clearly written lectures and definitions,” and were unable to progress beyond the initial activities due to “a total lack of direction.” One bluntly reported, “this was not the course for me.” Ironically, both reported being “excellent” students otherwise, one being an earth science teacher in the middle grades. The issue of cognitive readiness for critical thinking in science seems to be problematic even for seemingly qualified students. There is no doubt a variety of reasons for this, including past experience in school, particularly in traditional science courses, which de-emphasize critical thinking in favor of “covering material.”

Increased Time Demands

I found that as my students work harder in learning Astronomy, I work harder as well. This runs contrary to common notion that on-line environments are a way to cut costs in terms of instructor time. In AFE this was hardly the case. The increased interaction and depth of learning was rewarded by longer instructor hours. Class sizes in interactive on-line course should remain comparable to those in traditional courses and be staffed equivalently.

Conclusion

The implementation of electronically distributed AFE largely met the educational goals of critical thinking and rich cognitive interaction while providing for flexibility and convenience for students. While no learning environment can be pre-programmed to be "complete" in and of itself, the mostly-asynchronous distributed learning environment as implemented by the researcher provides a complementary blend of time independence, student ownership and accessibility, and teacher facilitation. It also maintains a dynamic, flexible teacher-owned platform for further development.

Introduction
In the mid-60s Federal money was beginning to pour into urban school districts to improve basic instruction. Money for science materials, reading texts and audio-visual equipment slowly transformed each classroom into a state of the art learning environment. The excitement of new hardware energized the teaching staff. But slowly the equipment that we loved to have in the classroom fell out of use. It was pushed into corners, never to see the light of day again. In the rush to spend the funds, a vital step was missed. We were never really trained to integrate the new technology into our instructional process.

Since those early attempts to integrate technology into the curriculum, technology itself has taken a quantum leap into the future. In some districts, unfortunately, technology itself has become the end. During many visits to local school districts, we have observed a pattern re-emerging. New computers and software were in the classrooms but were being used at best to be a reward for students who completed an assignment early. School media specialists reported that assignments given to students for research over the Internet consisted mostly of the student downloading information and submitting it to their teacher. It seems that the objective for this use of the Internet was to use the Internet!

The February 1999 issue of Educational Leadership was devoted to integrating technology into the classroom. One of the articles outlines a successful program’s philosophy by stating: “Technology became the new tool. The staff determined early in the process that technology would not be the driving force, instead it would be to provide curricular support. They adopted the philosophy: We use technology to learn, not just use technology.”

With this framework, we began to examine how the successful integration of technology into the instructional process could be institutionalized. The Pennsylvania State Department of Education helped in this quest.

State Program—Link to Learn

The State of Pennsylvania has established a $166 million Link-to-Learn initiative to serve as a catalyst for the effective use of information technology to enhance education, promote community partnerships, and support economic growth in a knowledge-based society. Institutions of higher education are encouraged to be innovative in developing delivery systems that will make systemic changes both in pre-service programs as well as in-service staff development processes. Providing hardware, software and training is a fundamental part of this program.

Grant Description

Chestnut Hill College proposed to increase the proficiency of its pre-service teachers to use technology to improve teaching and learning. As a result of this initiative, by June 2000, participating pre-service teachers will possess the following minimum technology competencies:

Ability to use word processing
Ability to use database software
Ability to use spreadsheet software
Ability to use timeliner, concept mapping, graphing, prewriting software
Ability to evaluate game and simulation software across the curriculum
Ability to evaluate and use Internet and Web resources
Ability to design activities in which students use Internet and Web resources
Ability to create support materials for the use of technology in classrooms by children
Ability to integrate use of technology into the curriculum, choosing age-appropriate software and creating activities that connect software used to topics being taught
Ability to organize the classroom’s physical layout and activities to maximize the use of one computer in a classroom

These competencies will support effective teaching of the emergent Pennsylvania academic standards in English language arts, mathematics, science and social studies for grade levels K-8.

Additionally, these competencies will support language arts, mathematics, science and social studies curricula for cooperating teachers in grades K-8.

These competencies were developed through examination of the standards for technology usage by classroom teachers articulated by ISTE (the International Society for Technology in Education) and NCATE (the National Council for the Accreditation of Teacher Education) and through content and technology standards articulated by discipline specific organizations (e.g., National Council of Teachers of English/International Reading Association; National Council of Teachers of Mathematics; National Social Studies Association; National Science Teachers Association).

To enable our pre-service teachers to acquire these competencies, Chestnut Hill College proposed:

1. to require a beginning course in Educational Technology of all pre-service students
2. to educate the methodology/practicum faculty on the integration of technology into their courses
3. to place pre-service teachers with in-service teachers who have been or are being educated about the use of technology in education (This is directly in keeping with the Pennsylvania General Standards for Institutional Preparation of Professional Educators [proposed], Section I-H which addresses both the quality and importance of field experiences.)
4. to educate in-service teachers about the integration of technology into their curricula so that these in-service teachers and their classrooms may serve as practicum sites for our pre-service teachers
5. in conjunction with the Graduate Program in Applied Technology, to establish and maintain a Technology-in-Teaching Resource Center for in-service teachers so that our pre-service students will always be assured of appropriate placements. (This is directly in keeping with Section I-I of the proposed General Standards which speaks to collaborations with higher education to “design, deliver, and renew effective programs for the preparation of school personnel…”)

In sum, in order for our students to learn to use technology in their classrooms, they must not only learn the technology and design lessons and units incorporating technology, but must also see the use of technology modeled in their practicum sites. Since the lack of appropriate sites remains a serious obstacle to full preparation of our pre-service teachers, by partnering with K-8 sites and educating their teachers, we create opportunities for our pre-service teachers to practice what they have learned.

During the funding period, this project is directly serving approximately 117 pre-service teachers and approximately 10 higher education faculty.

Chestnut Hill College should be able to sustain this initiative after Commonwealth funding by 1) creating a cadre of higher education faculty to serve as the basis for the Technology-in-Teaching Resource Center and 2) by establishing a pool of cooperating in-service teachers who can a) model the use of technology in the teaching of content areas and therefore benefit future cohorts of our pre-service teachers; and b) serve as mentors to other teachers in their school and in the neighborhood.
Actually, Chestnut Hill College partnered with two Philadelphia public schools, two Catholic schools and two private academies to develop a relationship between pre-service and in-service teachers. These schools provide a diversity of populations and promote a variety of teaching and learning styles. Like Chestnut Hill College, all partner schools are located in the northwestern section of Philadelphia and constitute Chestnut Hill College’s “service area”. During the funding period, this project will directly serve approximately 60 in-service teachers and approximately 1550 students in grades K-8. Once educated, however, these in-service teachers will continue to impact pre-service teacher populations from Chestnut Hill College as well as other teacher preparation institutions for many years to come.

Findings

In order to effect institutional change we found that teacher preparation institutions, local school districts and teachers as a sub-culture must all interface with a singleness of purpose. This of course is easier said than done.

The Teacher Preparation Institution

The Department of Education at Chestnut Hill College was more than ready for systemic change. It had recently revamped both of the graduate and undergraduate programs. New course requirements such as “Technology in the Classroom” and “Introduction to Special Education” were introduced while some of the traditional “methods” courses became electives. A two-semester generic methodology course was created. However for technology education to become a part of all of these courses, the department members themselves must be trained. Each of the department members as well as three faculty members from departments that were integral to the teacher training process took part in a course that was designed for them.

It was intended that each faculty member would incorporate these methodologies into their pedagogy thereby serving as a model for the pre-service teachers. This was not an easy process. Some of the faculty members embraced the changes while others were more reluctant. In the end faculty members cooperated in their own manner yet became significantly more skilled than before the course.

The role of the teacher preparation institution in effecting true change has been ignored or underestimated in the past. Local school districts must depend on colleges to provide an infusion of new ideas and procedures as well as the enthusiasm that new teaching staff member bring to the table. If the college faculty themselves are not committed to changing their practices, how can we expect the pre-service teachers to incorporate them into their methodology? At Chestnut Hill the Education Department and the Technology Department have formed an alliance that has been mutually beneficial. Other departments who also educate the pre-service teacher have seen the potential for significantly improving their courses by incorporating technology into their curricula.

We would like to digress for a moment to expand upon our use of the word “technology”. Technology as we use it is more than hardware; it is the Internet, software but also a state of mind. A desire to rethink old procedures and be open to new approaches to teaching which involves the manipulation and digesting of a torrent of new information which cascades over us each day.

The School:

One of the most difficult aspects of this project was to effect systemic change in the planning and implementation of the instructional program. We found that each school had its own unique decision making process in terms of curricular/technological change. As part of the project each school appointed a Link to Learn coordinator to work directly with the College. These individuals served as on-site “experts” to help cut through the school’s bureaucracy and provide a valuable source of information to the college on both suggestions for training for their in-service teachers and also the performance of the pre-service teachers.

However a fundamental question arose, “How does change take place?” Can an outside agency, a college or State Department of Education, encourage an individual school to incorporate technology into its delivery system? As usual we found that the answer does not fit nicely into a pre-determined mold. The outside group can provide motivation, training, and expertise and of course, funds to begin the process. Yet without the
commitment of the principal, who sets the tone for the school, and a core group of respected dedicated teachers who believe in the program change will only occur sporadically and without survivability after the project expires. This finding is not new. A school has its own culture that resists change of any kind. Therefore, we have found that it is equally important to know “who” should be involved as well as the “how” it will or should occur. There must be a schoolwide philosophy which outlines how technology will be integrated into the curriculum for success to be achieved.

The Teachers:

One of the requirements to receive funds for equipment for individual teachers was for those teachers to participate in a graduate course of their choice, which has a technology focus. We found that after they overcame their initial reluctance, they truly found the course to be extremely helpful and motivating. For many of the teachers this was the first course they had taken in many years. We also found that some used this course as a first step to an advanced degree.

The interaction between the pre-service teacher and the in-service teacher in the classroom help to institutionalize the technology changes into the classroom milieu. This forced interaction helped both individuals. The in-service teacher now had to change their methodology to serve as a model for the students and the pre-service teacher saw an actual lesson being taught that incorporated the theory they had been taught.

Implications for the Future of Technology-Education Integration:

The goal of this project was to create placement opportunities for our practicum and student teachers in which they would see technology used, as well as classroom instruction at the college that included technology (in courses other than the single hand-on course). This is essentially a process of changing behaviors, both of cooperating teachers and also of college faculty. We know that meaningful change happens slowly, and only when teachers own the process. This seems to be true in our case, for both groups of teachers.

Cooperating teachers in the six schools

The state made all the funds available to us almost immediately and expected that we would spend all the money and that we would do so quickly. This raised the issue of who made decisions. We chose to offer options to each of the schools and to each of the individual participants, options in courses as well as hardware and software purchases. The process took longer than the state officials seem to have expected. But this process seemed worthwhile to us. It seemed critically important to honor the individual needs of each school, and to move in rhythm with each school to make appropriate and productive decisions.

For instance, we did not create a “one size fits all” technology course for the cooperating teachers. Instead we called a meeting and explained the content of the courses we offered in the Applied Technology program, inviting each participant to choose a course that addressed his or her needs. This meant that some teachers took courses in the summer, while some took courses the following fall. If we think of this program as having duration of fifteen months, this is problematic, because placement sites would not be immediately available for the fall for all of our students. If, however, we choose to envision this program as the beginning of an evolving relationship with these schools, the deliberate pace with which we began allowed for some critical understandings to be established.

The first understanding is that each of these schools has a culture and a history, and that they must make decisions with which they can live. In addition to giving them course options, it seemed important to us to pass the decision-making power on hardware and software to each of the schools. We did the ordering of hardware, but only after the technology coordinator at each school indicated to us what would be required. It took longer to establish a useful base of equipment, but the purchases were all necessary and desirable. In fact our funding came through in February and March, and schools did not have their equipment until September.

Software purchasing followed a similar pattern. We refused to prescribe software for the schools, inviting teachers instead to wait until they each had taken a course, and knew what was available to support their curricula. Again, we used each school’s technology coordinator to oversee this process, to guarantee that teachers did not make redundant purchases. Most software was purchased in the fall. We had offered in April to do presentations for each faculty, demonstrating software and
talking about methods of evaluation. Only one of the schools was ready to take us up on that offer immediately. Other schools needed more time to have the equipment and begin the year, and then requested presentations.

The next understanding is that teachers need time to think about their curricular goals, and consider whether and how technology can be used to achieve those goals. The offer to do presentations for schools will be extended again as we begin our spring semester at the college, acknowledging that teachers may not all be ready to hear information at the moment we choose to provide it. We could ignore this reality, and have our presentations fall on deaf ears, or wait until they ask for a presentation, in the hope that this request indicates a willingness to listen.

**College faculty**

Educating the college faculty has been equally tricky. The grant provided funds to pay ten professors to enroll in Applied Technology courses. Five professors took courses (again of their own choosing) during the summer. This group included adjunct faculty members and professors from other disciplines in the college. Time constraints, professional obligations and just plain resistance have kept five of the full-time education faculty from taking a course and their endorsements of technology in their courses vary from professor to professor. We remind ourselves again that change takes time, and that meaningful change must be owned by the teacher. This lesson is true even when that teacher is a college professor.

We evaluate this program in terms of our long-term goals: providing students with placements in which they see technology used; and integrating technology into our college education courses. Our placements differ among themselves, of course, because the schools in which our students work have differing cultures, and because each teacher is an individual. But we feel secure that the opportunities are more readily available to demonstrate roles for technology in elementary classrooms as a result of this project. Our college courses will also vary in the extent to which technology is integrated in them. This is to be expected.

Moreover, our evaluation of the project is only a snapshot of the first days of the journey, as we begin to create what we think of as a professional development community. This community includes our college, with its teacher education program and applied technology program, and six distinctly individual elementary schools, all working to communicate about best practices and creative approaches to teaching and learning.
USING the INTERNET as a TEACHING TOOL to FIND STATISTICS for USE in GRADUATE EDUCATION

Fannie M. Cox
University Libraries - Ekstrom Library
University of Louisville
United States
fmcox@louisville.edu

Abstract: At the University of Louisville, many graduate students in Education take “Introduction to Research Methods and Statistics,” to meet their program requirements. As a teaching tool, the Internet is being used as a source for finding statistical data sets. The data sets are then utilized to complete various class exercises. While, the assignment sounds simple, it is not as simple as it sounds. Students in graduate school come from different backgrounds in terms of disciplines, level of knowledge, computing or Internet networking skills. Regardless of a student’s knowledge base, graduate students are expected to have a certain level of proficiency. This paper will be helpful to both the educator and students. It will discuss strategies on navigating the Internet to find needed information, how to capture statistics efficiently and critically evaluate an Internet site and the information.

Background

The University of Louisville (U of L) Libraries has a well-developed Information Literacy Program (ILP). “Finding, evaluating, and using information from a variety of resources is the essence of Information Literacy.” (IPL Index Page, 1999) The ILP provides several services to the U of L community of faculty, staff and students. A few of these services are:

(1) Jumpstart Classes are designed to meet the needs of students and the university community in general with finding computer and library resources;
(2) Short Courses are designed to meet the needs of faculty and staff related to computer and library resources;
(3) Research 1-On-1 is designed for individuals who need help with their research meet with a librarian to discuss the best resources for their project; and
(4) Librarian Visit is designed for a librarian to meet with a class and provide effective methods of research.

Another aspect of ILP is the Library’s Liaison Program. The Library Liaison Program at the University Libraries provides U of L faculty with a personal contact in the libraries. This contact, or liaison, can help answer questions about the libraries and inform teaching faculty about new services and products. The Library Liaison Program was established as an on-going partnership with teaching faculty. From this partnership, the libraries hopes to:

• build collections that reflect curriculum and research priorities;
• supply user-centered services;
• integrate information literacy into the curriculum;
• create resource-based teaching and learning programs; and
• encourage lifelong learning.

How does all of this relate to “USING the INTERNET as a TEACHING TOOL to FIND STATISTICS for USE in GRADUATE EDUCATION?” Librarians assist, instruct and inform faculty and students on how to access and use paper and electronic resources available both, in-house (locally) and via the Internet (remotely). In this instance, a Library Liaison to one of the departments in U of L’s School of Education was asked to provide instruction to students in a graduate level statistics class. The professor wanted the students to be able to find data sets on the Internet that could be downloaded into a spreadsheet or Statistical Package for the Social Sciences (SPSS). Clemmitt (1996) said, “good internet sites also give students a tremendous amount of control over data access.” So once students find good sites, they should be able to find data that meets their needs and be able to manipulate the data for various class exercises and projects. The class session was scheduled and the class visited the library to meet with
the librarian, in the Collaborative Learning Center (CLC). CLC is a classroom in Ekstrom Library designed with 25 student computer workstations, Internet access, and a high quality projection and audio system.

Many people have access to the Internet and are amazed at the abundance of information available on the World Wide Web (WWW). In a graduate classroom setting, students come from different backgrounds and are at various stages of their educational program. Someone may have recently received a baccalaureate degree, while someone else is returning for some sort of certification, and yet another, is pursuing an advanced degree, after being out of the field of education or school for several years. Some people may use the Internet regularly, while others may not even own a computer. Regardless of their level of education or familiarity with the Internet, students need to be able to find statistics and manipulate the data for various reasons. Students and educators need to know how to find data sets. While there is no easy or correct way to search for information on the Internet, there are searching techniques that will aid the user in searching the Internet.

The Search

Many libraries have subject guides, which provide students with places to start searching for their information needs. Basically, a subject guide is a list of books, periodicals, and electronic resources including databases and electronic journals that a librarian has reviewed to aid researchers in search of information on a particular subject. On the U of L’s Research Center Web page (Fig.1), anyone can use their mouse and click on the subject of their choice. While this list is not inclusive of everything available in the library or on the Internet, it provides a broad range of subjects to explore. A subject guide can be in either paper or electronic format. An example of an electronic subject guide on the Internet is available at U of L’s Research Center Web page see, (Figure 1), (The Research Center, 1999).

Figure 1. The Research Center is a virtual gateway to resources at the University of Louisville Libraries.

By clicking on a particular subject, from Research Center Web page, the library has provided the patron with basic information on that subject to begin a quest for information. When searching the Internet, it is strongly suggested that the user have a strategy. For a productive search, it is highly advised that students brainstorm a list of words that best describe the subject/topic for the information being sought (Crehan & Teitelman, 1998). These words should define or identify the unit of analysis and they will be used as keywords. It is the keyword that is instrumental in navigating the Internet. Once the keyword(s) have been identified, the search can begin.

Another method used to search the Internet is natural language or free-text searching. This method allows the user to type into the text box provided by the search engine, specifically in sentence form the subject being
searched. It should be noted that there are many types of search engines and they vary greatly. It may also be necessary to go to the help section and modify the keyword or the natural language search. All search engines are not the same, but they have similarities, see (Figure 2), (Internet Search Engines, 1999). According to an online dictionary, a search engine is a computer program that, when executed, retrieves a list of documents based upon the search strategy provided by the user (Webopeedia, 1999). For more information regarding searching and search engines visit the web page www.searchenginewatch.com (Search Engine Watch, 1999).

Figure 2. Web page listing various types of search engines and how they search the Internet.

Finding Statistics on the Internet

Locating statistics on the Internet to download is not a difficult task, but it can be time consuming. It would be helpful for the student to know the unit of analysis and how to evaluate information, before beginning the search. One can be overwhelmed searching the various Web sites given all the available data and the time it takes to determine if what is found is what is actually needed. A list of educational and governmental Web sites has been compiled to serve as starting points to browse and retrieve data sets. These Web sites were chosen based upon the criterion, which will be mentioned later regarding evaluating information on the Internet. Three examples of searches using government web sites for educational data sets are listed:

NCES - http://nces.ed.gov/ > Electronic Catalog > Data Access Tools > National Public School and School District Locator > Data > pick and click on a ZIP file (it may be necessary to use a Helper Application to unzip the file before attempting to save it as text) > open and save as .txt file > Open saved file in Excel

BEST COPY AVAILABLE
Printing and Saving Data

A procedure for printing a report or saving the report as a file depends on the browser or Web site. One may have the option of printing only specified pages of a report, or mailing a document as e-mail to oneself or someone else. Saving a file can be done through the save, save as, or load to disk commands when available. Many reports are in a fixed-width font, based on the 80-column format to provide maximum printer compatibility. These reports can be quite long, so it is advised that you check the length of a report before printing it.

Converting Data to Spreadsheet Format

These instructions are for Netscape 4.07 and Excel 97 SR-2. Procedures may differ with other software applications.

1) Once the full report is on-screen, choose file, save as and save the data with a .txt extension* (e.g. filename.txt)
2) Open the saved file in any text editor (such as Notepad or Simple Text).
3) In Excel, open a file.
4) Open the saved data file.
5) A dialogue box will open up offering methods of converting the text file to a spreadsheet.
6) Choose the Fixed Width/Delimited text radio button (it depends on the Web site).
7) Click next and you will have an opportunity to change the width and placement of the fields. Often Excel will interpret the field widths correctly. If not, you can add a column break by clicking, remove one by double clicking or move one by clicking and dragging.
8) Click next again to have a chance to change a field's data type. Leaving the type as general usually works fine.
9) Click finish and you will have the data in a spreadsheet.

Evaluating Information on the Internet

When looking for statistics on the Internet, one must be careful and evaluate the source of information. As we prepare to use the Internet as a source for finding statistics, we must remember what features makes the Internet, a World Wide Web (WWW) of information. It is a place where the quality of information varies tremendously. The Internet is a place where the lines that define entertainment, advertising, self-promotion and expression are blurred, and this must be kept in mind, when looking for information on the Internet, and this information must be evaluated critically. Five criteria (accuracy, authority, objectivity, currency, and coverage) are listed below that will be helpful in evaluating information found on the Internet see (Table 1), (Web Research Evaluation Checklist, 1999).

Web Research Evaluation Checklist

<table>
<thead>
<tr>
<th>Accuracy</th>
<th>Questions To Ask</th>
<th>Be Aware That...</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Are the sources for any factual information clearly listed so they can be verified in another source?</td>
<td>Almost anyone can publish on the Web.</td>
</tr>
<tr>
<td></td>
<td>• Is the information free of grammatical, spelling, and other typographical errors?</td>
<td>Most Web information is not verified by editors and/or fact checkers.</td>
</tr>
<tr>
<td></td>
<td>• Is it clear who has the ultimate responsibility or the accuracy of the content of the material?</td>
<td>Errors not only indicate a lack of quality control, but also can actually produce inaccuracies in information.</td>
</tr>
<tr>

<tr>
<td></td>
<td>• What is the nature and purpose of the page?</td>
<td>Often difficult to determine authorship of Web sources.</td>
</tr>
<tr>
<td></td>
<td>• Is it clear who is sponsoring the page?</td>
<td>If author's name is listed, his/her qualifications frequently absent.</td>
</tr>
<tr>
<td></td>
<td>• Is there a link to a page describing the purpose of the sponsoring organization?</td>
<td>Publisher responsibility not often indicated.</td>
</tr>
<tr>
<td></td>
<td>• Is there a way of verifying the legitimacy of the page's sponsor? That is, is there a phone number or postal address to contact for more information? An email address is not enough!</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Is it clear who wrote the material and are the author's qualifications for writing on this topic</td>
<td></td>
</tr>
<tr>
<td>Table 1. A Checklist showing five criteria that can be used to evaluate information found on the Internet.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Objective**
- Clearly stated?
- If the material is protected by copyright, is the name of the copyright holder given?

**Questions To Ask**
- Is the information provided as a public service?
- What biases might the author(s) have?
- Is the information free of advertising?
- If there is any advertising on the page, is it clearly differentiated from the informational content?

**Be Aware That...**
- Goals/aims of persons or groups presenting material often not clearly stated.
- Web often functions as a "virtual soapbox".

**Currency**
- Are there dates on the page to indicate when the page was written, first placed on the web, and last revised?
- Are there any other indications that the material is kept current?
- If material is presented in graphs and/or charts, is it clearly stated when the data was gathered?
- If the information is published in different editions, is it clearly labeled what edition the page is from?

**Questions To Ask**
- Dates not always included on Web pages.
- If included, a date may have various meanings:
  - Date information first written
  - Date information placed on Web
  - Date information last revised

**Coverage**
- Is there an indication that the page has been completed and is not under construction?
- If there is a print equivalent to the Web page, is there a clear indication of whether the entire work is available on the Web or only parts of it?
- If the material is from a work which is out of copyright (as is often the case with a dictionary of thesaurus) has there been an effort to update the material to make it current?

**Questions To Ask**
- Web coverage may differ from print coverage.
- Often hard to determine extent of Web coverage.

**Education and government web sites**

The Internet is an excellent source for information. The Web sites listed below do not begin to represent the many statistical web sites that are available on the Internet, but they are a place to start.

Abstract: This paper is a reflective narrative exploring the introduction of a modular in-service programme, using the device of the Hero's Journey (features of which are described). The programme is a response to an Irish government initiative which aims to integrate IT into the education system. Pedagogical and curriculum issues, rather than skills or technical matters, are central to the programme; it thus relies heavily on the inputs of experienced classroom teachers. Modules are taught at many centres both on- and off-campus. These features provide organisational challenges. The Hero's Journey proved to be an effective frame for analysing the experience, with both strengths and difficulties being identified and with the spiral nature of the process facilitating replanning. Reculturation, in Fullan’s use of the term, has been identified as the essence of the programme.

Introduction

In common with many countries, Ireland is seeking to prepare its education system to meet the challenge of technological development. The major response is entitled “Schools IT 2000” (Department of Education and Science 1997, FitzGibbon & Oldham 1998). It has as major foci to explore creative ways in which IT can be successfully integrated into the Irish education system and provide IT professional skill development for at least 20,000 teachers (Department of Education and Science 1997). Since it involves the whole country and seeks to include all teachers and schools, it is an example of a large-scale educational reform. The nature of such reform measures is, as Fullan points out, largely unappreciated; in his opinion what is involved is reculturation rather than restructuring of the institution. The former is a much more difficult task (Fullan 1999).

As part of Schools IT 2000, a National Centre for Technology in Education (NCTE) was set up, one of its tasks being to provide in-service courses in IT for teachers. These courses do not lead to certification, but they have created a demand for certified courses. The Education Department at Trinity College (University of Dublin) was already providing in-service courses in other disciplines, using a flexible modular approach in collaboration...
with regional Education Centres. The same approach was used in designing and running a programme of such courses in IT.

The introduction and implementation of the university programme is explored in this paper. The experience is analysed using the metaphor of a "hero's journey," as suggested by Brown and Moffett for exploring school transformation: "To walk the path of the hero's journey is to leave the state of unconscious innocence and move towards conscious acceptance that we are living in times of chaos, discord and disequilibrium" (Brown & Moffett 1999 p. 58). Importantly, however, such a journey is one of "hope" (Brown & Moffett 1999 p. 1). This metaphor is used as a frame for reflection on the experience of the programme for two reasons; first, it was perceived to offer insights on the successes and failures which occurred; and secondly, it provides a spiral approach, permitting the replanning and subsequent evaluation to become a seamless activity. The spiral nature of growth, both personal and institutional, is highlighted in the seven stages which are specified for the hero's journey (Brown & Moffett 1999 p. 14):

1. Breakdown and the Call: Innocence Lost
2. Chaos and Complexity: This Way Come
3. The Heroic Quest: The Search for the Grail
4. Gurus and Alliances: Companions Along the Way
5. Trials, Tests, and Initiations: Staying the Course
6. Insight and Transformation: Arriving where we Started and Knowing the Place for the First Time
7. A New Call: The Journey Begins Again

1. Breakdown and the Call: Innocence Lost

Breakdown is understood as the loss of unconscious innocence — hence, the recognition of a problem. In the case of the document Schools IT 2000, several sections focus on the need for various kinds of teacher development (Department of Education and Science 1997). As Brown and Moffett point out, "all great mythic quests and journeys represent movements away from the stability, comfort, and safety of the known in response to external opportunities or threats" (Brown & Moffett 1999 p. 41). IT represents both opportunity and threat for teachers, and this phase in the journey might be considered as arising from the sense that breakdown has occurred or is about to occur. The path for the hero is away from unconscious innocence towards enlightened engagement: that is, taking a path of direct experience in which change is confronted directly. The Call, for the government department, is the recognition that the education system needed to integrate technology into the curriculum, and the realisation that this has considerable resource implications: hardware, software and (crucially) teacher preparation were all necessary. Courses are now being offered by many institutions, including Trinity College, specifically the Division of In-Service Education within the Education Department. This is the unit the work of which is critiqued in the paper.

The loss of innocence for the Division was the recognition that it was not meeting the needs of teachers in the "Information Age"; certified courses which would build on the government-sponsored courses were required. The Call was to provide appropriate courses. In particular, there was a need to fill a perceived gap in the market. Other universities were offering courses focused on skills (proficiency in the use of applications packages) or technical expertise (in computer science and machine maintenance). The Trinity College modules were intended to complement, rather than compete with, these courses; in particular, they were to be aimed at teachers with an interest in curriculum and the teaching/learning environment, and with a curiosity as to whether these might be enhanced by use of IT. Thus, the content was to reflect curricular and pedagogical issues, with the aim of increasing capability: capacity building rather than product transfer (Fullan 1999).

To set the context for exploration of the "hero's journey," some organisational features of the programme should be noted. The main outlines for the modules were created by a small steering group with members drawn from three sources: the University Education Department, one of the regional Education Centres which collaborates extensively with the Department, and the ranks of IT educational consultants (teachers with extensive and recent classroom experience in the area but currently working in advisory or support roles). The first three authors of this paper are members of the group. Seven modules were outlined originally: Software and Resource Evaluation, Selection and Use; Communicating with IT; Curriculum Design and Delivery; Presentation using IT; Authoring for Multimedia and the Internet; Planning for IT; and Management Uses of IT (http://www.tcd.ie/Education/In_Service/index.html). It was intended that each module would be developed further by its own team, typically involving members of the steering group and practising teachers with particular expertise in the area concerned. The modules were to be taught at a variety of sites around the country —
reflecting the Division's commitment to an "outreach" model that has not been common in Ireland — and by locally-based teachers as well as Division personnel and those involved in module design. Teaching and learning approaches would be innovative, to allow for creativity as mentioned earlier. Innovation would also be reflected in the style of assessment, which would not be restricted to the production of papers in standard academic format (the norm for assessment for graduate diplomas in the University), but rather would reflect the use of IT and the participative and collaborative approaches that the modules were designed to foster. The remaining sections of this paper examine how these intentions were implemented.

2. Chaos and Complexity

The use of the two terms “chaos” and “complexity” in describing the second stage of the hero’s journey is interesting, especially in the light of Fullan’s assertion that they are the same thing. He prefers to use the latter term, considering that “the new science of complexity essentially claims that the link between cause and effect is difficult to trace, that change (planned and otherwise) unfolds in non-linear ways, that paradoxes and contradictions abound and that creative solutions arise out of interaction under conditions of uncertainty, diversity and instability” (Fullan 1999 p. 4). The Division’s experience echoes this understanding. With hindsight, it can be seen that the inherent complexity of the task guaranteed a measure of chaos. Brown and Moffett quote Bennett who describes the chaos present in schools as “the multitude of variables that can affect quality implementation of a sound educational innovation, chaos is doing too much too fast so that nothing is done well or connected to anything else. Chaos is the lack of a sustained focus” (Bennett, in Brown & Moffett 1999 p. 70). A pertinent question raised is: “How is it possible to improve the quality of teaching and learning ... [with] unrealistic time estimates?” (Brown & Moffett 1999 p. 73) (see Hargreaves 1995).

The In-Service Division had over ten years' experience of organising inservice programmes for teachers. Despite this experience, it was not able to anticipate fully the demands associated with the effective delivery of professional development in the area of curricular integration of IT. These included the need for the Division to engage in: curriculum design, software identification, software licensing and procurement, hardware specification, networking specification, identification of local venues and technical support, tutor identification and induction, identification and access to learning resources for participants (such as software and web-based resources), and identification and dissemination of assessment procedures.

Moreover, time estimates did indeed prove unrealistic. The seven modules listed above were outlined in winter 1997-98, and teaching commenced in Summer 1998. At Education Centres around the country, there was an immediate demand, not only for individual modules, but also for sets of four different ones, so that teachers could complete a diploma inside one year. This, in turn, meant that a larger team of lecturers (“tutors”) than envisaged had to be set up. In the first year of implementation, twenty nine modules were offered at seven sites, both on and off the university campus. This caused difficulties. For example, production of documentation was rushed; tutors were appointed in haste, without time for proper induction; designated computer teaching spaces were not available as promised; internet connections were not in place. These can be viewed as examples of external chaos. Examples of internal chaos would include, for the tutors, conflicting emotions and loss of focus when encountering organisational and technical difficulties; for the students, confusion with regard to the nature of IT in education (perhaps perceived as an efficient mode of teaching but encountered as a series of technical problems) and the role of the tutors (expected to be “experts” but not necessarily more expert than some of the participants, especially at dealing with the technical problems).

In this phase it is also necessary to confront the “shadow” elements within an organisation. These are defined as “unacknowledged and covert patterns of behavior that are in competition with the formal, overt components of a business or educational organisation” (Brown & Moffett 1999 p. 60). This includes the extent that the stated purposes or actual reality are at odds with the declared values, and the acknowledgement of limitations such as lack of knowledge and possibly lack of will. An example of the former would be the
contradiction between a declared aim of the Division, “to enable teachers to reach their potential” (as stated in the Students’ handbook), and the reality of insufficient attention being given to providing support for completion of the assignments. This was not sufficiently addressed by the Division initially. Perhaps this exemplifies the need for teacher educators to change their habits of practice towards a new model of professional development as outlined by Stein et al.; for example, a shift is recommended from “short duration with bounded personal commitments” to “longer duration with more open-ended personal commitments” (Stein et al. 1999 p. 244).

Because of the nature of the programme, assessment was always going to be a challenge. As indicated above, the course designers wanted to use a variety of modes, reflecting the innovative philosophy of some modules. Given the wide range of topics, tutors and conditions of teaching, it was difficult to ensure equality of standards; in particular, tutors without experience of third-level teaching were “thrown in at the deep end.” (In fact, it can be said that a side journey emerged; this was the development of the tutors, especially in relation to assessment.) Moreover, the fact that modules were being run at the same time as the national — non-certified — courses for Schools IT 2000 led to some confusion. Because of their experience of non-certified courses, a number of students queried the need to produce assignments, suggesting that attendance would be sufficient to obtain credit.

3. The Heroic Quest: The Search for the Grail

The vision quest, in the words of Brown and Moffett, is “embodied in our search for ways to translate all that we now know about quality curriculum, instruction and assessment into the daily lives of schools” (Brown & Moffett 1999 p. 82). The underlying aim of the Trinity College Education Department in seeking to introduce IT is that of many educators: to address the needs of increasingly diverse student populations and the complexities associated with the increased demands made on education by society. Finding the way in which this can be achieved can be equated to finding the Grail (see Fullan 1993).

The vision was initially outlined by the small steering group, so — contrary to the suggestion of Brown and Moffett — it was not developed collaboratively with the whole group of tutors. However, as “vision building is an open-ended, dynamic process” (Brown & Moffett 1999 p. 84), tutors were able to input their ongoing experience as part of subsequent group meetings, and thus claim ownership of the vision for themselves. This, together with the fast-changing nature of the discipline, has meant that course content has evolved continuously in the period. A contributory factor has been the continuing improvement in computer literacy of students entering the modules. An important aspect of the vision driving the quest was that it should address curricular and pedagogical, rather than technical, interests, as described above; while this remains dominant, it is now possible for some more technical modules (for example, on advanced web authoring) to be introduced, without contravening the spirit of the programme.

Altogether, therefore, it was possible for the process to be viewed as “hopeful,” another attribute of the Grail quest. Five recurrent patterns for this phase were revealed (Brown & Moffett 1999, Senge 1990):

a) personal vision building as a sacred commitment — once sure of our vision, we need to stand up for it;
b) shared inquiry as a cornerstone of the successful vision quest — no one can achieve the vision alone, and as it is a process, needs to be subject to constant inquiry;
c) self-mastery as the ultimate jewel in the lotus — all need to be dedicated to self-mastery without which it is not possible to move from unconscious innocence to confront the realities of chaos and complexity;
d) the capacity for collaboration as a prerequisite to achieving the vision — team skills are essential, and also to be able to stand aside from the team if necessary;
e) vision and the “razor’s edge of paradox” — to walk on the razor’s edge is to be balanced between following the vision and encountering opposition and obstacles.

These patterns were present in the tutors’ group, and were perceived to be developing to varying extents within the different class groups of students.

4. Gurus and Alliances: Companions Along the Way

An important part of the heroic journey is the acceptance that personal limitations require reaching out to companions, including wisdom figures, who embody expert knowledge and insight. The Trinity College in-service operation relies heavily on the participation of such colleagues from outside the university. For the IT courses, it was hoped that experienced classroom teachers would do most of the lecturing. Selection of tutors
presented some difficulty; the lack of relevant qualifications meant that many excellent practitioners of IT in the classroom were not formally qualified to teach in the programme (a Master's or higher degree being required). Initiation of the tutors' group, which maintained regular contact using email as well as having formal and informal meetings, was crucial. Members became "gurus" for each other at particular times. Collaboration was the norm, and tutors on a module in one centre shared their experience, presentations, notes, worksheets and other materials with a newer team in another centre. Companions along the way also included books — notably (Grabe & Grabe 1998) — articles, websites and other non-personal sources of information. Also, a model of collaboration as being the norm for educators was being presented to the students.

The students — the teachers attending the courses — are also companions who travel with us. It is envisaged that tutors and students together will be agents of change in the school system.

5. Trials, Tests and Limitations: Staying the Course

This stage recognises the difficulties involved. Those encountered at the beginning were outlined in section 2. Some touchstones suggested by Brown & Moffett are very useful in this context: problems are natural and inevitable, and learning occurs at the edge of chaos (Brown & Moffett 1999 p. 126 ff.).

To stay the course, a systems view must be adopted. One of the difficulties in offering free-standing modules, rather than intact programmes which are the Irish norm, is the higher rate of drop-out that tends to occur. Initial evidence suggests that students are staying with the programme, although a worrying factor was the lower than hoped-for number of assignments submitted (201 out of 527 registrations). In all, there were 29 modules, and sixteen diplomas were awarded in October 1999. More will presumably follow, as students have three years in which to complete assignments. Five students who had previously taken other modules qualified to enter the (follow-up) Master's programme (eight modules completed, with a suitably high average grade).

One aspect raised by Brown and Moffett is that of burnout — following John of the Cross, they term it "the dark night of the soul" (Brown & Moffett 1999 p. 125 ff.) — regarding initiative overload and program proliferation, resulting in cognitive disconnects and despair. "Giving up" did occur. Some tutors have chosen not to present during the first term of 1999/2000 academic year. Despair however, was not a contributory factor in their decision; rather, it was the reality of undertaking a full-time teaching job and a part-time tutoring one as well. The challenge to bring about change and transformation in the education system remains with them. In the drive to meet the needs of the students, insufficient care may have been taken of the tutors, for example with regard to the provision of 'amulets' (which could be as simple as encouraging them to say 'no' to requests for more teaching!) to assist them in their roles. New structures are being explored.

6. Insight and Transformation: Arriving Where We Started and Knowing the Place for the First Time

The hero's outcome is the arrival transformed at the point of origin, but knowing and contributing to the place "in a new, more fully conscious way." We hope that, as for a hero, our experiences have equipped us, and our students, with "insight, wisdom, efficacy and commitment" (Brown & Moffett 1999 p. 146). It remains to investigate the extent to which this is the case.

Students were invited to submit an evaluation form, which explored their perceptions of the lecturer, the venue and the suitability of the content, at the end of a module. Of the evaluations received, comments were very positive regarding the teaching, content and timing of the modules; the negative comments related to the technical difficulties which plagued the first modules in particular. Unfortunately, however, the responses were too bland to support further analysis. In many ways, the assignments presented for assessment were more revealing regarding the quality of understanding and level of the attainment of the students. Overall, the quality
of assignments increased as lecturers learnt to modify the task set in the light of their experiences. Several of the assignments reached a high enough standard to support a proposal that they should be made available to other teachers on a website. Students' appreciation of the difficulties of maintaining heavily-used equipment to a high standard of functionality, especially in regard to web connections, grew during the period. Indeed, to the question "what other content should be taught?", a common answer was the skills to maintain a networked system in a school. This lies somewhat outside the scope initially envisaged for the modules, but it is being addressed in a parallel Master's degree programme introduced in Autumn 1999 as a joint initiative between the Education and Computer Science Departments (http://www.cs.tcd.ie/courses/mscitedu), and co-ordinated by the fourth author of this paper.

Further work is planned on assessment and on the development of new modules to reflect the ever-changing field, possibly incorporating the use of web-based discussions and video-conferencing to integrate more local expertise with that in the university and to support students when doing their assignments. It is hoped that the most interesting projects will be made available to other teachers through either the College's web page or the NCTE site, Scoilnet ("scoil" being the Irish for "school"). One possible indicator of success to date is that modules very similar in scope and content to the Trinity ones are now being developed by NCTE.

One conclusion that can be reached is that the programme, and of course those of other institutions, has resulted in the establishment of nuclei of educationalists, critical and analytical of the role and potential of IT in education in the curriculum, around many of the Education Centres around the country. This is in accordance with the purpose of the hero's journey. The legacy of the transformed heroic educator includes being able to approach change fearlessly, to take responsibility for our actions, to know the darker side, to be reinvigorated regarding their role in education and their teaching, to know that we need others and to share with others, and to be aware of the need for resiliency: that is, to take care of ourselves.

7. A New Call

A temptation in undertaking a journey may be to cling to ways that are traditional and comforting and in some respects that happened in the planning and initial presentations of the modules. However the desire to facilitate the type of professional development experience which genuinely impacts on classroom practice has led to a realization that what is necessary is not simply an upskilling exercise but a re-envisioning of teaching and learning and a consequent reculturation of students, tutors and university (Fullan 1999). Students have had to be prompted to go beyond the understandable desire for quick-fix solution and concrete applications for the classroom, and to reflect on the underlying models of learning. Tutors, as a necessary pre-requisite to dealing with the complexity of the teaching task, have had to develop collaborative skills such as peer-learning and team-teaching. The university has had to review its models of assessment to take account of the new media and different modes of presentation.

As the first cohort of IT students proceeds to study for Master's degrees and new groups come forward to take up the modules (established and new), the cycle starts afresh and there is a new Call. We hope that we are approaching the next cycle with more appreciation of the tasks involved, but with the same sense of excitement and hope that promoted the original enterprise.

Classroom-based Technology Training for Inservice Teachers

Susan M. Gallagher, Ph.D.
Assistant Professor
Department of Professional Teacher Education
University of Nebraska at Kearney
USA
gallaghers@unk.edu

Abstract: An alternative technology training model for non-computer using inservice teachers provided teachers with classroom-based technology training. The training model included access to computers in the classroom as well as a technology mentor/support person for half a day each week. The teachers made significant progress in acquiring the technology skills to use computers and Internet resources for instruction in class. While highly successful for the teachers involved, the amount of resources required for this training model make it an unlikely training model for replication.

Background

Schools are acquiring computers and wiring for Internet access across the country. Along with the challenge of acquiring the equipment to make computers accessible as learning tools in the classroom, is the challenge of training veteran inservice teachers to integrate the new tools into their instruction. A common approach to providing inservice teachers with training is the "one-day workshop." Students are dismissed from classes and the teachers attend a workshop to learn computer skills. The content provided to teachers in these training workshops varies greatly, however, one consistent observation is that most of the workshop time is spent on learning the operating procedures for the computer without much time to focus on how to integrate the tools and resources into the curriculum. Additionally, learning procedures requires practice and rehearsal. The "one-day workshop" format does not provide the conditions necessary for this type of learning. Without opportunities for practice (or required practice), the teacher is not likely to remember the workshop content. Teachers are often frustrated by the low retention rate for the new skills from workshops in this format. Variables such as access to a computer following the training and the relevance of the training content to the teacher’s curriculum are important factors in determining the retention rate of the workshop.

In an attempt to provide teachers with a more effective training format, a training model that focused on providing training weekly in the classroom setting was developed. The training model addressed many of the concerns or frustrations that teachers reported experiencing while trying to integrate technology into their instruction. To address the access issues, the model provided five student workstations, a software budget to purchase curriculum appropriate resources, Internet access, a color printer, a digital camera, a laptop computer for the teacher, a LCD projector, and a technology mentor/support person for half a day each week in their classroom for each teacher participating in the project. The goal of the project was to provide training, model the integration of technology tools into instructional strategies in the classroom and then have the project teachers share successful technology lessons with other teachers at their grade level or content area in the participating schools. The project targeted veteran, non-computer using teachers at four different elementary grade levels and four different core-curriculum areas. The project was funded by a grant from a state agency and was designed to run for two academic years.

Research Procedures

This case study research describes the experiences of eight inservice teachers who participated in a classroom-based, inservice, technology training model that was implemented for two years in four school districts in a mid-western state. Data was collected through a series of surveys and interviews during the two-year period of
the project. The surveys used a three point Likert scale with one being low and three being high to determine the value, comfort level or confidence level for the teacher responses. The project teachers responded to interview questions via e-mail throughout the two years of the project. All of the training provided focused on instructional uses for the technology tools as opposed to classroom management or personal skills such as grade book programs or e-mail. The technology mentor also provided troubleshooting and technical help for the classroom teacher. The technology mentor was also interviewed at the conclusion of each year of the project. The project teachers could also have one half day of release time a month to plan and work with the mentor outside of the classroom setting if desired. The teachers learned about the computers and Internet resources by using them for instruction rather than in workshop settings. The series of surveys were given to both the project teachers and the non-project teachers in the participating schools. The results were compared between the two groups of teachers to determine the effectiveness of the training model.

Findings

The project teachers reported increases in their personal technology skills such as confidence in using and understanding technology vocabulary. By the end of the two-year project, teachers increased their understanding of technology vocabulary from a mean of 1.5 to 2.1 on a three-point Likert scale. Their comfort level using technology vocabulary also increased from a mean score of 1.1 to 2 on the same scale. The project teachers increased their confidence level when using technology outside of the classroom from a mean score of 1.7 to 2.6 on the same scale. Likewise, the teachers reported a higher confidence level at a mean of 2.4 up from 1.3 when using technology in the classroom for student instruction. The number of classroom lessons using technology they taught also increased from a mean of 1.8 at the beginning of the project to 4.6 after the first year and declined to 2.8 the final year of the project. The project teachers also increased their confidence in troubleshooting skills and reported helping other teachers in their schools with technology questions or problems. When asked how many technology lessons they had the opportunity to observe being taught, the project teachers reported an increase from .4 to a high of 6.4 after the first year of the project.

The teachers reported an increase in the number of computer applications they used from 12 total applications at the beginning of the project to 39 total applications at the end of the project. Participants also revealed the importance of providing modeling and classroom management strategies for using the five student workstations. Teachers increased the different types of instructional strategies they used with the technology resources in the classroom. The eight project teachers reported using a total of 8 instructional strategies for using computers for instruction at the beginning of the project with an increase to 30 total strategies by the end of the project. The teachers were asked to rate the value of eight different strategies for learning technology skills. The teachers consistently rated “someone to show me how” as the most valuable form of technology training experience. Finally, the project teachers reported an increase from a mean of 1.8 to 2.5 for their comfort level with the classroom-based technology training. The rating for the value of having the mentor in the classroom while they learned how to teach a technology lesson increased from 2.1 to a high of 2.75 after year one. The mean scores for the project teachers increased in every category over the two-year project. The non-project teachers who were surveyed did not show any consistent growth except in the use of the Internet for information searches and many times the mean scores remained at the same level for all three rounds of the survey.

Conclusions

All of the project teachers made more progress in integrating technology tools and resources into their instruction than did the non-project teachers. However, given the fact that the project targeted non-computer using teachers, they should have reported gains of some degree regardless of the effectiveness of the model. Since the project teachers would have included teachers who were already using technology, the results of those surveys would not have shown as much growth during the two years of the project. Since the training was based on using the computers for instruction, the teachers learned technology skills required for integrating the tools into instruction. Lessons focused on instructional activities to meet curriculum objectives in addition to more typical student productivity projects.

The teachers were more inclined to plan and teach lessons that used the technology resources available in their classroom rather than using computer labs available in the school. The majority of project teachers had little
difficulty in producing weekly classroom lessons or activities for their students. Usually there is a period of personal productivity as the teacher practices the skills until they have a comfort level that allows them to use the computers for instruction. Most of the teachers seemed to successfully move past this stage, but two of the eight project teachers were often hesitant and did not initiate their own classroom lessons using technology. They relied more heavily on the technology mentor to generate and teach the lessons each week. Comments from the teacher interviews reinforced the importance of being able to watch technology lessons modeled in the classroom.

The difficulties the training model encountered were the amount of time required for the teachers to learn basic machine skills and the amount of technical support required. The rate at which the teachers progressed in their technology integration was varied among the participants and appeared to be related to the personality of the individual teacher. Most viewed the opportunity in a positive way and made significant progress. Teachers who had limited time to invest due to coaching responsibilities or who were closer to retirement did not make as much progress during the project as the other teachers. The teacher's perceptions of the training model varied from being viewed as an opportunity to an additional obligation once a week.

There were problems maintaining the computers in some of the classrooms. Five of the classrooms were Windows platform machines and three were Macintosh machines. The Macintosh machines were literally maintenance free and reliable during the project period. The teachers in these classrooms were able to plan lessons without the worry of technical glitches that might interrupt or ruin the lesson. However, the brand of Windows machines purchased for the classrooms were unstable and frequently required troubleshooting, technical support, and repair above the level of the teachers. All teachers were concerned about maintaining their classroom technology activities without continued technical support after the project ended. The lack of adequate technical support in instructional settings is critical to empowering teachers to integrate technology resources into their teaching.

Summary

While all teachers made significant progress in integrating technology tools into their instruction, the classroom-based training model is extremely resource intensive. It requires providing a "model" technology classroom with equipment as well as support personnel for the teachers. The resources required to replicate the model probably make it impractical to be implemented in most school districts. Continued evaluation of the role of the project teachers in their school should be followed to see if they continue to share their teaching strategies and skills to help other teachers in their schools move toward integrating technology tools into their instruction. If this activity takes place in the schools, then the dissemination value in sharing successful instructional strategies for using technology tools in the classroom might make it worth the investment in resources.
Transforming Teaching Practice with Technology: Incorporating ISTE Standards and Performance Assessment in a Constructivist Approach to Graduate Teacher Education

Abstract: This paper analyses the importance of integrating appropriate technologies into graduate teacher education programs in an attempt to encourage the transformation of teaching practice into a form appropriate for the new millennium. It describes a site-based, graduate teacher education program based on a constructivist learning model. The importance of including in the program recognized technology standards; situated software training; technology based information management, problem solving and communication processes; and the integration of technology into the curriculum is stressed. The paper discusses technology training that assists graduate students to develop abilities to effectively conduct research using electronic information retrieval systems; to utilize technology to analyze, interpret and represent research data; to appropriately incorporate technology into classroom practice; and to utilize presentation software to communicate effectively with students, colleagues, parents and the public. Various types of performance assessments are discussed that require the demonstration of the inservice teacher's technology competencies.

Introduction

The use of computers and the Internet became a central feature of life in the final decade of the twentieth century. Schools saw a dramatic growth in the use of this technology from computerized grading systems to instructional games and simulations. Effective use of technology by teachers enhanced the teaching and learning process (Jonassen 1996; Kauchak & Eggen 1998). Educational technologies became an essential part of the instructional process (Teachers and Technology 1995) and helped teachers and students to restructure learning to a more meaningful, more individualized experience (Knapp & Glenn 1996). Many knowledge instruction classrooms have given way to knowledge construction classrooms in which technology plays a major role in assisting the teacher to engage and motivate the learner (Fisher, Dwyer & Yocam 1996; Kauchak & Eggen 1998).  

Technology skills and knowledge empower not only teachers but also students in their educational endeavors. Technology has allowed a much more flexible, creative learning environment where students are able to pursue their individual interests through the exploration of real-life problems and issues (Knapp & Glenn 1996). Further, students' acquisition of technology skills and knowledge in the school setting provides a basis for their later success in the technology age of the 21st century.

Undergraduate students are now graduating from teacher education programs that integrate technology into the program curriculum. However, many inservice teachers completed their initial degree at a time when little or no technology was incorporated into the program. Of these teachers, many have had minimal inservice activities or taken few if any courses related to technology in education. It is therefore important for graduate teacher education programs to address the development and enhancement of teacher technology competencies.
Background

The need to increase inservice teachers' technology competencies was one issue considered five years ago when a site-based version of The Master of Education (M.Ed.) in Curriculum and Instruction was developed at Wichita State University. Created for classroom teachers and other educators with responsibilities for improving curriculum and instruction, this program was designed to develop dynamic, reflective practitioners capable of monitoring and improving their own practice through the application of educational theory and research. A crucial component of this new site-based program was the role played by information technology in the process of graduate student learning.

Now in the fifth year of operation, the site-based M.Ed. program has been made available to 15 different cohorts at 10 off-campus sites with 280 graduates as of the end of the Spring semester, 1999. Another 240 students are currently in the program with 119 scheduled to graduate by the end of Summer 2000. Master of Education students enroll in a two year core of 24 semester credit hours with a cohort of between 30 and 40 students.

Each site-based program is taught by three facilitators, one from the university, one from the host site and a third person from the field who complements the expertise of the other two facilitators. Throughout the program, a heavy emphasis is placed on reflection on practice and action research. Students work on a variety of classroom, school and district level projects to improve curriculum and instruction. Projects may be conducted by an individual, by small groups from the cohort, or by a collaborative group comprised of at least one M.Ed. Curriculum and Instruction student along with parents and colleagues such as teachers, principals, curriculum advisors, and school curriculum and instruction teams. Project topics, identified by the student, focus on appropriate ways to address needs, concerns and questions about one's own personal classroom practice, school organizational patterns and school-community issues.

This paper discusses one of these site-based M.Ed. programs situated at a sixth grade center. The school’s library and adjacent 30 terminal computer lab is used for weekly class sessions and computer lab activities. The remainder of the paper, then, describes the approach taken at this site to integrate technology into the program.

Incorporating ISTE standards

There are six program goals with 29 program outcomes for the Master of Education in Curriculum and Instruction. The program goals state that graduates of the program should be able:
#1 to identify, analyze, and explain (a) successful curricular models and instructional strategies and explore the basis for their success, and (b) curricular and instructional problems impeding the improvement of learning and teaching in classrooms and schools, and propose sound solutions.
#2 to monitor, evaluate, and suggest means to improve instructional practice, including the evaluation of educational outcomes and programs.
#3 to assume responsibilities for the development, implementation, evaluation, and revision of curricula or programs of study in particular disciplines and/or for particular populations.
#4 to locate, evaluate, interpret, and apply appropriate research and scholarship to the study and solution of practical educational problems in curriculum and instruction.
#5 to plan and conduct action research, using sound theory and appropriate research designs, to investigate educational questions related to the improvement of curriculum and instruction.
#6 to demonstrate professional leadership skills and continued professional growth in curriculum and instruction.

To achieve the program goals, students are required to gain an understanding of technology concepts, operations, and applications; and the possibilities for the use of technology in the classroom. Additionally, students must develop and use a variety of technology skills to conduct research and give professional presentations to various audiences. The program uses the International Society for Technology in Education (ISTE) foundation standards to guide the development of the students' technology understandings and competencies. These standards include eighteen different technology standards classified into the three categories of a) basic computer/technology operations and concepts; b) personal and professional use of technology and c) application of technology in instruction.
Technology training in the program

Technology training begins in the first semester of the program with lab activities led by the instructional coordinator from the host district. During regular class time, students select labs that they feel are relevant for them, to learn to use e-mail, the Internet, Microsoft Word, Excel, Access, Powerpoint, and HyperStudio. These lab training opportunities continue throughout the two year core program in addition to individual tutoring sessions as needed.

Students also go on campus to be trained in conducting electronic searches. This training is led by library personnel at the Wichita State University main library. The following week after this training, another class period is spent in the library where students research a self-selected topic for a literature review project. It is expected that they will put into practice the skills gained in the previous week to use available electronic search resources. Students are further expected to complete electronic searches for other projects during the remainder of their M.Ed. program.

Technology and student research

After learning their way around an automated library system and gaining the skills of electronically accessing information, students research curriculum and instruction topics and issues relevant to their classroom practice. The use of software such as Microsoft Word, Excel, and Access, is also integrated into the students' action research projects. These software programs help students to analyze, organize and report the data they have collected. With them, students make tables and graphs that are used for poster presentations, in research papers, or in multimedia presentations that are developed to share research findings.

Technology and student communication processes

In between class meetings, students communicate via e-mail with course facilitators concerning course and program requirements; and with other students about projects being completed collaboratively. The usage of e-mail communication has increased dramatically over the last four years. In one of the first 1995 cohort groups, all of the students received e-mail addresses from WSU and were encouraged to use e-mail to communicate with the facilitators and each other. At that point roughly 20% of the students made use of it for program communication.

However, in the most recent cohort all but four of the forty students already had e-mail addresses before entering the program. E-mail is used on a regular basis to communicate general course and program information to all students. Additionally, almost half of the students already have utilized e-mail to communicate with one or more of the facilitators.

Integration of technology into curriculum and instruction

Technology is viewed by teachers as a viable method to enhance the learning and teaching in their classrooms (Kauchak & Eggen 1998). Teachers' action research projects focus largely on ways to better the education process for the students in their classrooms. Improving curriculum and instruction in any subject level at any grade level, often includes the integration of technology into existing curriculum (Knapp & Glenn 1996). Students conducted action research on technology topics such as using computer generated graphic organizers for reviewing and testing; creating a Web site for the school district and community; effectively using that one computer in the classroom; and using the Internet to benefit students' learning.

One teacher commented in her end-of-semester reflection paper that she had most enjoyed her action research that explored how technology impacts the mathematics classroom. She commented, "I integrated technology to a certain extent, into my math classroom before I began my study. But I had never replaced an entire unit with an Internet project. What amazed me the most was how well students carried the concepts over into the next unit."

Another context in which technology can play an important role is when teachers have occasion to serve on school Quality Performance Assessment (QPA) or accreditation committees for their school. Students
in the M.Ed. program have utilized their acquired technology skills to construct PowerPoint or HyperStudio presentations for the final review process. They also create charts and diagrams to use as displays, as well as school brochures to distribute to the community, parents and the accreditation review panel.

Performance assessment of teacher technology competencies

Students are required to complete 3 projects in each of the four core semesters of the program. The presentation of all of these projects requires the use of various technologies, thus creating the context of performance assessment for every project.

Projects are reported in four different ways. Following the more traditional manner of presenting research, one project per semester is written as a paper. This requires the use of computer software such as Microsoft Word and Endnote to write and format the paper; and Excel and Access to organize data into graphs and tables for insertion into the paper.

A second way in which projects may be reported is through a poster presentation. Students again may use software to make graphs, tables, titles and labels for their poster. Some students use a digital camera to record events relevant to the project, and then print the photos to display on their poster. A requirement for the poster presentation is that a handout of some type with a summary of the information be available with the poster. This handout often takes the form of a brochure created with software such as Publisher98.

Students can also present their projects orally. Often, students use technology to create visual aides similar to what might be used in a poster presentation. Additionally, video clips, filmed and edited by the student, may be used to enhance an oral presentation.

Finally, at least one multi-media presentation of a project is required during the four semesters of the program core. This requirement is usually completed during the third or fourth semester when students have acquired advanced technology skills.

A grading rubric has been developed by the site facilitators for technology presentations. The rubric shown in Figure 1 delineates for students the competencies required to gain a satisfactory rating for the presentation. A student's ability to successfully complete a technology presentation is based to a large degree on the student's attainment of the competencies set out in the ISTE teacher technology standards.

Conventional Standards for Technology Presentations

- True multi-media, two or more types of media in the presentation
- Used the Internet as a resource and credited the information used appropriately.
- Presentation complements but does not distract from the main idea or theme.
  (e.g. sound, graphics, video, etc.)
- Presentation layout is visible to all audience members
- Organizational skills are apparent in the planning for the final presentation
  (e.g. storyboards, etc.)

Rating scale (Circle one)

4 - Creates a product that exceeds conventional standards.
3 - Creates a product that clearly meets conventional standards.
2 - Creates a product that does not meet one or two of the conventional standards.
1 - Creates a product that does not address a majority of the conventional standards.

Figure 1 A rubric designed by program facilitators to assess student technology presentations.

Student insights into technology training and application

Evidence of the successful integration of technology into program structure has been evident from student reflections written at the end of each semester. Many of the students describe the initial self-doubts they had concerning their ability to become technology-literate. However, technology training sessions, individualized tutoring, and the completion of projects requiring the application of technology skills empowered the graduate
students with technology. Comments like the following testify to the fact that the program component of ongoing technology training and application greatly enhanced the students' competencies and positive attitudes concerning the use of technology for their professional development as well as in their classrooms.

“I enjoyed the library research this semester immensely. I have implemented several ideas in my daily classroom schedule that were discovered in the articles...My students gained quite a bit from my library research - whether they wanted to or not...The time spent learning about the various computer programs was extremely beneficial...I feel much better about the technology presentation we will be doing next semester.” Renee

“Another exciting project I worked on this semester was a PowerPoint presentation. After taking all the computer classes last semester I was able to easily present my project findings to the class.” Felicia

“Over the past two years, I have gained many important technology skills that have proved useful to me in this program and in my classroom too.” Thomas

“With the presentation of my research using PowerPoint..., I provided professional leadership and continued my personal professional growth.” Barbara

“Learning to use the computer system at WSU, ERIC and LUIS were important first steps in completing our first literature review... At first using WSU's library seemed like torture!! But now I feel much more confident about being able to walk in and access the information I need to research a topic.” Evelyn

Summary

This paper discussed how one Master of Education program successfully incorporated learning experiences to advance inservice teachers' acquisition of technology knowledge and skills identified in the ISTE foundation standards. It explained how lab activities and university training sessions are used for group as well as individual technology knowledge and skills tutoring. It also discussed the various types of performance assessment, required as part of the coursework that provides a venue for the students to demonstrate these competencies.

The authors wish to thank David McDonald and Darla Smith from Derby Unified School District in Kansas, for their suggestions and advice in the writing of this paper. They have served as co-facilitators since the beginning of the M.Ed. in Curriculum and Instruction site-based program, and have greatly contributed to the success of it with their professional expertise and innovative ideas.
ABSTRACT: The rapid changes in language learning involving technology of the last decade are having a great impact upon efforts at supporting up-to-date teacher training for language instruction. Due to tremendous advances in Multimedia-Based Content (MBC) and Technology-Enhanced Language Learning (TELL), especially those involving the World Wide Web (WWW), learners of foreign and second languages are pursuing self-paced, interactive study in the context of formal instruction. This paper presents background information, outlines important developments, and discusses problematic issues in language learning technology as they have an impact on teacher training.

INTRODUCTION

Owing to the extremely rapid, widespread deployment of computer technology in such a relatively short time, there have been few publications to date which discuss the changes necessary in teacher training programs due to this remarkable transformation. The references presented in this paper do show that the current research on technology in language pedagogy is enlivened by the creativity of individual practitioners, who then reflect upon their use of MBC and TELL. This paper builds on the two most recent and valuable contributions by Kassen & Higgins (1997) and Scott (1998). The ideas offered here are the synthesis of practice and reflection, which itself is a key component to training teachers to effectively use technology. Reflection on practices improves them (Kassen & Higgins, 1997). Kramsch & Andersen (1999) put the challenge of MBC in perspective by emphasizing that MBC requires even more mediation and interpretation by the instructor to facilitate student understanding. The very important process of mediation means that the role of the teacher in instruction is not endangered by the rapid deployment of MBC, but rather, that the need for the teacher to effectively mediate learning materials is even greater with MBC.

Language learners of today – both in the environment of traditional instruction and by independent efforts – are increasingly computer literate. Two labels accurately fit this audience: they are visually literate and entertainment-oriented. This generation is capable of working well with MBC and in a TELL environment, but also demands much of the materials, in terms of graphic user interface (GUI), help functions and navigational ease, and of the instructor mediating them (Goëtz, 1999). Although CALL materials have existed since the 1960's (Levy, 1997), the tremendous leap to multimedia and internet-based resources is having a greater impact. An expanding amount of interactive materials on the WWW, MBC on CD-ROM or DVD, and exciting TELL options, are transforming the ability to learn a foreign or second language effectively (Bush, 1997). Because today's language learners are so technologically sophisticated, they respond to materials and methods that give sensory stimulation and genuine feedback.

Growing from a basis in CALL, recent MBC and TELL materials, including resources in the WWW, will continue to transform the role of teacher and empower interactive, learner-centered language learning. While the practical advantages of MBC and TELL lie both in the presentation of culturally rich materials and in interactive feedback, the next generation of teachers needs to find adequate means of acquiring technological knowledge and skills, within specific language training programs leading to teacher certification or graduate language programs, in order to work most effectively with students. This discussion assumes that the current task-based instructional paradigm, which seeks meaningful contexts for speech acts, to be a viable theoretical basis for language learning (Savignon, 1983; Hadley, 1993).

One ever-present question is the appropriate starting point for this discussion: are the new technological options really necessary for students to learn in the most pedagogically effective manner? In
one well documented case, students using a multimedia computer-assisted language learning system (MCALL) at the Universiti Malaysia Sarawak, with absolutely no instructor help, earned significantly higher TOEFL scores, at a reduced cost to the institution, than students who were in conventional, instructor-led classes (Soo & Ngeow, 1998). Although the results of teacher-mediated MBC are still dramatically challenged by some scholars (Roche, 1999), the effectiveness and enjoyment of MBC involving an instructor in the language learning process is claimed by both students and teachers in many surveys and studies (Bush, 1997). The best argument for implementing MBC and TELL lies in its unique strengths.

THE STRENGTHS AND CHALLENGES OF MBC AND TELL

The strengths of MBC are that sound, still image, video and hypertext are superior to a course based on a textbook, because the learner has the visual and aural input of real speech in a context (Pennington, 1996; Levy, 1997). The use of interactive exercises in a TELL setting, which give better, immediate feedback based on the learner’s answers, is also superior to the completion of material which must be evaluated later. Self-paced learning with MBC and TELL, within the successful task-based instructional paradigm involving interaction with an instructor and other students, has become an effective course format. Examples of beginner-level MBC materials include video clips of dialogs and interviews, which a learner can use repeatedly, and often have many “help” features that explain the language the learner sees, hears and reads. Such features can be specific lexical items, such as providing an accurate translation for the given context, grammatical explanations, such as noting the use of the subjunctive form of a verb, or contextual notes, such as explaining that the use of a given slang term is perhaps only appropriate with friends or family. This pattern of repetition, combined with meaningful help on demand, is extremely effective in improving listening ability (Joiner, 1997). Examples of effective cultural resources include hypertexts illustrating the unique traditions and values in a given culture, as well as biographical and historical materials. The material which governments, organizations and businesses place in the WWW can also be adapted for language learning (Green, 1997; Glatz, 1998, Walz, 1998).

Multimedia materials are especially helpful with intermediate level learners, because progress at the level beyond beginner seems slow and student frustration is often high. Hypertext for intermediate level learners is a dramatic advancement, because it allows learners to hear passages, to see the related images and to use the extensive help features. The result of hypertext usage is rapid acquisition of vocabulary (Chun & Plass, 1996) and an improved ability to read (Martinez-Lage, 1997). Reading is an important vocabulary builder (Roche, 1999) and greatly accelerates the ability to comprehend speech, a factor in communicative competence. The entertaining aspect of multimedia is also motivating for learners. Both group – shared learning – and independent individual learning are options with hypertexts.

MBC learning experiences are culturally rich, visually oriented and less frustrating than the traditional, textbook-based instruction. The positive results of MBC materials include an increased ease of oral comprehension and reading ability, an emphasis on speaking in context, as modeled for example in video clips, and grammatical information integrated into the useful passages presented as hypertext. The use of MBC also lends itself to cooperative learning. Concentrated work on specific vocabulary, with which students have difficulty, is possible. The greatest benefit is in the use of better, immediate feedback in TELL, which helps to maintain continued interest in learning. Learners who use MBC and TELL materials are truly a new generation. The new MBC and TELL instructional options challenge students and instructors with many exciting, difficult and unresolved issues involved in converting traditional pedagogical methodology to effective practices mediated by computer technology. These issues relate to two areas of language instruction: (1) presenting of course content to the learner, (2) enhancing each individual’s learning processes with feedback. New teachers must become aware of the MBC and TELL materials available for their given language of instruction and fluent in their practical use.

EVALUATING MBC AND TELL MATERIALS

The challenges of implementing MBC and TELL materials must be preceded by active involvement in exploring and evaluating MBC and TELL materials, both in regard to technical and to
Pedagogical concerns (Kassen & Higgins, 1997; Scott, 1998). Such questions as to whether the given materials are able to account for diverse learning styles, or offer an array of "help" options, or have a range of level-appropriate scenes or exercises, must be given equal weight with questions as to whether the graphic user interface (GUI) is logical and inviting or whether the video clips can be effectively interrupted and repeated (Plass, 1998). In the process of learning to evaluate MBC and TELL materials, students training to be instructors attain the necessary level of technical comfort with computer operation. Knowing whether a program or a computer is not functioning correctly can be very important, especially if the number of computers or the time for student use is limited.

A teacher training model suggested by Kassen & Higgins (1997), which they label the Language Learning Technology (LLT) module, stresses that learning to teach with MBC and TELL materials involves five distinct phases: preparation, familiarization, exploration, integration and synthesis. Underlying each phase is the important opportunity for reflection on theory and practice, yielding both knowledge and skill. The end result is technological options integrated into the learning experience for students, from which the instructor can better evaluate other MBC and TELL materials for possible selection. Scott (1998) emphasizes that graduate teaching assistants (TAs) would do well to relate the technological capability of MBC or TELL materials to underlying pedagogical theories. Scott correctly views three basic learning modes, the sequential, the relational, and the creative, for each of which different materials are designed. It is also recommended that teachers in training develop research skills for studying how students react to MBC and TELL and their performance with various learning environments. Such inquiry is still quite unevolved, but will influence the development of future MBC and TELL materials (Chapelle, 1998). Scott's analysis compliments the ideas of Klassen & Higgins, also finding that the need for reflection in adopting technology to be crucial. The following points are meant to focus on those pedagogical concerns which future teachers confront in both evaluating and implementing MBC and TELL materials, followed by the more difficult area of creating such materials. Each area not only involves a keen concern with the how of technological options. It should be emphasized that teachers must also reflect on the what and why of the materials in a learning environment (Tedick & Walker, 1995).

**MEDIATING THE SOCIAL CONTEXT OF MBC**

The need for students being trained to teach a foreign or second language to understand the problematic creation and implementation of multimedia is extremely important (Krashen & Andersen, 1999). Because MBC is itself a mediated social context for language learning, altered and interpreted by the attempt to depict language usage, the crucial role of the teacher to explain and amplify the full cultural background of the material is not diminished, but increased. Although MBC is a much more improved starting point for productive classroom interaction than textbooks, it offers much more detailed material to the student and can therefore be overwhelming. The student enters into an exploratory mode of learning which must be mediated by the instructor for full understanding. Practical examples of successfully mediating the social context of MBC include: (1) interpreting the appearance and actions of people, (2) interpreting the patterns of interaction between people, (3) interpreting locations and living spaces, and (4) interpreting important objects. Meditation of these four aspects contributes to the acquisition of information in order to compare and contrast both the cultural and socio-economic background of the MBC with that of the individual learners. What may be depicted as common or ordinary, special or unusual, must be explored for its contextual background and language usage. Understanding the language used by the people in the given MBC, while the primary goal of the learner, is but one part of the material. The language is made living, but subject to even greater scrutiny. The competent teacher learns how to use the entire offering for positive learning by exploring with students all the nonverbal material that MBC provides. In focusing then on language usage, which is best understood in terms of this larger contextual background (Frommer, 1998), the teacher has mediated this material and related it to the specific language used.

**THE ROLE OF INDIVIDUAL LEARNING STYLES AND COOPERATIVE LEARNING**

The nature of an individual student's reaction to any learning environment reflects their unique and often complex motivation and personality, and the fit between classroom dynamics and the individual
student's learning style can influence language acquisition (Meunier, 1998). While learning style preferences vary and reflect personality differences, MBC and TELL materials are actually a means to bridge the learning style preferences of various learners in a class. An instructor using MBC and TELL materials can balance activities that involve linear and concrete thought processes with those that are more interpretative and open-ended.

Although the use of TELL materials is at times more problematic, as the nature of the given interactive exercise and feedback may not fit well with an individual's learning style, the key to effective use of MBC and TELL materials is to assume that any given computer activity is only one of many learning tools in working toward a specific goal. Some learners will indeed find TELL in general more effective for them than others, just as some learners will respond more positively to a certain type of TELL activity than another (Levy, 1997). Practical examples of successfully accommodating individual learning styles include: (1) stressing target vocabulary items by means of activities involving all four skills, (2) supplementing difficult grammatical points with additional oral practice, and (3) introducing tasks which involve negotiating meaning, bridge information gaps, and have many possible means of completion or allow creative answers. The challenge of MBC and TELL materials for the instructor is not so different from that of traditional methodology: to be able to monitor student progress toward language acquisition and provide additional material or activities when necessary.

The practical implementation of MBC and TELL provides rich opportunities for cooperative learning, whereby students work as partners or in small groups on tasks involving not only listening and reading, but also speaking and writing (Beauvois, 1998). The product of such work can then be taken up in classroom activities. Approaching MBC as a learning environment for students in isolation, alone at a workstation, fails to play to its strength as an engaging and entertaining medium, which allows productive partner and group activities that help all participants. Partners and groups, separated geographically, could in fact meet solely in the context of the same cyberspace learning environment (Hoven, 1999).

Beyond the real world limitation of perhaps not having enough workstations for each learner, which could then be made into an advantage, the use of cooperative learning strategies reinforces the mediated nature of MBC, owing to the interpretative nature of video clips and images. Practical examples of successful cooperative learning strategies include the following: (1) adopting techniques from the use of video in the classroom, such as previewing activities and description activities of images or video clips without sound, (2) basing role-play activities in small groups on the given situations introduced in MBC, and (3) adapting dialogs and interviews presented in MBC for team writing assignments. Many assignments for individual completion can be the basis of cooperative learning activities. The dynamic contexts of MBC naturally provide excellent material for subsequent class discussions.

CREATING MBC AND TELL MATERIALS

Few instructors or creators of multimedia have the personal experience of extensive language learning in such interactive, visual environments which are now available. Many teachers have also never been trained to evaluate and implement MBC and TELL materials. There is still, in general, a lack of institutional support for such training. The perception that authoring software is very difficult also remains a stumbling block. Multimedia is often not integrated into the curriculum and outcomes, but fulfills a supplemental role. Although rapid changes in hardware and software do occur, the stability of the WWW is a bright spot for development efforts. Digitizing existing materials (pictures, slides, music, texts, etc.) for use as language learning resources on the WWW, especially on cultural topics, has been a realistic goal for many instructors and programs, although substantial efforts do require the use of an advanced relational database (Pusack & Otto, 1997). The effort at creating cultural resources on-line, and directing learners to authentic materials on the WWW, is already highly developed (Green, 1998; Glatz, 1998; Walz, 1998). The creation of more comprehensive multimedia materials, with advanced interactive exercises giving useful feedback, is an on-going challenge. The need for future teachers to learn to be fluent in the creation of MBC and TELL materials can be best addressed in a course format which combines students with a technical background with language students. A good introduction to the process of design grows from evaluating MBC and TELL materials and should continue by offering practical experience in placing materials on the WWW. The ingredients for success would be an emphasis on incorporating various learning styles into the group projects and designing projects of an appropriate scope.
SUMMARY

The need for more MBC directed at target audiences based on age, level of instruction, and incorporating diverse learning styles, is crucial. The need exists for detailed analysis of learning patterns in order to improve materials (Chapelle, 1997). Because the need for language learning is strong in the highly mobile, communication-oriented world of the Information Age, and the important advancements in multimedia resources and technology suitable for language learning are greatly helping to meet the challenging requirements of language learners, the teachers of the future must master the technological palette available. While the need for students being trained to teach a foreign or second language to understand the problematic creation and implementation of MBC and TELL is extremely important, technology will not endanger the role of teacher. Empowering interactive, learner-centered language learning brings even greater challenges, but also greater rewards. New teachers, fluent in the materials available for their given language of instruction and in their practical use, will not simply passively implement commercially packaged content and interactive exercises. Well-trained teachers, who understand the theory and practice of mediating the social context of multimedia, the role of individual learning styles and cooperative learning, and the basics of creating their own content and interactive exercises, will be able to meet the challenges of technologically sophisticated learners. While the practical advantages of MBC and TELL lie both in the presentation of culturally rich materials and in interactive feedback, the next generation of teachers must critically adapt these technological options to the needs of their specific language program.

Abstract: The George Fox University Virtual Campus Learning Community (VCLC) is an internet environment designed on-site by professors to serve adult distance education students in professional programs. The VCLC is a grass-roots alternative to traditionally designed on-line course delivery systems. Internet course delivery systems are often conceived and implemented institutionally, driven by administrative goals of greater control, uniformity, and cost efficiency. VCLC is instead conceived and implemented “in house”, directly accountable to the needs of teachers, students, and other stakeholders. This paper will describe the rationale for undertaking grass-roots on-line course development, followed by a description of the VCLC’s technological and pedagogical framework. VCLC is more cost effective, and is better suited to needs of our professors and students than commercially available systems. The paper concludes with a narrative history describing the VCLC implementation to date, including “lessons learned” and recommendations for those considering grass-roots on-line course development.

The Education Department at George Fox University delivered web-based instruction for two years using “George Fox Online University,” a web course system designed by an external vendor and implemented by institutional initiative. The on-line system was plagued by high cost, required high-end user hardware and software, and designed and implemented with administrative needs in mind. Most crucially, however, the on-line system created dependency on a rigid, centralized technology structure, frustrating and disempowering faculty members and students. These factors combined to create an intractable situation for professors in our department committed to meeting the needs of professionals studying at a distance.

VCLC is an alternative model developed by George Fox University Education Department professors on-site. VCLC is relatively low-cost, uses “mid-range,” widely accessible software and hardware and is structured specifically to meet the needs of adult professional programs. It also enables professors to independently and creatively implement web-based tools which facilitate and support teaching and learning, communication, service activities and scholarship.

VCLC implementation began in Spring 1999 and has progressed gradually to include 6 professors teaching 12 web-based courses with approximately 120 students. The cost of development (about $5,000) has been absorbed by regular department budgets and a small community development grant. Training of professors has consisted of mentoring relationships with peers, combined with a once-weekly short meeting to share concerns, questions, and experiences. VCLC is continuously being evaluated and modified by the stakeholders whom it is designed to serve. While VCLC implementation has not been free of difficulties, the heightened ownership inherent in our “grass-roots” approach to development has effectively empowered our department to use the internet for quality teaching and learning.
Exploring a Blind Alley: Lessons Learned

In 1996 George Fox University undertook serious study of the potential benefits of using the internet to deliver distance education. The initiative, “George Fox Online University,” (GFOU) was conceived by top administrators as an efficient way to generate tremendous financial revenue for the university. Despite a faculty study group recommendation, based on the experiences of other institutions, that on-line course delivery does not provide significant financial gain, university administration pushed the plan forward. Rather than using on-site technical personnel to develop an on-line system, programming and hardware support was outsourced to an external vendor, isolating professors and students from the process of system design. By 1997 $250,000 had been invested in the On-Line University, with a commitment to about $400,000 more over the next several years.

In mid-1999, GFOU was discontinued after a substantial investment. A case study (Ankeny, et al, 1999) describing the rise and fall of GFOU lists several factors contributing to its failure:

- The financial estimates were based on marketing the system to undergraduate students (the largest population), not graduate and adult students as suggested by professors. Enrollment figures indicated that cost-effectiveness was only realized where the system was used to deliver graduate courses.
- Administrators mistakenly believed the GFOU would be a more efficient method of delivering instruction. In fact, it was less efficient for faculty, in that they needed to devote more time to online teaching than in face-to-face classes due to the interactive nature of the medium.
- The impact of disempowering faculty and students by outsourcing the technical design and implementation on the GFOU was underestimated drastically. The result was a system whose design and functionality failed to match the needs of students and faculty, and was intractable to change. As described in the case study (Ankeny, et al, 1999),

  “[the system designer] seemed to be enamored with technology and didn’t clearly understand how faculty taught. He thought the conversion of normal courses to online courses simply involved turning materials over to technicians who would then scan them into a digital format.” (Ankeny, et al, 1999).

- The culture of dependency created by the top-down nature of the GFOU made it impossible for professors to actively participate the creative use of technology:

  “Now that [faculty member’s] pages were built, he ran into his first major institutional roadblock: getting access to a web server. This was where the collision of ideologies about institutional approaches first came clear to [faculty member]. He was told that only administrators had accounts on the (singular) web server. Further, he was told that since these pages were accessible to the world, every page had to be reviewed for content and appearance by one particular administrator in the institution... Her office was clearly a bottleneck in the institution” (Ankeny, et al, 1999).

After the GFOU was discontinued, it became the responsibility of individual departments and units on campus to implement on-line course delivery as desired/needed. For the Department of Teacher Education, implementation was not a question; it was absolutely necessary in order to meet the needs of many students enrolled in programs at a distance. Can a department with limited technical means develop its own on-line course delivery system? What follows is an account of the process of our department went through to develop its own “skunkworks” for delivering distance education on-line.

Grass-roots Design and Implementation: Building a Skunkworks

After the demise of GFOU, the George Fox University Department of Teacher Education was left to its own devices to continue serving students at a distance. The department was afforded a unique opportunity to design and implement a system based on educational objectives and needs as seen by faculty, students, and administrators working together as a team. The model for planning and development has proceeded organically, a product of the input of shared voices and concerns. On-going development of the Virtual Learning Community (VLC) has led not
only to empowerment of department professors, but a shared sense of mission for all stakeholders. This process was referred to by a colleague as the building of a "skunkworks," a reference to its "learn-as-we-go," unofficial formula for action.

Laying The Foundation

A key consideration in the design and implementation of the distance education delivery system is an assessment of the needs and characteristics of faculty and students. It is important to determine the educational objectives of the teacher and learners and the teacher's basic assumptions about the learning process prior to the development of the delivery system. As Chang (1998) pointed out, technology must be consistent with the existing values of faculty members. Faculty members must see that there is real educational value in the use of technology, not that a technological system exists for the sake of technology alone. This section presents the rationale for accepting faculty input as a key step in the distance education implementation process. In addition, student-centered learning will be examined, as well as features desired by faculty in the distance delivery system.

Meeting Faculty Needs

While much has been made over the last several years about the need for distance education development to be a team effort, the faculty member is key to the success of the distance education program. In fact, as noted by Parisot (1997):

Faculty are crucial to implementation of any new technological change. However, little has been done to understand the changing role of faculty in adapting to technology and the changes in the psychological and physical environment promised by distance learning. Therefore, a more thorough understanding of the faculty experience in the distance learning environment is important to the formulation of institutional policies designed to guide the diffusion of distance learning into the teaching process (p. 1).

Policies related to the marketing and delivery of distance education programs must take into consideration the needs and characteristics of the potential teachers. Institutional desire to implement distance education often centers on concerns of finance and competitive advantage (see Levin, 1998; and Lawton and Bonhomme, 1998). A typical approach for an institution in implementing a technological innovation is to purchase a "system" and make it available for those that want to try it out. Faculty members may or may not be involved with identifying features and functions of a system that they would like to have to enhance the teaching/learning process. "Unfortunately, many academic institutions are swayed by the bells and whistles embedded in a fancy software package and do not consider what the learner can receive and handle as part of the learning process" (Palloff and Pratt, 1999, p. 63).

When faculty members have had the opportunity to describe important considerations in the functioning of distance learning delivery systems, the technological details are not cited as the primary concern. Needs and objectives of the participants are often the decisive factors for faculty members. Factors considered key for faculty members preparing to teach at a distance include: a) an ability to adapt teaching styles and methods (Lawton and Bonhomme, 1998: Chang, 1997), b) a working knowledge of the technology used to deliver the distance education program (Miller and Carr, 1997; Parisot 1997), and c) skill at facilitating learning (Knowles, 1993).

Faculty members need to be prepared and supported in the distance learning experience. What works in a classroom environment does not necessarily work in an electronic teaching environment. Having an appropriate virtual environment to work in is a key part of that preparation and support. There are a number of considerations in building an online teaching space. Faculty members seek technology that supports teaching and learning. Palloff and Pratt (1999) described elements of effective courseware for distance learning. An effective delivery system is functional, simple to operate for teacher and student, and user friendly. These characteristics speak to a transparency for the courseware that allows for the participants to create content, interact, move in and out of the learning space and troubleshoot problems unhindered by the technical system.

In addition to functional courseware, faculty seek opportunities and support in professional development related to distance education and resources appropriate for supporting their efforts at teaching in the distance environment. Support for teaching not only includes technical support, but support related to accomplishing their educational objectives in a new environment.
The Need for Student-Centered Teaching and Learning

Distance education researchers (e.g. Lawton and Bonhomme, 1998; Chang, 1998; and Harasim, et al., 1995) have pointed out that a traditional pedagogical model of teaching and learning is not well supported in a web-based learning environment. Internet-based distance learning seems to be supportive of a particular framework for education, one that features a student-centered approach. This section examines foundations for student-centered teaching and learning in the virtual environment.

Smallen, (quoted in Van Dusen, 1997) described the ideal learning environment. This environment contains subject engagement and interaction. Interaction is defined as, “consistent opportunities for students to interact with other students and the instructor, to test their own ideas and to learn from the ideas of others” (p. 15). While Van Dusen stated that learner-content interaction can be enhanced in internet based teaching, due to the variety of ways content can be conveyed, learner-learner and learner-teacher interactions are problematic. However, other distance educators (e.g. Machanic, 1998; Riegle, 1996) pointed to the possibilities of building strong interaction with students in internet-based courses.

Strong interaction leads to new possibilities for learning. Parisot (1997) pointed to a unique aspect of distance education. Distance education tends to democratize the educational experience. The web-based distance education program seems to operate best when the teacher assumes the role of a facilitator of the learning experience, as opposed to being an authority who transmits knowledge to the student. This creates a number of questions for the teacher and the delivery system. Are faculty members ready to give up a traditional transmission and control mode of instruction? Are faculty ready to abandon the traditional pedagogical model and adopt a different mindset, that of the facilitator? If, as Knowles (1993) suggested, the students' ability to take responsibility for their own learning is an important variable for success, than the teacher's ability to release that responsibility to students is also very important.

From Pedagogy to Andragogy

Although a number of models of teaching and learning could be considered in preparing distance education programs, adult education theory is especially important to consider. Knowles (1993) is noted as the developer of the andragogical model of adult learning. The assumptions of this model are that the learner is increasingly self-directed, the learner's experience is a resource for learning of self and others, readiness to learn comes from life tasks and problems, problem-centered approaches have the most meaning, and motivation for learning is internal. Knowles stated that the most important variable to be considered in working in the andragogical model of education is the level of the learner's skill in taking responsibility for his or her own learning.

Building on the assumptions of andragogy are process elements that describe the procedures involved with delivering educational experiences. Table 1 describes the process elements of a course and a description of that element in the usual pedagogical contrasted with the assumptions in the andragogical model.

</tbody>
</table>

Table 1: Description of elements in the andragogical model.

Considerations of these process elements should help in making decisions regarding the delivery system for distance education. If the assumptions of the andragogical model are accepted, then faculty members would seek a delivery system that would foster an environment of trust and mutual support. The system would allow for flexibility and joint control on the part of the faculty members and students. The system would allow for easy access and ongoing interaction.
When viewing internet-based distance education as an opportunity for developing a student centered approach, faculty members' assumptions about the learner and the teaching learning process lead to particular types of activities and an ongoing interaction among the participants. The delivery system must allow for the functions and processes desired by faculty and students.

Raising The Walls

The VLC's goal is to empower, giving maximum freedom for both students and professors to create their own teaching and learning environments on-line. To accomplish this, the department faculty as a whole worked to develop a flexible course template, in which the needs of technological beginners would be met, along with allowing expert users to use the space in creative ways.

The VLC Shell

At the core of VLC are CGI scripts that professors use to create a hollow course "shell," or template. The VLC “shell” can be recreated independently by faculty members, who are then able to configure their own virtual classroom using the shell’s functions. In some respects creating a VLC course resembles an old-fashioned barn-raising. The community provides the energy and work to erect a functional, but empty, course-space. It is up to the professor and his/her students to create within this hollow shell a functioning learning community based on the needs, talents, and desires of the group.

VLC Functions

The VLC supports features that map strongly to many of the assumptions and elements of the andragogic model, as well as meeting many of the previously cited faculty needs (Table 2).

<table>
<thead>

<td>Learning Journal: Private discussion space accessible only to professor and individual student</td>
<td>Supportive communication and availability, Mutual assessment, Negotiated setting of objectives</td>
</tr>
</tbody>
</table>

Table 2: Mapping VLC Functions to Andragogy

Living in the VLC

In Fall 1999, four members of our department including one off-campus adjunct faculty member taught courses involving nearly 100 students using the VLC framework. A short weekly meeting was held to provide an opportunity to share concerns about current courses and to suggest changes for “VLC 2.0,” the next iteration of the system. The total cost so far, absorbed by standing department budgets, has been less than $5,000. One faculty member summarized the difference between VLC and its predecessor GFOU:
"The Online University System had functions I found to be attractive, but it was a closed system. What I mean by closed is that I could not alter the appearance or functions of the system. I had to alter my goals or activities to fit the existing structure. The system was also closed in the sense that any suggestions I had for altering the system had to have the approval of administrators and technical consultants who advised me on the unavailability of programmers or the high cost of altering the system to address my concerns. The system was difficult to navigate in and didn't coordinate well with other software that I wanted to use. What I have found with the current VLC is that I have immediate access to the technical consultant, one of my faculty colleagues, who can either change the system to suit my needs, or instructs me in how I can make changes myself. The system allows for easy creation of content files and interactive space. We regularly meet to address concerns and make changes. I feel like I am a co-owner of this space, whereas with the previous system I felt like I was a sharecropper who was subject to the owner's mercy for addressing my concerns." (Professor Interview, 11/99)

Ironically, the VLC system is very comparable technologically to GFOU, utilizing many of the same programming tools and functions. The key distinction between VLC and GFOU is instead one of politics and flexibility. VLC professors enjoy being sharers and leaders in the development process, able to take creative initiative in developing and teaching their on-line courses, as well as contributing to the ongoing development of the larger system. Politics, unexpectedly, may be the crucial design factor in developing and implementing internet course delivery technology.

Active Learning Environments Prepare Teachers for Technology

Marilyn Heath
Southwest Educational Development Laboratory
Austin, Texas
United States
mheath@sedl.org

Abstract: The Technology Assistance Program (TAP) of the Southwest Educational Development Laboratory (SEDL) is currently involved with the Applying Technology to Restructuring and Learning project that involves 150 teachers in six site schools located in SEDL's five state region. The primary purpose of this study is to document how teachers and their teaching practices change as they integrate technology into their classroom. Another important part of this project is the design, development, and implementation of staff development sessions that model constructivist learning environments supported by technology. This paper will describe the development issues that faced the TAP Team when designing these professional development sessions, some of instructional strategies used in the sessions, various classroom management models, and the effectiveness of the professional development for helping teachers successfully integrate technology into their classrooms.

Introduction

Utilizing technology in teaching and enabling students to implement technology in their learning are two of the greatest challenges in today's classroom. Consequently, professional development for in-service teachers is one of our nation's top priorities—especially professional development that emphasizes the effective integration of technology into the curriculum. Current research shows that technology curriculum-integration rather than technology skills training should be the primary focus of technology-centered staff development. Instruction should focus on and illustrate how technology can support educational objectives via instructional environments such as collaborative problem solving and cooperative learning activities. And most importantly, activities should be designed that engage teachers both intellectually and professionally. (Brand 1998).

A recent national survey of teacher's use of digital content (Education Week, 1999) shows that "curriculum-integration" training seems to have a greater impact on teachers than "basic technology skills" training. Results of this study show that twenty five percent of teachers who had only basic technology skills training within the past year say they rely on digital content to a "moderate" or "very great" extent for instruction, the same percentage as among teachers who had no training at all. However, for those teachers who had only curriculum-integration training, the number of teachers who use technology for instruction increases to thirty seven percent. Fifty one percent of teachers who had six or more hours of basic technology skills training within the past year say they feel "much better" prepared to use technology than they did twelve months ago. However, sixty five percent of teachers who received six or more hours of curriculum-integration training say they feel "much better" prepared to use technology than they did twelve months ago. In practice, however, the average teacher receives less curriculum-integration training than basic technology skills training. Overall, some forty two percent of teachers had six or more hours of basic technology skills training within the past year, compared with just twenty nine percent of teachers with six or more hours of curriculum-integration training.

An analysis of most technology training curriculums for classroom teachers reveals that technology skills training is frequently the primary focus of these sessions; that is, training for basic word processing, draw/paint, database, spreadsheet, classroom management tools, multimedia and presentation applications, digital cameras and scanners, and telecommunications components. Effective curriculum-integration activities are often minimal. And when they are included, the most common strategy is to have participating teachers create a lesson plan that includes the use of technology. The weaknesses of this approach are that the teacher often does not implement the activity, it creates a false notion that a single technology activity is "integration," and the selected technology becomes the purpose of the classroom activity. In general, teachers are left on their own to figure out effective technology implementation strategies (Sun et al. in press).
Establishing a Theoretical Framework

Constructivist learning principles were the anchor for the Applying Technology to Learning and Restructuring project. However, during the initial planning stages it became apparent that team members held differing views of constructivist learning theory, how it played out in a classroom, and how technology supports the construction of knowledge. While “constructivism is not a theory about teaching but is a theory about knowledge and learning” (Brooks and Brooks, 1993, p.vii) it was important for the TAP team to develop a framework of understanding and explore the implications of these issues for teaching.

Over the course of several weeks, the TAP team reviewed the literature (Brown, Collins & Duguid, 1989; Duffy & Jonassen, 1992; Brooks & Brooks, 1993; Duffy & Cunningham, 1996; Jonassen, 1996; Maddux et al, 1997) and arrived at a common understanding which resulted in the following six principles of constructivism. These principles become the foundation for the Applying Technology to Learning and Restructuring project. (1) Learners bring unique prior knowledge, experience, and beliefs to a learning situation. (2) Knowledge is constructed uniquely and individually, in multiple ways, through a variety of authentic tools, resources, experiences, and contexts. (3) Learning is both an active and reflective process. (4) Learning is a developmental process of accommodation, assimilation, or rejection to construct new conceptual structures, meaningful representations, or new mental models. (5) Social interaction introduces multiple perspectives through reflection, collaboration, negotiation, and shared meaning. (6) Learning is internally controlled and mediated by the learner. By developing and sharing this common belief of how learning occurs, the TAP team was able to create more meaningful learning environments throughout the professional development series.

Design and Development Strategies

A common problem that faces staff developers in public schools is “efficiency.” That is, how to teach large numbers of teachers in the shortest amount of time. A review of delivery strategies for technology strands reveals that a three-hour or six-hour workshop is a popular and commonly used approach. In most cases a particular workshop will have a single technology focus, be led by a facilitator skilled with that technology, and be conducted in a computer laboratory setting. Just as with any teaching method, a workshop is helpful for some but not for others. Frequently workshops become professional development “events” and do not have the follow-through necessary to create impact over time. Sometimes they tend to be too long, create information overload and fail to engage the attention of participants (Sun et al. in press).

Because TAP’s goal was to model authentic learning environments in its staff development sessions, it chose to create activities that used limited numbers of computers rather than having a computer available for every person. The logic was that if teachers had to teach with a limited number of computers, it would be more meaningful for them to participate in sessions with limited computers. The object was to help them learn how to manage limited resources instead of becoming an “expert” in any single computer application. If the TAP team had chosen to conduct all of its professional development sessions in a computer laboratory setting, it would contradict the teams’ belief that learning is enhanced in authentic situations, promoted through collaboration, and is learner-centered rather than instructor-centered. This strategy was successfully used in the early sessions that promoted team activities at computer learning stations. However, when the TAP team was faced with the need for participants to learn a specific technology in more detail, it was tempted to use a traditional instructor-led lab setting approach. However, since some of the labs available for use either in the teachers’ school or school district were either too small or were not adequately equipped, the team couldn’t take the “easy way out.” The TAP team was faced with designing a different way of delivering training with a technology focus. To do this, the team found that it didn’t need to abandon its original goal of modeling authentic learning environments with limited numbers of computers. The following section describes three models that don’t require a lab setting to teach technology rich activities and can be replicated by teachers in their classrooms.

Constructivist Learning Environments Supported by Technology: Classroom Models

The design and development of sessions for the Applying Technology for Learning and Restructuring project evolved over a period of several months and strove to accommodate a variety of computer skill levels,
different learning styles, curriculum interests, and varying available hardware and software at the six site schools. Constructivist learning environments supported by technology promoted collaborative learning activities in a variety of group configurations. The models below describe some of those group configurations. The TAP team found that the type of grouping didn’t necessarily assure success in completing a project, solving a problem, or learning new skills. Having an engaging activity with an overarching structure and clear expectations, along with defined roles and responsibilities, proved to be key to the success for collaborative projects.

The Active Learning Stations model was designed with a thematic focus — “Your Community.” The teacher/facilitator presents the activity and then functions as a “consultant” for the remainder of the activity. With the goal of the project explained, teams of four to five rotate through three different “learning stations” to gather data and information. One station uses a digital camera to gather images, another station uses a simple electronic spreadsheet to analyze data, and a third station uses printed materials about the community. Each of the stations has roles for each of the team members as well as instructions for completing the tasks at that station. While the “learning station” approach is commonly used in K-6 classrooms, it is not as commonly used in the middle and high schools. However, once they had seen how it worked and actively participated in it, several middle school teachers in our project were able to use it successfully in their classrooms. The teachers who used this model report that it required advance planning and organization. They also caution “first timers” to focus on a manageable or simple project. A team of five middle school teachers used this model for a collaborative project but found that they planned too many activities. However, they also found that student interest and energy were high and they will definitely use this approach again — but next time on a smaller project.

The Navigator Model is another team approach designed by the TAP team. This model is more technology intensive than the Active Learning Environments model. This model was designed so that participants can learn to use a software application while learning a new educational concept. (One of side benefits of this model is that it helps to alleviate the problem of technology-competent teachers who “hog the keyboard” in team sessions.) Several teams of four are given a different part of a concept to explore within their team. To do this, they are asked to create a “concept map” using Inspiration software. While the team carries out its initial discussion, one person from each team attends “Navigator” training. Navigators are those teachers with medium to high computer skills and are selected in advance for that role. The facilitator spends approximately fifteen to twenty minutes with the Navigators teaching them the basics of Inspiration. Once they are trained, the Navigators return to their team. They then instruct the rest of the team on how to use the software. The Navigator has to abide by one specific rule ... they can only give instruction and cannot touch the keyboard. The rest of the team rotates using the keyboard so that everyone has a chance to use the software. Several teachers have found that the “Navigator” model helped them learn to resist putting their hands on the keyboard while they are helping students do work on the computer. They also found it very beneficial for managing those students who want to do all of the computer work for their classmates. By appointing these students as “Navigators,” the students are more conscious of their behavior with the “no hands rule.”

The Expert Model is very similar to the Navigator Model. However, in this model there may be several “Experts.” When using the computer, the Expert can be doing the work on the keyboard. The role may rotate to other members of the team. This model is useful for carrying out more complex projects that require different skill sets and levels of expertise. The Expert is not necessarily the team leader or facilitator. When TAP carried out this staff development session, it pre-assigned teams and distributed the technology skilled teachers across all of the teams with the designation that they would be the technology expert for that team. Teachers report that in their classrooms, student technology “experts” seem to occur naturally. Those with the interest and skill come forward. However, they report the tendency of some of the less skilled students becoming dependent on these more skilled students.

Summary

While many of the 150 teachers in the six project site schools for the Applying Technology to Restructuring and Learning project initially expected technology-skills training, they instead received a much richer technology curriculum-integration learning experience through active learning environments. Computer skills were learned in context through meaningful authentic learning experiences and greater control was placed in the hand of the learner. Each of the staff development sessions in the series is characterized by the following: (1) supported by constructivist learning theory and takes into account teachers’ understanding and beliefs about how students learn, (2) utilizes inquiry, problem-based teaching and learning, (3) uses commonly available
software found in classroom settings, (4) includes two or more instructional strategies for managing a constructivist learning environment supported by limited amounts of technology; and (5) through reflection activities at the end of each module, asks teachers to judge how the different instructional strategies could be applied to their own classroom setting. Overall, each module exemplifies instructional strategies that reflect a constructivist learning environment; includes a link to computers through hands-on experiences, links to curriculum competencies, collaboration among participants; and small group and/or whole group reflections.

Modeling Technology Use in Special Education Teacher Training

Marie Hegwer-Di Vita
College of Education
Education Specialist Program Area
California State University, Long Beach

Abstract: This paper summarizes a discussion of techniques for teacher educators to use for modeling technology use in credential program courses. While university faculty typically have access to sophisticated platforms and programs, few K-12 teachers have or will have such access. If, instead of exclusively using university systems, faculty use or model a variety of K-12 software programs, teachers may more readily see the usefulness of technology in their own classrooms. Such modeling often takes less instructional time, shows applications in action, and facilitates discussion of other uses of technology in all content areas and grade levels.

It seems obvious that the breadth and depth of available technology is rapidly increasing. At the same time, a teacher shortage and related political climate are encouraging university faculty to condense preparation programs and turn out trained teachers as fast as possible. Whether a credentialling program requires specific technology classes to cover technology standards or the program follows an infusion model in which students demonstrate competency of specified standards, class time is tight: It is steadily becoming more difficult to adequately cover concepts, applications, and evaluation of technology in special education teacher credentialling programs. Recent studies seem to document that technology applications are neglected in teacher training programs (Basinger, 1999; International Society for Technology in Education, 1999).

One simple and modest alternative may be for the instructor to increase the modeling of effective techniques in the delivery of the college course itself. Such a design would use principles of modeling as the instructor conducts the course using techniques and materials themselves readily available to most K-12 teachers. The instructor may also perhaps briefly discuss the technique or software program and other potential uses or generalizations. While many college faculty are trying to increase their use of technology both instructionally and to support their own work efforts, we often do so with recent software and high-powered institutional platforms not readily available in nor suited for public school classrooms and teachers. For example, while most faculty have access to very sophisticated test generator programs, local school districts generally do not. If course examinations are constructed using the university’s package, the students may not easily see or really believe how test generator software can be of use to them. On the other hand, if a software program such as Teacher’s Helper Plus is used to make the test, the instructor can also take just a few moments to share with the students how easily the test was made, state that the software is less than $50 for either Mac or IBM platforms, and discuss how K-12 teachers might use such a program for tests, quizzes, study guides, or worksheets.

Some other opportunities to model K-12 software in teacher training may be in the areas of instruction or course management. The present discussion includes only a few possibilities in each area. These general examples could be used in courses ranging from an introductory course on inclusive education to methods of instruction for students with learning disabilities to advanced behavior management and so on.

Instruction

In the broad instruction area, regardless of what the specific course content is, technology for use by K-12 teachers can be modeled in assessment, assignments, instructional techniques, and materials preparation. The test generator example discussed above is just one such example in assessment. Another assessment example relates to portfolio assessment which can be very useful in special education and is also increasingly common for credential candidates as part of their own professional development. Electronic portfolios such as Grady Profile or Portfolio Assessment Kit Supreme II are available for K-12 students and could be used by teacher candidates to prepare their own professional portfolios.
Other course requirements and assignments can be written to require students to use or include technology content in their responses. For example, virtually any class could include an assignment to find and review an Internet site related to the course topic. K-12 teachers could use a similar assignment by giving a menu of sites for their own students to review. A slightly more sophisticated assignments might be:

Specify a question or topic related to this course’s objectives. Investigate Internet sites on that topic and prepare an annotated list of three which are new to you and which specifically answer your question. Include an introductory paragraph on why you selected these 3 sites and how, as a whole, they answer your question and will support your future professional development.

Other assignments may require a student to use PowerPoint in making an oral presentation or to submit assignments electronically to the instructor and classmates. Common K-12 software such as puzzle generators (for example, Crossword Companion) or cloze generators (for example, Word Link) can be used to make a study guide for a chapter or other course handout. Again, a moment can be used to describe how the worksheet was made or for class brainstorming on how a similar technique could be used in their K-12 classes.

Credential candidates may be required to develop websites, often using something like Dreamweaver (Macromedia) or even HTML. It may be more effective to create sites using Site Central or HyperStudio which are more likely to be found in K-12 programs. An even simpler and more accessible option for K-12 teachers is to use TrackStar or another education website template site.

While faculty commonly use PowerPoint to prepare overheads, we can also model materials preparation with common word processors or graphics programs. It takes only a moment while presenting the content of the course to mention that “This overhead was made with X program and could also be done with something such as Y program. You could make similar worksheets for use in your classrooms.”

Course management

Technology can be used and modeled by faculty as they manage their university courses including tracking student grades, maintaining frequent communication with students, and developing syllabi and grading rubrics. Many if not most universities automatically provide faculty with sophisticated grade book programs. Alternatively, faculty can use a program such as Easy Grade Pro to keep student grades in a class on assessment. At midterm time or a little later, faculty may use the programs parent report options and easily prepare a family report for each student just as K-12 teachers can use that option to send home frequent progress letters.

Using email to distribute study questions before a lecture may increase a student’s motivation to use email. Email or a course listserv can also be used to distribute announcements such as job openings, campus events, newspaper articles or television programs on disability issues for which classtime might have otherwise been used.

Faculty frequently make assignment rubrics using word processors or spreadsheets. While such utilities are available to K-12 teachers, so are programs such as Teacher Timesavers which has added features of specific school examples in the documentation and subprograms such as flashcard generators. An instructor can also demonstrate how he/she used a spreadsheet program to make the course schedule and show how a K-12 teacher can use a spreadsheet to make rubrics and schedules.

A great source for technology support to faculty is The Electronic Scholar (Edyburn, 1999). While research productivity is Edyburn’s focus, many of the tools he describes are potentially useful in K-12 classrooms. For example, faculty (or K-12 teachers) could use ED Tech Tools to make interactive quizzes for their students whether the course content is advanced management theory or Harry Potter.

Other techniques

There are also some other simple and relatively passive techniques which special education faculty may use to increase the visibility of technology in teacher credential programs. Textbook selection is perhaps the most significant consideration. In addition to selecting a text by how well the content meets course objectives, texts may also be considered by how technology is represented in that content and how much technological support is available. For example, virtually all programs have some sort of generic introduction to disabilities course. Watson (1999) described 10 such texts but concluded that only 6 of 10 included any mention of technology. On the other hand, Lewis and Doorlag’s (1999) text includes extensive discussion of
technology, assistive technology, and educational software. Over 35 software programs are listed in the index and Internet sites are plentiful throughout the text. Another aspect to textbook selection is to use supplemental texts such as "Technology for inclusion: Meeting the special needs of all students" (Male, 1997) in introductory courses or beginning methods classes.

The number of texts with publisher-run websites is increasing. These websites typically include links to other Internet resources, text based quizzes, and chapter study guides. Using Internet references in course required readings or reference lists also models the use of a variety of media in instruction. The number of sites with full text information is increasing.

Requiring electronic collaboration in fieldwork and other classes also models a technique teachers can use throughout their career. Requirements may also include subscribing to a professional listserv, newsgroup, or chat room (Birnbaum, 1999).

It is also important to continually keep “low tech” possibilities in mind. Fax, phones, voicemail, and snail mail are all increasingly easily accessible technologies with applications for K-12 teachers (Carlson, 1999).

Conclusion

There are many technological resources and techniques which work effectively for college teacher trainers while realistically modeling and discussing what a local classroom teacher can also do. As faculty, we can consciously use the techniques we teach in the delivery of our own course content. Taking time to specifically mention the techniques and materials we use may motivate our students to use more such materials and techniques with their own students.

Abstract The Virtual Learning Technology Community (VLTC) is a collaborative technology professional development model that supports k-12 students, k-12 teachers, university faculty, university preservice teachers, and instructional technology staff developers at local service agencies. The mission of the VLTC is to establish and support a community of regional institutions actively engaged in using existing and emerging technologies to support learning by all members. The vision of the VLTC is to provide assistance to additional PK-12 schools seeking support for improving the use of technology to help students develop competence in [a] finding and evaluating information and ideas, [b] using available learning tools, and [c] communicating effectively. The VLTC has impacted 400 teachers in 27 schools, 6,000 students, and 20 preservice interns. The long-term impact of the model is enhanced by dissemination activities, archiving and sharing successful strategies and institutionalizing essential support structures.

Introduction

Over the next ten years, more than two million new teachers will need to be hired and trained to use technology. Yet, most institutions of higher education do not adequately prepare teachers to use technology. Teacher education institutions, state education agencies, and school districts are further challenged to meet the technology staff development needs of experienced teachers. Thus, new models of support in which educators at all levels (university teacher educators, k-12 teachers, preservice teachers and k-12 students) learn together must be developed to make use of scattered expertise and limited resources.

The Virtual Learning Technology Community (VLTC) is a three-year project, which began in November of 1997 funded by the University of Wisconsin System. The VLTC model creates a virtual community where teacher educators, k-12 teachers, preservice teachers and k-12 students communicate, share, and learn together through a variety of activities, thus improving technological literacy and skills of all participants. The community develops new and spin-off projects that expand the impact on learners (e.g., k-12 teachers, k-12 students, university students and university faculty instructors for student teachers and graduate students in the k-12 schools). The VLTC supports communication, collaborative learning and sharing, and efforts to generate new resources. To date, the VLTC has reached over 260 teachers and approximately six thousand students across 30 schools.

Description of VLTC Goals and Activities

Phase I VLTC activities focused on establishing the model, working on communication strategies and identifying teacher needs. Personnel were identified, roles and responsibilities were defined, and assessment strategies and tools were developed. The VLTC web site was established as a resource base and communications tool (http://www.uwec.edu/Academic/Cl/vltc/vlct.htm). The coordinator identified schools where staff development could be conducted, recruited teachers to participate and lead activities, and identified classrooms where teachers were already beginning to integrate technology into instruction. Concurrently, teacher educators began recruiting interns and developed technology support packages (laptop, software and communications tools, video conferencing tools, and scanners) to ensure access to some advanced tools.
Phase II emphasized building links between the VLTC and Regional institutions. Interns were placed at three different schools sites to (a) supply some technical expertise, (b) work with teachers to explore new tools (e.g., video conferencing) and develop new strategies for using technology, and (c) provide release time for the teachers to attend and lead staff development. VLTC teachers began attending and teaching workshops, revising curriculum, and identifying advanced staff development needs. UWEC and UW Stout responded with a series of graduate offerings including ITV Instructor Training, Computers in Education: On-line Communications and Information Retrieval, Information Literacy, Instructional Design and Development, Technology in Science and Mathematics instruction, Creating Multimedia Productions, Distance Learning Networks, and Web Design. Initial efforts reached 52 teachers and approximately 1,000 students in fourteen small districts.

Phase III (Strengthening links among Regional PK-12 Schools) activities emphasized strengthening the social context to support high-risk activities associated with changing long-held teaching and learning paradigms. Through a variety of face-to-face and electronic mechanisms, VLTC participants shared their developing knowledge of current regional projects, established new ways to communicate, and publicized ongoing efforts. Participants were encouraged to think about technology as a tool for learning subject matter rather than just learning about technology. Projects ranged from introducing desk top video conferencing into classrooms and using asynchronous learning environments such as NiceNet and Lotus Notes Learningspace to building class web pages to using video editing tools and graphics design tools.

Three current projects focus specifically on context building. Each project took a different approach to bring together educators from different places and levels to focus on common goals. The Technology Mentors program uses a multiplier model to support k-12 staff, university and high school students, and preservice teachers as they work to redefine curriculum, instruction, and assessment in technology-rich classrooms. During the first year of the program, nine master mentors participated in technology staff development and leadership activities to prepare them to work with other building teachers. Each teacher worked with two additional teachers to build a network of 27 teachers prepared to support others and to serve as hosts for preservice teachers. The design for the second year required that each master mentor and building mentor work with two additional teachers (thus supporting 54 additional teachers). The success of year one activities was so high that 42 new teachers applied for the Mentors program. By the end of the project, the original target of 81 teachers will be surpassed. Over 160 teachers will receive advanced staff development aimed at increasing their ability to integrate technology into instruction. Fifty-one teachers will participate as staff development leaders by conducting training, presenting model integration strategies for peers, and coaching teachers in classroom settings.

You’re I.T. (Integrating Technology into the Curriculum) blended 70 VLTC and Technology Mentors staff and teachers in a two-day symposium and staff development series in March 1999. The symposium began with a dinner and debate examining the pros and cons of bringing technology into classrooms. Participants were divided into teams one month before the symposium and assigned the task of finding evidence from the literature to support their argument. Listservs were set up to facilitate team planning and sharing of information. The debate was moderated by an area School Board President. The following day, a series of breakout sessions provided opportunities for the Technology Mentor teachers and VLTC teachers to share strategies with an audience of invited teachers, university educators, preservice teachers, and k-12 students. Sessions were structured to emphasize integration strategies and discussions of successes and failures rather than just showcasing technology. The symposium closed with an evaluation session and discussion of networking strategies to ensure that participants were able to connect with presenters and each other. You’re I.T II will extend the success of the first symposium by including additional participants, increasing staff development responsibilities of mentor teachers, and showcasing projects completed by student teachers and interns.

FastforWord (involving 6 K-12 students, 30 undergraduate students (preservice teachers), 1 graduate student, 1 university faculty member and 1 K-12 teacher) assesses the validity of a CD-ROM and Internet based program that claims to improve the language skills of children with specific language impairments, and specifically, dyslexia. The focus of FastforWord is evaluation of commercially developed support technology. Participants will conduct research to determine if the program improves the temporal
sequencing deficits that cause specific language impairments and dyslexia. FastforWord provides an opportunity for teachers and students to take a more critical stance toward the integration of technology into learning by testing developers' claims against independent evaluations. Consequently, teachers and students will develop a clearer view of the time, processes, and resources needed to assess the impact of technological tools on student development.

Phase IV (Supporting New Projects Impacting Students In VLTC Schools) activities emphasize (a) extending participants opportunities to work together, (b) institutionalizing new groups, courses, and connections, and (c) disseminating the VLTC model. VLTC will continue phase III activities, particularly the FastforWord, You're I.T. and Technology mentors activities. In addition, several new projects such as small grants for teachers, and advanced graduate studies drawing on Phase III activities, have been introduced.

Phase IV also includes evaluating the impact of VLTC. Tracking the influence of VLTC activities on teacher knowledge, classroom practices, and student learning is complicated by the very nature of the project. As the variety of activity increases, tracking impacts on practices becomes more complex and difficult to document. Table 1 at the end of this document illustrates the links among project goals, activities, outcomes, and assessment strategies. Current activities include collecting post data using survey instruments, assembling portfolios of teacher and student work, and conducting exit interviews with students and teachers. Each data set documents ways the project influences practices and helps identify new questions deemed important by the participants. A sample of teacher projects, complete analyses of survey and workshop interview data, shared presentations at conferences and descriptive data illustrating patterns of participation will be archived through the VLTC web page.

Using Outcomes to Support the Transition to a Self-Sustaining Model

When the VLTC project began, we envisioned a set of small districts developing links with each other, and with regional agencies and Universities. The partners would work together to increase the amount and quality of student learning through a variety of uses of technology. During the course of three years, the community has grown from an initial set of six schools to include more than 30 small schools and one large urban/suburban district. By the end of the 1999-2000 school year, 300 K-12 teachers and their students will have been impacted in some way by the community activities. Twenty teaching interns will have completed semester-long experiences focused on different ways to enrich student learning through technology. VLTC established a regional technology staff development symposium drawing 75 - 100 participants, supported teacher development in the use of distance learning technologies, and draws participants from preservice teachers, university teacher educators, K-12 teachers, and K-12 students. We face significant challenges, though, in moving from an externally supported to a self-sustaining community. Several important transition issues are highlighted below.

Maintaining a teacher-driven model. While the initial impetus for VLTC came from a small collaborative group, the identification of teacher development goals rests mainly in the hands of the participants. By respecting participants’ changing perspectives and helping them develop better ways to learn from each other, the community is internally driven. One indicator of the success of the internally driven approach is the sheer increase in participants in VLTC activities at a time when teachers are inundated with technology-oriented staff development opportunities through graduate courses, service area workshops, and other local, regional, and state-supported opportunities. The need remains for participant-driven development that offers something different from the “shopping mall” available to educators. We are challenged by demands on participants’ time, changing expectations about costs/benefits of participation, and just getting lost in the total volume of opportunities.

Institutionalizing community activities. A second important element is securing and maintaining institutional support for community activities. Two new courses initially funded by VLTC now exist as regularly offered on University summer and academic year schedules. Two distance education initiatives are now attracting internal funding; interest and hardware/software resources generated through the VLTC experience provide a sufficient base for continued pilot project development.
Large scales summer staff development opportunities have sufficient history and visibility to attract some institutional support, but are more difficult to sustain. Competition for larger amounts of institutional resources may limit the long-term feasibility of such initiatives, especially as educators are faced with more and more choices for investing their time.

Five schools now contribute $4,000 per intern to bring advanced preservice teachers into their districts to complete student teaching and work with classroom teachers to integrate technology into teaching. The interns complete a technology integration project in the host school. They provide release time for supervising teachers to attend staff development, work with other teachers, and engage in resource development. Hardware/software support for the interns and their supervision will continue through University funding. However, as more projects offer internships and compete for quality preservice teachers, we face limitations in the number of qualified preservice teachers available to fill the slots offered by schools. Without continued successful placements, K-12 districts will shift resources to other projects.

Our experience clearly highlights the need for a coordinator who is a recognized, active member of the school communities where staff development is occurring. The coordinator is in a unique position to identify linkages and common needs across buildings and districts, and make the "people connections" necessary to create and sustain the conversations needed to bring groups together. The current coordinator position will be continued with support from a regional agency.

Summary

The VLTC has achieved the goal of creating a community that is driven by internally-defined goals, includes a variety of learning opportunities and communication possibilities, and brings together educators at all levels. The project web site provides an archive and "one-to many" communications tool. Sharing mechanisms such as You're I.T. highlight the gains in technology skills and instructional integration made by community members and help sustain connections among participants.

Sustaining the community concept requires that the participants have gained sufficient value during the project that they begin assuming responsibility for the costs and organizing activities required to bring people together. As the VLTC funding cycle ends, we are working to develop strategies for sustaining the community concept. Our success in shifting some grant-supported activities to institutionally supported events is encouraging. However, we will need to develop more strategies to sustain links among VLTC teachers, foster new staff development projects, and help teachers make increased use of distance learning technologies.

Abstract: This paper presents a case study describing the efforts of teachers to improve communication among their colleagues at their respective schools, an elementary school and a college of education. Frustrated by the lack of time to collaborate with fellow teachers the creators used the Internet to improve communication and to work toward developing a community of learners among teachers. Still in their infancies the two sites are constantly changing as their use suggests improvements, but the goal of the endeavors has been reached: the creation of learning communities among teachers, replete with a true sense of communication and collaboration.

Introduction

A great deal of research is currently available describing on-line communities of learners created via the Internet. Many of these "virtual communities" are created to connect students to teachers, students to students, and teachers to teachers. Kowch & Schweir (1997) defined learning communities as "collections of autonomous, independent individuals who are bound together by natural will and a set of shared ideas and ideals, and who are engaged by influencing each other within a learning process.” A whole new dimension has been added to the creation of learning communities with the use of technology. Virtual or online learning communities are materializing on the World Wide Web. A virtual learning community works in the same way as the nonvirtual community to extend the participant’s professional community, but it can extend the reach of the community far beyond the walls of a classroom (Dyrli, 1998). A review of the literature reveals evidence of learning communities being established at all levels, elementary school through higher education (Jorn, Duin, & Wahlstrom, 1996; Kowch & Schwier, 1997; Tinto, 1997).

As new learning communities are established, learning goals need to be determined, and specific tasks to be completed must be created. To do this successfully Jorn, Duin, and Wahlstrom (1996) suggest that the perspective participants must be the focal point of
consideration. It is their belief that a learning community will be effective only if the participants want to interact and communicate.

**Background**

The lack of time to collaborate with her fellow teachers while attending to the many daily responsibilities assigned to elementary classroom teachers frustrated a fourth/fifth grade social studies teacher. As the social studies chairperson she spent a great deal of time locating resources for other teachers and wishing for more hours in the day to be able to really help her colleagues. This frustration inspired her to use her personal Web site as a means of connecting the teachers at her school to social studies resources.

The idea for this Web site was inspired when the teacher was invited to co-teach a graduate level general methods course. In preparing for the course, she was referred to a Web site created for faculty. In an effort to enhance consistency in course material, delivery of content, and communication among the large number of faculty who teach the two general methods courses in the undergraduate and graduate programs at a state university a virtual learning community among faculty had been created.

The courses were developed to address the needs of beginning teacher education majors and graduate students seeking initial certification. As the courses are requirements for certification, there are many sections offered each semester to accommodate the large student population. As such, there are numerous instructors, including adjunct faculty, who teach the courses. The Web site is designed to create a learning community among the disparate faculty.

When an individual, like the social studies teacher, accepts the responsibility of teaching one of the general methods classes he/she is directed to the Web site instead of a generic course syllabus. The new faculty hire may still be in different state, but thanks to the virtual learning community created by the Web site, he/she is instantly connected to all faculty who teach the course and many resources available to help plan and teach an exciting semester of work.

**Elementary School Web Site**

Creating a Web site for the faculty at the elementary school was easily initiated by expanding an existing Web site. The social studies teacher used a personal site she created for sharing school information with students and parents. Her learning goal was accomplished by adding a link for communicating with other teachers at the school. Here other teachers can find links to the Sunshine State Standards (required on all lesson plans), the National Geography Standards, sample lesson and unit plans, and Internet resources. She has organized these resources into two categories, teacher resources and resources for use with students. As she locates interactive things for student use like crossword puzzles, seasonal stories and jokes, or music to coordinate with themed work, she connects the locations to her site.

Thinking ahead for summer work on the Web site, the elementary teacher plans to survey her colleagues to receive their ideas and suggestions. She wants to be certain that the Web site continues to be designed with the perspective participants as the focal point of consideration. One suggestion thus far has been to write and include lesson plan ideas for all
grades at the pre K – grade 5 school. In the future she hopes to connect her faculty site to the Florida Council of Independent Schools Web site so that all member schools will have easy access to the information. She is also exploring software that will allow her to establish chat rooms to facilitate online communication in two directions for the teachers.

University Web Site

The university site is made up of several different components. Essential course elements comprise the first component. Information contained in this component is linked with other sites where instructors can access specific authors and information associated with a particular topic. There are links to Internet sites for faculty use and a separate listing for links for student use. Some of the sites are local, like the link to the university library’s site, Beyond Yahoo! Finding Everything on the Web. This site explains how to conduct successful interest searches. Other sites are more global in nature. ERIC Clearing House on Assessment and Evaluation is found under the heading of assessment sites. Links to other sites are grouped by the course content, like a methods and approaches site, a multiple intelligence theory site, and a teaching tips site. Each is easily available for faculty perusal.

Within Instructional Strategies, the second component of this Web site, can be found the methodologies recommended for curricular inclusion. These strategies will be linked with corresponding researchers and authors. Plans are also being made to secure videotaped examples of different methodologies and to incorporate them within this Web site. Thus, a variety of strategies can be observed while online. It is hoped that viewing an actual strategy being implemented, with literature discussing the strategy will enhance faculty understanding and eventually facilitate student use of each strategy.

Because of the large number of students who are enrolled in the college of education, consistency among all sections of this course, in content and delivery, poses a major challenge. Some semester there may be as many as sixteen sections of the course offered. As a response to requests by new instructors for access to course materials created by veteran colleagues, the Web site will also include faculty-developed materials and activities. A generic syllabus as well as black-line masters of transparencies and assessment instruments is available. Instructors using one of the recommended textbooks will be able to access chapter outlines of that text. The availability of microteach documents, such as lesson plan formats and evaluation forms, will greatly facilitate the incorporation and execution of microteaches, a time-consuming but integral component of this course. A supply of highly successful, instructor-generated activities will also be made accessible by means of this Web site. As the list of videos for this course can become quite cumbersome, a video bibliography will be included. Each video will be linked to sites dealing with the main topic of the video, thus enhancing the depth in which material can be delivered.

Finally, in the Resources/Assignments/Activities component of the Faculty Web Site, a Professional Portfolio link has been developed. Because the portfolio is an entrance requirement for student teaching, it is imperative that education majors receive accurate, consistent, and timely information regarding the portfolio format and content as well as portfolio submission and evaluation from their professors. A link delivering current portfolio workshop and training session content has been developed and is accessible via the Professional Teaching Practices Faculty Web Site. As this course is the forum within which the introduction to the professional portfolio is to be effected, it is vital that faculty teaching
the course have access to the most current and accurate information regarding this college of education requirement.

The Professional Teaching Practices Faculty Web Site is viewed as a vehicle to facilitate curricular design, enhance consistency of content and its delivery, and expedite communication among faculty members. The Web site will also consist of a component that will allow faculty to communicate with one another, both online as well as via a listserv. Direct email links are listed on the first page of the Web site, which connect to regular faculty members who teach the course. The adjunct faculty members who are not assigned office space on campus, and who often work full-time away from the university campus, especially appreciate these links. The adjunct faculty have easy access to request shared materials, or simply ask a question.

Conclusions

The full potential of these two Web sites as a means of communication and in the dissemination of information has yet to be determined. Currently in their infancy states, the sites are being continuously updated and expanded as teachers/instructors contribute new materials, resources, and knowledge of possible links. It is anticipated that once the Web sites are fully developed and faculty are informed of their existence and trained in their usage, the objectives for these sites will be realized. We hope to enhance consistency in course material, incorporate resources and activities within the course curriculum and improve communication among faculty. Regardless of the numerous modifications made to the Web sites as they undergo construction, our ultimate goal remains unaltered: to create a learning community, replete with a true sense of communication and collaboration among its members.

Metaphoric scaffolding: Using digital video techniques to overcome teacher apprehension about new approaches to learning

Abstract: This paper is a work-in-progress report on an approach to help teachers break the traditional barriers to learning that occur under transformative learning conditions. Teachers typically want to be taught innovative new techniques using the learning approaches that they have successfully used in the past. Introducing unfamiliar new learning approaches coupled with often-intimidating new technologies seems to be at odds with the objective of helping teachers apply constructivist methods including modeling the desired learning outcomes through their own examples. The authors explore the use of a metaphoric scaffolding technique that disguises much of the learning environment in order to give teachers a more familiar and comfortable realm in which to achieve learning success. As success is achieved, the teachers are led back through the metaphor to understand how they have used the new technology to produce tools that will be of direct benefit to them in the classroom.

Introduction

A recent study by the American Association of School Administrators (AASA), titled "Preparing Schools and School Administrators for the 21st Century", identifies guidelines that schools must recognize in order to prepare students to succeed in the new millennium, beginning with the premise that the definitions of "school," "teacher" and "learner" are reshaped by the digital world. In this paper, we are primarily concerned with both the definition of teacher and the role of teacher-as-learner:

"In the past, many have considered the teacher's primary role to be a dispenser of information. Great teachers have always far exceeded that expectation. In the 21st century, students have increasing access through the Internet and other sources to as much or more information than their teachers. That means teachers will take on a mantle of even greater professionalism, serving as orchestrators of learning and helping students turn information into knowledge and knowledge into wisdom" (Withrow, F. et al, 1999, p. 66-72).

According to the study, the 21st century will require knowledge generation, not just information delivery, and schools will need to create "a culture of inquiry." "We talk about lifelong learning for everyone in society," says futurist/forecaster Marvin Cetron, a member of the AASA study. "We need to be sure we offer lifelong learning for our teachers, as well. Our teachers need to be the catalysts in setting a culture of academic excellence," he adds (Uchida, Cetron, et al., 1996).

In order to prepare teachers for this environment, the first and most difficult hurdle to get over is the idea of accepting change. Accepting change is an individual process in which the "acceptance time frame" is going to vary with the staff. Understanding that a total buy-in is rarely achievable at the beginning of a change effort will also keep the teacher from labeling a behavior, response or attitude as "resistance to change."

In this paper, we relate our efforts at using the metaphor of movie production as the scaffolding ‘prop’ to expedite the learning process of teachers in a graduate level multimedia design course. We began...
by examining teacher's apprehension about learning how to integrate technology into instruction. We observed that teachers who were predisposed to learning experiences that offered immediate "use it tomorrow" applications, were equally committed to (but often anxious about) learning experiences that required greater risk-taking.

While most teachers are eager to learn how to apply technology to help students learn more effectively, others have continued discomfort with technology and believe that computers are not necessary to do their job (Stone, 1998)... "Computers apparently have not really changed the way we teach." Even the most receptive teachers often want to be taught the latest technology integration techniques the same way that they have always been taught. The teacher's prior experience of being a student, and the cultural expectations of the teacher's role greatly influence the acceptance of new instructional strategies (Stigler & Hiebert, 1998). Strategies that vary significantly from familiar, traditional methods may produce stress that ultimately becomes a barrier to the learning experience. The use of metaphor served as a substantial bridge to link teachers' comfort level with predictable learning experiences to the "professional stretching" level of transformative learning experiences.

The learning paradigm from the past has usually consisted of traditional instructional delivery techniques: set and listen lectures, show and tell workshops, and a variety of other teach-by-telling methods. These traditional approaches greatly influenced the design and use of early computer technology applications such as the tutorial structure of computer-assisted drill-and-practice programs and brought a degree of rigidity to technology integration. Today's new paradigm for professional development is based on the goal of preparing teachers to transform their thinking, teaching and learning. At the same time teachers must be able to "coherently combine curricula, tools, and standards...the process must be ongoing, acknowledging the gradual nature of change and respecting teachers' needs to maintain control of their evolving professional goals and commitments" (Grant 1999). The "gradual nature of change" presents the greatest challenge to innovation and the notion of gradual is inconsistent with the need to expedite the infusion of technology into instruction. The situation is exacerbated by the need to produce more and better teachers. "Over the next decade we will recruit and hire more hire more than two million teachers for American's schools. More than half the teachers who will be teaching 10 years from now will be hired during the next decade (National Commission on Teaching and America's Future, 1996).

At least 20% of the teachers in the pilot course are highly uncomfortable using approaches other than those that they identify with successful outcomes in their own past learning experiences.

**Metaphor strategy**

The development of a metaphor strategy evolved from answering the question: What type of learning experience will allow teachers to embrace change and break away from their traditional reactions to transformative learning experiences? The answer lies in admitting that in order to embrace something new it is often necessary to either remove or realign something already in place. Ineffective or inappropriate teaching practices needed to be gently replaced with a "user friendly" learner-driven model of instruction that could be easily replicated in any teaching-learning environment. The use of a metaphor allows combining the novel with the familiar and serves to lower anxiety while raising interest.

An effective strategy at the beginning of any change effort is to acknowledge four basic assumptions: 1) previously used traditional methods are not wrong but are not matched to the instructional goals of the program; 2) teaching is a strategic act of engagement that requires both teacher and student to understand the learning dynamics; 3) changing how a teacher teaches takes more than conveying information or presenting activities; and 4) learning to change a teaching style is as difficult as learning to change a learning style (Bellanca 1998).

Until teachers are comfortable using and accessing information with technology, there will be no significant change in instructional practices in the classroom. When questions and concerns are addressed in a compassionate, professional manner, there is a high likelihood that the new technology will be adopted successfully. A preservice teacher shared this insightful remark: "The way you are taught in college is the way you will be apt to teach when you begin your career in teaching. I'll be more comfortable to use this type of instruction in my classroom now that I have experienced it in my graduate courses."

The metaphor experience was piloted in a multimedia graduate course and grounded on principles of a constructivist approach to pedagogy for technology integration. The course incorporates scaffolding techniques that encourage teachers to model desired outcomes with students in a project-based learning environment. To overcome anticipated apprehensions, the pilot class of 12 graduate students (practicing K-
12 teachers) applied a meta-instructional model: using the methods being taught in order to model the
instructional process, applying appropriate scaffolding and leading the teachers through the same process
the graduate students will be using with their K-12 students. We chose the metaphor of producing a digital
video “movie” as something that was intuitively familiar to most teachers. Giving the teachers a familiar
metaphor within which to consider their own learning experience proved to greatly help the scaffolding
process and lowered the barrier to learning. The metaphor reflects the scaffolding construct that anchors its
use and transforms the learning experience.

Scaffolding strategies are reflected in the instructor’s “diagnostic” discussion with each student to
determine the level of skill and degree of apprehension that could either strengthen or compromise course
activities. Students are then placed into teams designed to support members who may oppose change or be
overly anxious about using unfamiliar technology. Support comes from knowing that someone on the team
knows about the anxieties produced in the face of change and understands how to provide a learning
‘safety-net’ to reduce stress and increase confidence. One project in Kentucky created an alternative
“techno-academic” classroom where support and encouragement for efforts to try the untested facilitated
the transition from passive to active learning. The environment continually reinforced actions and ideas that
broke away from traditional roles of teaching and learning. While learning new technology, questions could
be asked and doubts could be vocalized.

Based on the Vygotskian notion of making abstract processes more visible, scaffolding can take a variety of
forms – teacher can model strategies and provide suggestions. Scaffolding can also be provided in the form
of prompts and questions that help students understand the process involved in learning (Krajcik, Soloway,
1998).

Using this approach, the instructor takes the role of director, the teachers in the class become the
actors—mastering their roles under the guidance of the director, in a teaching environment that is facilitated
by the producer... an expert in the new technologies being used. The producer provides appropriate
technology support and scaffolding to ensure a successful learning experiences for all participants. The use
of pedagogical roles allow teachers to create and evaluate new instructional techniques and “gain insight
into teaching approaches and further their knowledge of technology (Deal 1998).”

To further support this metaphor, the class uses actual digital photography and editing techniques,
producing case-related video material that, at a minimum, becomes part of the electronic portfolio produced
by each of the teachers. The motion picture industry provides a good analogy to help understand production
in many media. The areas of photography, art direction, sound editing, special effects, lighting,
screenwriting and adaptation, directing, editing, and all other stages of pre and post-production provide a
media model with a century of success upon which to draw. The global public has developed a level of
expectancy from every screen that begs attention. No matter that the screen is 70mm Imax or 15-inch
Compaq the audience/students usually expect at least the level of production quality they commonly see on
their home television sets.

Applying the metaphor

Fortunately, it is now reasonable for K12 schools and graduate programs to produce high quality
digital video sequences, which can be distributed on film, CD-ROM, or streamed Web video. The cost of
digital camcorders and desktop video editing systems have dropped dramatically in the recent past.
Achieving the potential of media in our future means "unlocking its power through understanding." At this
stage, leadership may turn out to be the most important single factor in advancing the social and industry
understanding of media and the new telecommunications world. Dwight D. Eisenhower used to
demonstrate the art of leadership with a simple piece of string. He would put the string on the table and say,
"Pull it, and it will follow you anywhere. Push it, and it will go nowhere at all." Producers should lead by
example and inspire by mastery of their craft. A traditional producer must be “a creative administrator...a
judge of creativity” who guides and supports others toward a common purpose. (Houghton, 1991)
Similarly, the teacher may be producer and/or director of the learning experience and fully responsible for
providing the wisdom of an off-stage sage and at the same time guiding students to create their own
technology rich productions.

In the context of leadership in producing new and better programs, media communications can
create richer, more elaborate relationships and enhance education. Now, the strategies must be right and
practitioners must understand the "why" as well as the "how" of media production. It is no longer enough to
produce by rote or formula. One must understand media psychology to produce well in media. People are
driven by their emotions when they are correcting a deficiency, engaging in personal development or simply having fun.

Outcomes

In many graduate technology courses, students collaborate on project-based teams, and create a formal "production" guided by a set of rubrics. In one course, the product is a CD-ROM containing one or more lessons incorporating the technology and learning approaches that have been integrated into classroom instruction. The teachers, as part of the production company, have contributed to a common resource and have developed instructional strategies to be used with their own students. In another course, teachers create web-based learning modules to deliver both synchronous and asynchronous mentoring.

Abstract: The Alliance for Catholic Education (ACE) at the University of Notre Dame endeavors to develop a corps of highly motivated and committed young educators to meet the needs of some of our country's most underserved elementary and secondary schools. In this paper, we provide a brief overview of the nature and history of the ACE initiative, its partners, and its interface with the AmeriCorps National Service Initiative. We next explore the role of technology in the current program, followed by description of recent adjustments. We look at a needs-analysis in progress, including a technology survey of schools where the ACE participants are situated. Results of the needs analysis will be shared at the SITE conference.

Overview of the ACE Program

The Alliance for Catholic Education (ACE) at the University of Notre Dame endeavors to develop a corps of highly motivated and committed young educators to meet the educational needs of some of our country's most underserved elementary and secondary schools. ACE combines the efforts of the Institute for Educational Initiatives (IEI) at the University of Notre Dame, the National Catholic Education Association (NCEA), the Departments of Education at the United States Catholic Conference (USCC) and the University of Portland. Founded in 1994 by Fr. Timothy R. Scully, C.S.C., and Sean D. McGraw, ACE recruits, educates, places, and supports talented, committed, and professionally trained recent college graduates as K-12 teachers to serve in under-resourced Catholic school systems throughout the southern United States.

ACE has become an innovative and successful model of teacher formation, targeting gifted and service-oriented applicants from a broad variety of undergraduate disciplines and representing a diverse set of ethnic and cultural backgrounds. To prepare and guide ACE teachers through the challenge of this two-year immersion experience, the program is founded on three central pillars: professional education, community life, and spirituality. Such emphasis on the holistic development of new teachers has resulted in high retention rates (92%) and high principal approval rates (97%) over the life of the program.

ACE participants include recent graduates from the University of Notre Dame and Saint Mary's College, as well as a number of other select colleges and universities. These graduates teach in approximately 90 parochial schools throughout the urban and rural Southern United States. To carry out its core teaching
mission, ACE recruits talented graduates from a broad variety of undergraduate disciplines, representing a
diverse set of backgrounds and experiences, and provides an intensive two-year service experience
encompassing professional development, community life and spiritual growth. These three components are
at the heart of the ACE initiative. Its aim is to provide excellence in education and to maximize
opportunities for personal and professional growth for program participants. Students accepted into ACE
and the Masters in Education (M.Ed.) program are provided with the opportunity for a high quality
master's degree experience, which builds on their solid undergraduate academic backgrounds in their
disciplinary majors. The program leads to a Masters in Education, 2 years of experience as an instructor of
record in a school system, and an initial teaching license.

From its inception, ACE has made every effort to insure that its members are prepared for the rigors of
teaching, leading, and serving in a challenging classroom environment. ACE teachers experience an
intensive teacher education program designed and administered by the University of Notre Dame. Under
the direction of Dr. Michael Pressley, the ACE professional training spans two years and integrates
graduate-level course work with an immersion experience in teaching. Over the first two summers after
admission to the program, ACE teachers live and study together at the University of Notre Dame. The
summer sessions combine an innovative teaching curriculum taught by seasoned practitioners and select
faculty from the University of Notre Dame with supervised field experience in both the public and Catholic
elementary schools of the greater South Bend, Indiana area, and in the Upward Bound program at Notre
Dame.

At the completion of the first summer training component, ACE teachers travel to needy parochial schools
of the South and Southeast to serve as full-time teachers during the regular school year. In addition to the
support of mentor-teachers in the parochial schools where they teach, all ACE teachers are brought together
twice during the school year in a retreat setting to deepen and enhance their commitment to becoming
professional educators. Upon completion of two years in the ACE program, participants have fulfilled the
requirements for a Master of Education degree, and have provided an urgently needed presence in the lives
of our nation's most needy school children.

ACE teachers live in community, sharing the challenges and rewards of beginning teachers. Each local
ACE community becomes a mutually supportive environment, forming part of the local parochial and
neighborhood school community. The program offers an ongoing evening seminar during the summer
session, as well as two workshop-retreats during the regular school year, to provide participants with skills
to live a healthy community life. In addition to the support ACE teachers receive from one another, local
diocesan resource personnel and Notre Dame Club members assist the teachers in establishing an effective
presence within the local communities

ACE and AmeriCorps

ACE is a member of the AmeriCorps National Service Initiative. AmeriCorps is the national service
program that allows people of all ages and backgrounds to earn help paying for education in exchange for a
year of service. AmeriCorps members meet community needs with services that range from housing
renovation to child immunization to neighborhood policing. The Alliance for Catholic Education enjoys a
unique association with the Corporation for National Service and AmeriCorps. In 1994, the Corporation for
National Service selected ACE, in a highly competitive national competition, as one of 11 National
Demonstration Programs. Through the Corporation's Learn and Serve America: Higher Education and
AmeriCorps departments, the corporation has provided both program funding (including the innovative
summer teacher-training and service-learning program) and a substantial education award to all qualifying
ACE participants, who are thereby considered full-time AmeriCorps Members.

ACE and Technology

In keeping with its continuous improvement goals, ACE has initiated an effort to enhance and further
integrate the role of technology in its year-round teacher training. In addition to their summer coursework,
ACE teachers installed in the various dioceses assume additional coursework throughout the academic year
via distributed learning. Online courseware (Web-CT), listservs and e-mail are utilized as primary or supportive technologies. With some exceptions, listservs were the primary tools used for course discussion. ACE faculty observed problems stemming from e-mail accounts coming from various sources, use of listservs, etc. Two educational technology consultants were hired in the spring of 1999 to evaluate Internet issues and begin to explore avenues for integrating technology into the curriculum, including the intensive summer pedagogical experience.

Some of the Internet concerns were addressed during the summer of 1999 by determining a standard delivery and response mechanism (including Web-CT, listservs, and the Netscape Communicator with its various e-mail, browser, and chat features) supported by the University of Notre Dame educational and technology support services. All new and returning ACE participants received training in Web-CT, an online courseware tool. Interested faculty members were also trained in this application, with additional faculty training slated for small group and one-on-one training through the year. Listservs remain in heavy use by faculty.

Faculty poll: The 1999 summer faculty were polled to determine what types of software and hardware applications they used/would like to use and what types they taught/would like to teach. The summer faculty elected to use mostly current Mac or PC desktops or laptops. Many of the national faculty brought their own equipment. The great majority of faculty used integrated software applications such as Microsoft Office or ClarisWorks. Many supplemented their instruction with one or more Internet applications. Some were quite sophisticated using a range of tools from Web-CT to Hypermedia.

Instructors were also asked to identify what aspects of their content area they would like to explore for technology infusion? Some faculty coordinated student training in PowerPoint and WWW search/evaluation of lesson plans and instructional sites with ACE technologists. Each training session was oriented to a specific course. Students were required to integrate their newly acquired skills into their assignments. Other faculty delivered their own introductions to relevant software, arranging “hands-on” computer sessions for one or more class sessions. Many modeled use of technology infusion with software applications relevant to course material.

Survey of ACE schools: A survey was developed to evaluate the level of technology in the various schools where the ACE participants are serving. Mailed in August 1999, survey responses arrived intermittently throughout the fall. A total of 53 of 90 possible schools responded to the survey for a response rate of 59%. Analysis commenced in November and is ongoing.

The survey was developed in accordance with established principles and precepts (Babbie, 1990; Dillman, 1978; Krathwohl, 1993) and somewhat similar to various technological survey formats (QED, 1999; Becker,1995). The survey is comprised of a mixture of closed and open-ended questions. Respondents were asked to select some responses from a list provided by the research form. Respondents fill in a numeric or text response according to direction), dichotomous response questions or (“yes/no”), multiple choice questions (respondents choose from several options), checklist questions (respondents choose as many as may apply). We devised two extensive open-ended questions and several opportunities to describe “other” options in questions groupings. These permitted some freedom in answering the questions and an opportunity to provide some depth in the response.

Quantitative survey data was collected in Microsoft Office 2000 Excel in compliance with the coding structure developed from the survey form. The results were imported into SPSS 9.0 for Windows for data analysis. Frequencies were calculated for all coding categories. Some preliminary results are discussed in the following paragraphs.

Of the 53 schools that responded to the survey, 11 were elementary only, 27 were elementary plus middle schools (K-8), 4 were middle/secondary schools, and 11 secondary schools. More than half of responding schools were K-8. Many of the elementary and K-8 schools also contained pre-kindergartens as well. Fifty schools responded to the questions about number of teachers and students in each school. Of these, they
reported 1,226 teachers and 18,009 students for an average of 26.7 teachers and 360.2 students per school. The overall teacher/student ratio is 1:14.4.

Schools participating in the ACE program reported a strong orientation toward PC platforms, although there was some Macintosh usage in elementary or K-8 schools. Where used, the Macintosh computers are dated. Macintosh use in secondary schools is rare. The quantities of computers reported in Pentium I or II category are larger than the combined totals of computers in all other categories. Factors contributing to this predominance were not collected for this study but may reflect price and performance considerations given the constrained resources of the many of these schools.

</table>

Table 1: Type and Location of Computer Access in Schools

Ninety-four percent of responding schools reported some form of Internet access ranging from dial-up modem to ISDN. The most common forms of connections were T1 or ISDN. Those schools without Internet access intend to hook up by 2002 or earlier. Eighty percent of the responding schools had a library/media center with at least one computer and Internet connection. Eighty percent of the respondents reported a computer lab, 72% of these were connected to the Internet.

We also wanted to explore school access to a variety of instructional equipment. The results are displayed as percentages in the Table 2. Please note that this information does NOT reflect quantities of equipment. Instead, it indicates whether the schools have access to equipment in a computer lab, an instructional room, or a library/media center. For example, a school might report access to a TV/VCR, but one TV and/or VCR may be shared among many rooms.

The majority of the instructional rooms have access to an overhead projector (78%), a television (82%), and a VCR (67%). More than 40% of the schools reported classroom access to some type of printer (42-46%). Nearly half of schools (49%) reported access to CD players instructional rooms while only 21% had access to a laserdisc player. There is very little access to digital cameras (4%), video cameras (9%), or fax machines (3%). Classroom communication equipment is constrained by very moderate access to cable TV/Satellite dish (24%), telephones (17%) and fax machines (3%). Graphing calculators were not widely available, although many of these skills can now be acquired using existing, available computers.

Understandably, a much larger percentage of schools reported access to various types of equipment in the computer labs and the library/media centers than in instructional rooms. Laser printers were more like to be available in computer labs (63%) and library centers (38%). Nearly half (45%) of the computers labs had access to scanners; approximately one third benefited from telephone access. Library/media centers afforded more access to communications equipment and image capture equipment: telephones (70%), cable TV/satellite dishes (48%), video cameras (34%), digital cameras (17%), and fax machines (4%). Percentages of access to scanners, TVs, and VCR were similar to corresponding classroom access figures.

There was no reported access to assistive or adaptive technology for instructional rooms. Only one school had assistive technology accessible in a computer laboratory. Two schools noted access within a library or media center. The ACE program will begin to address this issue as part of a new exceptionality initiative at the University of Notre Dame.

Table 2: Types of equipment available by type of room in Schools using ACE pre-service teachers.

As may be seen in Table 3, virtually all schools reported access to extensive integrated software packages such as Microsoft Works, Microsoft Office, ClarisWorks, etc. Approximately 25% of the schools also reported access to word processing applications in computer labs, instructional rooms, library/media centers, and administrative offices. A smaller percentage reported access to presentation, database, or spreadsheets instead of or in addition to integrated software packages. Overall, 24% of the schools indicated access to at least one hypermedia application such as HyperStudio in their computer labs. Only 16% of secondary schools, however, reported access to a hypermedia application.

</tbody>
</table>

Table 3: Percentage of Schools Reporting Software Titles in at least One Room

28% reported access to image manipulation software in computer labs. Nearly half of the schools reported that computer labs and instructional rooms had one or more software titles for mathematics, science, and/or
reading (range of 39%-51% by type and location of software.) These elements, in conjunction with evaluation of relevant technology trends across the nation and a review of pertinent literature, will be incorporated into a cumulative needs assessment report. Since 46% reported access to scanners in the computer labs, it would appear that the respondents might not have considered the software applications that usually come bundled with the scanners.

**Conclusion**

We expect to further define and explore the acquired survey data by identifying and aggregating appropriate combinations of variables. These elements, in conjunction with evaluation of relevant technology trends across the nation and a review of pertinent literature, will be incorporated into a cumulative needs assessment report. Some aspects of needs assessment are already under consideration.

- The introduction to educational technology should be tightly focused on immediate usability, given the brief, intense duration of their summer training component. Wherever possible, short-term assignments should be coordinated with other faculty to reinforce and model integration of technology into the curriculum. One project and/or several substantial assignments, due after the ACE students have initiated their professional practice, would reinforce and enrich their summer introduction in technology.

- Given the preponderance of the PC platform, it appears prudent to focus additional hours in technology instruction to develop their skills on the PC platform. To assure that students can function on whichever platform available to them in their assigned schools, we will continue to provide crossplatform training. Since the integrated software applications are nearly ubiquitous, pre-service teacher training might be best served by focusing on the goals of teacher productivity and methods for integrating word processing, spreadsheet, database, and presentation software into the curriculum.

Additional efforts will include recommendations for hardware, software and procedural modifications relevant to technology and its integration across the curriculum within the ACE program. We plan to share our findings to date with peers and colleagues at the Site 2000 conference and invite their comments, suggestions, and constructive criticism.

CTER On Line: Providing Highly Interactive and Effective Online Learning Environments

Sandra R. Levin
Educational Psychology
University of Illinois
United States
slevin@uiuc.edu

Gregory L. Waddoups
Educational Psychology
University of Illinois
United States
gwaddoup@uiuc.edu

Abstract: New computer and network technologies have opened the possibilities for practicing teachers across the world to update their teaching skills and engage in lifelong learning activities. Online courses and programs are growing in number, yet some early reports have stated that students are not satisfied with the quality of these courses. Many colleges and universities are recording lectures; transferring their syllabi and multiple choice tests to the web; and expecting students to listen, read, and learn with little instructor feedback. Using a different, highly interactive model, faculty at the University of Illinois created an online Master of Education program. We will report on this model, including an in-depth evaluation of its effectiveness in providing an online learning environment for practicing K-12 teachers and administrators.

Introduction: CTER On Line

Beginning in the summer of 1998, the College of Education at the University of Illinois revised several graduate level courses into an online format and currently provides practicing teachers the opportunity to complete a Master of Education degree that focuses on Curriculum, Technology, and Education Reform (CTER). http://cter.ed.uiuc.edu A series of eight courses taken over a two-year period includes topics such as: (a) Using technology in a classroom setting, (b) Revising curriculum to include the use of technology, (c) Addressing issues related to classroom management, ethical, legal and school policies dealing with educational technologies, (d) Assessing and evaluating the use of educational technologies, and (e) Changing classroom and school practice to enhance learning. In this paper, we report on the process of developing highly interactive and effective online learning environments.

A combination of synchronous and asynchronous technologies is used in these courses. Course descriptions, syllabi, grading procedures, student participation and expectations are available on the web. A variety of communication tools have been used depending on the type of interaction needed. At the present time, instructors use the WebBoard® conferencing system for asynchronous discussions and synchronous chat sessions. Individual email and group reflectors are also used for one-to-one or one-to-group correspondence. RealPlayer® is used to stream audio and video files. Text translations of audio files are provided for hearing impaired students. Audio narrated PowerPoint® presentations have been created for some topics. TappedIn, a multi-user object-oriented environment (MOO) coordinated by SRI International provided interactions between the CTER students and educators across the country. A specialized tool, known as CTERbase/TEbase, was developed to help faculty provide individual feedback to students, grade assignments, and publish exemplary work on the web (Levin, Buell & Levin, 1999). In each course, the instructor first determines the type of interaction he/she wishes to have with the students then picks the technologies that best handle the interaction.

CTER OnLine instructors combine multiple methods of instruction to enhance student learning (Levin, Levin & Waddoups, 1999). The framework developed for online asynchronous discussions allow students flexibility to participate on their own time. Students currently teaching in K-12 and college settings are given the opportunity to implement their coursework into their classroom practice. Simulations are used to provide experience when dealing with sensitive topics and issues. Various grouping arrangements have allowed students to learn from one another. These multiple instructional methods have
been used to also demonstrate how current theories of learning can be incorporated into educational practice. Indeed, many students have incorporated these methods into their teaching practice.

**Dimensions of Effective Online Teaching and Learning**

The dimensions of effective online teaching and learning have been developed over the two-year-long formative program evaluation. Data has been collected from all students including pre- and post-surveys and university course evaluations. Case studies of four students were also conducted during the same period, and included interviews, site visits to the practicing teachers’ classrooms, and collection of their electronic communication and completed assignments. Many have discussed the need to address issues of quality and effectiveness of online teaching (Campbell, 1997; Findley, 1997; Powers, 1997). We think the dimensions of effective online instruction are particularly relevant for providing educational opportunities for K-12 teachers, but perhaps have wider application.

**Relevant and Challenging Assignments**

We have found that students in an online program have more of a consumer orientation. Repeatedly, students ask that the assignments, discussions, and readings be relevant to the work they are doing in their schools and classrooms.

One of the hallmarks of good teaching, regardless of medium, is helping students connect learning to their lives. Relevance is important to the students in the CTER program because they are practicing teachers who see their participation in this program as an extended professional development opportunity. Relevance in the online context should be thought of as helping teachers prepare curriculum and develop practices directly relevant to their teaching while also expanding their ideas about what is and should be considered relevant in their professional practice.

The most popular instructional activities in the CTER Online program are the assignments that ask students to create curriculum projects that can be used immediately in their own classrooms. Survey and interview data indicated (81% or 18/22) that the projects they developed or evaluated for their own professional practice were the most useful. This captures the idea of relevance in its most basic form.

One course in the CTER sequence focused on educational reform. In this course, small groups of CTER students worked together to write proposals to implement some form of educational change in their school or district. One group of students working at the same school put together an implementation plan to create a community school. The objectives of this plan included “creating a learning center to involve parents, students and community members coming together to enhance the neighborhood ties”. They continued: “Our newest project will be the creation of the Publishing station. Students, faculty, community members, and alumni at this elementary school will write and publish their created books. Each book published at the publishing station will become a permanent part of the elementary school library. This is just one of many examples of how CTER students created curriculum activities in their CTER courses that they immediately implemented in their own classroom and school.

Additional evidence of quality in online instruction can be found when students expand their notions of what is relevant to their professional practice. The Internet provides a particularly helpful environment for connecting practicing teachers to other educators to collaborate on ideas that are relevant for K-12 teachers.

Many teachers in the CTER online program were initially content to focus on curriculum projects for use in their classrooms. However, in the CTER Online program we have provided them with opportunities to engage in activities that have expanded their notion of what is relevant for their teaching activities. Assignments are not relevant simple because teachers can use them in their classroom, but because teachers can see that engaging in the assignment will provide an opportunity to engage in practices and develop skills that may be relevant for a teacher’s professional practice. In the CTER Online program, we have included assignments that are not directly applicable in the classroom, but engage them in learning activities that extend their thinking of what it means to be a teacher.

An example of expanding the notion of relevance can be found in a simulation that was used in a course about Ethical and Policy Issues in Information Technologies. A fictitious student named Suzie created webpages containing materials that would be considered improper for a school setting. CTER students were asked to reflect on how they would handle the situation and to discuss issues raised with their
peers. While controversial at times, the activity heightened their awareness of information on the Internet and its potential impact on a school setting. For their final project, students developed a set of Educators' Guides on a number of issues centrally affecting the ways in which new information and communication technologies are changing schools today. The topics include: Access Issues, Credibility and Web Evaluation, Free Speech vs. Censorship, Privacy, Commercialism, Intellectual Property, Copyright, and Plagiarism, and Computer Crime and Technology Misuse. These guides are available online at: http://hrs.ed.uiuc.edu/wp/.

Constructing seamless online learning environments

In addition to relevance, students expressed the desire for classes that are clearly organized so they do not have to search for the assignments and wonder whether they are following the schedule. This is particularly important in online courses, because students can follow the class only to the extent that there is a relatively clear structure that has some level of cohesion. What this typically means is making it more explicit how the class fits together and making an overt attempt to address issues of organization to the students. Being more explicit can be as simple as placing dates throughout the syllabus instead of using more generic terms such as Week 1 or Week 2 and using consistent headers and terminology when using multiple software tools.

What we are suggesting is that a seamless learning environment is one in which the threaded asynchronous communication tool, the syllabus, and the homework completion system are connected. The first week’s topic described in the syllabus should be directly linked to and easily identified in the asynchronous communication tool used for discussions for that week and instructions for the assignment should be clear and concise.

Another element of a seamless online learning environment is providing technical support. We have found that there are three levels of technical support needed in an online course for both faculty and students: development, training and ongoing support as shown in Table 1.

<table>
<thead>
<tr>
<th>Levels of Support</th>
<th>Faculty Support</th>
<th>Student Support</th>

</thead>
<tbody>
<tr>
<td>Development</td>
<td>Deciding which tools are most appropriate to use in the course and assisting in the development of the course in an online format</td>
<td></td>
</tr>
<tr>
<td>Training</td>
<td>Initial training in how to use the tools</td>
<td>Initial training in how to use the tools and access course content</td>
</tr>
<tr>
<td>Ongoing</td>
<td>Assistance when using some communication tools</td>
<td>Technical support with access, hardware and software issues during courses through email, telephone, and voice mail.</td>
</tr>
</tbody>
</table>

Table 1: Kinds of technical support for faculty and students to create seamless learning environments.

First, there are a number of decisions that an instructor faces when moving to an online environment. The instructor must consult with other instructors and technical support staff on which tools are currently in use and which would be most appropriate for the type of course offered. Once tools are selected, an instructor must gather and create the course materials. Often, technical support staff is needed to convert files from one format to another, digitize video and audio segments, transcribe audio files for students with hearing disabilities, and create usernames and passwords for student access. We have found that online students tend to have more of a consumer mentality and ask to see all course materials available at the beginning of the class so that they may pace the workload according to their own schedules. This is very often different than the way most university professors prepare for face-to-face instruction normally done just prior to each class meeting. Not only are professors changing the way they prepare and teach, but also they are learning how to use these new tools. This preparation and training takes a considerable amount of time.

Instructors also need ongoing support when using some of the latest technology tools. When audio or video streaming is used, technical support staff must be available to set up equipment, manage the cameras and microphones, and be on-hand in case of a technical failure. Even when synchronous chat is
used, the instructor is busy discussing course content and relies on the support staff to handle other questions through a “whisper” command that provides private conversations during a chat session.

Students also need to learn how to use the software tools that will be used throughout the program. For CTER Online, this support is initially provided in a face-to-face orientation meeting just prior to the beginning of the first course. Technical support continues throughout the program dealing with a variety of issues from access to consultations about hardware purchases and software upgrades. This type of support is provided through a combination of email, a technical support help line, and voice mail that can be accessed by the support staff in the evenings and on the weekends. Providing technical support throughout the program is essential to handling day-to-day problems that arise with the use of technology.

Providing a seamless online learning environment also involves developing a sense of community between the instructor and students. If provided with some face-to-face interactions throughout the program, faculty and students get to know one another on a more social level which alleviates the sense of isolation that is often felt in distance education courses.

**Providing adequate and timely feedback: Teacher-student interaction**

We have found that providing adequate and timely feedback to students is another important element of online teaching. Because students are remote, it is important to develop mechanisms that provide feedback to students on their progress. There are three levels of feedback that are necessary in the online classroom. These include online office hours, instructor response to individual and groups work, and feedback on individual assignments. To successfully provide these layers of feedback in the online course the instructor must have, or develop, a good facility using different types of communication technologies.

Conducting online office hours is one way in which student-teacher interactivity can be accomplished. In the CTER Online program, we have utilized two-way synchronous chat spaces and a combination of one-way streaming audio used by the instructor and synchronous text chat used by students for the purpose of office hours. Office hours are used as a time for students to interact with the instructor in real-time, to ask questions about the assignments, or to clarify a topic in the readings. While the questions tend to be specific, the entire office hour is archived and all students can view the chat discussion at a later time. Students have responded that the consistent use of online office hours has helped them feel more connected with the instructor.

We have noticed two patterns of instructor response related to individual and group assignments and discussions. One form could be described as just in time response and the other as archived response. Just in time response refers to the instructor responding to individual assignments or discussion messages from students as they occur in the ongoing discussion. Archived response is used when the instructor reads all the students messages (for the day or week), then replies to the entire class in one message addressing the points he/she would like to make.

Instructors provide individual feedback on student assignments through a specialized tool we developed called CTERbase. Students submit their assignment or enter a URL pointing to their assignment, and the instructor can review and reply back to the student on what they might want to consider changing before submitting the final version. Instructors can also provide feedback in a more public forum, like WebBoard, so that all the students can see the instructor’s comments and modify their work accordingly. This second method of instructor feedback is more efficient for the instructor by providing adequate feedback for students, however, some students have reported their preference for individual feedback.

**Constructing rich environments for student interaction**

Another indicator of quality in an online course is the creation of highly interactive learning environments for interaction between and among students. In the CTER Online program we have used a variety of methods to organize group and one-to-one student interactions.

Three methods we have used to form groups include student-selected, topic-selected, and instructor-selected groups. Each method offers both positive and negative results. Student-selected groups allow students who know one another or work in close proximity to work together on group activities. When students are able to choose their own groups, they have arranged meetings at a member’s home or
local pizza restaurant to work on assignments. On the other hand, students who are constantly given the chance to self-select group members tend to pick friends or individuals they know which actually narrows their scope of learning, minimizing opportunities to share ideas with students in other geographic areas. Some instructors have allowed students to choose a topic of interest and formed groups based on that topic. Depending on the course content, topic-selected groups can produce a mix of interests among the group members or narrow their scope of learning as in the self-selected group. Instructors have also assigned members to groups to ensure that each group have a particular mix of interests. While this grouping method can provide a wide range of expertise among its members, it can also lead to more tension or personality conflicts. We have found that using different methods for selecting groups throughout the course provides a good opportunity for students to work with different students to minimize negative group dynamics.

To maximize communication in an online environment, it is important to provide online conferencing space or conference call opportunities for each group to communicate among themselves. Instructors can provide simple group assignments in the beginning that build upon subsequent assignments and become more challenging toward the end of the course. Another effective strategy includes heavy instructor involvement in group activities early in the semester with less involvement as time goes on.

Research on distance education has repeatedly pointed to a high drop-out rate related to students feeling isolated from a social setting (Keegan, 1980; Kember, 1989). We have attempted to address this issue by providing a number of activities that foster student to student discussion. Students enrolled in our online courses come to the university for a three-day face-to-face orientation prior to their first online course. This time is provided to train students to use the software tools needed to participate in the program while offering time for students to socialize and get to know one another. Students share common goals, strengths and interests with other classmates in face-to-face and online activities. Chat and online conferencing space is provided so students can interact on a social level throughout the course. Students are also encouraged to provide peer reviews throughout the program.

Fostering anytime anywhere teaching and learning

Many students registering for online distance education courses are interested in the flexibility this medium of education provides. Therefore, another important element of quality online instruction is the careful balance of asynchronous and synchronous communication—to foster anytime anywhere learning. For an instructor this means choosing the appropriate technologies for the task they are trying to accomplish. Indeed, the technology and task fit is an important principle for those designing and delivering online distance education courses. One model we have used successfully combines the use of asynchronous technologies to facilitate much of the classroom interactions and synchronous communication to facilitate small group interactions and course office hours.

Of course, the right balance between flexibility and the need for interactivity will vary with each course. In some cases, an instructor may use all asynchronous communication for classroom and group communication and limit synchronous interactions to online office hours. At other times, weekly real-time video or audio conferencing may be most appropriate for the topic.

Another consideration to anytime, anywhere learning can be described as anytime, anywhere teaching. Both synchronous and asynchronous communication can be accomplished effectively by instructors regardless of location. This is most evident when instructors travel to conferences to report on their research instead of providing a substitute instructor for the course. They can now pre-record an audio or video presentation for the students to view at their convenience. With a laptop computer and telephone line, instructors can continue to respond to student email or online discussions away from their office. In addition, these new technologies offers the flexibility universities sometimes need to hire adjunct faculty to teach online courses or more easily involve experts in a particular field to participate as a guest lecturer or discussion participant.

Conclusion

The Internet and communication technologies provide educators with a wide array of educational tools to create highly interactive and effective learning environments. The question for many is how best to utilize these technologies. In this paper, we have reported one model for developing an online learning
environment that promotes high levels of interaction among K-12 teachers as they learn to integrate technologies into their classrooms. We have suggested that there are many issues to consider including making assignments relevant to teachers' experiences, constructing seamless learning environments, providing timely feedback, creating rich environments for interaction, and providing for flexibility by fostering anytime anywhere teaching and learning. Paying attention to these dimensions has led to the creation of robust learning environments for K-12 teachers to become leaders in the use of educational technologies in their classrooms, schools, and districts.

Using WebCT to Extend Learning in Graduate Educational Technology Courses

Mhairi (Vi) Maeers
Faculty of Education
University of Regina
Canada
maeers@uregina.ca

Abstract: This paper examines the use of WebCT in two graduate level Educational Technology courses. The paper briefly describes the content of both courses and the ways in which WebCT was used in each course, and the reasons for that usage. Data on how WebCT has enhanced or extended the learning of course material has been collected from reflective e-mail responses from all the students in the Fall 1999 class, from bulletin board postings, and from taped interviews with three students who were registered in both classes. This data has been interpreted to address specific features of WebCT responsible for this enhanced learning. Of particular interest is whether WebCT is an effective learning tool and medium by which and through which graduate students can more effectively learn course content.

What is WebCT?

WebCT (or Web-based course tools) is a software program that generates a course template. It is especially useful for busy professors, to enable them to create "sophisticated web-based learning environments" (http://www.uregina.ca/webct/facultyintro.html page 1). WebCT can be used as a complete on-line course, with no face-to-face contact, as in the WebCT version of Math 101 at the University of Regina (see http://www.math.uregina.ca/MathOnline/) or it can be used as a course supplement. The WebCT program has a variety of tools, divided into four main groupings (communication, study, personal account information, and quizzes and surveys). People developing courses using WebCT select the tools they require for their course. In both of the WebCT courses discussed in this paper, the major tools selected were the communication tools (bulletin board, private mail, calendar of course events, and on-line chat), in addition to icons for the course outline and course content.

Why Use WebCT?

My reasons for using WebCT in any form in two Educational Technology graduate courses are four-fold:
1. The provincial education department, Saskatchewan Education (http://www.sasked.gov.sk.ca/) is increasing its use of WebCT for distance education of classes in rural parts of the province.
2. I was part of a proposal in 1998 which received $24 000 to create an on-line version of Mathematics 101 (a first year mathematics course). I have followed the development of this course and the success of students taking this course (for more information on this course see Weston, SITE 2000).
3. A number of professors at the University of Regina are experimenting with different features of WebCT for course development.
4. The graduate students in my classes are mostly teachers or consultants and are likely to come into contact with a course being offered using the WebCT format, or they may wish to create a course using this format. They should therefore have some idea of the features of WebCT and of how to mediate the learning experience.

The First Education Technology Course

This course, offered in May-June 1999, can be located at http://webct.uregina.ca:8080/ Click on course listing, then on "Classroom Computers: Advanced" (the title of the course) and then enter guest as
user ID and password. This was a new course and was therefore run on an experimental basis; it included eight graduate and eight undergraduate students. Explored in this course were advanced features of Power Point, Internet searching, Hyperstudio, web design, how to teach in a one-computer classroom, how to use e-mail effectively in teaching, and so on. Students in the course were expected to create integrated curriculum projects using multiple multi-media tools, to regularly participate in bulletin board postings, to respond to numerous readings, to participate in the chat room, and to do class presentations.

An instructor-directed organization was visible throughout all the material posted on WebCT and most of the activity that occurred on WebCT. Students were given a user ID and password and accessed and used WebCT features only as students. All the content to be taken in the course was presented to the students on the first night. Their feedback was welcomed and any suitable modifications became a part of the course. All course content was organized into modules and posted on WebCT at the above address. Course readings were organized by module and distributed to students in advance. For each topic I created a forum for WebCT bulletin board discussion.

Within the above structure there was opportunity for students to exchange ideas, help and encourage each other, present to each other, learn from each other, and in general be a community learning together. WebCT, specifically bulletin board discussions, played a crucial part in this exchange of ideas. The boundaries between the graduate and undergraduate students merged. The undergraduate students excelled in their technology skills and in the creation of multi-media products. The graduate students excelled in their ideas of how to apply the technology to their classroom learning environments and in how to integrate the technology to the curriculum. Each group needed the other to attain a holistic idea of how to use technology effectively in classroom-appropriate ways. Each group was impressed with the knowledge base of the other.

Each week students formed reading groups (4 students to a group) and were responsible as a group for reading and responding to all of the readings. One member of each group was responsible for posting on the bulletin board a summary and critique of one reading assigned to the group. Others in the same group could respond to that summary and critique. Members of other groups could also respond. The articles for each week formed a topic and this topic was assigned a bulletin board forum; not only were the readings relating to that topic discussed, but the conversation among class members evolved to discuss the topic in more general terms. It was very exciting for me as the instructor to read and participate in the conversation of the different groups of students discussing a topic.

The Second Education Technology Course

The second Educational Technology graduate course was offered in the Fall 1999 semester. This course can be located at http://webct.uregina.ca:8080/ Click on course listing, then on "Internet and Curriculum Integration" (the title of the course) and then enter guest as user ID and password.

This course had a significantly different focus from the one offered in May-June. It was designed solely for graduate students who are familiar with basic computer-related technology skills and concepts, and their pedagogical appropriateness in the K-12 classroom. Specifically, the course was designed to explore effective and appropriate integration of the Internet into the curriculum. Students examined different ways in which the Internet can be organised, with frameworks such as:

- Virtual Environments [the work of Chris Dede -- see Dede (1991, 1998)].
- Filamentality [the work of Bernie Dodge and Tom March -- see Dodge (1995) and the original WebQuest home page at http://edweb.sdsu.edu/webquest/webquest.html].

Students explored these frameworks in order to develop a conceptual understanding of possible ways that the Internet can be effectively used in the classroom and integrated into meaningful curriculum-based activities. In conjunction with the above exploration students were immersed in learning theory, where they examined different learning theories such as:

- Cognitive apprenticeship and situated cognition (Lave, 1989; Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991)
- Communities of learners (Rogoff, 1994)

We also explored different world views about teaching and learning (e.g., objectivism and constructivism). From an examination of the world views and the theories, groups of students compiled charts which looked
at the world views and the theories according to the commonplaces in education—role of the teacher, learner, subject matter/content, and milieu (Schwab, 1978). Technology use was a part of each commonplace. The purpose of this exercise was to determine (1) if different views of teaching and learning would alter the commonplaces and affect how each commonplace would 'use' technology and (2) if we could see emerging a best use practice for using technology, especially the Internet, in pedagogically appropriate ways. For more information on this see Fulton, Couros and Maers, SITE 2000.

WebCT, and the learning involved in creating pathways and posting topics, was an important but secondary part of the course. All students were expected to regularly access and use the bulletin board and chat room features of WebCT. In addition, all students were given instructor access privileges to the WebCT course. This enabled them to explore all the features of WebCT in the event that they may need to develop a WebCT course in the future. The students (in groups) were expected to create the content of one of the course topics, and, thereafter, to post it on the WebCT home page.

This course was not structured for the students in advance. At the beginning of the course (in September, 1999), the students and I examined the overview of the proposed course content with its emphasis on exploring learning theory and the work of Seymour Papert, Internet organizational frameworks, and critical literature. Student input into both the course content, and course development was welcomed and incorporated into the overall course structure.

I mediated both the structure of the course and the course content. I enabled (with some expert assistance) students to post topics on WebCT. I distributed some readings appropriate to topics studied, but they also brought readings. Readings for future topics were discussed in class and each person responsible for any reading explained the purpose of the reading and if and how a summary and response would be made. Some external experts related to some of the course topics were invited to share their work with us. We also heard from students in the class who are experts in their work. The sharing of this expertise was encouraged by everyone. It is important to note that students recognized and celebrated this individual expertise and learned from each other. The students (in groups) created and posted course content modules on WebCT (this will be completed by the end of the Fall 1999 semester).

Investigating the Use of WebCT in the Above Courses

Because I had used WebCT in different ways in each course I was interested in finding out how students had learned through the different WebCT organisations. I designed a questionnaire which was e-mailed to all students in the Fall 1999 class, asking them about how WebCT as an element in the course enhanced their learning of course content. I also interviewed three students who were registered in both classes and I examined bulletin board postings for any indication of how the actual process of using the bulletin board affected learning of course content. In addition to these procedures I also had my own notes on the use of WebCT in each course. All the above information was examined for recurring themes that related to the use of WebCT. These themes are outlined below. Unless otherwise indicated all comments relate to both classes.

Findings

Skill Development

Some of the Fall 1999 students initially experienced frustration with the skill component of accessing and using WebCT. This frustration related to locating the part of WebCT they wanted to use, reading, responding to, and posting 'articles' on the WebCT Bulletin Board, and to creating and posting the course content. There is a steep learning curve in using this course tool technology. Although the students realized that WebCT was being used as a course supplement, and the focus was not on learning about WebCT, the students felt that more skill-based modules about how to use WebCT features would have been beneficial. University experts on the use of WebCT came to class and took us through a summary of how to use WebCT as instructors, and how to create and post course content. For most of the students, this instruction came too early and was presented too quickly. When it came time to 'post' course content material they had forgotten most of the earlier instruction.
Course Content Modules

As stated above, the actual posting of the course content modules proved to be a difficult and somewhat frustrating experience for most of the students. But, once posted, everyone appreciated having the entire presentation of the content, and all of the links, available at one place on the WebCT homepage. All the WebCT content postings looked professional and contained up-to-date and very interesting material. Most students reported that they have revisited the content modules and their corresponding links a number of times.

Bulletin Board

The class met every Tuesday from 4-8 p.m. Monday evening and during the day on Tuesday saw the most activity on the bulletin board each week for both classes. Students in both classes stated that the bulletin board was their most popular feature of WebCT. All class members in the Fall 1999 class reported that their use of the bulletin board enhanced their learning of course content. The following are what the students reported as the main advantages of using the bulletin board. This information addresses the use of the bulletin board in both classes.

Fora and Organization

In the role of instructor students were able to create a bulletin board forum if one didn't exist; as students they could select an existing forum into which they could post their 'article.' Some students in both classes were avid composers, making comments in almost every forum and about every presentation. Others chose specific fora or specific 'articles' to respond to. Each group of students in the Fall class was responsible for monitoring one forum (the one created for the course module they created). Monitoring involved posting to the forum, reading and responding to other postings in the forum, and writing a summary of the 'conversation' of the forum. The students generally liked being in charge of a forum, but the fora were not all created at the start of the class. They were created at the time of the group module presentation. Thus, if a module was presented in mid November, there would not be as much 'traffic' in that forum as in others that had been created earlier. The discussion around the presentations was disappointing for the presenting groups in both classes, as it occurred mostly around the time of the presentation. Some students suggested that all the fora be created at the start of the class and that students be assigned a forum and be expected to post one 'article' to the forum very soon after the start of class. Another idea was to give the bulletin board more structure at the start of class and have each student responsible for a topic throughout the class. Although the articles were threaded, there appeared to be few main threads running throughout the course. Some students stated that some articles were quite long and perhaps should not have been in the bulletin board, but perhaps part of an 'article' pathway, or maybe have a separate forum for longer articles and even a forum for article summaries. The students said that at times the bulletin board was like a chat room to get to know each other, to ask (dumb!!) questions and that perhaps a separate chat area or more informal forum be created where students could conduct more informal dialogue. Other students felt that all the articles should be organized according to the forum most related to the article topic.

Time to read and Digest Material

All the students stated that having the bulletin board was a great comfort and anxiety-reducer. A lot of the course content material was new to the students, was controversial, exciting, dynamic and at times quite overwhelming. Being able to discuss the ideas in class, read about some of them in hard copy articles and/or electronic articles, and then having time to digest the material and respond to it on the bulletin board, and to read the responses of others, helped the students have a much deeper understanding of the material and a greater respect for the opinions of others.

Busy Lives—a Class Beyond a Class

All the students in the Fall 1999 class, and half of the students in the May-June class are teachers, consultants, or principals—very busy people. Some said that the bulletin board helped them to stay on top of things, keep up to date with what was happening in class, stay up to date with what others were reading (and thinking)—all at home in their own time outside of class hours. The class was like 4 hours on Tuesday and at least four more hours on-line, reading bulletin board comments and/or visiting websites recommended by classmates. The students were all very conscientious about keeping up with the bulletin board postings—it was almost like they didn’t want to miss out on any part of the conversation about the
course content. One student reported "I find, especially at the graduate level, that a classroom discussion does not end after an hour—it does physically, but mentally it does not; my mind keeps on mulling over the topics that have been discussed. Using the bulletin board as a place for ongoing reflection, during the week (as opposed to only during class time), has extended/expanded the range of reflection. Further, I can respond to the reflections of others and add to the group discussion/reflection."

**Clarify/Stimulate Thinking**

Because much of the course content was new, and many new and quite different ideas were presented continuously, the bulletin board became the depository for at least a summary of the class content and offered the students a place to go to (at leisure) to review and reflect on the ideas discussed in class. One student reported "it stimulated many thoughts on how I would apply the learnings to areas within my own school and professional environment. The postings provided me an opportunity to spend some time reflecting on situations and events I was experiencing or had experienced in schools." Another student stated that "the bulletin board was a good way to keep conversations going between classes. It provided us a chance to 'clarify,' ask questions if needed, and to exchange ideas."

**Sharing Websites, Books, Articles etc.**

It was very difficult to take class 'notes' as new material and ideas were constantly being explored. Note taking would have resulted in missing part of the conversation. It very quickly became clear to the students that the bulletin board was the perfect environment to share great websites, new search engines, books that have been read and reported on in class, journal articles, sites with on-line articles, electronic journals, class power point presentations, and so on. Knowing that everyone would have immediate access to most of what was happening in class took the pressure off taking notes and enabled students to focus on understanding and thinking critically about what was being presented.

**Learning from Peers**

Most students reported that anything they posted on the bulletin board was an idea in progress to be shaped by responses from others. Some students felt uneasy about posting content that they did not feel completely grounded in and thus felt they were taking a risk in being challenged. All students found at least one topic that they felt comfortable with and knowledgeable about to post and respond to. The bulletin board became a place for all the students to read about what others have been reading and to learn from others. Individually, each student did a vast amount of background reading and research both for their course module and for their public presentation.

**Bulletin Board vs Chat Rooms**

Some students compared their use of the bulletin board to the chat rooms, and also to some experiences we had with Tapped-In, a virtual environment or MOO at Pepperdine University. While some (who are fast keyboarders) quite enjoyed the chat rooms, others stated that they much preferred the relaxed style of the bulletin board. One student stated "I found the chat line frustrating. I can't type, read peoples' comments, and think all at the same time. It was too rushed for my liking. I hate making mistakes in front of other people. The bulletin board is more my style where I can think about things and post it at my convenience." In both classes the chat room features were formally used on two occasions—in class, but the main advantage in having chat rooms is to use them when we are NOT in class. Students recommended that specific chat times could be established for discussions, and specific questions be posed.

**Personal Reflections**

In the Fall 1999 course, in retrospect, I made assumptions about the students' ability and interest in pursuing and using a variety of WebCT features with minimal help. As stated earlier, the purpose of this course was not to teach students how to use WebCT either as students or instructors; it was not to learn WebCT, but rather to use WebCT to learn. In the May-June course I created the WebCT content, with the assistance of an expert WebCT planner sitting beside me walking me through every step. The students used WebCT only with student privileges: they were not expected to post course content, create pathways, student lists, passwords, and so on. Because WebCT was new to all the students in the May-June class (and also quite new to me) I did spend some lab time teaching the students how to compose 'articles' for the
bulletin board—and assign these 'articles' to the appropriate forum, how to enter information in the calendar, how to access the course schedule, and so on. The student use of WebCT is not very difficult. But the instructor use is quite complex, even for the few features that we focused on. Having a number of 'instructors' working in groups, all working on different computers, in different locations, using different design software (e.g., Hyperstudio, Power Point, different websites) and then coming together in the lab to merge and post all their work proved to be a major undertaking. I have since discovered that many professors do not even attempt to create and post their own course material directly on WebCT. They usually create it on an Office application, perhaps as an HTML file, and then an 'expert' WebCT designer will upload that content and create the course in WebCT. It has become quite clear to me that if students are to learn how to use WebCT as students perhaps a number of short introductions to the use of various features is fine, but if students are to be expected to become familiar with a variety of tools as instructors, they need a lot of assistance at many points throughout the course. Naturally, the students all experienced some frustration when it came time to post their course content. One student reported, after reflecting on a WebCT presentation, "The initial explanation of how the WebCT worked was mind-boggling and gave me the feeling that I wouldn't ever know how to do anything on it. That discussion now (at the end of the course) would be quite a bit more useful."

For all the reasons stated above, students would not have had time to read everything that was discussed in class (thus summaries really helped), nor would they have had time in class to engage in the extensive and substantive dialogue that occurred on the bulletin board. At times this bulletin board discussion was fragmented as the students kept developing new areas of interest and new topics to discuss. Within the bulletin board feature of WebCT there was need for more initial structure and guidance for the students in how to start and maintain discussion on specific topics.

From the survey questions completed by the students and from the interviews with three students it is clear that the use of the bulletin board on WebCT played a crucial role in extending the learning of the content of the course. The students have a much deeper understanding of how technology can be meaningfully integrated into the curriculum and much of this understanding can be attributed to what they have learned from each other through the bulletin board.

Abstract  The goal of the professional development project was to facilitate the integration of instructional technology in the classroom. Twenty-five teachers in grades 3-5, from 9 different schools, participated. The project consisted of four workshop modules on technological training and five modules on development of interdisciplinary thematic units for integrating materials to achieve the Mathematics, Science and Technology, and English Language Arts New York State Learning Standards. Effectiveness of the project was determined by giving all participants a General Pre-test to determine baseline measures for each of the aspects of the Project and a General Post-test. Results indicated that the project was highly successful, although teachers did identify several limitations that need to be considered for future professional development activities.

Introduction

The Targeted Instructional Staff Development Project was a professional development project to facilitate integration of technology in the classroom. The ultimate goals were: to empower students to use technology in all phases of their education, to facilitate teachers as learners, and to achieve the New York State Learning Standards by developing interdisciplinary thematic units focusing on Mathematics, Science and Technology, and English Language Arts. At the same time, the project attempted to facilitate integration technology into the curriculum. The one-semester project consisted of nine separate workshop modules. See Bauder, Rossi, & Mullick (in press) for a description of three of the technology oriented modules.

The purpose of this paper is to describe the evaluation procedures used to determine the effectiveness of the project. Literature suggests that one major limitation of action oriented research has been the particular research designs employed. In 1997, Bauder, Carr, Mullick & Sarner reviewed research techniques employed in evaluating effectiveness of programs and found that few employed sound research designs.
As a result, the authors developed a set of guidelines for researchers that were adopted for the current study. A pre-post test design was employed. This design is particularly appropriate for assessing both formative and summative information. Because each subject acts as his/her own control it minimizes any random influences of extraneous factors and determines the effects of the project on changes between pre and post-tests.

Previous research by Ely (1990) and Bauder (1993) has shown that there are a number of conditions that facilitate or impede implementation of educational technology. An additional goal of the evaluation aspect was to determine the effects of the project on changes on some of these perceived barriers to integration of educational technology into the curriculum.

The Evaluation of the Project

All participants were given a General Pre-test to determine baseline measures for each of the aspects of the Project. Upon completion of the nine workshop modules, a General Post-test, consisting of many of the same items, was administered to the participants. These questionnaires provided summative information regarding the overall impact of the various modules on teachers' responses. In addition, pre-test and post-test questionnaires were administered for each of the individual modules. The individual results were used for formative information and allowed the procedures and information being presented in each of the modules to be monitored. The results were also used to refine the activities during the modules and to refine questions asked on subsequent surveys. Only the results of the General Pre and Post-tests will be presented in this paper.

The Questionnaires

The Pre and Post questionnaires had four common parts. Part I contained demographic information and examined frequency of use of hardware and software, perceived importance of these technological aspects in achieving the New York State Learning Standards, and the teachers' degree of comfort in using each of the items. Part II examined teachers' experience with technology including the use of technology in the classroom and the specific activities for which students used technology. Part III examined the extent to which teachers integrated technology into the classroom and Part IV tapped teachers' perceptions of barriers that impeded integration of technology into their classroom instruction. The Post-test included a final section that asked teachers to rate each of the modules on three dimensions. These responses provided an overall summary of the teachers' experiences throughout the project.

Results

Demographics

Twenty-five teachers from 9 different schools participated in the Targeted Instructional Staff Development Project. Of the 25 teachers, 80% were females who taught grades 1 through 5. The minimum number of years of teaching was 1 and the maximum was 30 with an average number of years of 12.84. Approximately 82% of the teachers had five or more years of teaching experience. Therefore the participants were relatively experienced teachers.

Pre-Post Changes to Determine the Effectiveness of the Development Modules

Part I: Frequency of Use and Degree of Comfort Working with Hardware and Software

For summary purposes, Total Indexes were developed by summing the ratings for the subsets of items related to frequency of use of hardware, frequency of use of software, comfort in using hardware and comfort in using software on both the pre and post-tests. Table 1 shows the average scores for each Total
Index. In general, teachers rated the items higher on the post-test than the pre-test. The only exception was average comfort in using the hardware items. For that item, the average on the pre-test (52.00) was higher than on the post-test (49.96).

To examine the data more fully, t-tests for dependent (paired) samples were performed using the Total Indexes as the dependent variables to determine if significant changes in teachers' responses occurred as a result of their participation in the project. The findings from the analyses of the t-tests for the Total Index for frequency and Total Index for comfort of use of hardware and software are displayed in Table 2.

Table 2: Summary of the t-tests for dependent samples on changes on indexes for total frequency of use total comfort in using hardware and software.

These results show that comfort ratings for using both hardware and software, were higher at the completion of the project than at its onset. Only one t-test failed to achieve significance. The t-test for changes in the teachers' overall ratings of level of comfort in using the hardware was not significant. This finding is not surprising in light of the fact that the types of hardware used during the project tended to be the same types that teachers reported having experience with prior to the project. However, it is important to note that their frequency of use of hardware did significantly increase by the completion of the project.

Part II: Changes in Experience with Integrating Computing into the Classroom

Changes in responses dealing with experiences involving technology in the classroom yielded similar results. All of the t-test achieved significance. These results indicate that teachers believed they were better able to implement technology into their curriculum at the completion of project. They also believed that they were better able to integrate technology into their curriculum and into specific units, guide students in the use of technology and, at the same time, accommodate different levels of expertise. In addition, teachers were better able to relate technology to curriculum objectives and to student achievement. Finally, the teachers indicated that upon completion of the project, they felt more confident in developing materials for student management using instructional technology and in preparing materials to be used by students in the classroom.
Part III: A Comparison of Perceptions of Teachers Use of Computers in the Classroom Compared to Students

Part III of the Post-test compared teachers' perceptions of frequency of various activities involving the use of technology in the classroom by the teachers themselves and by their students. Teachers believed they used computers more frequently compared to their students for organizing and storing information, for e-mail and for retrieving information from the Web. However, no significant differences are perceived between teacher and student use on text editing, creating non-visual graphics, developing Web pages and performing calculations.

Part IV: Changes in Perceptions of Barriers to Integrating Technology into the Curriculum

Part IV of the post-test was designed to examine the teachers’ perceptions of some of Ely’s (1990) factors that impede their ability to integrate technology into the classroom. In addition to examining changes for each of the individual factors, a Total Index of Perceived Barriers was developed for both the Pre and Post-tests. The results of the t-test analyses in Table 3 indicate that participating in the project did significantly effect the teachers’ perceptions of the extent to which the factors act impediments to integrating technology into the curriculum.

All of the analyses yielded significant results, except for one. In the pre-test teachers believed that Technology integration is a high priority within their school and therefore did not act as a barrier to integrating technology in to the classroom. The result in row 6 of Table 3 supports this perception. Even after participating in the project, teachers still perceived their school’s commitment to integrating technology as a minimal barrier. In all other cases, the perceptions of degree of impediment of integration of technology into the classroom significantly decreased. This change in perception may have occurred because as teachers gained more confidence in their abilities to work with hardware and software and as they learned new ways for integrating technology into their curriculum, they also perceived these factors as less of an impediment.

Table 3: Changes in perceived barriers after completion of the project.
Part V: Overall Evaluation of Each of the Modules of the Project:

In order to obtain summative information for the impact of each of these individual modules the last part of the Post-test asked teachers to evaluate each of the models by: giving an overall favorability rating to each, indicating the extent to which they believe that each Module would be beneficial in achieving the New York State Learning Standards and, indicating the extent to which they expected to apply information from each of the module in their future classes. These responses provide an overall summary of the teachers' experiences throughout the project.

The results show that teachers had a favorable impression for each of the modules. On a nine-point scale where a rating of 9 indicates high favorability, the average rating ranged from 6.48 to 7.88. The average ratings of the extent to which teachers' believed each of the modules would help to achieve the New York State Learning Standards were also highly favorable with mean ratings ranging from 5.84 to 7.6. Ratings of the extent to which the teachers expected to apply information from each module in their future classes showed a similar pattern of results. The mean rating for each module ranged from 6.4 to 8.0. In all cases,

Three separate Analysis of Variance analyses for repeated measures using teachers' overall ratings for the modules as the within-subjects using the overall ratings were performed. None of these analyses achieved significance. These findings indicate that although the teachers' overall ratings of the individual modules were not significantly different from one another. All modules were rated consistently high.

Overall Evaluation of the Entire Project

Three items were included in the General Post-test to assess the respondents' overall evaluation of the entire project. On the item that asked them to indicate the overall evaluation of their experiences in the entire Targeted Instructional Development Project, the average rating was 8.70 out of a possible 9.0. When asked if the teacher would recommend this project to their colleagues, the average rating was 8.65. The final question to determine the overall evaluation of the project asked teachers to indicate the extent to which they agreed or disagreed with the statement "If given the opportunity, I would participate in a project like this again". The average rating for this response was 8.35 indicating a strong degree of agreement. Taken together, these results clearly indicate that the participants had very favorable experiences in the project and believe that the knowledge and information they gained will be helpful to them in integrating technology into the classroom. The results also indicate that teachers would be willing to participate in similar projects in the future.

Open-ended Responses

On each post-test, teachers were asked to indicate the single most valuable feature of the module/project and the weakest feature of the module/project. A review of these statements indicate that teachers liked the interaction with other teachers, hands-on activities, learning strategies for integrating technology into the classroom and the ability to create materials that could be used in subsequent classes. The most common responses regarding the weakest feature tended to focus on lack of technical support; lack of equipment, connections and software; and the feeling that there was too much material covered in too short of a time period.

Conclusions:

The Targeted Instructional Staff Development Project was highly successful. The analyses of the results of the questionnaires indicated that the experiences of the participants were indeed favorable and that the project had a significant impact on the teachers' ratings.
There were three major sets of findings. First, the teachers’ responses indicated that as a result of participating in the project they were using both hardware and software more frequently in their classrooms than they had prior to the project. Second, teachers believed that these activities helped them to learn new ways to integrate technology in the classroom and they felt more confident in using technology themselves and in guiding their students in the use of technology at the completion of the project. The third major finding was the significant change in perceived barriers to the integration of technology in the classroom. Factors that had been perceived as barriers prior to participating were seen as significantly less of an impediment as teachers gained new experience and knowledge about technology and learned new strategies for integrating technology into their curricula. This finding is particularly interesting since few of the activities within the project addressed the perceived barriers directly.

The duration of this project precluded the opportunity to conduct a long-term follow-up to determine if changes actually were integrated into the teachers teaching strategies and lesson plans. However, the Post-test did ask teachers about their future intentions of implementing these changes. Teachers indicated that they expect to apply the information they learned in their future classes. They also indicated that they not only would be willing to participate in similar projects in the future, but they also would be willing to act as resource persons to other teachers in their school.

Participants did identify several limitations of the project. Specifically teachers felt that the activities were too concentrated and there was too little time to deal with the material adequately. They also indicated that a severe limitation to integrating technology in the classroom is the lack of technical support when they returned to their schools. Finally, they felt that a major problem to participating in the project was the difficulty in finding substitute teachers to free them up from their classroom obligations. Future projects should therefore address these concerns.

Abstract: Since 1997 the Amsterdam Faculty of Education (EFA) has the status of experimental teacher-training programme. To support the experiment several research projects take place, aimed at providing the EFA with data that can guide the innovation process. As part of one of these projects a model is developed that can support teachers in developing innovative learning environments. The function of the model is bipartite. It is expected that the use of a model will lead to the development of learning environments that correspond to the innovative ideas of the EFA and at the same time fulfil a role in the professional development of teacher educators. In the study a method of development research is used. In several cycles of development and formative evaluation a definitive design model will be developed and tested. In this paper the specifications for the design model and a description of a first prototype are given.

Introduction

In 1997 the Amsterdam Faculty of Education (EFA) was awarded the status of experimental teacher-training programme by the Dutch Minister of Education. In the same year the institute started to develop and implement a new dynamic curriculum to replace the traditional static curriculum. Important parts of the dynamic curriculum are Learning Practices (LP's). LP's are learning environments in which students develop competencies essential to the teacher profession. In LP's students independently accomplish complex authentic tasks that must lead to a meaningful product. EFA has named this approach productive learning. Anticipating the importance of Information and Communication Technology (ICT) in the future profession, all LP's have an ICT component. Furthermore it is important that an LP consists of more than only physical facilities. It should contain the main characteristics of the professional practice, such as, feeling responsibility for the quality of your work, a necessity to work together in a group, the need to search for new information and a stimulus to call upon expertise (Wielenga, 1998). In the vision of EFA the dynamic curriculum must enable students to shape their own learning processes. The students must also have more freedom to organise themselves the evidence they want to present to prove that they possess the necessary teacher competencies. It is expected that the dynamic curriculum, will enable EFA not only to respond more accurate to the rapid changes in the field of education, but also that student teachers will be better prepared for their teaching careers (Dietze, Snoek & Wielenga, 1998).

From the start the EFAs' teaching staff has been involved in the innovation process. The opportunity was given to all EFA teachers to participate in developing the new curriculum. For this reason the Expertise Centre for Curriculum Development (ECCD) was set up. During one or two months a year members of the teaching staff are relieved from their teaching duties and can dedicate this time to the design and development of
Learning cycle consisting of a string of action and reflection. This phase must also lead to concrete indications for the fourth phase is explored whether actions that are part of the design development. Methods of data collection in this phase are interviews, questionnaires and evaluation of LP's.

Quality and effectiveness of the model but also on the learning needs that emerge from the process of case and so on. In this way four cases will be studied. During the test-phase data will be collected not only of this method is that experiences from the first case can immediately be used for improvements in the overlapped cycles of LP development. This method is named a staggered experts. The third phase is the test-phase in which teacher-educators will test the design model in four second phase of the study a first prototype of a design model is developed in the first phase. This prototype will be revised on ground of comments of ECCD staff, EFA staff and other interviewee-educators. However, formative evaluation revealed that some of the LP's, developed by teacher educators, show little resemblance to the concept the EFA aimed at, at the start of the innovation. The researchers also noticed that interviewed teachers-educators had not had sufficient opportunities to learn during the developing process (Voogt, Odenthal, Taks & Otter, 1999).

Both problems are not unique for the EFA, but have been reported before. A changing view to education together with the aspiration to integrate ICT in the classroom urges teachers to develop learning situations that differ considerably from traditional classroom teaching (Sandholtz, Ringstaff & Dwyer, 1997). It appears that teachers underestimate the complexity of developing such learning situations. As a result learning situations not always possess intended and necessary innovative characteristics (Voogt & Odenthal, 1999; Voogt, Odenthal, Taks, Otter, 1999). The second problem reported is connected with the method of professionalisation that EFA employs. The concept shows similarities with action learning, a form of action research, which is based on the notion that we learn from our experience through cycles of reflection and action (Brook & Watkins, 1994). Revans (1982) defines action learning as learning from and with peers while tackling real problems. A condition for actual learning by solving problems is that there must be an equal emphasis on both learning and doing. In practice however the emphasis is more on solving the problem and therefore on doing. Also people do not know innately how to learn from their experience and should be supported with it (O'Neil, & Marsick, 1994).

In this study a combination of an instructional design model and an action learning model is developed and tested. In the first part of the study the emphases is on the development of an instructional design model that fits the needs of teachers-educators developing innovative learning environments with ICT. In the second part of the study the main focus is on combining action learning with the design model.

The Study

In the study the method of development research is used. In development research a researcher works with a group of practitioners to define a problem, and then experiment with potential solutions to the problem. Data are collected on the results of the experiment and fed back to the group. If it is determined that the solution was not successful, the researcher together with the practitioners redefines the problem, further experiments are developed, and again and again the group cycles through this process of experimentation and reflection. The main role of the researcher is to guide data collection and analysis (Brook & Watkins, 1994). The research method of development research ensures that outcomes are useful to the practitioners and is seen as tool to support the implementation of complex innovations. The desired result of a development research is twofold, (i) development of prototypical products, including empirical evidence of their quality; (ii) generating methodological directions for the design and evaluation of such products (Van den Akker, in press).

This study will concentrate on product development, in this case an LP design model. The study consists of four phases. In the first phase exploration of the context leads to accentuation of the definition of the problem and specifications for the design model. Methods of data collection in this phase are study of literature, interviews with teachers-developers of the EFA, interviews with ECCD staff and evaluation of LP's. In the second phase of the study a first prototype of a design model is developed on the basis of specifications defined in the first phase. This prototype will be revised on ground of comments of ECCD staff, EFA staff and other experts. The third phase is the test-phase in which teacher-educators will test the design model in four overlapped cycles of LP development. This method is named a staggered case study (Walker, 1998). Advantage of this method is that experiences from the first case can immediately be used for improvements in the second case and so on. In this way four cases will be studied. During the test-phase data will be collected not only on the quality and effectiveness of the model but also on the learning needs that emerge from the process of development. Methods of data collection in this phase are interviews, questionnaires and evaluation of LP's. In the fourth phase is explored whether actions that are part of the design process can simultaneously be part of a learning cycle consisting of a string of action and reflection. This phase must also lead to concrete indications for
the ECCD staff how to support and stimulate the learning process of the teacher-educators during the development process.

Specifications for the LP design model

At this moment the first phase of the study is completed. Literature research and interviews with ECCD staff resulted in the first specifications for a design model. Specifications for the LP design model are based on the following assumptions.

- The LP design model has to fulfil different functions. Firstly it must support developers in efficiently developing LP's. Secondly it must ensure the quality of LP's. In the third place it must function as a communication device and improve communication between developers among themselves, communication between developers and ECCD staff, communication between developers and other EFA staff, and finally communication between the developers and students. The LP design model should therefore offer a clear communication frame.

- Development of innovative learning environments is a complex process (Richey, 1995). Support is desirable in view of the reported problems (Voogt & Odenthal, 1999; Voogt, Odenthal, Taks, Otter, 1999). Prescriptions however are not advisable exactly because of the complex and incidental character of the development process of innovative learning environments and the aversion that teachers (as most developers) have to models and prescriptions in particular (Gustafson & Branch, 1997). The LP design model should therefore support the process of development but not prescribe it. The LP design model must form a heuristic basis from which the developers can begin to develop their own LP.

- A design model should consist of at least the following major activities; analyses of the context and needs; design of a set specifications for effective, efficient, and relevant materials; development and construction of all materials and supporting processes; implementation of the product and processes or anticipation on the implementation; formative and summative evaluation of the product and processes (Visscher-Voerman, 1999). The LP design model should at least consist of the above mentioned activities.

- The development process must not only result in an LP but also have surplus value for the professionalisation of the developers themselves. In complex situations where one best solution cannot easily be advocated, forms of action research can be a useful learning strategy (O'Neil & Marsick, 1994). Action research is the reflective process whereby in a given problem area, where one wishes to improve practice or personal understanding, inquiry is carried out by the practitioner – first, to clearly define the problem; secondly, to specify a plan of action- including the testing of hypotheses by application of action to the problem. Evaluation is then undertaken to monitor and establish the effectiveness of the action taken. Finally, participants reflect upon, explain developments, and communicate these results to the community of action researchers (McKernan, 1996). The LP design model should not only contain support for the development of LP but also provide a model for action research.

- The new curriculum of the EFA is centred round the concept of productive learning. In productive learning aspects can be recognised of contemporary ideas from the field of education such as constructivism (Wilson, 1996) and situated learning (Brown, Collins & Duguid, 1996). In these concepts learning is seen as a process that results from a complex set of interactions between the actors within this learning space (Gustafson & Branch, 1997; Voogt & Odenthal, 1997; Wilson, 1996). In traditional design models development of instruction is generally understood as the process of selecting the best instruction method, given the desired outcomes under set conditions (Winn, 1993). In innovative learning environments however the characteristics of the learning space determine the nature of the learning process that actually will occur. The LP design model should therefore address those characteristics of the LP necessary to raise productive learning.

- One of the basic assumptions of the concept productive learning is that during the learning process students are confronted with their learning needs. The learning environment cannot be fully defined and prepared in front because these learning needs are not always predictable. Also the role that the teacher has to perform is often uncertain in advance because it is expected that the teacher meets the needs of the students (Wilson, 1996). Inherent to the concept productive learning and the connected concept of LP's, is therefore the continuation of the development process during the learning process. The LP design model should take into account that specific characteristics of the LP can not be specified in detail in front but should be specified
at a later point by the teacher or by the students as part of their learning process. Also, to ensure that an LP includes proper support and guidance, in the development of the LP should already be taken into account that characteristics of the LP might have to be changed or adapted several times. The LP design model must therefore reflect the iterative or recursive character of the process of LP development.

First prototype of the LP design model

On ground of specifications a first prototype for an LP design model was developed. The model consists of three related parts, a process model, a product model, and a learning model. At this stage the learning model has not yet been specified. The intention however is to insert a model of action learning. Action learning is a strain of action research and it is directed at improvement of professional practice. An action learning model includes questioning the framing of the problem, collecting data, and trying solutions (Brooks & Watkins, 1994). The process model has to facilitate communication between ECCD staff, EFA staff, students and LP developers. In the process model the preconditions for the development of the LP are created, such as time, financial and personnel support. The process model is therefore mostly determined by the organisational context of the EFA. Although developers and in practice can exchange information as often as chosen, the EFA demands two obligatory instants of evaluation. In the first evaluation by means of a project plan is decided whether the LP has enough potential to be developed. In the second evaluation the further development of the LP is delegated to teachers and students. After that teachers and students conduct a third evaluation, both as part of their learning process.

Figure 1: Prototype of LP design model consisting of a process model, a product model and a learning model.

Centre of the LP design model is the product model. Included in this model are the main components of an LP. These components are, content & goals, roles of teachers, roles of students, and materials &
infrastructure. In the model the LP is embedded in the institute of education as well as in the educational practice. For each for each of the components of the LP, the embedding in the institute, and in the educational practice characteristics are defined.

For the first prototype a list of characteristics of LP's was composed in co-operation with EFA staff (Voogt, Odenthal, Taks & Otter, 1999). It is the intention the list will be updated yearly on ground of state of art knowledge and results of the evaluation of LP in the preceding year. The actual development process of an LP starts with a definition phase in which for each component a first outline of core characteristics is given and for other characteristics realised in the specific LP. Important are not only which of the characteristics the LP will contain but also whether the characteristics of each of the components are in balance. For example, if in an LP students are expected to act independently, characteristics of materials and infrastructure as well as the characteristics in the roles of the teachers must support this independence. The definition phase results in a project plan that contains the first outline of LP including the characteristics the LP possess and how is it is embedded in the institute and the practice.

After the definition phase an iterative recursive process of LP development begins in which developers alternately work on the realisation of specific LP characteristics, develop materials and supporting processes for the LP and evaluate the process by comparing prototypes of the LP with the outline of the LP. This results in a LP manual which contains next to the description of the characteristics of the LP and their specifications, an instructions for the teacher and the students. In the LP manual should also be specified which of the characteristics of the LP need to be further developed by teachers and students together with indications of how these development can take place. Finally the LP manual contains specifications for evaluation of the LP and adaptations that might be necessary in practice. The development process is completed with an evaluation phase in which students and teachers test the LP.

WE HAVE THE EQUIPMENT—WE NEED THE TEACHERS TO RUN IT

Davenport Plumer—School of Education, New York Institute of Technology USA
dplumer460@aol.com

Abstract

For at least the past decade national, state, local and philanthropic policies have focused on the goal of getting more computers into the schools and more computers connected to the Internet. These policies reflect the belief that Information Technology (IT) is a powerful teaching/learning tool and an essential skill set for future employment.

Recent surveys and state-specific data suggest, first, that the goal of providing IT access to all students is being realized and, second, that IT is not reaching its full potential because teachers are either not using it at all or using only its most limited capabilities.

This paper will discuss one masters program that is successfully preparing teachers to use the full potential of IT.

Access to Information Technology

The past decade has seen major policy and program initiatives designed to increase K-12 student’s access to computers and the Internet. Wire the schools day, E-Rate, $9.9m in USDE Community Center Grants and a similar private sector program, PowerUP aimed at closing the "digital divide" in Internet access—these are only some of the programs driven by the belief that IT is a powerful teaching/learning tool and also a skill set essential for successful employment.

Following the federal lead, state budgets have increasingly included support for hardware and wiring; and individual school districts have undertaken large-scale bond issues to support increased IT in schools. California, for example, has spent over $400 on its Digital High Schools Program since 1997. The result is 19.3 students per Internet-connected computer.

Similarly, the New York State Legislature has approved $213m, $239m, and $292m over the past three years to support IT, producing a ratio of 15 students per Internet-connected computer.

These and similar efforts in other states have led to the conclusion that “a critical mass has been reached. More than half the nation’s classrooms are connected to the Web, and schools have an average of one instructional computer for every 5.7 students”. (Education Week, September 22, 1999)

Utilization of Information Technology

While the goals of IT availability are being met, utilization of these resources by students and teachers shows a less encouraging picture. One reason for this may be the computers themselves. Of the computers being included in the availability counts, 19% consist of Apple IIe’s and 386 machines that will not run recently created software or provide Internet access.

This percentage is consistent with the finding that teachers tend to underutilize the capabilities of computers at their disposal. A study conducted by researchers at UC Irvine and the University of Minnesota found that secondary science teachers are more likely to use computers for word processing and information finding than for “doing science”.

Similarly, the 1998 National Assessment of Educational Progress in Reading found that student computer use in the fourth and eighth grades was infrequent at best. Eighty percent of fourth graders reported using computers either “not at all” (39%) or “once or twice a month” (41%). For eighth graders the respective percentages were 38% and 44%.

On a more personal note, I recall pushing and cajoling teachers who have the hardware and software but have their students use it as an electronic encyclopedia or search the Internet for material already available in the local library.
What Explains Underutilization of IT?

Answers to the underutilization question vary. Teachers say they do not have enough time to learn the courseware or enough computers. Administrators say the teachers are not prepared to use computers.

No matter what the explanation de jour, the consensus points to teachers. Experts with a firm command of the obvious conclude that teachers are the key to increased, more skillful use of IT.

There is an equally strong consensus that neither pre-service nor in-service training is adequate to the job of preparing teachers for effective IT utilization. This inadequacy shows up in both the type and the amount of training. Most training focuses on operating systems and perhaps word processing. Yet teachers report that this type of knowledge/skill is insufficient to launch them as active IT users.

In terms of the amount of training experienced by most teachers, eleven hours a year is a high-end average figure.

One problem may lie in the fact that the skill levels and the time it takes to achieve these levels are not well understood or accepted. Any plan for training or assessment of training effectiveness must be based on a model or ideal of the trained professional. Most models envision four stages of development or proficiency. (See, for example, “Professional Skills for the Digital Age Classroom” www.milkenexchange.org/pec/)

Level One in this and similar schemas is basic skills—computers 101: how to operate a computer and use one or more of the big three applications, word processing, database and spreadsheet.

Level Two is adoption. At this stage teachers are developing the knowledge, skills and disposition to try out ready-made courseware for classroom use. This could be CD-ROM on some aspect of the environment, a math drill, or a Jostens reading program. This is “as is” instruction and typically does not require the teacher to change his/her style of teaching.

Level Three is adoption. Teachers at this stage are modifying and combining elements of IT to fit the needs of their students and the goals of the curriculum. Usually, the teacher will start to modify his/her teaching style at this stage. One example is a peer tutoring arrangement that involved fourth graders working with a class of first graders. The older students used PowerPoint to put up a picture and the first graders’ stories about that picture—usually something about a sibling, their grandmother or their pet.

Level Four, Integration, occurs when a teacher has a solid base of technical skills, knowledge and disposition to integrate a range of IT elements to achieve a variety of curricular goals. A teacher at this level knows how to teach IT as a subject and how to use IT with her students.

A level four teacher might, for example, want to have students learn how to weigh evidence and develop theories. To achieve this goal she enlists the help of several other science teachers who are members of a listserv. All four agree to have their students build simple air quality measures and report the data to each other daily using e-mail. The data are stored in a database for several weeks. The students then develop and share theories about the way the data are behaving. “Maybe our equipment isn’t working right”; “maybe air quality changes with the direction of the wind”; “maybe air quality is different at different times of the day”. “Why don’t we measure air quality inside?”

The students share their data and their theories, continue to gather data to support or not support the theories. They present their results to a home audience or each other using hyperstudio.

The most important point is to note the difference between level one and level four—huge. The other point is that teachers at level one can have little or no effect on student achievement. As teachers move toward level four proficiency, their impact and the impact of IT increases.

Few teachers pass quickly and effortlessly from one stage to the next. With constant effort and support, most teachers will take three years to reach level four. This is why some studies
have shown a confusing relationship between years of teaching and computer use. The expectation is that the younger teachers will show the highest levels of computer use. Often, however, these beginning teachers are at level one and will be teaching for several years before they reach higher levels—provided they have strong professional development support.

Because of the cost and time involved, progress toward a four-stage model of IT proficiency has been patchy. For example, 42 states now require some demonstration of IT work as a requirement for licensure. However, only four require any documentation of continued IT training for recertification.

Nonetheless, state and federal grants are increasingly requiring budget commitments of 20 to 30 percent for training. The Literacy Challenge Grant is one example. Local bond issues are slowly starting to follow suit.

**The Role of Teacher Education Programs**

Teacher education programs do not generally get high marks for preparing graduates to be effective users of IT. Both the National Council for the Accreditation of Teacher Education (NCATE) and the International Society for Technology in Education (ISTE) have looked at the effectiveness of teacher education programs as preparation for using IT and found serious shortcomings.

NCATE, in 1997, concluded, “Bluntly, a majority of teacher preparation programs are falling short of what needs to be done. Not using technology much in their own research and teaching, teacher education faculty have insufficient understanding of the demand on classroom teachers to incorporate technology in their teaching”.

A year later ISTE surveyed 416 teacher education institutions (mine among them). Their report “Will New Teachers be Prepared to Teach in a Digital Age?” also faulted teacher education institutions. The survey found that while IT facilities were rated “adequate”, teacher education faculty, by and large, did not use these facilities to model teaching/learning using IT. Further, the study found extensive evidence that while virtually all institutions reported requiring a version of Computers 101, few offered courses in curriculum integration. In terms of the four-stage paradigm, the institutions were addressing level one only.

However, it may not be realistic to expect a pre-service program to take students all the way to level four. Instead, the model educational program most likely to reach that goal is one that combines preservice teacher education, a mentored year in a school with current IT and an IT proficient faculty, followed by a masters program (or the equivalent) to complete the progression. Such a model may involve jurisdictional overlap between preservice, teaching and inservice institutions, but it may be a better way to think about how to achieve level four proficiency. The remainder of the paper will examine a masters program that functions as part three of the model noted above.

**New York Institute of Technology Masters in Instructional Technology**

NYIT’s 36-credit masters program satisfies one requirement for permanent teacher certification. All of the students have provisional certification and are teaching full-time—not, unfortunately, all in well-equipped schools. Many come in at level one, having taken a “Computers in Education “course as undergraduates.

The courses form four groups. The first group consists of three courses (Introduction to Computers, Survey of Instructional Technology, and Multimedia Classroom Applications) and is roughly equivalent to the skills level in the paradigm. All three are lab courses.

Students learn the basic technical skills and knowledge: operating systems (MAC or PC or both), the big three applications, productivity tools like grade books, navigating the Internet and multimedia for instruction. Each of these topics is illustrated by classroom applications.

The second group of courses address adoption, adaptation and integration by having students apply the work of the course to their classroom teaching. Courseware Evaluation explores sources of courseware and develops evaluation schema for each of the students in each course. Sources of useful evaluation are compared as are specific evaluation criteria like the degree if diversity in a piece of courseware. Mostly this course works at the adoption level.
Technology for Special and at-Risk Populations identifies courseware and applications for two hard-to-reach populations. This is mostly an adoption course, but since it is often offered on line it also models the use of the Internet as an instructional medium.

Higher Order Thinking Skills focuses on sets of skills rather than a particular population. Students study courseware and applications that promote students' ability to, for example, analyze, synthesize and evaluate. This course begins to put curriculum and learning outcomes in the driver's seat. Based on their own classes, the graduate students create teaching/learning units using IT with their K-12 students.

The curriculum course—Instructional Systems Design—emphasizes integration by having students "plan backwards", starting from the skills and knowledge goals of a unit of instruction. By that time in the course the students have a menu of options to select from as they design a teaching/learning unit for their classes.

Each of the courses in this grouping is taught in a computer lab. Some are to one degree or another web based, with materials and the course outline all on line. Some courses have students submit work on-line.

The final two required courses focus on research, teaching the standard research skills as well as developing an extensive review of the IT literature in their discipline and conducting an experimental study of IT-based learning in their classroom. These courses spend one session in the lab using statistics software. Students use various Internet search engines and strategies to gather material for their review.

The two electives can be satisfied through transfer credit or two courses from the department. Examples include Networks—a lab course for computer coordinators and Instructional Application of the Internet. This course is entirely on line and models a constructivist approach to using the Internet.

While these 12 courses have helped a great many students achieve a level four proficiency, the program still needs improvement. First, there needs to be a tighter integration between the graduate students' K-12 teaching and the masters courses. As students move through their courses and attain levels two, three and four, they should have the opportunity to apply this coursework in their classes. For all the obvious reasons, this does not always happen. Having a strong district based professional development program also helps if one is available.

Another way to make this a tighter integration is to have each graduate student’s curriculum available to both the instructor and the rest of the class. This would provide a broader context for curriculum development and would underscore the mantra of the program “Curriculum drives the Technology”.

Second, the program needs to address the issue of assessment more vigorously and creatively. Given the dollars and the expectations behind the IT buildup, it is only natural to expect "results". Accountability at the state level generally means improved scores on standardized state tests, and the improvements should not be too long in showing up.

However, the desire for quick results is at odds with the four-level paradigm. It is not reasonable to expect improved student performance in a year or two if the time required for teachers to develop the requisite proficiencies may be as much as three. Thus our students must have a variety of alternative ways of showing results. The best approach is to show actual student work, but the masters program does not spend enough time on portfolios of student work that would demonstrate skill and knowledge development. Similarly, our students need to become familiar with the ISTE K-12 standards and be able to show that their classes are meeting these standards.

We know that curriculum is a zero-sum game. Adding work on assessment means dropping other topics. But unless we make these hard choices, we may not have the time needed to develop the fourth level of competency and the time for these skills to produce the results that justify the large expenditures and high expectations for IT.

Technology Autobiographies in Teacher Education

Carole S. Rhodes
Adelphi University
School of Education
Garden City, New York 11530

Abstract
This paper explores the impact of the integration of an online interactive website in a graduate pre-service literacy education class through an analysis of students autobiographical reflections. Students wrote their literacy and technology autobiographies as part of the requirements of a course. Through analysis of the autobiographies and follow-up interviews with students, several key themes emerged revolving around issues of teaching and learning, the responsibility of a university to adequately prepare teachers and the role of technology in the personal and professional lives of these students.

Purpose
The purpose of this study was to examine the technology lives and experiences of teachers through an analysis of their written, on-line literacy and technology autobiographies. The process of exploring their socio-personal history enables teachers to understand better and make sense of their own pedagogical positions and develop a deeper awareness of the factors that shape their teaching and learning (Schon, 1983; Friere, 1970). One outcome of this research is to encourage teachers to reflect on their technology experiences to become aware of their classroom practices.

Theoretical Framework
Richardson (1990) in calling for an "individualistic, psychoanalytic approach" to teacher education recognizes that the lack of reflection leads to "an idiosyncratic view of teachers. That is, the teacher teaches as he or she is. How then do we think about affecting change?" (p.13). Autobiography has been suggested as a possible way to help teachers alter what they do (Diamond, 1990) and is viewed by many recent researchers as critical to the process of professional growth and development (Solais, 1992; Duff, Brown and Van Scoy, 1995; Parsons and Matson, 1995). Knowles (1992) notes that we increasingly believe biography to have a significant bearing on the classroom behaviors and practices of teachers. Knowles, like Richardson, recognizes that by not adapting and dealing with the life history of teachers in preparation, future teachers are bound to become teachers who teach in the manner in which they were taught and who will be limited in the ways in which they can professionally develop. In Psychology of Personal Constructs, Kelly (1955) notes that people use experience to create constructs through which they create new experiences and then verify or modify other experiences. We build each experience, then, upon experiences that are, in turn, modified through future experiences. This process is one in which we view the participants as "explorers" investigating their own historical landscapes (Pope and Keen, 1981). Autobiographical explorations can help teachers heighten their awareness of their own learning and the teaching-learning process.

This study builds on previous work that examined the literacy autobiographies of pre service and in service teachers. (Ringler and Rhodes, 1998).

Methodology
Eleven teachers enrolled in a graduate teacher education program at a major urban university volunteered to participate in this study. The participants were in their 20's, 30's and 40's and are studying for advanced graduate degrees in literacy education. They indicated varying degrees of familiarity and comfort with technology. These
levels ranged from those who had never interacted on-line either personally or professionally, to those students who identified themselves as very comfortable with email and on-line personal communications. None of the students reported using on-line communication in any of their undergraduate or graduate level classes.

As part of their course requirements, students were to write their technology autobiographies and post them on an interactive web site that we created for this course. Students were encouraged to read and respond to each other. We then conducted and designed follow-up interviews to provide insight into the specific links between autobiography and the ways in which it can impact upon the participant's current thinking and classroom practice that went beyond the information in the written autobiography.

A structured interview script was used as a basis for very broad questions. Responses from the first interview suggested the need for elaboration, and we conducted a follow-up interview to ask each participant about categories that were either not clear or sufficiently detailed. As a result we interviewed each participant twice during a two-month period.

**Data Analysis**

Interviews were first transcribed from the audiotape and then coded using the categories generated from the interview script. During the initial coding, we coded technology in all of its implications. During the subsequent coding, the participants' thoughts about their current philosophy and teaching practices, specifically we coded the use of technology in educational settings. Using the information from both the written autobiographies and the interviews, we identified themes. Finally, we constructed a life story for each participant beginning with their initial introduction to technology, their current views on technology and its uses and concluding with information about their current teaching philosophy and practices. We gave the participants the opportunity to read their "life stories" as constructed by the researchers for accuracy and to make any corrections or additions.

**Implementation and Discussion**

I set up an interactive web site so that the students in this literacy education class would have experience with such technology. I felt that during their careers as educators, they might be in the position of deciding whether and in what ways to incorporate distance learning in their classes. Several students were concerned, confused and worried that they would not learn all of the content of the course. We spent a great deal of time talking about the logistics of the course and the concerns of the students. We talked extensively about technology and its role in teaching and how this course could provide a demonstration of such a teaching/learning situation. We talked about taking risks as teachers and as learners. Most of the students agreed that this would be an interesting experience. A few said that they would never use technology in their teaching and two resented the inclusion of this component in a literacy class.

Since this was a course for future teachers, we decided to focus not only on the content of the course but also on the process of being engaged in a distance learning situation. We explored the research on teachers as reflective practitioners as we navigated through the course. Students were continually asked to reflect on their experiences as learners as well as in their role as future educators.

**Results**

While there were differences in the experiences of the students, there were many similarities. These similarities centered on several themes. Preliminary data analysis revealed the following key themes: A Desire to Maintain Current; Technology Talk with Little Practice; Affect of Technology on Philosophy and Practice; and The Personal Uses of Technology/Professional Uses of Technology. The following is a brief discussion of some themes that emerged.

**A Desire to maintain current**

Most of the participants recognized that technology would play an increasing role in their teaching and their lives overall. While three of the participants did not like this, the remainder felt that technology could be a
positive force. All, however, recognized that they must be knowledgeable about technology to be current. The following are typical of some comments made and written at the beginning.

In order to survive, I'm going to have to deal with technology. Even though I am not convinced that it is beneficial, I have to know it in order not to be considered a fossil. I remember teachers who always seemed outdated and I do not want to be like them, they really weren't respected. (Jane)

As a writer, I think the impact of words is vitally important in our lives and I fear that the internet will use so many visual cues and clues that words will be rendered secondary. So, therefore, I have a vested interest in maintaining the integrated of the printed word, whether it be printed on line or on paper. (Greg)

Technology talk with little practice
Leslie's concern for remaining current also addressed a limitation in the University teacher education program. Leslie and others pointed to the fact that a university should be demonstrating technology and making it a natural part of the courses. This, they felt, is even more crucial in a teacher education program.

If I'm going to look for a job next year, I think I have to know about technology and teaching. I like hi-tech stuff and think I might be a good candidate for the incorporation of technology in my classes. The problem though, is that we talk about it in classes at Pace, but we never use it. If I'm going to be able to talk intelligently at an interview, I have to have had experience—not just at home doing fun stuff, but also experience using technology to teach and learn. (Leslie)

All of the students expressed similar concerns about this issue.

I need to walk the walk not just talk the talk. Our school is supposed to be modeling best practice but we really don't see that. There are so few professors who are using any sort of technology. Aren't they supposed to be on the cutting edge? For some teachers, it seems that high tech is using a slide projector. I think there is a bit of hypocrisy going on here. How can you teach future teachers if you don't know the material itself? (Jeff)

In order to teach math, we need to learn math. In order to teach technology we need to learn technology. (Sue)

Impact of technology on philosophy and practice
During the semester, I continually asked students to reflect on their emergent philosophy regrading teaching and learning. For those students who were new to technology, they often used these experiences to reflect on what their students might be going through as they study new areas and try new things. They most often related their frustration with technology to the frustrations their future students must feel when they are grappling with ideas and information which are difficult.

As I struggle to connect on line and navigate our website, I find that I am constantly thinking of how very young children learn to read (this is, after all, a literacy course). I think I can better relate to them and the difficulty they have, then I realize, that I am a relatively successful adult, and I sometimes feel like I'd like to pack it in due to my frustration. Of course, I can, I've chosen this new career path and if it gets too difficult I can just toss it. Little kids can't just opt out of school. Computer and me is like a little kid learning to read. It's all a bit confusing and overwhelming, but I need to master it in order to function in the real world. (Barbara)

This has been a great exercise in relating to the struggle of our students. I've always been an accomplished learner and scholar, but going through this experience has given me a keener insight into the experiences of others. (Jeff)

The personal uses of technology/professional uses of technology
Four students were not convinced that they would incorporate much technology in their teaching, but, like all the other members of the class, they felt much more comfortable with technology and much more enthusiastic about its role in their lives. The four students saw the value in internet research for their students but questioned their ability to help their students critically evaluate the sites and information on the web. The remaining students found that even during this one semester, they were using the web more, connecting with family and friends via email and seeing technology as a normal part of their lives. Jane said,

I really feel much more comfortable. This must have been what people felt like when the telephone became prominent in people’s lives. It is like a new horizon and all of us have to get on board or we’ll become extinct. I found myself checking our online site each day and when I did, if I did not see any new messages or posting, I felt disappointed and disconnected. It was like when I was a teenager, sitting by the phone, waiting for one of my friends to call. If they didn’t I felt sad.

Findings and Implications

Besides the themes represented above, this project enabled the students to take more control of their learning as they posted topics of discussion, interacted between and among themselves without heavy reliance from the professor and they engaged in collaborative conversations. In addition, they continually reflected on their experiences as learners and as future teachers. The data shows that this experience helped them to begin to articulate and examine their own teaching philosophies and gain a deeper appreciation of the struggle of students to learn new information and learn in new ways.

While this research is at too early a stage to draw any general conclusions, the findings support those of others (e.g. Green, 1978; Pinar, 1981; Richardson, 1990; Schon, 1983). However, we do have some preliminary thoughts. If affecting change is one objective of teacher education programs then using autobiographical material may be a way of helping teachers to understand themselves better and what they do in the classroom. The process, impact and uses of autobiography for teachers are still in their incipient stages and will, hopefully, serve as a vehicle to inform both teachers and teacher educators in the future. If teachers are successfully to integrate technology into their teaching, teacher educators must clearly do so too. By modeling behaviors and utilizing various technological activities that are natural adjuncts to our teaching we can begin to help pre service and in service teachers effectively incorporate technology into the lives of their students.

Research on the efficacy of integration of technology within traditional classroom settings is in its infancy. Technology is changing the way we learn, the way we interact and the way we teach. Pre-service teacher education students will need to incorporate technology in their teaching practices. Teacher education programs need to give students varied and numerous experiences that immerse them in technology and its uses. By studying the impact of technology within teacher education classes, we may gain valuable information that will enable us better to facilitate our students’ transactions with technology. During this reflective process, numerous questions emerged which will be considered in future endeavors:

In what ways does the role of the teacher change or differ from that in a more traditional course?
In what ways, if any, does the content or structure of the course vary with the use of technology?
What role should the teacher play in facilitating the use of technology?
How can students and teachers best incorporate aspects of telecommunications?

Abstract: This paper describes an intranet developed for an international project for adults' teachers lifelong learning (TUTORPEA), funded by the Socrates program of the European Community. TUTORPEA attempts the design, implementation and use of an Interactive Tutor System, addressed to adults' teachers. The objective is not programming a course, but creating an interactive environment that fosters cooperative reflections on specific situations that adults' trainers usually face with. With the help of a tutor, concrete solutions will be given to those situations lived with some difficulty by the teachers.

Introduction

The training period does not conclude with our formal schooling, but it lasts a lifetime. With the emergence of the Information Society, everyone must upgrade their skills constantly and obtain new qualifications. This acquiring of new aptitudes and abilities should therefore no longer be limited to formal schooling (primary, secondary and higher education), but should involve all sections of society: youngsters, middle-aged and older people; people at all levels of vocational qualification; people in work and the unemployed (Delors 1996). Education and training are to play a central role in the advance towards an information society, which will be a learning society, as asserts the White Paper on Education and Learning of the European Commission (European Commission 1995). With
the Socrates program, the European Community, through its Directorate General XXII (Education, Training and Youth), is taking action in the field of education aiming at enhancing its quality, by means of European co-operation. The project described here, named International Project for adults' teachers lifelong learning (TUTORPEA), is enclosed in the Socrates section for Adult Education. The following institutions are taking part:

- University of Aveiro – Portugal
- SEA-AIDEA (Sviluppo dell' Educazione degli Adulte – Assoziacione Italiana di Educatenone degli Adulti) – Italia
- CEDETEL (Center for Telecommunication Development in Castile-Leon) – Spain
- Provincial Directorates of the Department of Education and Culture from Salamanca and Palencia – Spain
- University of Salamanca (coordinating institution) – Spain

TUTORPEA is addressed to adults' trainers and must be understood as a training network attempting at giving concrete solutions to specific educational situations. That is, the training plan is not organized based on contents but around real experiences the trainers usually face with. Therefore, it is not intended to program a course (with a start and an end), but to create an interactive environment where these trainers cooperatively think, study and take decisions about those experiences.

The geographical structure of the training network involves educational researchers and professionals from Aveiro (Italy), Castile-Leon (Spain) and Liguria (Italy). These three regions are characterized by similar circumstances:

- Adult education is programmed at regional-national level.
- There is a sparse population with small localities, where the trainers are full time dedicated to this task.
- There are institutions doing research in the field of adult education.

Up to twenty four trainers constitute the experimental group of the network. The intranet has been implemented in a Research Work Group called “Canalejas”, constituted mainly by Pedagogues and Telecommunication Engineers from the Universities of Salamanca and Valladolid (both of them located in Castile-Leon). The research of this interdisciplinary and inter-university group is focused on “Educational Multimedia and Telematics Networks in an Educational Context”, evaluating the possibilities and advantages of applying Information and Communication Technologies (ICTs) to the learning process. Canalejas Work Group is integrated within CEDETEL, a Technological Center that has leading the Spanish region of Castile-Leon into the Information Society as one of its main objectives.

**Description of the Tool TUTORPEA**

TUTORPEA has been developed taking into account the needs for adults' teachers lifelong learning: continuous teaching of learning units about useful subjects, and other ones required by themselves. It includes the possibility for urgent questions, real-time seminars on the net and the possibility for managing and sending big quantities of data on any kind of format (video, sound, text).

The system is focused on what we call “the learning unit”. The learning unit consists on the analysis of a real situation, taking as a starting point the problems and difficulties the trainers have to face in their own educational experiences. Each country proposes some different topics (with a psycho-pedagogical nature) and the learning unit for the semester is determined by them all.

As for the real-time seminars (chat or IRC -Internet Relay Chat-), these have exclusively been designed and programmed for TUTORPEA for two reasons: the on line chat must be easy to use and it must be integrated within the whole application.

We next mention the services offered by TUTORPEA:
The first one is the SOS Service, whose main objective is solving, immediately, the most urgent questions that may arise to the teachers. Its corresponding icon will be moving in case there are questions not answered or not clarified.

In the Learning Units Service, teachers can check in the current learning unit, propose new learning units that may be of their interest, and view information of learning units that have already taken place.

With the Task Service teachers may be assigned tasks within a learning unit. Besides, it can be a meeting point for the participants to exchange information.

The Questions and Answers Service is the same as SOS Service, but without the urgent nature of the latter one.

The Participant Service lists all the participants in the learning unit. We can contact them, navigate to their personal web page, etc. and check the tasks they have already done.

In the Calendar Service different kind of events can be published.

The Discussion Service is a real time chat, a meeting point for the participants where they can exchange different viewpoints on a particular subject.

As the Discussion Service, the Seminar Service is a chat, but with a specialist tutor that supervises the discussion.

Finally, there is a Glossary Service, that was asked for by the teachers on the very early tests. It relates different terms from different languages that might be misunderstood.

**Development Process of TUTORPEA**

Due to the experience acquired during the development of other projects, it has not been difficult to define the phases of the implementation process of TUTORPEA, nor to fulfill these phases with a perfect coordination between the teams of pedagogues and telecommunications engineers.

We briefly describe each of these phases:
1. Planning. In this phase, some decisions were taken:

   The application is supported by Internet, and, concretely, by the World Wide Web, due to its extended use.

   A Windows NT Server 4.0 was chosen as our server, the Web Server was the Internet Information Server (IIS) and the access to databases was accomplished through a component of IIS called the Internet Database Connector (IDC), and also with the help of ASP (Active Server Pages) when needed.

   Microsoft Access was used as Data Base Management System (DBMS).

   The modules and services that should be offered by the system were defined.

2. Design. The second phase consisted on the design of the database and the graphical interface of the whole application, including the IRC client. The data base should include data from the participants (teachers and tutors), the learning units and the seminars. The graphical interface should be an easy-to-use and intuitive interface, since some of the teachers participating in the project had never used such an environment.

3. Programming. In the third phase, the application was programmed, in the following order:

   Creation of the database.

   Development of the two modules of the application: participants (teachers and tutors) and master. This included the programming of the IRC with Java (a programming language perfectly integrable within the Web environment).

   Establishment of the relations between these two modules and integration into just one application: TUTORPEA

   Interaction of the application with the database.

4. Testing. Finally, the last phase of the development consisted on testing and checking the application with target users.

Future Lines and Conclusions

The imminent action to be taken is translating TUTORPEA into the other two languages of the participants taking part in the project (Portuguese and Italian). The teachers will be able to participate with their own language, although they should understand the other two. This is not a problem, taking into account the three languages come from the same mother tongue, Latin, and consequently are similar.

The first learning unit has not started yet; there are some proposals and one of them has to be selected. Therefore, we can not get any results yet, although an evaluation of the training network is already taking place. It includes four aspects:

   Satisfaction level of the teachers

   Knowledge and attitudes acquired

   Efficiency in the educational experience

   Interest level aroused in other teachers that are no taking part in the project.

To conclude, we would like to emphasize that the facts that the participating teachers, coming from different countries, collaborate and think about their own acts are achievements themselves. This collaboration aids the construction of a global education and a global culture. And the training process does not only consist
on increasing and improving teachers' knowledge but, as well, on raising their awareness about the importance of reflecting on their acts and training experiences.

Abstract: According to national studies, there is an urgent need for in-service projects designed to assist teachers in learning ways to integrate technology into their curriculum, not simply to master the mechanics of the computer. Teachers have identified many barriers to the use of technology in instruction, including: poorly focused training, lack of time to revise lessons to include technology, and lack of time to share experiences and ideas on technology integration with other teachers. This paper describes one project that attempts to address these barriers while emphasizing curricular areas identified by the U.S. Department of Education as needing strengthening in the schools.

Introduction

In their 1996 “Technology Literacy Challenge,” President Clinton and Vice President Gore identified four goals or “pillars” that provide the foundation for the preparation of every student in America to use technology. One of these four technology goals calls for professional development activities to prepare all teachers to integrate new technologies into the curriculum. “The creation of new content should be bolstered by continuous professional development for teachers that goes beyond the acquisition of generic computer skills to include mastery of technology applications specifically designed to improve student academic achievement. Teachers must learn to seamlessly integrate these new learning tools in the curriculum” (Steele 1998, p. 12). Despite increased emphasis on professional development, recent studies (Trotter 1997; U.S. Department of Education 1998) indicate that a large majority of the teachers surveyed continues to feel adequately prepared to integrate technology into classroom instruction. One explanation for this lack of preparation is that professional development in the area of technology often continues to focus on the mechanics of hardware and software despite repeated calls for professional development projects designed to assist teachers in integrating technology into their curriculum (CEO Forum 1999; Conte 1997; U.S. Congress, Office of Technology Assessment [OTA] 1995). In addition to poorly focused training, teachers in these studies also identified lack of knowledge about how to teach with technology and lack of time both to revise lessons to include technology and to share their experiences and ideas on technology integration with other teachers as barriers to their use of technology (Conte 1997; OTA 1995). According to Byrom (1998), a key professional development strategy that will increase the likelihood that teachers will use technology is “to begin with teaching and learning, not with hardware and software” (p. 4).
Grant (1996) and McKenzie (1999) identify several strategies for designing effective professional development for teachers. These include: using assessment tools to guide the planning of professional development activities to match the needs and preferences of the participants; relating professional development activities to the teachers’ classrooms, curriculum, and objectives; forming teams of peers possessing both common goals and interests, and diverse ideas, skill levels, and experiences; providing opportunities for collaboration with peers and experts to create cross-curricular thematic lessons for use in teaching; and supplying follow up support and classroom consultations. This paper describes a professional development project that addressed the barriers to technology use identified in the first paragraph and employed many of the strategies identified for effective professional development for teachers.

Project Description

The Teacher Education and Arts and Sciences faculties at Harris-Stowe State College actively participate in several partnerships and collaborative projects with schools in the St. Louis metropolitan area. These many and varied partnerships provided ample opportunities to learn of the professional development needs of in-service teachers. A professional development project was created to focus on mathematics, technology and content-area reading instruction in an integrated, unique plan to meet these needs. Two of the project objectives specifically address the integration of technology into curricular areas: to help teachers of third, fourth and fifth grade students develop and implement integrated thematic units of instruction for classroom use and which integrate mathematical concepts and applications, reading, technology and authentic assessment; and to increase teachers’ knowledge and use of technology in mathematics and reading instruction. Three Harris-Stowe faculty members, each with expertise in one of the three areas of emphasis, worked with representatives of partner schools to develop the project. Twenty teachers from four urban schools participated in the project, which is funded through the Missouri Eisenhower Professional Development Program. The four elementary schools varied widely in the types and amounts of technology available.

Central to the project was the development of instructional and assessment activities for use in the participants’ classrooms. Additionally, the teachers requested to work with curriculum materials they were currently using in their classrooms. Therefore, participants used technologies, books and materials available in their schools to develop activities. This was done in an effort to ensure success and usability of the products produced in the project. The teachers worked collaboratively in three, grade-specific teams. Key components of the project include three workshops interspersed over nine months; an intensive summer course on Integrated Methods of Teaching Mathematics, Technology and Reading in the Elementary School; on-site classroom consultations and mentoring by college faculty members; production of a booklet of the thematic units developed during the intensive course, and creation of a web site designed to support the project participants and increase the project’s sustainability. Each participant developed grade-level appropriate curricula for each of three mathematical content strands, discrete mathematics, geometric and spatial sense, and recognition of patterns and relationships. Each thematic unit included daily lesson plans, materials, instructional methodology and authentic student learning and assessment activities. Activities emphasized connections across the curriculum and to real world problems and were tied to the state of Missouri’s Show Me Standards (Missouri State Board of Education 1997). Throughout the course, time was allotted for teachers to work together, share resources, and discuss and critique developing thematic units. In the final session of the course, each team presented an example of the activities in one of the thematic units developed by one member of the team.

Participants learned to use and integrate a variety of instructional technologies into the thematic units. Prior to the summer course, each participant completed a survey in which the participant rated his/her knowledge and expertise with a variety of technologies. The information obtained from this survey provided a basis for the level of formal instruction and types of technologies covered during the summer course. Technologies were introduced through authentic contexts and examples related to the specific grade levels the participants taught. Because of the range of types of technology available in the four schools, tool software available in a variety of platforms was emphasized. The teachers also gained familiarity with the resources available on the Internet. Participants had opportunities for informal technology use with just in time assistance, and at the participants’ suggestion, the opportunities for informal use of computers increased as the summer course progressed. The level of technological expertise of the participants ranged widely from non-users to experienced users. Experienced users regularly shared their expertise with the less experienced users during sessions in the lab.
Examples

The following brief examples provide a small sampling of the thematic units developed by teachers in this project. The description of each project emphasizes the variety of ways technology was integrated into the units.

Corliss Hinton, third grade teacher at Baden Elementary School, used a theme of “what’s cooking?” for her unit. The third grade teachers’ team selected this theme for their presentation in the last session of the course. The teachers demonstrated a variety of ways that technology might be integrated into this unit, including having students sample a variety of breads, survey each other on favorite bread and use a spreadsheet to illustrate the results of the survey. They also suggested having students use children’s Internet search engines to research bread-making in preparation for writing a report.

Susan Oberkirsch, third grade teacher at Epiphany of Our Lord Parish School, developed a thematic unit using the story, “Cloudy with a Chance of Meatballs” by Judi Barrett. Reading objectives included increasing students’ abilities to recognize and understand figurative language and to be able to use it in writing. Students learned weather terms to increase their understanding of the story. Math objectives stressed being able to complete basic operations involving money. Objectives included the ability to compute and provide the correct change in various situations. Students analyzed parts of a newspaper and the different types of articles in preparation for using a children’s desktop publishing program to create a class newspaper. Students were encouraged to use figurative language in writing human-interest stories and advertisements for the newspaper. They sold the completed newspaper to students in other classrooms.

Nadine Camp, fourth grade teacher at Gateway Elementary Math, Science & Technology Magnet School, used Justin and the Best Biscuits in the World by Mildred Pitts Walker as the basis for her thematic unit. She used technology in a variety of forms throughout the unit. Students were introduced to western living and rodeos through a teacher-created PowerPoint presentation. The teacher developed an on-line scavenger hunt to help her students research African American cowboys, and in another part of the thematic unit, students used KidPix software to explore perimeter and area.

Joyce Barron-Hughes, fifth grade teacher at Waring Academy of Basic Instruction, based her thematic unit on disasters and tornadoes on “The Night of the Twisters” by Ivy Ruckman. Students used Encarta Encyclopedia for research on tornadoes and HyperStudio to present the findings of this research. Instructional objectives for this thematic unit related to reading, mathematics, social studies, science and technology.

Implications

Input from the teachers through on-going evaluations collected during the course helped the college faculty members be more responsive to the needs of the teachers. One barrier identified in the beginning of this paper was not fully eliminated—lack of time. While we increased available time for the teams to work together, most participants continued to request more time to work on individual curricula and in the computer lab. At the conclusion of the summer course, participants were asked again to rank their levels of expertise with a variety of technologies. Without exception, all participants who responded indicated increased levels of expertise with the technologies used in the course and rated their ability to integrate technology into their teaching as improved.

Among the best indicators of the success of a professional development project is whether participants are using what they learned and created in the project. Participants met in a follow-up workshop two months into the school year, and completed a questionnaire on how they have been able to use the information obtained from the summer course in their teaching. Responses were overwhelmingly positive. The following comments provide a sampling of the responses related to the technology emphasis in the course. “I feel more confident about using the Internet. The web sites are very helpful.” “The computer information has been invaluable. I used it during the summer and am continuing to use it.” “Yes, I have been able to use the technology skills more effectively.” “Although I have not been able to use computers in our lessons, my attitude at the beginning of school was one of anticipation and still is even though our computers are not hooked up yet.” “Yes, Yes, Yes. Many ideas I’ve shared with co-workers. Thank you for the experience.” “I usually use thematic units to teach various modalities of learning. This summer I learned about filamentality, web pages, various web sites and I have a much better understanding of spreadsheets and other programs.” “I have made a concerted effort to use technology more often and plan better around it.” “My comfort level with computer usage has been greatly
improved. I can also see how helpful it can be in all curriculum planning. I feel much more challenged and anxious to make better use of our classroom and lab computers."

Did the teachers view the structure of this professional development experience positively? In the fall workshop, the teachers were asked to reflect on their experience in the course now that it was two months later and they were back in the classroom. They reported that they particularly enjoyed the opportunity to share information and work with other professionals, to create lessons using materials available in their classrooms and related to their curriculum, and to learn new strategies for integrating curricular areas. One participant concluded his evaluation with the comment that he wanted to “commend you for a job well done in providing teachers very valuable experiences enhancing our ability to provide our students the best possible education.”

Abstract: This paper presentation will focus on a successful model of inservice training for teachers. The model, used by a multi-school five year US DOE Challenge Grant includes five day and three day training sessions in the summer, followed by a 2 day retreat in the winter, as well as on-site inservice training and on-site coaching by both educators and technologists. The focus of the grant is to improve teaching, with a goal to engage the learner in the classroom. The training includes technology integration, lesson design, and brain research.

Introduction

"The Connections Project: Strengthening Learning Through Technology-Based Integrated Curriculum and Professional Development" has been successful in training teachers to use technology effectively. This effort is a five million dollar United States Department of Education Technology Innovation Challenge Grant, which includes four Nebraska school districts and two adjudicated youth centers as lead sites. The project is designed to improve student learning through effective teaching that included technology-integrated curricula reflecting state curriculum frameworks based on Goals 2000 and national standards. In addition, special focus is given to high risk students, as well as developing partnerships among educators, business, agriculture, industry, and parents. The grant evaluation team is from the University of Nebraska at Omaha College of Education Office of Internet Studies. The process of change used in this grant is important to teacher education, as all learn from the successes of P-12 schools and teachers. The professors on the evaluation team use the ideas and examples in their own lesson plans for both undergraduate and graduate teacher education classes.

The grant summer workshop consisted of a three day multi-topic sessions, that were presented at three different Nebraska sites. Participants were recruited through mailings and were given a stipend for mileage, lodging, and participation. The workshop was divided into three learning areas: technology, brain research, and lesson design. Each day the participants were given the opportunity to spend approximately two hours in each learning area.

Throughout the workshop, the trainers modeled many teaching strategies with a variety of activities that included technology, multiple intelligences, learning styles, brain based research, interdisciplinary teaching methods, constructivist theory, and effective lesson planning. The entire workshop and the workshop facilities were set up to model ideas that were learned in the workshop.
The trainers were teachers who were currently teaching in a classroom environment. In addition, these trainers completed a five-day in depth study of technology, brain research, and lesson design followed by four additional days dedicated to polishing the strategies to be used in the three-day workshops. During the four-day planning session, the trainers prepared presentations, handouts, and activities that modeled the grant goals. These trainers were continually provided with up to date information in the aforementioned areas. The well educated trainer added to the validity of the workshops because the participants could ask for and get actual new and needed ideas to take to their classroom.

The following is a note sent to the trainers by a participant in the Summer 1999 workshop held in Seward, NE. “Thank you so very much for your motivating and inspirational presentation on Wednesday afternoon after lunch. I had been depressed thinking about school starting because after 32 years I wasn’t coming up with new ideas to get myself stimulated. Thank you for giving me the boost I needed. You all did a wonderful job. I gained a lot from this workshop.” In addition, other participants responded as follows: “I can actually use what was taught in the inservice.” “I can’t wait for school to start to apply some of these strategies in the classroom.” “Best inservice in my 25 years of teaching. I didn’t want to go back to school and now I cant wait.”

From reading these comments, it seemed the workshops had been very successful. With teacher behaviors changing and increased enthusiasm for trying new strategies, the classroom settings of the participants changed. It was hoped that student learning had increased as a result.

**Topics for the Workshops**

The workshops focus on three areas: Technology, Brain-Based Research, and Lesson Exploration. The explanations for each area is included below.

**Technology**

An important aspect of the Connections Project was the integration of technology into the teachers lessons. Several sessions within the first two days of the workshop were spent exploring the most current educational software and hardware. The participants were given time on the third day to integrate these new technologies into one of their own lessons. Teachers were encouraged to start by using one or two new technologies learned at the workshops. As Nebraska educators began to effectively use technology and curriculum integration to promote student learning and achievement, teachers were also encouraged to communicate with other participants through technology. This technology can facilitate shared learning, expanded educational resources and barrier free collaboration across Nebraska and the United States to further the national educational goals of educational reform. The following are brief descriptions of the technology pieces used in the summer workshops.

- **Video Editing**: Avid Cinema was the software program used in the workshops. The lessons included three parts: inputting video, clip art and pictures, editing clips and adding effects, and processing movie and sending to videotape. Teachers were given guided instruction to adding video, sound, text, and transitions to video clips. Students and teachers used the program to make videos for a variety of classroom activities.

- **Desktop Publishing**: Pagemaker, Clarisworks, and Microsoft Office, were the software programs used to spice up old documents and create exciting new documents. Graphics, columns, borders, charts, headers, and footers were just a few of the tools that were learned in the workshop sessions.

- **Web Publishing**: Claris HomePage was the web publishing software program used in the workshops. As World Wide Web expands, teachers are continually called upon to publish pages for educational purposes. Web publishing programs do not require users to be proficient in HTML and participants took their web publishing skills back to their classrooms and taught these skills to their students.

- **Presentation**: Hyperstudio and Powerpoint were the presentation software programs used in the workshops. When teachers share this knowledge with their students, the students can then merge smoothly into the business world with the ability to create presentations which are enhanced with color, sound, transitions, graphics, and short video clips.
Brain-Based Research

The participants understanding of learning styles, multiple intelligences, life skills and brain functions strengthened potential educational achievement of all students, especially students who were deemed high risk. The three day workshop included interactive models of how to integrate strategies to support these theories in the classroom.

Lesson Exploration

The third part of the workshop was integrating the technology and brain-based research into practical, teachable lessons. This training focused on providing web resources, practicing lesson integration, and building new lessons. These sessions gave participants time to revise a tried and true unit of study in their particular discipline.

Application of Training

Each participant was given eleven CDs that included tutorials, presentations, bibliographies, and other information used in the workshop. The participants were asked to share the ten CDs and their newfound knowledge with other Nebraska educators. Through the sharing of the CDs and knowledge, participants were applying the new learning immediately after the workshop. Participants were asked to provide the grant director with a list of CD recipients. Many trainers continued to hear from participants who had successful changes in their classrooms because they used knowledge gained from the workshop. The success of the workshop was evidenced through the waiting list for the next two summer workshops. Applicants had to be turned away because the workshops were at capacity.

Revision and Assessment of Training

Project personnel continually seek opportunities to be trained in new technologies and remain current with teaching/learning research. The trainers meet periodically to garner new information and revise their presentations. The coordinators from the lead sites meet monthly with participants to assess, to practice and to study the newest research in these areas.

Summary

The Connections Project Challenge Grant has begun to change the way teachers teach and the way students learn. This workshop could be replicated in a variety of educational scenarios. The workshop described is available at <http://ois.unomaha.edu/connections/>, <margohir@esul6.org>, and <tamiesh@esul6.org>. As the project continues, more and more training will be provided, and student learning will continue to be impacted.
The Computer Mediated Communication Environment as it Fosters Collaborative Ways of Knowing, Teaching, and Learning

Mary E. Wildner-Bassett
Department of German Studies and Interdisciplinary Ph.D. Program in Second Language Acquisition and Teaching (SLAT)
University of Arizona Tucson, AZ USA
email: wildnernb@u.arizona.edu

Abstract: This paper will summarize and give examples from a retrospective ethnographic and pedagogical theory analysis of some key features of a course concerning Graduate and Inservice Teacher Education and Instructional Design. The title of the course was “Researching the Paradigms: Collaborative Ways of Knowing, Teaching, and Learning.” The course involved synchronous and collaborative computer mediated discussions (CMC) as well as asynchronous CMC written conversation and full use of the World Wide Web. The goal of the course and of this report of it is to explore and push the boundaries of possibilities for addressing the web of relationships among collaborative and other forms of non-foundational graduate and teacher education; collaborative language, literacy and culture learning; and multiple literacies including those only possible in CMC and hypertext environments. The results explicate the possibilities made available by fully implementing information technology and CMC for teacher education and instructional design.

Introduction

A group of inservice graduate student instructors and one faculty member worked together to address the web of relationships among collaborative and other forms of non-foundational graduate and teacher education. Our foci were on collaborative language, literacy and culture learning and multiple literacies, including those only possible in CMC and hypertext environments. Our acculturation to a new way of thinking, learning, and teaching based on a “non-foundational paradigm” was itself both formed and expanded by the opportunities available in the CMC environment. According to this model "knowledge is a consensus among the members of a community of knowledgeable peers -- something people construct by talking together and reaching an agreement" (Bruffee, 1993). Some of the results of our mutual and class-related development of this kind of knowledge will be explored here, and the possibilities made available by fully implementing information technology and CMC for teacher education and instructional design will be illustrated using examples from the course and the data from its participants.

Class Members, Course Concepts, and Research Goals

This class of advanced graduate students, who are also inservice teachers of language and literature, along with myself as the faculty member who originally developed the course concepts, became proficient in using the CMC environment as both a model and a tool for co-creating the content and the ways of knowing and learning in the new learning community that we were forming. This non-foundational and co-created paradigm led us to a learning and research space that took critical research and experiential looks at some of the characteristics, as discussed in (Bruffee 1993), of collaborative and non-foundational learning environments: 1) The active role of both teachers and learners in the educational setting; 2) The culture of the learning environment; 3) The view that knowledge is not transferred from
expert to learner but created and located in the learning community. We also added the fourth essential element to this list, namely the exploration of the effects of CMC and of using instructional technology as the vehicle for the new learning paradigm, which in fact is then essential for defining the paradigm. Indeed the CMC sessions helped us establish a discourse community, and a community of mutual help and encouragement, trust and respect, that would have been very different, if even possible, in a traditional classroom setting.

In summarizing the key elements of the ethnographic analysis and the interaction of instructional technology, CMC, and a non-foundational learning and teaching paradigm in this paper, I am expanding on topic descriptors and definitions which we as a group crystallized from our experiences. These concepts will be illustrated with examples from the class texts and the web site portfolio (http://www.coh.arizona.edu/planet-xeno/) which I will be quoting from below. The site was composed by Claudia Kost under intense collaboration with Sumru Akcan, Adrian Wurr, Lisa Jurkowitz, Judith Arbella, Paula Gunder, and myself. Both I as the teacher and the students of the class had little idea of the kind of adventure we were embarking on, as we assembled for our first class of the semester. With time and some initial guidance and insistence from me, the seven individuals together began our acculturation to a new way of thinking, learning, and teaching, based on non-foundational paradigm described above. As the class gained more and more familiarity with the theories, terminology, and especially the practices of non-foundational learning and teaching, we became members of a new, transitional knowledge community.

Each of us has recollected several important moments that highlight class experiences and processes toward new ways of knowing. These moments are crystallized in the list of nine descriptors, which capture our identity as a classroom culture, and as a transitional community moving toward non-foundational, collaborative, reciprocally interdependent ways of knowing, learning, and teaching. When we realized how different this experience was from anything we had experienced before, we decided this was like being on a different planet, hence the name Planet Xeno. Since we spend most of our time traveling back to a more foundational context during the rest of our work and learning contexts in the university, we know we aren't permanent residents of Planet Xeno, merely resident aliens. The goal of the web site we developed, and of this paper, is to bring back what we learn on Xeno to other interested educators and like-minded travelers.

**Developmental Stages of Inhabiting Planet Xeno**

In reflecting on the developments and experiences of this non-foundational educational encounter, we realized that we were creating a reciprocally interdependent group, where one group member's output becomes another's input and vice versa. Group members have different roles and specialties. We also realized that we had to overcome some difficult and at times downright painful resistance on the part of the students, and to a lesser extent some limits in my own powers of imagining truly non-foundational education and communication within the traditional university environment. It is after all still, in most cases and in most graduate classes at most institutions, the assumption of all concerned that the role of the teacher is the "sage on the stage," playing to an audience of avid but essentially receptive audience members, called students. Having done the work for and within myself of distancing myself from the "sage" model to one where I considered myself the "guide on the side" who accompanies the students in their own development, I had to not only convince them that this was a valid and actually more fertile model for graduate education, but also that CMC was an essential tool for us to make this happen in our own context. One of the students, who had been pleasant but quite vocal about not really seeing the virtues of using CMC ("Why can't we just talk?") eventually pointed out to us all that she was realizing that the use of computers transformed the individual experience of writing to make it a social experience as well.

Most of the students voiced concerns and difficulties that they were accepting the essential role of computers and especially CMC in our undertaking. Reshaping social and individual experience relating to CMC became a focus of the members of the course.

As we worked through our resistance, we came to a turning point at midterm in the semester. It was at that point that most if not all of the members realized how CMC sessions help us establish a discourse community, and a community of mutual help and encouragement, trust and respect. These are important values that are not often thematized explicitly in graduate course work, and we all had to reorient ourselves to adapt to the new community which I eventually dubbed "Planet Xeno."
With growing trust among the members in our class and feeling more comfortable with each other, working together becomes easier. Students began to report that everyone enjoyed working with their partners in the CMC environment, and nobody felt overpowered or dominated by anyone else. We also experienced both pleasant and powerful communication dynamics develop in the group. One essential ingredient became known to us as "the giggle factor". The giggle factor became a running theme for us. We would, as a group, have fun, laugh, or be very serious and on task, or at best, laugh a lot and be very serious and on-task and taking risks in our safe community all at once. These were aspects of the "giggle factor" as an affective variable in our learning community. We would comment on its relative effects at any particular working session. It was always a positive aspect of our community and it was an indication of new growth and difficult developmental stages of inhabiting Planet Xeno.

Another key moment in becoming more comfortable with living on Planet Xeno was "Birds of a Feather Day". That is the day we came into class and were randomly grouped by a slip of paper telling us what kind of "bird" we were. Then we responded to one of the questions that the whole class had submitted in an asynchronous preparation session (posted on a conferencing site called POLIS) about "Assessment in a collaborative or non-foundational setting", based on the reading from (Shohamy 1998). As we used synchronous and face-to-face CMC, as made possible in the facility we call the COHlab, we discussed the difficult issues surrounding assessment, and we had an excellent and very flowing discussion. Much of what was written and discussed went further and deeper into the issues than the original article. I wrote in my own evaluation of that day: "The quality and quantity of the responses (to be foundational about it all) seem excellent today, and for whatever reason better than we've had before. I agree with whoever said, "it was good" in that response. That person also wrote, "I guess we're getting better at this COHlaborative stuff with practice! " We're over some of the shock and disconcerting moments of have been rocketed off to Planet Xeno, and now we're getting pretty good at being here. Plus, everyone seems fully engaged in being good citizens of Xeno. Thank you, one and all. I'm frankly tickled pink with these developments (even though I wasn't in the flamingo group)."

How to Launch A Group to Planet Xeno

So far I have highlighted the positive developmental aspects of this approach to fostering collaborative ways of knowing, learning, and teaching in this graduate level class. There were, predictably perhaps, also many frustrations at the beginning. Graduate students and inservice teachers taking a graduate level course are perhaps the group of learners and teachers who are most vulnerable and most resistant when confronted with non-foundational and collaborative learning. These people have, in order to be successful students sitting in the class in the first place, been rewarded for and supported in the exactly opposite ways of knowing, learning, and teaching. They have become successful at being individual, foundational audience members for various "sages" on various "stages," doing work that is solely their own responsibility (e.g. individually authored papers and exams), and for carefully considering anything they write or speak in class before taking the risk of exposing their ideas. In essence what I was asking them to do in this class was to (temporarily) discard all they knew about teaching, learning, and knowing in an academic environment, all that they had been successful at and rewarded and awarded for, to try something non-foundational, collaborative, and computer-mediated. It was a big leap, and a serious risk for all of us. It is thus not surprising that I found myself, as the leader of the group that was still very resistant and prone to sitting like an audience in each class before the midterm, very frustrated with the success of my experiment so far.

The result was that I threw a bit of a tantrum. The issue at hand was that, since the beginning of the semester, I had been urging the group to consider the possibilities of a non-foundational midterm "exam". They were asked, in writing and repeatedly in class discussion, to make suggestions for alternatives for content and form of a midterm examination. I had only declared that it was worth 100 points (a clearly arbitrary valuation that consciously reinforced the reality that we were still connected to an institution with the constraints of assigning grades at the end of a semester). There had been no response at all from the students. In my frustration, I made a CMC based and tantrum-like call for engagement to the midterm event. This call proceeded to be the initiator of an important re-thinking of the whole class
structure by all involved. This is not to say, however, that I was able to anticipate that outcome at the time I made the call. I was reacting mainly out of frustration and a lack of trust, in both myself and in the students, of being able to actually accomplish what I had set as a goal for the course. I wrote: "If there is no concrete suggestion, collaboratively arrived at by the group, as to the form, content, and grading of the midterm, I will assume this responsibility. The fact that the class members were/are hesitant, or passively resistant, or apathetic, or too overworked to have taken any initiative so far, is a matter of great concern to me. What should we do, and how shall this task be organized and accomplished by Thurs, March 4, 1999, at 2pm?"

This fairly tantrum-like moment had as the goal, and then as the result, as well, compelling the class as a learning community to commit to the idea that collaborative and interdependent learning requires learners to define their own learning needs and to take responsibility for how they will learn it. At the time I felt myself to be teetering on the edge of giving up on a non-foundational and collaborative approach to co-creating a graduate course. It seemed that this might be the end, and that none of us, myself included, were able to think or interact beyond our institutional learning and knowing habits.

In retrospect, it was just this process of hitting what seemed to be a "last straw" wall that injected enough energy into the system of our struggles toward collaborative learning to really launch it into a new arena, as evidenced by the remainder of the midterm events. I see the complex adaptive system of the midterm events, which spanned over two full weeks and beyond, as the the center of our journey to Planet Xeno. Just before the midterm developmental events, I had written in a general journal that I was "having a hard time getting my class to come with me to the 'learning space'". By this I meant that I knew we would need to move to an entirely different set of ways of knowing and ways of learning in order to really accomplish several of the class goals. But I also was at quite a loss at that point as to how to get people to go there, to follow me there, or to lead us all there. I was ready to just give up and move back into the familiar comforts of the "foundational space". I had recognized that the midterm would be a boundary zone for us all. It was a place where the typical institutional needs and constraints could meet what we had been gradually trying to create and then research as a non-foundational and creative, if turbulent, new kind of learning space. I had wanted us to all take the risk of modeling a non-foundational, collaborative, and learner/learning centered form with our own class activities, and then to take a step back and look at and research how it was working. Before the midterm, I had started to "realize", or talk myself into, the idea that I had wanted to take us all, including myself, too far too fast. I had hoped for more than was possible, I thought, and I had lost the energy to try to subtly guide and "irritate" the group into discovering it on their own. I felt I was going to give a really traditional, though fair, midterm and let it fall where it would. And if the class decided to sit back and let that happen, then I was just going to read and discuss for the rest of the semester—slip back into good old foundational mode. So I sent a perturbed email to everyone, drawing a line in the sand as to the future of our class in general, and the form and function of the midterm in particular.

When we got to class, it was a frustrated and pretty negatively inclined professor who entered the room. Suddenly, though, (all I said was, "let's discuss the reading, but first, what do you want to do about the midterm?") the class members took off. There was an intense and very earnest discussion about various options for the midterm. One of the students started the real interaction by making a non-foundational suggestion for what could be done to co-create the midterm. There was a lot of excellent, engaged, respectful, and creative discussion, with several different suggestions made. There were different levels of willingness for risk-taking behavior or non-foundational thinking among the members, but most of the group was getting more and more engaged. I took the role of a (delighted) observer for much of the time. Here and there I raised some more questions in a directive line in the sand as to the future of our class in general, and the form and function of the midterm in particular.

It is on that day, before the midterm, that we became a community of learners and teachers (note the plurals) in a new learning space—one that is indeed non-foundational and co-constructed, collaborative, and connected to computer mediated communication in several modes. The energy, the changes of perspective, and the willingness for risk-taking in a community of people who are open and ready to seriously consider suggestions, content, and process from each other and with high mutual respect, has been maintained, even beyond the end of the semester.
The quality of the actual midterm event was also quite special. The students all suggested and voted on, in asynchronous CMC sessions, various extended interpretive essay questions based on our readings and discussions. The questions were randomly assigned on the day of the midterm event (we decided that calling it an “exam” was too foundational for what we were doing). The students then wrote essays in pairs, using the conferencing features of POLIS, our on-line instructional web based system, so that their discussions and gradual merging toward a consensus essay were evident.

As I read the products of this process, I noticed many differences in approach by the dyads, but I mainly noticed a very high quality of “answer”, of engaged discussions that complemented each other in many instances, and of a collaborative and co-constructed event and product that was certainly much more than the sum of its individually contributed parts. This had been a real formative assessment event, where several voices had a chance to synthesize several of the ideas in ways that we had not been able to do before. I think my biggest challenge in the midterm event was to keep my mouth shut. It wasn’t that I wanted to re-direct any part of the process; it was that I was (and am) so pleased with what was going on that I kept wanting to say—“Did you hear what you just said?” “Did you notice how that interaction just moved from a foundational to a non-foundational moment?” “Did you all hear the insecurity in participant X’s last comment? What is the source of that, do you suppose, and what can we do to re-direct the insecurity?” The observer/teacher in me was being deluged with teachable moments, yet I didn’t want to interrupt the wonderful process as it was unfolding in order to comment on it. Part of our continuing research into the products and process of the class is based on a detailed ethnographic and communication analysis of the CMC portions of the event.

In sum, I consider the midterm events to be the turning point in our class and in my own understanding of what interdependence can mean in a classroom setting It remains with me, in affective as well as in cognitive terms, as a key event, as a “top-of-the-mountain” experience in teaching and learning. Mainly I feel thankful that everyone jumped in, took the risks, and made it happen.

Descriptors, Definitions, and ‘Artifacts’ from Planet Xeno

Given the time and space constraints, I can best sum up some of the further products and processes of the Planet Xeno events by listing and briefly describing a set of descriptors that the class participants extracted from our experiences. These are a kind of artifact from our ethnographic study of Planet Xeno. I would again refer you to the web site portfolio of our class for more comments on and more voices describing or illustrating these artifacts. There it becomes clear what I can only report here, that our diverse and polyphonic voices shape the meaning and interpretation of all aspects of the new planet. Here the summaries remain as descriptors of some of the essential aspects of the landscape of Planet Xeno.

Collaboration is an interactive and interdependent act of working together in order to generate new ideas, increase knowledge, and achieve common goals which could not be accomplished individually.

Communication is a necessary prerequisite for any collaborative effort. It includes listening to what others have to say (i.e. understanding what they mean and not what one wants to hear) and having the chance to give one’s own opinion. It requires mutual respect and trust for the negotiation of meaning.

Autonomous, active, engaged, interactive, interdependent learning process are terms which describe non-foundational learning. In this new learning environment, the roles of teachers and students change and students gain a higher sense of responsibility for their own and others’ learning.

Process – product are ideas that highlight the habit of focusing more on the process of learning, and on the mutual exchange of ideas rather than exclusively or primarily on the outcome. The product, however, is also important and a matter of responsibility for outcomes presentable to others.

Co-construction and meaning making occur when people exchange their ideas on a specific topic, collaboratively creating new knowledge, a tangible product, or a common understanding of a concept, and reacculturating this knowledge into their own belief and knowledge systems.

Community of support is the power or energy that people give one another when working together to accomplish a desired goal. Such a community involves reciprocal interdependence where one member’s output becomes another’s input, and vice versa. Members work together and trust each other in a co-creative symbiosis. This community is a safe place for risk taking and voicing opinions without fearing sanctions.
Dialoguing implies the suspension of judgement in the exchange of ideas and opinions. In dialogue, the goal is not to reach a conclusion, rather, it is to foster an environment where multiplicity of opinion is valued.

Ways of knowing is our approach to challenging the positivist paradigm, which values one truth. In our context we placed value on a multiplicity of perspectives, the process of sharing, exploring, and hypothesis testing. Teachers who thought they were teaching knowledge that they considered "true knowledge" have to "unlearn" what they thought was true, and instead, integrate different perspectives into their teaching.

Coloring outside the lines refers to learning without limitations on ways of being, thinking, and knowing. Collaborative writing, learner-initiated tasks, inclusion of multiple literacies, especially computer mediated communication (CMC). Here process-oriented evaluation, encouraging and assuming reciprocal interdependence, and the co-construction of knowledge are all examples of moving away from the traditional paradigms of teaching and learning towards a non-foundational paradigm.

Concluding Remarks

In this beginning exploration of these rubrics, and using the texts and experiential reports by the members of the class, I have begun to illustrate and point toward further possibilities for the essential use of CMC and non-linear, complex, dynamic ways of knowing, learning, and teaching as the future for fully implementing information technology and CMC for teacher education. These ideas, brought into juxtaposition here, clearly support teaching, learning, and research paradigms that investigate multiple ways of knowing as the epistemological home for this inquiry. In the words of (van Lier 1998):

Traditionally we have thought of scientific research as a matter of looking into causes and effects, and benefits have been cast in the shape of generalizations from a sample to a population and of accurate predictions of future occurrences. This research scenario...will no longer work once we venture forth into the real world of complexity, in which many people and circumstances act and interact. Here there are no simple causes, and predictability must yield to contingency. Research must be aimed at increasing our understanding, both holistically and in the smallest details, of the social setting as a complex adaptive system. (pp. 157-58).

This descriptive account shows, then, how a groups of teachers and learners could explore and push the boundaries of possibilities for addressing the web of relationships among collaborative and other forms of non-foundational graduate education, collaborative language, literacy and culture learning, and multiple literacies including those possible in CMC. Learning to inhabit Planet Xeno as resident aliens there meant acculturation to a new way of thinking, learning, and teaching, based on the non-foundational paradigm described here. As we found ways to live and learn the theories, terminology, and especially the practices of non-foundational learning and teaching, we became members of a new complex adaptive system which we know as our transitional knowledge community.

Abstract: An increasing number of teachers returning to the Faculty of Education for advanced coursework are interested in learning technology skills—with a specific emphasis on learning how to effectively use computers in their classrooms. These teachers explain that the alternative has been to learn on their own or attend professional development days which often only focus on skills such as word processing, grading programs, or use of the internet, but not how to use technology to enhance student learning. In this longitudinal study, we utilized a constructivist approach (Duffy & Cunningham, 1996) facilitating the development of teachers' skills to increase their competency in using technology in the classroom. The primary focus for the use of technology in the classroom was to enhance opportunities for student learning and to develop higher order skills such as critical thinking and problem solving (Jonassen & Reeves, 1996). Through interviews, questionnaires, and observation, data were collected to address the specific research question, how can practicing teachers best learn to use technology to enhance the learning experiences for their students?

Background

In Canada, the implementation of technology in public schools lags considerably behind what can be found in comparable school settings in the United States. In the United States, hardware and software is more prevalent, however meaningful integration of technology within the classroom, particularly to enhance learning still falls short of expectations (Hill, 1999; MDR, 1998; O'Donnell, 1996). This study takes place in British Columbia where elementary school districts are just beginning to plan for the wiring and development of other infrastructure systems to support the integration of computers into the classroom and computers are just beginning to be available in classrooms throughout the school (BC Ministry of Education, 1995b). A curriculum document (called an Integrated Resource Package—IRP) with learning objectives in instructional technology for K-7 was recently developed (BC Ministry of Education, 1996) but then pulled from circulation and has been put on hold indefinitely. At the secondary level, computer use is most frequently found in computer science courses, with increasing use in technology education, science
and the fine arts. In most institutions, students graduating from universities from a teacher education program are not required to take technology coursework or pass exit requirements based on technology competencies and therefore enter the school system unprepared to integrate technology into the teaching/learning process. As computers do become more prevalent in the school setting, there is a great need to provide professional development for teachers so that the computers can be used effectively to enhance learning in the classroom.

Many professional development efforts to date remove teachers from their school setting and take them into a district computer center, often with equipment much different from that which would be found in their local school setting. Teachers are taken through step-by-step instruction on common software programs or introduced to the internet. Educational software is seldom presented and little instruction is provided to the teachers on how to integrate the use of computers into their classroom or connect technology experiences to the curriculum. Learning basic skills is of import to the teachers, most of whom have little to no formal training in the area, but the efforts fall short of what the teachers say is really needed. As O'Donnell (1996) comments, "the majority of teachers who are utilizing computers in their classroom have not fully integrated them into the curriculum but have only incorporated the computer with little change in actual curriculum and classroom strategies" (p. 3). Teachers are learning how to use computers, but not in a manner that appreciably impacts students' learning or connects to curricular content.

Participants

Five groups of teachers and two groups of parents participated in this on-going study of in-service efforts aimed at providing teachers with the skills to successfully implement technology and new media into the classroom to enhance the learning experiences for their students. All research was conducted in the Lower Mainland in British Columbia. In the mid-1990s, O'Donnell (1996) remarked that, “there are no studies that asked a broad spectrum of classroom teachers what their specific needs are for integrating computers into the classroom” (p. 16). To begin our studies, we were interested in first looking at what teachers think about the use of technology in the classroom and how they were currently using technology. Little research beyond Ministry-sponsored reports (BC Ministry of Education, 1995a; 1995b) is available from within a Canadian context, particularly in Western Canada, so our first research efforts were to gather baseline data.

Four small groups (n=8) participated in the first stage of the research aimed at looking at what teachers and parents think about the integration of technology in the classroom. Separate focus group interviews were held with these four groups; one group of teachers consisted of elementary level (K-5) teachers, the other group were lower secondary level teachers (grades 6-8). Both groups of teachers were non-computer users, in the sense that they did not actively incorporate the use of computers in their classrooms. We included both new teachers and more established teachers from across their stated primary discipline affiliations. The parent groups were also grouped by grade level of their children (grades 3-5 and 6-9). During the second stage of research, an inquiry was made to find out how elementary school teachers were currently using computers in the classroom. In contrast to the focus group interviews, teachers in this group actively used a computer within their classroom. An effort was made to include teachers from a broad stated range of comfort and knowledge about using computers; every effort was made to be inclusive and not limit the participants to those most comfortable with technology. 120 teachers were surveyed to find out how they were using computers in their classroom. From this group, 16 teachers participated in an in-depth interview.

During the next stage, actual in-service efforts were examined. From our research, the district-arranged professional development did not seem successful in the teachers’ opinions. In light of this, it was decided that we would next focus our attention on school-based and university-based efforts. Following the lead of literature recommendations (Duffy & Cunningham, 1996; Hill, 1999; Wilson, 1996) we focussed on programs that utilized a constructivist approach toward learning.
The first in-school group consisted of 14 teachers in a secondary setting, who came together as a community to learn how to use the internet in their classroom. They were guided by the computer studies teacher but were asked to develop their own goals. The CS teacher also took on the role of researcher in this study. The teachers were followed for one school term (six months). The other school-based group had just received a grant for new equipment and software—the school as a whole was looked at for how they decided to implement the technology and provide training for the teachers and students in the school. Fifteen teachers were observed in the computer lab setting (the researcher was on site as a participant observer three days per week for a period of six months). In-depth interviews were conducted both before equipment was purchased and after a routine of use had been established. (Follow-up research during the current academic year is being conducted to look at the sustainability of the efforts to engage teachers in integrating technology in their classroom).

The final group was university-based and consisted of 16 teachers from both the primary and secondary levels. This group shared some course experiences together, but was brought together as a community primarily through the use of a web-based course tool, WebCT and informal sharing sessions both on and off campus. In these three groups, the focus was on learner-centered and directed learning experiences (Duffy & Cunningham, 1996; Hannafin, Hill & Land, 1997; Wilson, 1996)—learners developed their own goals, constructed their own knowledge building experiences (facilitated by others in the group), and applied their learning to their individual classroom settings.

Methodology and Data Collection

For the focus group sessions, a professional interviewer was hired to interview teachers about ways to improve learning in their classroom. The teachers did not know the particular topic of interest, only that researchers were on the other side of a two-way mirror and were interested in the teachers’ ideas about the teaching-learning environment. The interviewer was asked to guide the discussion toward how classrooms could be improved through the use of technology and what problems they saw in the implementation of technology. With the parents, the interviewer was directed to steer the conversation toward the topic of what the parents would like their children to know about technology and the skills they felt were important for their children to acquire related to technology. The group of researchers had a variety of research interests including the development of technology products that could help teachers in the classroom as well as how teachers’ apprehensions about the use of technology in the classroom could be overcome. The interviews were tape-recorded and transcribed. In addition, the researchers during the interviews made extensive notes. In follow-up meetings, the team of researchers pulled out themes that seemed to emerge from the data and utilized a modified-Delphi technique to arrive at agreement on major themes, concerns, and issues that related to technology that surfaced from the interviews.

To look at the current state of affairs in the elementary setting, a survey was sent to 120 elementary teachers in British Columbia. A total of 89 questionnaires were returned for a response rate of 71%. Follow-up interviews with 16 of these teachers were held to confirm survey information and to provide a more in-depth look at the use of computers in the classroom. Interviews were transcribed and data triangulation methods were used to find convergence between survey data and interview data.

Based on the information gained during the focus group interviews and the survey of elementary settings, it seemed important to look at efforts to build technology skills of teachers both within school settings and through university coursework. Three separate case studies were initiated to provide a multi-faceted view of teachers learning to use technology. In all three settings, the researcher acted as a participant observer (Bogdan & Biklin, 1992). Interviews, observation, and personal research journals were kept as data sources. To identify and establish patterns or trends in the data, the constant comparison technique described by Bogdan and Biklin (1992) was used. Teachers in the settings were asked to develop their own goals and to connect their goals to projects that they would actually implement in their classroom setting. Their written documentation was also used as a data source and a method of comparison of how they intended to implement technology (learning goals, objectives, and instructional strategies) and what they were actually observed doing in their classroom settings.
Results

From the focus groups, it was immediately apparent that the teachers were uncomfortable with technology in the classroom. Their concerns focused on three areas: their own lack of preparation and experience; the assumed chaos that would result if students were allowed to use computers on their own (at a learning station or computer center); and the teachers' inability to "fix" the computer when something went wrong (the teachers shared a perception that something was always going wrong with computers). This is consistent with Reeves' (1998) finding that across many studies, teacher confidence is a factor limiting computer use in the schools. The parents on the other hand were anxious for their children to develop a variety of computer skills ranging from basic word processing to the development of multimedia presentations and use of computer languages. The parents in both groups were convinced that their children's future success depended on strong computer skills.

From the survey of elementary teachers, it was clear that teachers learn their technology skills on the job and do not share common strategies for integrating computers in the classroom. Learning more about how to integrate the use of computers into the classroom and connect technology experiences to the curriculum was a common concern. District efforts were judged to be of less value, whereas learning on their own and interaction with other colleagues seemed to best aid teachers in implementing their goals. Obstacles to using computers were lack of time, inadequate hardware and software, and lack of appropriate training. This is consistent with findings from the U.S. as well (Becker, 1994; Chiero, 1997; Hope, 1995; Reeves, 1998; Sheingold & Hadley, 1993).

Additional findings were that teachers and students worked together to decide how to use the computer in the classroom and that groupings at one computer were usually in pairs or individuals. Teachers across the study agreed that the ideal set-up was to have both a computer in the classroom to help facilitate integration within the classroom, but to also have a computer lab for skill instruction and full class projects. 73% of the teachers said that having a computer in the classroom did not affect the way in which they taught. The focus group on the other hand felt that it would be chaotic to have a computer in the classroom and worried that they were unprepared (and in some cases unwilling) to change their instructional methods to accommodate computers. Because the survey group was comprised of computer-users, it may be that they were more comfortable with an open classroom approach (where students move about from their desk to the computer) and thus did not find integrating computers to be disruptive to their normal class routine.

In the first study in the school setting with 14 teachers interested in using the internet in their classroom, it was found that the development of a community was important in initiating an effort to increase the teachers' levels of competency. The project was started by the computer science (CS) teacher who offered to meet once per week with teachers on Friday afternoons to help the teachers develop and fulfill their own specific goals. These meetings turned into hallway conversations as the CS teacher found himself engaged in supporting the community during every free moment away from his regular classes. At the conclusion, many of the teachers successfully implemented the use of technology in their classroom, but to great cost on the part of the CS teacher. His thought was that the effort might not be sustainable without his direction. (The sustainability of the effort is being addressed in a follow-up research effort). The key to success from the view of the CS teacher was that the teachers chose their own goals for how to use technology in their classroom and that their efforts were supported by on-going interaction with other teachers in the school. The CS teacher also found that it was important to provide instruction that helped teachers reach their stated goals rather than offer general one-size-fits-all workshops. When the teachers were provided with the support they needed to develop their in-class technology goals, their engagement with technology overall increased and they were successful in implementing their planned projects. It was also found that these teachers were implementing technology in their classroom with the same constructivist principles that were guiding the development of their own learning. Students engaged in using the internet to solve problems of personal importance and to connect with students in different locations to gather information, opinions, and feedback. Their feeling was that the students in their classroom increased their ability to use higher order skills such as critical thinking and problem solving (though this is anecdotal, as they were not systematically measuring this).
Similarly, the university-based group formed a community of learners to support each other throughout the course of the project. They were also asked to develop ideas articulated in the form of a “contract for learning” describing what they would like to learn about technology and to specifically connect their learning to experiences that would enhance their students’ learning in the classroom. This departs from the norm, where university technology courses often present theory or present a variety of skills to teachers unconnected to their classroom environment or to their previous level of experience in technology. In this research project, the teachers could choose at any time to attend workshops that focussed on the skills that they wanted to learn; participate in group discussions about technology issues; learn on their own or with peers; or work in an open lab setting with opportunities to consult with graduate student peers or the instructor. All learning experiences required the teachers to use their chosen in-school project(s). The teachers agreed that they learned far more from this initiative (as contrasted to previous experiences) and that they all were able to see the results of their efforts in their personal classroom setting.

The focus of both of these efforts was primarily to look at how teachers could learn to use technology in their classroom, facilitated by a university-based effort and a local school-based effort. The ideas for technology implementation were observable when they worked on their projects with the facilitators of these efforts. As well, interviews provided data that helped to draw conclusions about what happened when the ideas were actually tested out in the classroom, but direct observation of how the students engaged with technology in these teachers’ classrooms did not occur. As stated previously, we were most interested to see that teachers used a constructivist approach when integrating technology in their classroom. Because many of the projects developed required students to use the computers as tools to develop and construct their own knowledge, it was felt that in many cases this was the approach used by teachers.

The final case was an examination of how one school addressed the implementation of technology after receiving a large grant funding equipment, software, and limited training. Initially, one teacher became recognized as a Lab Coordinator (though his appointment was as a fulltime grade 6 teacher) and made decisions regarding the development of a computer lab and class use schedule. He also organized and conducted lunchtime professional development workshops once a week. Of the 15 teachers on staff, about four teachers would come to any one workshop. After some initial prescribed workshops, the teachers began suggesting themes or topics for the workshop. Attendance at the workshops usually consisted of those teachers who were interested in a particular topic being offered or if they needed help to implement their ideas in their own teaching setting. The majority of the teachers used the lab for their class when it was scheduled, though some were sporadic while others tried to gain additional access. Because the Lab Coordinator was also a teacher and could not be in the lab during use, the researcher who was acting as a participant observer in this study (and was present 3 days per week, all day in the Lab), the researcher found himself in the role of facilitator. He was often asked to help students or to aid the teachers in achieving their goals. This also provided the direct observation that was missing in the other two cases.

Although both the Lab Coordinator and the researcher discussed using an open-ended learning environment (Hannafin, Hill & Land, 1997; Hill, 1999) to promote the development of the teachers’ skill with technology, the initial training efforts more closely resembled direct instruction. Later as teachers initiated dialogue about what and how they would like to learn, a more open approach was used. This was particularly the case in the lab sessions when teachers interacted with the researcher in this study. The nature of his involvement clearly impacted how many of the teachers learned about and then used technology in their classroom as he took on more the role of facilitator rather than an observer. We did not feel that this compromised the study, as it further provided evidence that teachers are most comfortable initiating their own projects for the classroom and then seek the help of others to facilitate the integration of technology.

Our final observation in this study was that the comfort level with technology impacted significantly the way in which technology was used. A few teachers put on a false front, bringing their classes to the lab because they thought they were supposed to; others taught computer skills; while about half integrated the use of computers throughout their instruction and used the computer as a tool to accomplish instructional goals. Teachers who were more comfortable with technology (or were not afraid to let students see them as less than an expert) were able to engage students in a variety of opportunities to use the computer and
demonstrated a more student-centered approach toward learning. All teachers acknowledged that time was a major factor inhibiting them from fully realizing their goals. They spoke both of the time it would take for them to learn how to use the computer in a meaningful way and the time it takes students to learn the technology.

Conclusion

Early indications are that developing a community of learners to support each other in learning about technology and implementing it in the school setting may be of more value than district-provided professional development efforts as they are currently organized. Further, it seems important to have teachers connect their technology learning to actual teaching and learning experiences in the classroom and to play a more significant role in their own knowledge development. In addition, these efforts provide a more thorough understanding of how teachers are learning to use computers in Canada.

Abstract: This paper examines how a bilinear instructional strategy incorporating both linear and nonlinear problem-based teaching approaches was designed and then implemented in a graduate applied technology course. It outlines how the course Multimedia and Internet for Educators was developed, and reports the responses of students in the course to the instructional approach used. These findings include student attitudes toward the following: usefulness of the course, effectiveness of learning process and learning atmosphere, proficiency in multimedia and Internet, perception of technology integration on completed projects, and additional information gleaned about student attitudes. Conclusion and recommendation for using the bilinear problem-based approach are provided.

Introduction

The importance of preparing future teachers to integrate technology continues to be a critical concern at the national level. A report published in 1997 by the National Council for Accreditation of Teacher Education (NCATE) entitled Technology and the New Professional Teacher – Preparing for the 21st Century Classroom, states “The nation’s teacher education institutions must bridge the teaching and learning technology gap between where we are and where we need to be. Teacher education institution must prepare their students to teach in tomorrow’s classrooms. Rather than wait to see what tomorrow’s classrooms will be like, they must experiment with the effective application of computer technology for teaching and learning in their own campus practice. Today’s teacher candidates will teach tomorrow as they are taught today (p 1).”

The traditional way of conducting technology courses must be considered inadequate for the needs of the 21st century classroom. The exclusive use of a didactic model is not only pedagogically ineffective, but reinforces a practice that will likely be reincarnated later. Cooper and Hirtle (1999) reported that a formal didactic transmission approach caused students to learn just enough to be successful in the context of the course they were studying, yet, the acquired skills were quickly diminished. They found in subjects a lack depth of conceptual understanding and an inability to construct meaningful
applications. Educational technology is a field in which knowledge, content, and skills change very rapidly. New technology such as multimedia and Internet are too complex and too multi-contextual to rely on traditional models of instruction. We need to find ways to prepare students not only to use technology in meaningful ways, but also to integrate it authentically into their teaching.

Problem-based teaching strategies have received the increased attention of many educators (Cooper and Hirtle, 1999). Problem-based approaches provide the student with the ability to more authentically interact with their subject and make connections that are more inherently meaningful to their own lives and previous learning. In an applied technology course, they provide an opportunity for students to develop greater technological competency while reflecting on their own learning processes, develop a deeper understanding of the tasks they are engaged in, and enhance skills needed to solve real-world problems.

Forcier (1999) describes two models for problem-solving strategies - linear and non-linear. A linear approach is characterized by a direct, sequential and outcome-driven strategy. A nonlinear approach is characterized by an indirect, random and process-driven strategy. This study examines the adaptation of a combination of both strategies implemented into an applied technology course, where each was employed sequentially to obtain the most authentic and effective combination.

The Study

In order to provide its students with experience in using updated technology to enhance instruction and professional development, the School of Education at the State University of New York at Oswego created a new graduate course, EDU 505 Multimedia and Internet for Educators. In an effort to construct the most authentic and effectively delivered course possible, the choice of course design was re-evaluated from those previously used, and the decision was made to employ an alternative model from the traditional course structures using formal, didactic transmission models. Ultimately, EDU 505 was designed using a model characterized by the following components:

1. A problem-based approach to processing content.
2. A sequence of linear and nonlinear instructional strategies.
3. The application of productivity tools for creating multimedia presentations.
4. The use of computer-based technologies including telecommunications to access information and enhance personal and professional productivity.
5. The use of computers to support problem solving, data collection, information management, communications, presentations, and decision making.

(ISTE-Recommended Foundations in Technology for All Teachers: Personal and Professional Use of Technology, 1998)

The Course

EDU 505 was offered in summer 1999. Enrollment in the class was restricted only to graduate students. The class was limited in size (16 students, 4 males and 12 females) and met for 3 hours twice a week for 6 weeks. The course covered three major topics: (1) Use of the major Internet tools for K-12 teaching and research, (2) Design and development of multimedia programs, and (3) Design and development of basic educational web projects. Coverage of each area was divided into a linear and non-linear component. Forty percent of the instruction was based on a linear outcome-driven approach intended to instruct students in the use of applications and provide guided problem based exercises. In this component, problems were designed to lead students through deliberate stages of facility with each of the requisite operations. Sixty percent of the instruction was based on a non-linear approach grounded in an inquiry/problem-solving model. In this component students were given tasks with more open-ended criteria. The focus here was placed on inquiry and self-directed, creative, collaborative problem solving.
The instructor was the primary designer and instructor for the course, and participant-observer in the data collection of the study. Two colleagues acted as additional participant observers and design consultants throughout the duration of the course. Data were collected from the following sources:
1. Field notes taken by the co-investigators
2. Interviews with students
3. Final reports from students

Component One: The Linear Problem-Solving Phase

Most students entered the course with word processing experience, but little exposure to multimedia and Internet applications. They had minimal experience with e-mail or Internet browsers, and had limited skills and understandings needed to integrate updated technology with their instruction. Therefore the initial emphasis of the course was to create a foundation of necessary concepts and skills.

The linear problem-solving approach follows a deductive cognitive pattern consisting of two phases; analysis and synthesis. The analysis phase includes defining of the problem, understanding the component tasks. The synthesis phase includes designing a solution to the problem, developing a solution to the problem, and then evaluating the results (Forcier, 1999).

To initiate each of three new topics, a problem was introduced to the students in the form of a case study. Both instructor and students collaborated to analyze the problem, seek the solutions, apply related computer technologies, evaluate the final product, and discuss possibilities for integrating new technologies into real-world problems/projects.

The following instructions were provided to students for each of the 3 projects:
1. Simple and general – initial analysis involved student-driven idea/topic generation. Students majored in different fields, so it was crucial to make sure students could understand the content and had a sense of their collective common interests and related their own experience to the project/problem. EDU 505 was organized around three general problems: finding a lesson plan on the Internet (topic 1); Powerpoint presentation on “Welcome to SUNY Oswego” and HyperStudio jeopardy game on “Do you know Oswego?” (topic 2); and the web site “Introducing EDU 505” (topic 3).
2. Straight and sequential – students had different learning styles, they viewed the same case of the problem with different perceptions. To ensure the prerequisite basis for effective problem-solving, the instructor provided the students with clear definitions, an understanding of the problem, the requisite task skills related to the problem, and possible strategies to help students find solutions. During the independent practice portion of the activity, the instructor assisted in the development of project storyboards, supplied content outlines for each problem/case, and provided formative feedback to students throughout the process.
3. Small and applicable – students entered the course with different computer technology capabilities, and experience and background were varied. This created an inherent problem related to how much depth and at what level of detail each application should be introduced. Given this, consideration needed to be given to the most appropriate applications and tasks for each problem/case. To reduce computer anxiety and students being overwhelmed by the vast capability of each application, the instructor begin with small and selected features of each application. For example, the instructor allowed basic multimedia functions to be included in products/problems without requiring students to engage in detailed programming. It was found that this introduction of basic skills and concepts was probably the best way to develop students’ knowledge and confidence in this “hands-on” setting. A good rule is to teach simple concepts when the anxiety level is high, and more complex ones when there is a high level of comfort.
Component Two: The Nonlinear Approach Phase

With each topic, after an outcome-driven grounding using a direct linear problem-solving approach, students were ready for a transition to a nonlinear collaborative-inquiry approach. The main purpose on this phase was to let students operate in a flexible environment that would be more comfortable for more random thinkers and challenging and exciting to the more concrete and sequential thinkers. In addition, this phase has the added factor of being motivational, given that students selected their own direction and projects.

The nonlinear approach allowed individuals the room to determine their own path to goal attainment without having a hierarchical structure or predetermined outcome imposed on them. This strategy consists of a sequential three-part process: The first part is the “given” and is characterized by the information in the learner’s possession. The second part is referred to as the “to find” phase and is characterized by the information the learner is seeking. The third part is the “procedure” characterized by the process the learner is going to use to reach her/his goal.

Three integrating projects were assigned for the semester. The following section outlines how the three part nonlinear strategy was implemented for each of the projects.

Project One: Using Internet as Educational tool
Given -- Related web sites: Sink or Swim: Internet Search Tools & Techniques (http://www.ouc.bc.ca/libr/connect96/search.htm), Online Resources for Educators (http://www.berksiu.k12.pa.us/kevin/); evaluation standards on web sites.
To develop - A clear, concise, convincing review article on one or more education area.
Procedure - Identify key words on interested topics, apply search engine strategies; review the related web sites; find separate sources that say the same thing, organize thoughts clearly; copy and paste cited web sites into a word processing file; and write final review.

Project Two: Educational Multimedia Project
Given - Multimedia applications (Powerpoint and HyperStudio); different multimedia examples and ideas (make a proposal or recommendation, present a research or scientific report, give a lesson or instruction, report progress or status, make a book report).
To create - A group multimedia project dealing with real world teaching and learning.
Procedure - Negotiate project topic with team members; plan the structure or create a storyboard; decide the purpose or goal of the project; create a time line for the completion of the project; assign roles to team members; search for information using textual, electronic, and pictorial sources of information; decide how information will be represented (text, picture, video); decide how the information will be organized, and evaluate and revise the design of the project.

Project Three: Educational Web Site Design and Development
Given - Web design software (Claris Homepage, FrontPage, and Netscape Composer); types of educational web sites (class web, web lessons, learning webs, educational resources, virtual field trips, and individual webs).
To develop - A group or individual educational web site.
Procedure - Decide the intended audience, project topic; decide the web site format; make internal pages (text, picture); evaluate and choose external links (reliability, authority, appropriateness, validity); structure the internal and external links.

Being graduate students and current teachers, class participants recognized the attempt made at a bilinear model and appreciated the opportunities it afforded. In this phase, the instructor mainly stayed in the role of resource, guiding students in potentially fruitful directions and answering questions related to technical aspects of the course. When students were unclear as to how to best accomplish their project, the instructor acted as facilitator to help students “solve their own problems,” and examine the lessons within the problem itself. While the students were given ultimate freedom, the instructor often needed to assist students in their decision-making regarding how to segment and sequence information to make it understandable, how information could best be represented (text, pictures, video), and how the information could be organized (i.e., hierarchy, sequence) and linked most meaningfully. In this phase, a primary role of the instructor was to act as technical consultant. In many cases, the technical problem’s solution was best “discovered” by the student using their own resource and inquiry skills. However, some
problems substantially inhibited a student's progress, and in those cases the instructor needed to intervene to provide solutions and/or micro-teach lessons on application capability and use. In this phase of the instruction, students were strongly encouraged to collaborate with peers. As problems lead inductively to novel solutions and innovation often "two heads were better than one." Quality performance was judged less in this phase by product as by process outcomes.

Findings

Findings from written surveys reflected positive student reactions in the areas of instructional effectiveness, usefulness of the integrated model, and affect on classroom atmosphere. Student responses related to the use of the bilinear instructional strategy demonstrated that they felt their experience was for the most part both meaningful and productive. This could be seen in the following set of written comments: "I like the structure of the course because it allows graduate level students to explore and learn on our own with support from professor. I know that there are various levels of computer experience, so this allows everybody to receive the amount of help that they need." "The course was a useful one. It enabled us to do some things that other classes do not have the time for. This class enabled each person the opportunity to create a web site, and perform a multimedia presentation. The hands-on approach really was beneficial." "I feel that the class as structured was super. So many classes are just straight lecture and honestly I feel little information is actually retained. This class was instruction and then tons of hands-on practical experience which is the best way to learn. Instructor gave excellent step-by-step procedures on how to work on the project and always gave examples which I find extremely helpful when trying to understand a concept." "The learning process was fundamentally easy and satisfactory because theory and hands-on were combined into one. The professor did an excellent job presenting the materials in a level that everyone can understand. I enjoy the hands-on side of the course and the autonomy to be creative." "I appreciated the manner in which we were taught how to use specific tools and then allowed to utilize them immediately. In this way, the lessons were fresh in our minds and the skills were easier to master." "I enjoyed the way this class was run. Once the professor shows me the way I like to take my own course to reach the end product. This style was perfect for me."

Students felt overall that the integrated and hands-on nature of the course was conducive to their making meaningful applications to their own work. These sentiments were reflected in the following comments: "The use of technology for my projects made it more enjoyable and interesting. Not only did my proficiency in the subject matter increase, but also at the same time I improved my computer application skills. It is almost like two courses in one." "The material I created in this class will be used in my classroom. This is exactly what I was hoping to get out of the course." "It definitely enhanced its appearance and clarity. Technology can be used in so many different ways that creating some of the projects we've done in this class is only a stepping-stone to what can be done with our students. It offers a more focused use of technology within our classes." "I plan to use the things I have learned in my classes. I set up my web site for my students. It includes some information about myself, my expectations for each class, and students' grades and homework assignments. I mentioned the idea to my summer school students and they said that they thought it would be very useful. I am really excited about showing the site to my principal and colleagues. The best thing about this course is that I have learned some things that I can actually use." "I think technology integration enhanced my project and enabled my audience to understand clearly my point of view." "My proficiency in multimedia skills and using the Internet has increased quite a bit. I plan to use both the PowerPoint and web page in my class this year, so my efforts will be well rewarded both in the near and distant future." "Being a technology teacher, this course relates directly to my field of study, and NY State curriculum for technology education. I feel through this course I have increased my knowledge of the Internet and I got exposure to a new multimedia program HyperStudio."

Finally, students reported that the linear-nonlinear collaborative problem-solving approach created a positive environment in which to learn, seen in the following comments: "The learning atmosphere was great with many of us working together and helping people." "The format of the class was very laid-back, and a non-threatening environment was provided for learning." "Although I found all
of this overwhelming I was grateful that professor allowed us to work with partners. My partner was a patient teacher and made me do all the steps even though he knew how and it could have gone much faster.” “The best thing about the class was the supportive atmosphere. There was not any pressure or stress when working on the computer. There was always help when you need it.” “It was also nice that other students in the class were willing to help each other.” “I feel that our class was a very safe and comfortable learning environment.”

Discussion

As the findings suggest, using a purposeful combination of both linear and nonlinear strategies within a problem-based approach, provides students with dimensions of learning that neither one alone can achieve. To reduce students’ computer anxiety and enhance technology integration, computer-based courses should be relevant to students’ interests and learning styles, and incorporate an instructional model that employs a cognitive developmental framework most suited to the needs of the learners. The learning program should provide hands-on learning, opportunities for feedback, supportive and caring instruction, and active learning experiences in which students work on their own projects and see the application of computer skills to their area of study, (Yang, Mohamed, and Beyerbach, 1999; Comer and Geissler, 1998). The linear component outlined here also provides the concrete sequential learners, of which a high proportion are teachers (Shindler, 1998), a safe and well matched starting point. Likewise, participants’ comments reflected a true appreciation for the challenging and self-responsible nonlinear component to each project. The more random and abstract minded learners were able to unleash their creativity while the more concrete learners could move more confidently into a less structured horizon having been grounded in the earlier linear experience. All students seemed to appreciate that whether the learning was outcome-driven and direct, or process-driven and indirect, it was “hands-on” and problem-based. Concepts and procedures, whether direct or indirect, were experienced within the context of an exploration of “real and material” action. Students walked away from their technology experience having developed a meaningful understanding of its capability within an authentic context. Moreover, because these teachers often find themselves reproducing the instructional environments that they themselves have experienced, the bilinear problem-based model provides a sound and innovative practice to add to their teaching repertoires.

Abstract: The present article documents a particular model for inservice faculty development at a computer-technology magnet school in a Midwestern city. Using the ACOT model the article recorded the beneficial training activities leading the faculty through different stages of developing their core technology skills and implementing instructional technology in their daily teaching. The most important strategies utilized in this school setting was task-oriented training, which contributed greatly to the faculty development of technology competency and the understanding of technology-related issues in classroom practice.

Introduction

In 1998, an ISTE (International Society for Technology in Education) national survey showed that information technology is increasingly available in schools. Related similar studies showed that K-12 schools in the United States have approximately one microcomputer for every five students. At the same time, past studies have also documented that teacher professional development including both preservice and inservice teacher training, has not kept pace with the rapid changes in the quality and quantity of information technology. During the next decade, the teacher work force is expected to experience a rapid turnover, not to be replaced by technology as such, but by teachers with technology skills and implementation strategies. (ISTE, 1999)

The Burlington Community School District Computer-Related Technology Plan states that “The effective integration of technology assumes that teachers are facilitators of learning, designers of individualized programs, and learners themselves. Efficient operation and management requires staff skilled in the use of technology tools. On-going training and access to information technologies are essential.” (http://www.burlington.k12.ia.us/TECHDEV.HTML) This statement makes clear the role that teachers are expected to play. According to the U.S. Department of Education National Center for Education Statistics, relatively few teachers (20%) report feeling well prepared to integrate educational technology into classroom instruction (Teacher quality: A Report on the Preparation and Qualification of Public School Teachers, January, 1999).

Staff development or inservice training is a scheduled or regulated practice in both private and public schools. With an increasing time investment dedicated to training inservice teachers with basic technology skills and the skills of integrating instructional technology into their classroom teaching, there are correspondingly high expectations of seeing more technology implementation in the students' learning and their outcomes. Among the existing models popularly used in the schools, the Apple Classroom of Tomorrow (ACOT) sponsored by Apple Computer Inc., has gained particular recognition among the practitioners. The book, Education & Technology edited by Charles Fisher, David C. Dwyer, and Keith Yocam (1996) provides reflections on computing in the classroom. The most commonly shared realization among the participants is that technology implementation should bring changes not only in the learning environment, in teachers' roles and student behaviors, but also in the learning outcomes. Also those involved in training the inservice teachers should come to realize that teachers need ongoing emotional, technical, and instructional support during this process. Teachers go through different stages in the development of their respective perceptions of technology and their skills to implement and integrate instructional technology in their classroom. The following five stages were proposed by ACOT:

Entry ➔ Adoption ➔ Adaptation ➔ Appropriation ➔ Invention
While the above model can be viewed as a template for training inservice teachers, one must be mindful of the fact that variations on this theme will generally be necessary to make the model applicable in any particular situation. Furthermore, the transition from any one of the stages to the next can be an arduous one. Years of experience have taught us that the success of training very much relies on strategies that fit the special circumstances of a particular school or district, such as those related to financial resources, technology facilities, faculty perceptions and commitment, attitudes of administrators, and support from the community.

In Alan November's article "Drill the Teacher, Educate the Kids" (http://www.anovember.com/articles/drill.html), we find that "The goal should be to train teachers not to master specific technologies, but instead to design learning environments in which technology helps children learn." However, this statement is incomplete as one must strive to train teachers to have technology skills beyond the rudimentary levels, as well as to look into methods of implementation and creating interactive learning environments for our children.

Analysis of the School Situation

The present article documents a particular model for inservice faculty development at a computer-technology magnet school in a Midwestern city, thus fleshing out a particular version of the ACOT model given above. It is likely that small variations on this model will apply to other schools, as well. In the course of this faculty development, we found that the transition from the adoption in the ACOT model to the adaptation was especially difficult. Below, we describe this difficulty, as well as document how a solution based on project-based learning was effected to bring about a successful resolution of this difficulty.

The school in question had five hundred students covering grades K-5, with most of the students coming from low-income families. Part of a three-year federal grant was used to purchase 450 computers, to be distributed into four computer labs each with roughly 20 computers, and into individual classrooms, each having 12 computers. In addition, various instructional software packages were purchased and installed, which over the course of the three-year grant, included over 300 different software packages in all subject areas and covering all levels (K-5). Finally, one salaried teacher (trainer) with a Master's degree in gifted education was given the responsibility of curriculum development and of training the full-time faculty, which included 24 homeroom teachers, six special education teachers and close to fifty additional administrators and staff. Six times each semester during the period of the three-year grant, the teachers participated in technology staff development, with a portion of the grant money used to hire substitutes to cover the inservice teachers' classes. The training was primarily to help teachers become familiar with the school network, as well as with the software. Every teacher and staff member had one personal computer for administrative and instructional work.

The Beginning Stage

After a few basic orientation sessions for the teachers and staff, the trainer divided the teachers into two groups, grades K-2 and 3-5. The K-2 teachers were trained in the basic functions of word processing, use of spreadsheet and database software packages, and in the use of Kid Pix for graphic and text applications. Those in grades 3-5 were trained to use HyperStudio as a multimedia application in addition to the basic software packages mentioned above. The goals were for the teachers were not only to learn the basic skills in using these technology tools, but also to apply them in their teaching and to assist their students to use the tools in order to promote learning. Beyond this second stage in the staff development process, however, the teachers reached a plateau, learning very little in the way of real instructional applications of the technology. Where there was some use, this was generally of a record-keeping or organizational nature, rather than innovative instructional applications. Despite the training, by the end of the first year too many of the teachers did not feel sufficiently comfortable with what they had learned to create a technology-supported learning environment.

In order to help the teachers resume their learning, as well as to enhance confidence in the use of technology to deliver a more meaningful education, the training sessions were modified so as to be more project-based in their approach (Zhang, 1999). That is, rather than having the training being based on a variety of
microscopic skills in technology, it was decided to divide the remainder of the training into using technology to generate a few (four in all; see below) much larger-scale projects. This not only made the technology much more meaningful for the teacher trainees, but also it gave them a better opportunity to work closely with the students, as this was necessary for seeing the projects to their successful conclusions.

Computers and technology, unlike the vast majority of the more classical academic subjects, has found a relatively large number of devotees, even among the relatively young school-aged children. Popular stories already abound that describe the young enthusiast who spends hours of free time each week, honing his or her skills on the computer, often to a level far in excess of the teachers. This can be at the same time a challenge and an asset for the teacher trying to become sufficiently competent with the technology to find creative uses in the classroom. In the learning project under discussion, it was our conviction that those students already having far surpassed their teachers in computer and technology-related skills should be used in an integral way, for the benefit of both the remaining students as well as for the teachers in training. Therefore, such students were identified and asked to serve as teachers' assistants to help facilitate the completion of the assigned projects. These "assistants" proved to be important catalysts in both the teacher training as well as in the student development.

**Task-Oriented Training**

The projects themselves were chosen to be both meaningful and relevant and mirrored similar real uses of technology in society.

- **Project 1.** Using audio-visual technology, students produced a 15-minute news broadcast, covering school or classroom news and events, student interest stories, student awards, as well as other special news.
- **Project 2.** Using Microsoft Publisher, students produced a school monthly newspaper, complete with news stories and editorials, as well as a literary section, drawing from students' stories and their writings, together with student photographs.
- **Project 3.** Using Kid Pix or PowerPoint as the primary software packages, students created highly professional-looking presentations covering a wide range of subjects. Some of the presentations were even dubbed onto video tapes and broadcast by the local TV station to the entire community.
- **Project 4.** Using a combination of desktop publishing tools and related products, different groups of students each month created monthly displays highlighting diversity as a theme. Classes were paired together to work on this project, with upper-grade students helping lower-grade students. This taught not only the technical skills, but also cooperative skills as well.

The above projects were valuable and meaningful introductions to technology for the students, and the teacher trainees also developed a much better appreciation of the potentials for creative introduction of technology into their curricula. In addition, these designated projects with specific responsibilities for particular groups of students were valuable in motivating teachers to assume their roles as facilitators and as leaders. As a result, after this third year, most returning faculty had the confidence, knowledge and skills necessary to apply instructional technology in creating an enriched environment for students learning. Of the teachers in the training project, fully 80% of them continue to use technology as integral components of their instruction as well as of their administrative duties.

With the completion of the above three-year training session, we were able to bring the teacher trainees, many having previously only the most rudimentary training, from the entry stage to a point well into the adaptation stage of the ACOT model. Many of the teacher trainees had come so far in the realization of the potentials of the application of technology, that they had made the further transition into the appropriation stage or even into the invention stage. This was brought about by a training session not only with specific goals and creatively conceived tasks, but also by a degree of flexibility to allow for solutions of unforeseen difficulties. The final result, quite apart from the better-trained teachers, is a new generation of technologically-literate students ready to meet the challenges of an increasingly complex society.

**Conclusions**

The above model can be considered successful partly because it brought a certain degree of pride among the teacher trainees, helping them into the process of becoming a self-regulated learners. Not only have they not stopped learning, but they have established a solid foundation on which to further their self-directed learning. In
turn, many have developed confidence to the point where they can play leadership roles in assisting technology trainers in educating future teachers in important basic technology competencies and implementation strategies.

Abstract: This paper examines, from a constructivist perspective, the ways in which student teachers seek to improve their Information and Communications Technology (ICT) skills in order to gain Qualified Teacher Status (QTS). All trainee teachers in England and Wales have to meet nationally agreed standards of competence in the use of ICT in order to gain QTS. These standards (DfEE 1998) cover a wide range of skills and include both personal skills and the application of ICT within a school and classroom setting. The research examines the sets of conditions which prove most enabling for students integrating technology into their teaching and the implications for future course design in teacher training.

The education system in England and Wales draws a distinction between IT, the study of information technology as a subject, and ICT, the application of these technologies to teaching and learning situations in all areas of the curriculum. In this paper, we will use IT for all aspects, except when quoting papers that make specific reference to ICT.

Introduction

Over the past few years, the Department for Education and Employment and the Teacher Training Agency have introduced far reaching regulations and standards for schools and for pre-service teacher education. In this study, we are principally concerned with Circular 4/98 (DfEE 1998), which sets out the information technology standards all students must demonstrate. These include skills in their personal use of the technology and the ability and judgement to use the technologies successfully and appropriately in the classroom. These standards apply equally to all students, irrespective of their subject specialism.

Each September some 200 postgraduates enter our one-year Post-Graduate Certificate in Education (PGCE) to train to teach in 'secondary schools' (ages 11 to 18). The year is divided into two semesters and in each, students have a short serial placement of two days per week in schools, followed by a longer period of full-time school experience during which their teaching load rises to 75% of a full timetable. The majority of the PGCE students are “mature on entry” — the median age is usually 31 or 32 — and they have a wide range of knowledge of IT. A rapidly increasing proportion have worked in jobs involving regular use of IT and the younger or more recent graduates will have had to make use of IT in school or on their degree courses. However, their IT experience is rarely “balanced”: they may have been involved in DTP or as a multimedia designer, yet have little or no experience of spreadsheets or databases. A number of studies have considered the general spread of students' IT skills at the point of entry (notably Denning and Sellinger, 1999) and for the past six years we have monitored our students' IT skills both at entry and exit.

In previous years, following the initial IT audit, we have provided personal IT skills training for those in need. Such training was, in effect, voluntary, as there was no requirement to have any particular level of competence, nor to demonstrate its use in the classroom. Thus, those students who were “naturally” interested in new approaches and those who, for whatever reason, had an interest in information technology took up the training whilst, it seemed, those who were most in need could “safely” ignore it.

With the changes in the regulations for teacher training, all student teachers must now attain a high level of personal ability across a wide range of IT and must demonstrate, in their school placements, that they can apply these appropriately in a professional setting. In considering the relationship between 'knowing' and 'doing' we are using the comments offered by Pilkington and Groat (1999) "The distinction
between skill and knowledge is that a skill embeds knowledge in procedure.” Thus, to demonstrate their IT skills, students’ must show evidence that IT has become embedded in their teaching-related activities.

The required standards (DfEE 1998) are quite explicit about both the personal and professional aspects of students’ IT skills and the requirement to demonstrate these cannot but have an effect on the students’ approach to the use of IT. For example, the standards regarding classroom use say that “students must be taught [inter alia] how to:

- decide when the use of ICT is beneficial [or not] to achieve teaching objectives in the subject and phase
- use ICT most effectively in relation to subject-related objectives
- identify in their planning:
  - the way(s) in which ICT will be used to meet teaching and learning objectives
  - key questions to ask and opportunities for teacher intervention
  - the way(s) in which pupils’ progress will be assessed and recorded
- ensure that judgements about pupils’ attainment and progress in the subject are not masked because ICT has been used
- [judge the] impact of the use of ICT on the organisation and conduct of the subject lesson and how this is to be managed’

They must also be taught “the most effective organisation of classroom ICT resources to meet learning objectives in the subject” and must “be given opportunities to practise, in taught sessions and in the classroom.” (The standards are, in fact, several pages long and can be found at http://www.dfee.gov.uk/circulars/498/annexb.htm).

The methodology which students use seems likely to have a great bearing on how easily they achieve these standards. There can be little formal teaching: the standards have been introduced into what is already widely felt to be an overcrowded and under-resourced curriculum: nor has there been additional resourcing to match the additional requirements. Basic training and development guidance will be offered, but it seems inevitable that students will play a large part in training themselves. Students will be faced with the need to use IT skills in planning and resourcing, teaching, monitoring and assessing and in recording and reporting. We, their tutors, need to learn how students improve their IT skills and how they learn to apply them if we are to plan effective courses for the future.

The Study

Our current research is not simply concerned with levels of resources or what particular skills are needed. We are more concerned with how the individual students build on their knowledge of and expertise in IT, what are the conditions for success and which circumstances lead to the use of IT becoming embedded in the students’ planning, teaching and assessment. Research of this nature inevitably raises many questions: for example,

- does an initial facility with a word processor make it more likely that students will gain expertise in, say, using a spreadsheet to track pupil progress?
- does an initial positive attitude to IT lead to its use becoming embedded in the student’s teaching?

To maintain good practice in teacher education, we need to understand the sets of conditions which prove most enabling for students integrating technology into their teaching. In assuming a constructivist basis for this integration (Brooks and Brooks, 1993), we shall examine the implications for future course design in teacher training.

There is support in the literature both for the general approach to the problem and for the nature of the questions asked. For more than a decade, researchers have argued that the effective use of information technologies in the classroom requires some shift from “teacher as source of knowledge” to “teacher as facilitator of learning”. Chatterton (1985) showed that, when using IT in lessons, “The teacher is encouraged to work in a much more supportive role: he/she is no longer simply giving instruction (in the didactic sense) but ... reinforcing some aspects and/or extending the pupil’s awareness into new areas.” In similar vein, Gonzales and Thompson (1998) argue that “In order to tap the increased access to information made possible by technology, a shift in pedagogy from the model of ‘teacher as information-provider’ to the ‘teacher as facilitator’ is needed, but the change process is slow at best.” It is by using a constructivist model that we hope to show the extent to which newly trained teachers can make this shift! Gonzales and Thompson go on to quote one example in which “[the] educator began with word processing in which case
the technology was used to do the same things always done, only faster. It appears that it is only with much personal experience with the tools that the potential is realized, such as using word processing to compose more effectively."

Willis (1993), importantly argues that "questions about hardware, software and how to use applications are no longer the most important topics in educational technology. Today, the major issues are related to instructional strategies, instructionally appropriate software, professional development and how to provide continuous administrative support." While this statement is certainly true in terms of the 'most important topics' and ones which we would be most interested in discussing, some of our students are still struggling with outdated computers inefficiently organised and situated within schools. They then have to expend considerable time and energy working with a system, the knowledge of which will not be of much benefit to them in future. As one student explained: 'Teachers haven't talked much about IT, but have explained which error messages indicate that it's better to give up at that point.'

The BECTA (previously NCET) publication *Managing IT* (1996) used a model developed by the MIT's 90 Research Group which modelled the extent of IT integration within organisations in relation to its effects and benefits. The adapted model used five strategic levels of application of IT: localised, co-ordinated, transformative, embedded and innovative. The model may be used holistically so schools which are at the 'embedding' stage may well have teachers whose expertise varies widely but the school policy will in practice encourage all staff to improve their IT skills and use them as part of their teaching repertoire. However, in a school where the IT practice is localised within departments some may be excellent while others are failing to innovate at all and the school policy will not in practice implement IT across a range of subject disciplines. If we use a similar model here, concerning students and their IT development, then it is very important to gauge where a student is in terms of that development. We suggest, from the evidence gained so far from our students that 4 factors are of crucial importance, degree, job experience, subject area and placement school. Whatever the students do in terms of improving their own IT skills within the professional year the experience gained in those 4 areas is cumulative and significant. Students can only move so far in terms of their own personal skills, that experience itself promotes confidence but, unless teaching experience at school is available, they cannot develop as far or as fast as we would want them to. It seems likely that students are affected by the stage of implementation the school has reached. So, for example, Business Studies students are often asked to teach IT basic skills to pupils of 11–13 years of age, and they are not only encouraged to use IT labs with suites of computers but have to do so. When they are in the labs the work is often already organised for the pupils so that the teaching students can go around and help with the teaching. English students find themselves in a different situation, where they know there are IT suites but they are often booked up, they do not see many English teachers using IT in their lessons and they are not asked to help with basic IT skills teaching.

Denning and Sellinger (1999) in their extremely useful commentary on data relating to student competences in ICT, pointed out the range of variance in school equipment, teachers' ICT expertise and the knowledge and experience of students (self-rated) when they began one year post-graduate courses in teacher education. They cited findings by Goldstein, (1997) that overall standards in IT varied unacceptably between schools and by the McKinsey group (1997) that penetration of ICT across schools was extremely variable, and that the experience, skills and attitudes of teachers and the way ICT was used varied widely. Denning and Sellinger, in their analysis of questionnaires from 983 students, also found that 'there are clear differences between the reported competence of students with different subject specialisms'.

Our research has looked specifically at students from different subject areas, placed in schools and colleges serving a wide range of communities. In phase 1 (reported here) we interviewed 24 students on the postgraduate course, 12 expecting to teach Business Studies and 12 English. At the time of this interview, the students were half way through their first teaching placement and so could be expected to have a fair knowledge of the school and its procedures and to have developed some opinions on the use of ICT in education. In a semi-structured interview, students were asked about their experience of IT before joining the PGCE course and what views of IT this experience had engendered. They were then asked about their experiences of IT within the university-based part of the PGCE course and within the school-based part. They were finally asked about their own use of IT in teaching, its benefits and drawbacks, and their views about what helped and/or hindered their own progress. The students' self-assessment questionnaires, completed at the time of their initial interview as PGCE candidates, were also available to the project. At the end of the academic year, when we will have interviewed the students during their second placement in a second school, we will have a year-long profile of their IT development.
Student Responses

All the students interviewed (and 91% of the cohort) had a personal computer at home, many of which had been bought, at least in part, because they were coming on this course. Most students had acquired confidence in basic IT skills before starting the course — a marked change in the last four years — and most had experience of IT in the workplace. Without exception, all the students who had worked with IT reported that *having to use IT* was a very significant factor in building their confidence. It should be noted that IT was used as a tool, they were not employed as IT specialists. Jobs ranged from marketing, to customer relations, to banking and insurance and these students generally had little or no experience of IT before starting work. Surprisingly, banking and insurance gave little training, but "left me to get on with it" as more than one student said: a situation with some resonance in teaching.

Of the younger graduates, with only vacation work experience, the degree course was inevitably more significant. All had had to use a word processor to submit assignments and, for the English graduates, that was all they had to do. Business degree students had surprisingly little further experience, in many cases using spreadsheets for finance as far as it went. However, many of these younger students regarded themselves as "part of the computer generation" and expressed confidence in their ability to cope with IT issues and there was no significant difference in the attitudes of the English and Business Studies graduates. We found this surprising, as prejudice would suggest that business graduates would have much more computer experience.

In schools, however, there was a marked difference in the frequency of use of computing: given the nature of the subjects this was to be expected: English students used computers less than Business students. However, the story is not quite that simple: some of the English students were using IT more than some of the business students were. This would appear to be, in large part, a function of the resourcing of the school and of the attitude of the schools' staff: the two may well be related. In one school, an English student was encouraged to send small groups of pupils to the computer room as part of the normal process of the lesson. In another school, IT was not used for business studies below Year 12 (grade 12). In almost all schools, business studies had only limited access to computers and any given group was, typically, timetabled in an IT room for 25% of the time. In contrast, most business studies students found themselves teaching some IT to classes in the lower age-range of the school. This seemed to have a positive effect on their ability to deal with the technicalities of the school system and with the issues of classroom management and control.

How, then, do students bring their IT skills to bear in the classroom? Basic skills in IT seem to be transferable in a way that is not expected in many areas: simple maths problems may suddenly be found difficult in science lessons. When asked, students felt that these skills transferred because they, the students, had to be able to use IT and had to provide the evidence for it. Most of the students interviewed said that they had been involved in planning for the use of IT and all the business students and about half of the English students said that that they had already taught using IT. In a number of schools' English departments, the staff made little or no use of IT: the fact that our students were compelled to use IT was seen to be encouraging the department to make provision. This fits nicely with statements from the government and others about students and NQTs being 'agents of change' in schools.

Two cameos are presented here, to indicate the range of IT knowledge and use and also the range of expectation and possibility within our secondary schools.

*Cameo 1:*

Student A is at a secondary school which is a 'City Technology College', one of a small number of specialist schools built in inner-city areas, with matched funds from the private and public sector, to provide an IT rich environment. The initial influx of funds provided for hardware and software purchases in a modern, purpose built school.

Student A is 45 years old, used IT in his degree course and used many software applications during his 15 years in business. Since he came to the university for his PGCE course, he has used the intranet for contacting the library, for reference and for looking in FirstClass for information from his tutor about assignments, but otherwise he already had all the IT skills he has needed in teaching.

"All my lesson plans, schemes of work, proformas, PowerPoint presentations are on my own computer at home. The school has 480 computers for 900 kids. The place is brilliant, I'm enjoying it. I'm using skills I've already learned but, because I'm in a work environment, I can apply them in different ways. I'm experimenting too - when you're at work you don't have the time to deviate from the things you normally use. I'm getting a lot off the kids, I must say ... in
effect they were actually teaching me. I say, 'Come on guys, you're wizard with this, show us the way.' We use IT for research, the Internet or CD-ROMS and encyclopaedias. I stipulate they have to use the information not just download it. ... It's really weird, the kids queue up at a quarter to eight, there's 300 of them waiting at the door in a line to get into school, to do emails, research. ... I like to involve the children in the lessons. I use real live scenarios or past scenarios that were real live events - I try to relate it to the children's own experience. For example they have to do a job evaluation, I've asked them to draw up an evaluation sheet for what they needed when they joined, what they had to have, what were advantages, what were bonuses as skills. Using IT allows me more time to interact with the children. They tend to be engrossed in what they're doing -- if you took 4 or 5 minutes with one pupil in a normal class then the rest would tend to drift off task but with IT, it keeps them on task, focused on what they're doing. This school is a one-off in some respects. In some schools, for example my daughter's, there's a limited amount of IT ... but I've always seen IT as something positive, as a tool to do whatever I'm doing. It hasn't changed in that respect.'

Cameo 2:

Student B is aged 21, also at an inner city school, but one that has not been funded as a Technology College, teaching English. She didn't learn anything about computers in the school she attended as a pupil.

"I used a word processor for my assignments and things like that during my degree but not often. I just thought I'd better learn to do it, I didn't go on any courses or anything so I was basically self-taught. When I came for interview here, I filled in the questionnaire about using computers and afterwards I was asked to go on the pre-PGCE IT course, which was great. I learned to do spreadsheets and went on the Internet. But I haven't done so since then. None of the teachers has said anything to me about using IT at school and I haven't observed anyone using computers. No one has suggested I book any of the IT rooms. My mentor has discussed IT with me, as part of the student profile thing, and she was very helpful. She showed me where they had set up a system for making worksheets so I have used that often. But really I've learned more from my fellow student (who teaches IT) than from anyone else. He's often in the staff room when I am. I definitely use more ICT now, since I started on the PGCE course, mainly for worksheets."

Student A was able to talk volubly about his pupils and his teaching and the school itself, when discussing IT usage. Student B said far less, although, recently, she has used IT a great deal more, has developed her own skills and is learning from a peer in a context which is meaningful for her. It is interesting to speculate on the causes of this difference.

As part of the monitoring of students' IT experience, we have been considering a points scoring system where, for instance, a student gains up to 5 points in each of the following five categories: previous educational experience of IT; experience of working with IT; experience in the university-based part of the PGCE; semester 1 school experience; semester 2 school experience. On this basis, student A entered the PGCE with 10 points and is probably now at 20 points and is able to learn from every environment and his own pupils. Student B, however, gained perhaps 2 points from her degree and 3 from the PGCE course and 2 from her school/colleague, giving a total of 7. This scale is at the earliest stage of its development, but it is interesting to speculate that prior IT experience is directly transferable to this setting and greatly aids the students' development.

University staff were seen to use IT extensively in the preparation of lectures and seminars and, in schools, students followed this practice: all students said they did all their preparation — lesson plans, worksheets, evaluations etc — on their computer. This was seen as a great time saver and, equally importantly, students felt that this was 'expected' of them by the school pupils. PGCE students clearly felt that their materials should be produced to a good standard because pupils were used to well-presented material in the media. They felt that it would devalue the subject if material were poorly presented.

The interviewees were clear that having basic IT skills is essential to self-confidence. They felt strongly that they should be given help with learning about IT in the classroom and that this could be integrated into the normal university subject-based sessions, perhaps with an IT specialist working with the subject tutor. The example set by tutors is important: many students commented on the encouragement given by tutors and they felt it was good that they had seen materials prepared using IT as it gave them good ideas for their own preparation. Pupil-motivation was recognised as an important feature of IT but, more unusually, students themselves felt motivated by IT and most enjoyed the fact that pupils sometimes appeared to know more about IT than they did. IT was seen as increasing the pupils' self-worth and as directly beneficial to both pupil and student teacher. One student said, 'IT engages their attention and is more interactive. IT is such an important element [of learning], it lets you do things in new and different ways - this is important, pupils can be inspired to a better view of English and see it as relevant to them.'

Students recognised changes in teaching and learning styles when using IT, although most think of changes in teaching style in limited terms of differences in class management. Few considered changes in their behaviour without prompting and then only in limited terms - probably an indicator of their inexperience. There was marked disagreement between students about whether using IT makes classroom
management easier or harder. Those who found it harder tend to think in terms of room design, seeing the backs of pupils' heads, and problems with the physical side of the technology such as leads falling out, printing problems and so on. Those who felt it was easier tended to talk about pupils being absorbed in their work, sharing problems, teacher talking 1:1 with pupils etc.

Conclusions

Prior experience was, without doubt, a major factor influencing the students' attitude towards IT and their ability to make quick progress with relatively little direct intervention. PGCE courses are notoriously overburdened and it seems difficult for students to make a 'standing start' in IT: the 'flying start' given by prior experience is a huge advantage. Experience in schools also varies considerably, both between schools and between departments within a school. English students were likely to get little encouragement to deal with the school IT system; business students were expected to be closely involved in teaching IT. We would suggest that all students not teaching IT as part of their normal timetable should have to work as a classroom assistant in one IT lesson per week in the lower school. This would not involve planning or assessment, but would enable them to develop confidence in their own abilities in a relatively safe, but focussed setting.

Making use of pupils' knowledge of IT was generally felt to be beneficial for all concerned, although it is recognised that student teachers need to be secure in their place in the classroom to make full use of it. The mutual learning which can take place in such settings was positively encouraged by most schools and, from the student viewpoint, it was felt to encourage good relationships in the classroom.

Relationships with pupils were an important factor in issues around classroom management and control when using IT. Students who were, perhaps, less sure of their class management skills felt threatened by pupils facing the monitors rather than facing the teacher. This is, in part a function of how rooms have been adapted to house computers - typically with the computers on benches running round three walls, leaving the centre of the room for tables for non IT work. Conversely, the ability to see all the monitor screens in this arrangement was seen as positive by more confident students.

Our constructivist hypothesis that students will build on prior experience and knowledge of IT has been borne out. Students are at a conjunction in their teaching career where situation (the two schools where they spend the majority of their time) and context (government requirements regarding IT competences) matter significantly.

References

As technological changes sweep through society, the demands on teachers to use a more interactive, student-centered, technology-based curriculum are increasing. Because of technological advances, students today have grown up in an environment where they are largely in control of both the access to and the flow of information. Accordingly, educational systems must keep pace with the explosion of content and the evolution of teaching systems. The presentation of information is changing; vivid images, streaming video, and audio clips supplement information that was formally presented solely through text (Strommen & Lincoln, 1995). Computers are ideally suited to bring technology into the classroom by virtue of the flexibility they can provide to enhance instruction while fostering flexible thinking (Spiro, Feltovich, Jacobson, & Coulson, 1992). As the field of instructional technology rapidly develops, the need for strong instructional design increases. Though many design models exist, the following authors impart their perspectives and address these design aspects as they impact their educational experiences.

Albion begins this section discussing the design of teacher education programs that include the preparation of teachers for working with Information and Communication Technology. The balance of student characteristics, prospective employer requirements, education authority requirements, community aspirations, university policy, and resource constraints is given due attention.

Next, Aris, Abu, Ellington, and Dhamotharan, discuss the design and development of a flexible and user-friendly interactive multimedia courseware package to improve Malaysian adult teachers’ knowledge of and attitude toward instructional technology in education. During this design process, the ADDIE model of instructional design was used.

Bakoyiannis and Grigoriadou propose an information model for evaluating educational software. They look at factors such as the changes that educational software will cause in the role of the educator, in the student learning process, in the curriculum, in the meaning of the school book, and in the class/laboratory structure. Both qualitative and quantitative methods are utilized.

Howard’s article addresses the dissatisfaction of constructivist instructors who attempt to develop a browser-based multimedia curriculum using traditional instructional design methodologies. He discusses various instructional development techniques, such as rapid prototyping, being mindful of student needs, iterative evaluation, and versatility and reusability of development tools, used in the creation of Iowa State University’s browser-based Masters of Agronomy program.

Hunt and Karl continue the discussion concerning the instructional design and development of web-based curriculums. This paper is intended to serve as an instructional design blueprint for other curriculum designers and educators to use when dealing with curriculums based on scientific theory and data that incorporate a variety of emerging technologies, Internet tools, and innovative instructional strategies.

In many instructional design models, the use of storyboarding is a stage in which output, inputs, and navigation are determined and blueprinted. Liu presents PowerPoint as another means of storyboarding beyond the traditional forms such as index cards or other paper forms.

Maxey introduces an alternative approach to traditional instructional design models by suggesting that participatory communication theory creates a process which values the learner’s voice. This paper defines the theory, explains how it works, discusses examples of participatory communication projects, and explores the uses and ramifications of the theory in an instructional design model.

Montgomery and Whiting report the findings of an action research project which was conducted during the course of an undergraduate “Technology in Education” class for preservice teachers. A constructivist approach was used in designing a learning environment which incorporated principles of brain based and engaged learning.

Moseley creates a context for design and a supportive environment to create applications for those who are physically challenged. He explores the use of direct manipulative user interfaces that have been specially enhanced for a learner’s special needs.

Staupe and Hernes present the design and development of an on-line learning environment from a constructivistic and situated learning point of view. Basic principles of
learning theory are explained before moving on to the structuring of virtual learning environments on the Internet.

Summerville discusses the need for instructors in higher education to design, develop, and deliver courses via the World Wide Web. Her article explains the process of developing a Masters-level instructional design course for delivery on-line. The rationale, development procedures, successes and failures, and prescriptions for future developers are addressed.

Röbling and Freisleben address the growing interest in supplementing course materials with animations that illustrate the dynamic behavior of the content being presented. Several freeware tools are reviewed.

Romereim-Holmes and Peterson focus on the challenge for classroom teachers to design instructionally sound curriculum materials for diverse learners that utilize technology effectively. The process described in this paper shows teachers ways to develop an awareness of universal design principles in creating on-line materials.

Toma discusses the use of a new device called the video sequencer which can complete real-time automatic segmenting of sound and images. Coupled with IBM ViaVoice, the teacher can speak during this time span to create the necessary contextual help for an easier aural comprehension.

Tu suggests the current computer-based tutorials are constructed with a linear approach in which learners go through a long list to select one or more tutorials. In response to this problem, Tu reports the pros, cons, and revisions of a web-based database-driven tutorial used to support pre- and in-service teachers in learning web page creation.

Wilcox and Wojnar summarize a “how to” workshop that focuses on the design guidelines used when moving from an onsite course to an online course. A model is presented to guide teachers in designing online courses to increase learning and thinking through improved teaching.

This section concludes as Zhang reports how a group of inservice teachers who were involved in designing interdisciplinary units of instruction used a systems approach to fulfill the requirement of a graduate course. The application of Dick and Carey’s Systematic Design of Instruction was met with initial resistance, but later adopted and utilized by the participants to successfully produce their final products.

Setting Course for the New Millennium:
Planning for ICT in a New Bachelor Degree Program

Peter Albion
Department of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: The design of teacher education programs, including the preparation of teachers for working with Information and Communication Technology (ICT), requires careful balancing of multiple considerations. Due attention should be given to the characteristics of students, the requirements of education authorities and prospective employers, broader community aspirations and local institutional imperatives including university policies and resource constraints. The process of preparing for the re-accreditation of teacher preparation programs at the University of Southern Queensland (USQ) provided an opportunity for a review of the provisions for teaching and learning about ICTs in the light of a changing policy environment for education. This paper describes how the existing degree program at USQ incorporates learning about ICTs and discusses some adjustments being proposed to ensure that the revised degree program may better meet the needs of graduating teachers in the new millennium.

When studies of computing first appeared in teacher education courses they were rightly seen as visionary innovations directed towards a distant future in which computers would be readily accessible in typical classrooms. Although computers were seen as important elements of the future in which students would live and work, they were rare and expensive pieces of equipment. Hence, the emphasis was most often on computer literacy and learning about computers. Even when personal computers became more affordable and began to appear in classrooms there were few programs, educational or otherwise, available off the shelf. Inevitably the incorporation of computing into teacher education courses tended to take a technocentric approach which included programming in BASIC or some other language.

Since that time there have been very significant developments in information and communication technology (ICT), its accessibility in typical classrooms and its treatment within teacher education courses. The hardware and software available in classrooms has advanced far beyond the level where it was necessary for teachers to have knowledge of computer programming in order to make use of the computer. Sophisticated computer hardware and software is widely available in classrooms and in Queensland the Government is committed to connecting every classroom to the Internet by 2001 (Education Queensland 1998b). By now most teacher education courses include required courses in computing. Moreover, the emphasis in those courses has moved away from technical knowledge and aspects such as programming. Instead the focus is likely to be on developing fluency with common software tools such as word processors and on the evaluation, selection and integration of software for the classroom.

Now as we enter the new millennium there are multiple factors which should impel us to evaluate and consider appropriate changes to current teacher education course provisions in respect of ICTs. Access to information and communication technology is now a given in most circumstances in western societies. Community aspirations for education have broadened to include expectations that students should both acquire skills in the use of ICTs and should have their learning across a range of areas magnified by their power. Recent discussions of the "new basics" for Queensland Government schools have included the proposal that the preparation of a multimedia presentation and the construction of a page on the World Wide Web should form part of a series of benchmark tasks for eight year olds (Education Queensland 1999). At present such a performance would be beyond the experience of many teachers or teacher educators and it presents a challenge for teacher preparation and professional development.
The Policy Environment for ICTs in Teacher Education

The preparation and employment of teachers is increasingly subject to advisory or mandated standards in relation to ICT. In the USA the ISTE/NCATE foundation standards (NCATE 1992) have led the way but additional requirements apply in some jurisdictions. In the UK the requirements for initial teacher training (DfEE 1998) include prescriptions for the capabilities teachers must demonstrate with ICTs. In Queensland, Education Queensland, which as the operator of the Government school system is the major employer of teachers, has adopted a set of minimum standards for Learning Technology to be achieved for all teachers by 2001 (Education Queensland 1998a). More recently the Australian Council for Computers in Education has begun work on a national document about teacher competencies in respect of learning technology (ACCE 1999).

Although technical skills in the use of ICTs remain an important component of the various standards prescribed for teachers, they are no longer seen as the sole addition that should be made to a teacher education program in order to prepare teachers for teaching with ICTs. The Education Queensland (1998a) minimum standards for learning technology are presented in four sections which deal with IT skills, curriculum applications including classroom planning and management, school planning (for IT) and student centered learning. The standards are as much about knowledge of curriculum and pedagogy as about technology reflecting a shift in emphasis away from IT as content with an orientation to future work skills and towards IT as a tool for teaching and learning.

To date, the formal ICT requirements for graduating teachers in Queensland are minimal and may remain so because the Education Queensland standards have been developed and interpreted in such a way that accreditation can be achieved only in the context of a specific school. However, there is a strong expectation that teacher education programs should prepare students to the point where they are immediately capable of demonstrating all but the most context specific competencies when they graduate. Other factors being equal, graduates with these capabilities will be advantaged in seeking employment as teachers.

Against this background it seems clear that any new or revised teacher education program to be offered in Queensland should include experiences which will prepare students for teaching effectively with information and communication technology. A first step in revising the approach to ICTs in a teacher education program should be to examine the provisions of the existing program to determine which aspects are effective and what might be improved.

Existing Provision for ICTs in Teacher Education at USQ

Students undertaking teacher preparation at the University of Southern Queensland (USQ) may be exposed to ICTs in one or more of three program elements.

The first of these elements is the "core curriculum" which was introduced some years ago at USQ as part of all undergraduate programs. For students in teacher education programs it comprises three key areas, namely, communication and scholarship, computing, and studies of Australia in relation to the Asian and Pacific region. For students in most other courses it also includes an introductory statistics subject. These areas were selected for inclusion in the belief that they would be fundamental to the work of future Australian professionals. The core curriculum is generally experienced by students in the form of four units of study each of which is equivalent to one-eighth of a standard student load for a year. Thus all undergraduate students study one unit in general computing which, for most students, concentrates on basic theory and common applications.

The second way in which education students at USQ may undertake course work relevant to ICTs is in an option (minor) study. The four year education degree comprises 32 credit points of which four points are taken in an option study selected by the student from a range of packages offered by different departments. Students may select from such areas as visual arts, music, sciences, mathematics, business and so on. A four credit point option in educational computing is offered within the Faculty of Education and includes such topics as desktop publishing and presentation, Logo, hypermedia creation and instructional software. Students may take an additional two credit points (above the normal degree program) to qualify for a specialization in educational computing. The additional units focus on the application of ICTs in the classroom with the intent of graduating students who have sufficient background to provide some leadership in the use of ICTs for teaching.
The third way in which students are exposed to ICTs is in the context of their general studies in education subjects where, over time, some instructors have begun to integrate the use of ICTs. Practices have included the use of applications such as word processors and presentation packages, demonstration and review of curriculum software, communication activities using email and optional or required activities involving creation of web sites. Although integration of ICTs is encouraged the adoption of new practices is scattered and does not form part of any coherent strategy to integrate ICTs into teaching within the Faculty.

Although each of these offerings confers some benefits for students, individually and as a package they exhibit some serious limitations and deficiencies.

Fewer than 30% of students undertake the option study in educational computing. Hence, most students experience no coherent course work component related to the integration of ICT into their teaching. Their only exposure to ICT is in the core subject. The program structure places the core subject in the first year to ensure that students have essential computing skills to support their university study.

The core unit is taught as a service unit by another faculty and makes only limited concessions to the specific requirements of education students. It does not significantly address the educational use of computers because it is done at a point in the program where students have little or no background in education and because it is taught by faculty with expertise in computing rather than education.

An increasing proportion of new university students is arriving with essential computing skills acquired in secondary education or prior employment. For them a core computing subject with a focus on introductory skills acquisition is probably unnecessary. For those who arrive without computing skills, the learning curve in the core subject is sometimes too steep and they might be better served by a more gradual approach with a clearer connection to their major areas of study. For both groups, the difficulties described above in making explicit connections to education may diminish the value of the subject as a preparation for future professional application of ICT.

The subjects which make up the option and specialization in educational computing were originally specified when the present degree program was accredited in 1992. Although they have been adjusted over time to reflect more recent developments in ICT such as the World Wide Web, they would benefit from significant revision to address emerging issues in the educational use of ICTs. They could also benefit from a clearer focus on topics relevant to the needs of future teachers who may be expected to accept a degree of responsibility for offering leadership in the use of ICTs within their schools.

Teachers who reflect on their practice recognize that there is a natural inclination to "teach as they were taught" and that to change teaching practice requires a conscious effort. Access to appropriate models of teaching is an important aspect of teacher preparation and teacher educators are one significant source of such modeling of practice. The importance of students being presented with appropriate modeling of computer use within their teacher preparation program has been noted elsewhere (Parker 1997; Zachariades & Roberts 1995) and at USQ there has been a noticeable increase in the use of computers within various subjects in the teacher preparation program. However, there is as yet no systematic approach to integration of ICTs.

Almost all of the computers available to students at USQ are installed in 20 seat laboratories that are timetabled on a fixed schedule for each week of a semester. This is unlike the model used in primary schools where computers are more likely to be found in groups of 3 to 6 in or near to a standard classroom. This arrangement restricts the opportunity for modeling the integration of computers into standard classes.

A second significant source of models of teaching behavior are the teachers with whom students work during practicum experiences. Some of these teachers are confident, competent and consistent users of ICTs in their classrooms but many are not. Students returning from practicum during 1999 remarked on the variability in integration of ICTs in the classrooms where they worked, reporting a full range from an unused computer at the back of a classroom to curriculum activities which used Internet resources as a focus. Because of the number of students who must be placed, there is little chance of the university being able to ensure that every student
Integrating ICTs in a Revised Teacher Education Program

The most significant deficiency in the existing program is that most graduates have had little or no explicit preparation for integrating ICTs into their teaching. All should have at least basic skills in the use of common applications on personal computers. Those who have studied the educational computing option or specialization will have both substantially enhanced skills and preparation for using ICTs in teaching but they represent fewer than 30% of graduates. To address the expectations of employers, the revised bachelor degree program will need to ensure that all students are adequately prepared for teaching with ICTs.

USQ remains committed to the core curriculum requirement in undergraduate programs. However, some programs such as Engineering have negotiated the use of a specifically designed subject in place of the standard subject taken by students in most programs.

Historically the core subject in computing was introduced to enable students to develop computer literacy appropriate to the professions into which they would graduate. Since the subject was first introduced the understanding of computer literacy has developed and it is widely accepted that it may mean different things in different professional contexts. Now that the major employer of teachers in Queensland has identified a set of minimum standards for Learning Technology it is reasonable to argue that this statement constitutes a *de facto* definition of computer literacy for the teaching profession. Hence, if the USQ core curriculum is to remain true to its original intent, these standards should provide a foundation for determining which aspects of ICTs should contribute to the core curriculum for teacher education students. Examination of the Education Queensland standards reveals that more than two-thirds of the content is tightly bound to educational contexts. This should be reflected in the way that ICTs are incorporated into the teacher education program.

Skills that are taught in the existing core computing subject should not be neglected. They will be fundamental to success in both university study and professional practice in the new millennium. However, many students already enter with significant skills in computing. Hence, rather than mandate a full subject in basic skills for all students it may be preferable to monitor entry skills and offer short courses and mentoring for those whose skills are insufficiently developed.

To supplement this approach other subjects in the program should be reviewed and aspects that might be enhanced through the use of ICTs should be identified. Key skills could then be taught or reinforced in appropriate contexts. For example, word processing could be developed in association with communication and scholarship studies, spreadsheets might be used in mathematics and science methods, and computer graphics in the arts. Integration of learning about ICTs into contexts where their use is a natural adjunct to the work being done should increase students' motivation. Under the existing arrangements at USQ, skills in the use of ICTs are often taught in isolation from their application and students do not appreciate their relevance. By the time students encounter situations where the skills might be applied they have sometimes lost most of the fluency they had acquired. Learning skills closer to the context of real use should also encourage reinforcement of learning through additional opportunities for practice.

Integrating learning about ICTs across the teacher education program should increase the exposure of students to modeling of the integration of ICTs into teaching and learning. However, there will be challenges to be met. Although the staff who contribute to the teacher education program are mostly comfortable with the use of ICTs to support their own teaching and scholarship, many would not be comfortable with a requirement to integrate the use of ICTs into their classes or with teaching relevant ICT skills to students. Mentoring is one approach which has been found to be successful in assisting staff to develop both the competence and the confidence to integrate ICTs into a teacher education program (Stewart 1999). Because the integration of ICTs into teaching will necessitate some cultural change the process will require time but the level of acceptance of ICTs for personal use achieved over the past decade suggests that such change is possible.
Among the goals set in the Schooling 2001 project for Queensland Government schools are the use of learning technology in every subject at every year level and the connection of every classroom to the Internet (Education Queensland 1998b). Both goals imply that ICTs in schools should not be restricted to isolated laboratories but should be distributed across classrooms. Schools are progressively extending network connections to classrooms and creating mini-labs of 3 to 6 computers in classrooms or adjacent spaces.

In order to model these learning environments within the teacher education program it will be necessary to provide equivalent facilities. In some (secure) teaching spaces it will be appropriate to create a mini-lab. Teaching in other spaces that are less easily secured may be served through the use of sets of laptop computers and mobile multimedia systems. An application for a special grant to initiate these developments has been made to the University and additional budget options are being considered.

There are multiple reasons why the present core computing subject in the teacher education program is unable to appropriately address educational aspects of computing. The first is that the subject is taught by members of the Department of Mathematics and Computing in the Faculty of Science. Their expertise lies in computing as a discipline and not in education or the educational application of ICTs. A second reason is that students study the subject in the first year of their program because that maximizes their opportunity to utilize the skills during their university study. However, it precedes study of educational theory that would be required to support their appreciation of issues in educational use of ICTs.

If it were possible to excise the core computing subject from the program by some combination of substitution of short courses and integration of basic ICT skills in other subjects, then it would be possible to replace it with a unit taken later in the program. That new subject could address the ICT competencies identified in employer requirements and other key policy documents.

Because of the importance of appropriate modeling of behavior in the process of learning to teach, a subject dealing with the educational use of ICTs should include opportunities for students to observe and participate in the application of ICTs for teaching and learning in classrooms. Ideally this might be achieved through appropriate practicum placements associated with the subject but the variability in teachers' use of ICTs makes it difficult to ensure that all students could be appropriately placed. A partial solution might be found through the use of relevant multimedia case materials to supplement field experiences. Multimedia materials for this purpose have been developed (Gibson & Albion 1999) and the underlying principles of their design have been described elsewhere (Albion & Gibson 1998a; Albion & Gibson 1998b).

It seems likely that for the foreseeable future ICTs will continue to evolve rapidly. The implications for education include a continuing need for educational professionals with specialized skills in the application of ICTs in education and a capacity to offer support to their peers. The existing option and specialization in educational computing at USQ is intended to graduate teachers with these capabilities. Some revision of the subjects will be required to ensure that they adequately address current issues in the educational application of ICTs and that they articulate with other elements of the teacher education program. Because some of the introductory material currently contained in these subjects will be incorporated in the general program there will be additional opportunities to address more advanced matters such as planning for and managing ICT resources in schools and providing colleagues with support and leadership in the application of ICTs.

Conclusion

There appears to be general acceptance that ICTs are important to education both as content and as aids to teaching and learning. Widespread availability of ICTs in schools and the wider community will surely result in students entering teacher education programs with increasing levels of skill. Nevertheless, the rate of development of new technologies and growing sophistication in their educational use makes it likely that, for the anticipated seven year life of the re-accredited program, there will be a continuing need for specific instruction about ICTs and their educational applications.

The program should provide students with early opportunities to develop any additional skills they may need for study at university. Every encouragement should be given to students to use ICTs wherever appropriate in their
studies and, so far as possible, the teaching and learning methods promoted in the program should model effective approaches to the integration of ICTs. Formal consideration of the educational application of ICTs should be deferred until students have encountered relevant educational theory. Students with a particular interest in ICTs should have opportunities to extend their study in related areas.

There are no certain answers in a rapidly developing field such as the educational use of ICTs. The approaches recommended here are based upon a reading of the policy environment in respect of ICTs in education, experience of the recent past, and consideration of current research. Only time will tell how successful they may be in charting a course for ICT in teacher education into the new millennium.

Abstract: The Malaysian Ministry of Education has given adequate opportunity for teachers to acquire knowledge and skills in operating the computer and information technology (C&IT) in order to fully utilise C&IT in the learning and teaching process, as well as, in the daily running of the school. Realising the vision of the Malaysian Ministry of Education, Universiti Teknologi Malaysia’s teacher education curriculum was reinvented. New, efficient and cost-effective learning methods were also used to supplement conventional teaching methods. Computer-based learning (CBL) materials were used because many research studies that looked into the effectiveness of CBL on adult learning about IT have proven to be successful. Based on this fact, is it possible to improve Malaysian adult teachers’ knowledge of and attitude to IT in education by giving them access to a flexible and user-friendly interactive multimedia (IMM) courseware package – Computer-based Educational Resource and Development In Information Technology (CERDIk IT)?

INTRODUCTION

Ellington (1995) believed that multimedia personal computers (MPC) have the potential to make a very significant contribution to the educational field. Interactive multimedia (IMM) courseware, therefore, has the potential to enhance learning by creating a realistic and appealing presentation of virtually any subject matter. Although the benefits of this learning technology have been documented, it appears that this educational resource has been under utilised for educational development, particularly for adult learners.

Szabo (1996, p. 219) made a point that “interactive multimedia is so new there is little research on it as a whole”. This statement is supported by Thompson, Simonson and Hargrave (1996). In their book,
"Educational Technology: A Review of the Research", they confirmed that not a great deal of IMM research has been conducted in education. Therefore, it is not surprising that very few research studies are available related to adults learning about C&IT- both on cognitive and non-cognitive outcomes (Baldi, 1997).

THE RESEARCH STUDY

Many research studies that looked into the effectiveness of computer-based learning (CBL) materials on adult learning about computer and information technology (C&IT) have proven to be successful. Based on this fact, is it possible to improve Malaysian teachers' knowledge of and attitude to C&IT in education by giving them access to a flexible and user-friendly IMM courseware package?

A formal and comprehensive research study was thus conducted at Universiti Teknologi Malaysia (UTM) to supplement the existing body of research related to the use of an interactive learning technology and adult learning about C&IT. The research study was in line with the thinking of several prominent figures in the area of educational technology.

For instance, according to Percival, Ellington and Race (1993, p. 3):

"... many people became aware that there was much in education and training which could be improved by thinking more carefully about all aspects of the design of teaching/learning situations. Such considerations led to a new, broader interpretation of 'educational technology' as the entire technology of education and training rather than merely as the use of technology in education, with the latter being regarded as merely a part of the former rather than the whole field..."

The objectives of the research project are as follows:

- To determine the content of an IMM courseware package (in a CD-ROM stand-alone format) through teachers' needs analysis, experts' opinions and the Internet.
- To develop a user-friendly prototype IMM courseware package (based on the ADDIE Model, which incorporates adult learning principles, instructional design principles and software engineering principles) regarding IT and its application to the field of education in Malaysia.
- To conduct formative evaluation via a pilot study in order to produce a fully-tested IMM courseware package (in a CD-ROM stand-alone format) which caters for different existing knowledge levels and attitudes and preferred learning styles on the part of the teachers.
- To conduct summative evaluation via a full experimental study in order to measure any significant improvement in teachers' knowledge of and attitude to IT as a result of being exposed to the IMM courseware package (in a CD-ROM stand-alone format).

The systematic methodology underlying the production of the IMM package was based on analysis, design, development, implementation and evaluation (ADDIE) model (Molenda, Pershing and Reigeluth, 1996), and incorporated adult learning principles, instructional design principles and software engineering principles (Aris, Abu, Ellington and Mogana, 1999). This research project thus involved the preliminary needs analysis, design, development, implementation and evaluation of an IMM courseware package at UTM.

Prior to the production of an IMM courseware package, both the objectives and the content to be included in the IMM courseware package were determined by analysing the needs of adult practising teachers. These needs were later compared with experts' opinions. Experts' views were obtained through books, interviews and via the Web. Based on a detailed and comprehensive analysis, appropriate and essential content was included in the IMM courseware package. The package offers information related to the general overview of C&IT, Malaysian Multimedia Super Corridor (MSC) and Smart Schools, history of the computers, computer hardware and software, communication and networking, and significant applications of C&IT in education (Aris, Abu, Ellington and Dhamotharan, 1997).
Instructional design principles include aspects such as instructional strategies and instructional presentations. An essential feature in any IMM courseware package is interactivity. This capability, as manifested by features such as clicking and touching, click-able objects, push buttons, scroll bars and moving objects was fully built into the package. Many of the screens in the package contain several navigational buttons to help the adult student teachers to move about within the system. These buttons give the adult learner the choice as to whether to process the information linearly using the ‘Forward’ and ‘Back’ buttons (Graphical User Interface), or on a ‘need to explore’ basis by using the ‘Topics’ button (Text User Interface). An ‘Exit’ button (Graphical User Interface) affords immediate exit capabilities. The navigation buttons were placed in the same relative positions on all appropriate pages. The ‘Forward’, ‘Back’ and ‘Exit’ buttons were placed at the lower right, to ensure ease of interface and consistency, while the ‘Topics’ button were placed in the upper left hand corner of the screen. This standardisation proved to be of considerable assistance in ensuring that the package was 'user-friendly'. Another extremely powerful aspect of multimedia is the ability to convey information and create an impact on the learner through the effective use of several audio-visual elements. The overall audio-visual layout design in the courseware was consistent with respect to style and format objects.

CERDIk IT, which stands for Computer-based Educational Resource and Development In Information Technology, is a Malay word for 'IT Intelligent' (Aris, Abu, Ellington and Mogana, 1998). Under this acronym, the first CERDIk IT package titled ‘IT in Education’ was produced with the main purpose of improving teachers' knowledge and changing their attitudes toward the use of C&IT in education. This user-friendly, easy-to-use and IMM courseware package was designed and developed by Baharuddin Aris. This IMM multimedia courseware package will henceforth be referred to simply as the CERDIk IT.

Macromedia Authorware version 4.0 was the authoring software chosen to develop the CERDIk IT. This software uses icon flowcharts and a drag-and-drop flowcharting metaphor. Instructions are obtained from dialog boxes with pull-down menus. This particular system was selected because it was user-friendly, and provided all the basic facilities that were required. Simple and readable text was used in the package. The computer graphics created in the package was used to support the content. The graphics and animation software used in the CERDIk IT included a very simple and user-friendly software called Ulead Cool 3D and the more advanced 3D Studio. Digitised still images file types used in the production of the CERDIk IT were bitmaps (.BMP), CompuServe GIF (.GIF) and Joint Experts Photography Group (.JPG). To create images from an external source, a scanner and a digital camera was used. These still images were used to enhance the appearance and to support important messages in the CERDIk IT. Digital audio format used in the development of the package was wave (.WAV). A SoundBlaster 16 sound card was used to digitise analogue audio recorded via a microphone. Sound Forge was used to edit digitised audio and add special effects to it. The analogue video footage was recorded using a video cassette recorder. It was then converted into digital format using a Video Blaster IES500 video capture card. Adobe Premiere was used to edit digitised video and add special effects to it. The digital video formats used in the development of CERDIk IT were Quick Time Movies (.MOV) and Video for Windows (.AVI). Digital video requires much more hard-disk storage space than any other form of medium. For example, a digital video clip in the CERDIk IT courseware package that runs for 20 seconds on the AVI (Video for Windows) format took up 44.9 Mb of hard-disk space. The digital video will require a smaller hard-disk storage space if it is converted to Quick Time Movies (.MOV) format.

The prototype version of the CERDIk IT was evaluated during its design and development phase (formative evaluation). Changes were made on the prototype version. prior to summative evaluation. Summative evaluation was conducted to determine its effectiveness in a university setting.

The sample selected for the research study consisted of 72 adult student teachers, mostly females. They had undergone a post-graduate diploma in education programme at UTM. They are generally in the age range of mid 20's to late 30's. These teachers have usually been in school for several years, and have taught subjects such as English, Mathematics, Science, Biology, Business and Basic Economics.

Data were gathered utilising multiple methods in order to obtain a variety of perspectives about the topic under investigation. Therefore, research instruments such as questionnaires, observation schedule, courseware evaluation form and interviews were used in the research study.
FINDINGS

The results of the research study were based on both formative and summative evaluation of the courseware package. Both quantitative data and qualitative data were collected to determine the effectiveness of CERDIk IT and the approach used by adult student teachers in learning a particular content area using a CBL material.

Three academic staff from the Department of Educational Multimedia and three adult students at UTM participated in the formative evaluation. Comments and opinions were made based on the design and usability of the CERDIk IT prototype package, and on the validity of the courseware evaluation form. For the purpose of this paper, only brief comments by the academic staff were highlighted.

The whole program certainly followed sound instructional design principles, such as, Gagné’s ‘Events of Instruction’. For example, the introductory sequence was very motivating. It was able to grab hold of the users’ attention. The package was also easy to operate - move forward, move backwards and exit. Guidelines in operating the package were provided at the very beginning (right after the montage) of the package, or before the main menu of the package was highlighted. However, it would have been more convenient if there had been an option to by-pass the guidelines, especially for users who had not been there for the first time. It would be very annoying for these users to see the guidelines, over and over again.

The different topics in the main menu were systematically organised. So, the users could choose either the linear approach (as prescribed by the designer), or according to their preferences, without having any worries of getting lost in cyberspace. “The users will not be lost in the cyberspace”, commented one of the staff.

Even though the screen design adhered to the rule ‘KISS’ (Keep it Simple and Straightforward), overall, the package still looked very professional, and very pleasant to look at. In general, the package had a simple user interface. Both the text and graphical user interfaces used in the package were easy to remember, and their placements were consistent throughout the whole program. The branching did not go beyond three ‘hops’ to avoid a more complicated branching. This, in return, will normally make the users more confused.

In general, the graphics that were used in the package were helpful in understanding the message in the content. They also found that the quality of visual display in the package was motivating, although some pictures needed to be changed. Some of these pictures must be suitable with the message being delivered on the screen, and also, needed to be clearer. The digital video was beautiful and appropriately used.

With respect to texts, bold letters were displayed in the package, with at least a letter size of 12. There were texts in Arial Black font. The evaluators suggested that the text should use commonly-accepted fonts, such as Times New Roman. This is because not all personal computers have Arial Black font installed in them. It was good advice, because some of the letters were missing when the package was played in a personal computer without Arial Black font installed in it. Scrolling text was used with a purpose. For example, users were able to scroll the objectives of the package with ease and speed, without having to move from one page to another, with the intention to recall the objectives of the package. So far, it was not easy to ‘crash’ the program.

Overall, the CERDIk IT package, even at the prototype stage, was very easy to use and very interesting to learn with. Apart from the comprehensive content, the package was able to hold the users’ attention throughout the program. All of the staff agreed that the CERDIk IT could be used as part of the course ‘IT in Education’ at UTM.

The overall findings from the summative evaluation revealed that, as a consequence of being exposed to the CERDIk IT as self-directed learning approach, many of the participants admitted that their knowledge about and attitudes toward C&IT improved significantly.

Based on the quantitative data collected in the research study, the CERDIk IT promoted significant amounts of learning during the pre-test to the post-test interim at 0.05 level of significance (pre-test: mean = 2.50; post-
test: mean = 4.01; t value = 11.41). This clearly shows that the adult students have become highly knowledgeable with respect to C&IT and its applications in education.

Adult student teachers’ attitudes toward the content ‘IT in Education’ was positive. The post-test scores were significantly higher than the pre-test scores at the 0.05 level of significance (pre-test: mean = 3.23; post-test: mean = 4.43; t value = 14.65). They considered the content useful to their career, after using the CERDIk IT. Adult student teachers also believed that CBL packages, such as the CERDIk IT, could be effective in delivering the content ‘IT in Education’. Evidence has shown that the post-test scores acquired from the student teachers were significantly higher than the pre-test scores at the 0.05 level of significance (pre-test: mean = 3.04; post-test: mean = 4.34; t value = 18.83. Student teachers were more willing to use CBL package for self-directed learning. Post-test scores derived from the student teachers were significantly higher than the pre-test scores at the 0.05 level of significance (pre-test: mean = 2.53; post-test: mean = 4.40; t value = 19.20.

Additional research findings, based on qualitative data, disclosed that most of the student teachers interviewed found the CBL method exciting, easy to use, flexible and helpful for autonomous self-directed learning. They unanimously agreed that conventional lecture can be improved by coupling it with the CBL method.

Observing several groups of adult students using the CERDIk IT, the approached used by the adult teachers in learning using CBL materials was identified. Based on the results in the study, most of the students approached via the same strategy (linear or serialist) when using the package. All of them looked at the overall picture (holist) of the package first, before choosing their preferred topics.

CONCLUDING REMARKS

The data derived from the research study is consistent with recent findings in the use of interactive multimedia courseware as a learning and information tool in academia and corporate staff development. Therefore, the CERDIk IT (in the form of a CD-ROM stand-alone) has demonstrated its capabilities and potential as a support learning material in the ever-changing learning technological world.

RECOMMENDATIONS

UTM, particularly the Faculty of Education, not only has a teacher education curriculum that is C&IT-based in nature, but the techniques of delivering learning materials to its students are C&IT-based as well. This is because the successful use of C&IT in schools requires the student teachers themselves to be aware, knowledgeable and competent in the use of such learning technology.

Two lecturers who are experienced in designing and producing interactive multimedia courseware, Jamalludin Harun and Zaidatun Tasir who are under the Department of Educational Multimedia at UTM, have implemented the CERDIk IT with their students. CERDIk IT was used during the second semester of the 1998/99 session with students sitting for a two-credit course in ‘Information Technology in Education’. The delivery method consisted of lectures, with the package being used as one of the supporting materials. Based on these lecturers’ observations, they were delighted that the package was very helpful in their classes. They would definitely recommend its use to other Malaysian student teachers, inside or outside UTM, and also to Malaysian schools’ practising teachers. Furthermore, these two lecturers also recommended that a nation-wide staff development programme should be implemented, with the CERDIk IT as a support learning material. They added that nation-wide research should also be conducted for greater generalisation of results in relation to the effectiveness of multimedia-based learning experiences among Malaysian student teachers, as well as, Malaysian adult practising teachers.

Apart from designing and developing interactive multimedia courseware on a CD-ROM stand-alone format, the Faculty of Education has also taken the initiative to implement the use of Web-based learning materials in
C&IT-related courses. Lecturers under the Department of Educational Multimedia, such as Mohamad Bilal Ali, Rio Sumarni Shariffudin and Manimegalai Subramaniam, have developed courses on the Web. These online courses can be located at Cyberdidik, http://161.139.52.251. For the purpose of on-line learning, CERDIk IT should also be converted and implemented in the Web-based learning environment. This alternative approach will further enhance the flexibility of adult student teachers learning using CERDIk IT.

To complement these on-line courses, formal research has been initiated by Noraffandy Yahaya to determine the effectiveness of his Web-based integrated Learning (WiLL) development tool. Lecturers at UTM will thus be able to use the WiLL in the design and development of on-line courses in their area of specialisation. In addition, easy retrieval of educational resources from databases should also be developed. Thus, a Management Information Resource System (MIRS) will be initiated by Mat Jizat Abdol.

INFORMATION MODEL FOR EVALUATION
EDUCATIONAL SOFTWARE

S. Bakoyiannis
Department of Informatics, University of Athens, Greece, sbakogia@atlas.uoa.gr

M. Grigoriadou
Department of Informatics, University of Athens, Greece, gregoradi.uoa.gr

THE PROPOSED MODEL FOR THE EVALUATION OF THE EDUCATIONAL SOFTWARE

Upon the incorporation of the software in the educational process, all the changes that it will cause in the role of the educator, in the learning process by the student, in the curriculum, in the meaning of the school book, in the class - laboratory structure and elsewhere must be provided. (see Squires D., Mc Dougall Anne 1994) (see Willem J. Pelgrum-Tjeerd Plomp 1993). Therefore there is a clear need to formalise the use of the educational software and its incorporation plan in the educational process. The educational software should address a means of didactic assistance to the teacher, but also give the possibility of a didactic approach to cognitive items by the student. After this the proposed evaluation model examines, whether the educational software is structured in such a way that could respond to cognitive sections that are required according to the didactic and pedagogical planning, whether it is suitable for the age to which it addresses, has a term equal to one didactic period, as the one defined by the educational environment and whether it responds to the school reality. It also evaluates whether the exercise / practical part of the educational software, that results from the aforementioned planning, observes this time limitation. Another point of evaluation is whether it has the ability and the application characteristics of multimedia of exploratory type and whether it operates in a network environment with ease in the use and communication, both in a local level and in a level of wider netting. (see ICMCS 94) Finally it controls whether its use can constitute a help for the educator in his daily work for the support of the learning process, and especially in his cognitive object as well as with intra-thematic possibilities and whether it gives the student the possibility of a didactic approach to cognitive objects.

THE USE OF FORMAL INSTRUMENTS OF DATA COLLECTION FOR THE SOFTWARE AS A MEANS OF EVALUATION

The use of formal instruments of data collection by the evaluators such as: check lists (see Barker P., King T. 1993), lists of characteristics and capacities (see Jacob Nielsen 1997) (see A.Dix, J. Finaly 1998), special tables of projects etc. (see IBM corporation 1997) is a basic evaluation instrument, whether these concern the educators, or the informatics and multimedia technologies specialists, or any other category of evaluators can be considered. In the said project the first check lists that corresponded to the characteristics of educational software were created, as this one has been analysed earlier and a research has been conducted, the purpose of which was to explore the readability and the response of the questions that evaluate an interactive multimedia software. After taking into consideration the results of this research, the check lists for the proposed evaluation model was designed. In the proposed evaluation model, the evaluators are distributed in the following categories: (see Chinien C., Hlynka D. 1993) (see Murray Tom. 1995) 1. Evaluators – educators of the cognitive object treated by the educational software, some of whom have a special experience in the evaluation of educational software. The evaluators of this category are used both in the formal quantitative evaluation process, and in the provided qualitative evaluation. 2. Evaluators – pedagogues and specialists in the didactic methodology who value the pedagogical and didactic approach of knowledge through the use of the educational software. 3. Evaluators specialised in the technical approach of the creation of an educational software, such as informatics specialists, experts of sound, colours, direction, video etc. 4. Evaluators – students who use the educational software in their educational process. For each of the aforementioned categories of evaluators an appropriate check list has been materialised through which the characteristics of the evaluated educational software are explored. For each characteristic a particular percentage of significance has been given.
THE OBSERVATION DURING THE USE OF THE EDUCATIONAL SOFTWARE AS AN EVALUATION OBJECT

During the evaluation process upon the use of the educational software the interaction and the experiences of the students - users are registered and afterwards analysed, either by video recording or by observation by educators who are assisted and co-ordinated by the person in charge of the process. The central idea is based on the presentation of some projects to a number of students - users and who thereafter use the educational software. The evaluators - educators evaluate the planning of the connection for the possibility of interactivity that it provides and they try to recognise any possible faults. The method uses an appropriately planned check list by which the marks of the evaluators are registered. In the version Jogthrough (see Bonekamp L. W. F. 1991) (see Duchastel, P.C. 1987) a video camera is used for the recording of the comments and the suggestions of the evaluators and as a result the process is accelerated. In the present project the Jogthrough version has been modified and materialised in such a way, that the evaluation of the educational software would be measurable according to the proposed check lists and especially through significance coefficients for each partial sub-question of each question. The purpose of the questions is the evaluation of the cognitive dimension of the interactive environment through the continuous use and the control of the possibility provided by the educational software in the specific action to be evaluated, for the concentration of the student's attention in the understanding of the projects as defined objects and not just as projects in the connection (click, drag, etc.). Therefore according to those aforementioned this is a formal evaluation based on a session of evaluators - educators specialised in the evaluation, or educators who are simple users and who: 1) observe characteristic projects during the period when the students uses the educational software, 2) note their estimations for each project in a special check list and 3) discuss about the (subjective) quality of the planning of the environment, 4) This process is completed with the filling of a check list, for the registration of the evaluators' judgements, that takes into consideration the factor «time of familiarisation» of the student - user with the interactive environment.

DESIGNING AND MATERIALISATION OF THE INFORMATION SYSTEM

The model of evaluation described is designed and implemented as an open information system, with complete description of the methodology. The information system consists of the following components: 1. A tutorial on the evaluation of educational software. It includes the evaluation method, the purpose and the specific objects of evaluation. 2. A data base containing the proposed questionnaires and the corresponding check lists for each category and type of evaluation. The questions in every questionnaire have different significance percentages. The categories of evaluations also have different weights. Finally, the two types of evaluation also participate with different weight in final result. All the significance percentages and anything relevant to them can be modified according to the judgement of any researcher. Also the check lists, as well as any included text can be modified and printed. The filling of the check lists is done in a simple way by selecting the evaluation mark or by filling in the necessary data. The system verifies the completeness of the filling and controls it if possible. In each check list there is the possibility of a hypertext for reference in explanatory texts, which facilitate the understanding of the included questions and must be answered upon the evaluation. These texts can also be modified. Also, at the end of the corresponding list each evaluator can enter remarks concerning the software. 3. A mechanism for data processing and extraction of the final result of the evaluation. The evaluation results are given, as a sum for each category of evaluators and for each evaluator. (Final marks = Quantitative Evaluation x X% + Qualitative Evaluation x Y%). Moreover, special evaluation results are given where the attitude and the particular characteristics (e.g. origin of school, students level regarding their knowledge etc.) of each evaluator are explored. Finally, there is the possibility for the user of the information system, to create simple or complicate statistical questions that were not provided and are considered necessary for the research of the evaluation of the educational software. The best marks of each check list as well as the best marks of all the evaluators in the quantitative formal evaluation are 300. In the qualitative formal evaluation the best evaluation marks depend on the number of the projects and the actions to be evaluated. The proposed methodology provides two projects of evaluation with five actions each. The best evaluation marks of each project are 120. Therefore the best marks for the proposed model, which requests 2 projects with 5 actions each are 1200. Anyway it lies at the disposal of any researcher who will use the proposed evaluation model to modify the significance percentages in each evaluated characteristic that is included in each check lists, of each category of evaluators, as
well as of each evaluation type. He also has the possibility to annul, if he wishes so, some characteristics or to replace them or to annul a certain category of evaluators or a certain evaluation type and the proposed model is adapted to the specific demands. Nevertheless we feel that in the proposed method all the categories of evaluators in both types of evaluation should participate.

ANALYSIS OF THE RESEARCH RESULTS

The selection criteria in the schools where the research took place, were the existence of educational software through which the research took place in the school, the use of educational software by the educators in the school, the land-planning distribution of the schools, the demographic origin of the students, the type of the school and the possibility of filling in the check list for administrative reasons. The educational software upon which the research was conducted, was Physics of High School of the company Inter*learn, which has been selected based on the criterion of its completeness regarding the characteristics of the educational software and its use by as many schools as possible so that we could have a more easy choice of research subject, educators and students.

From the answers of the educators (In the research there participate 15 educators) and from the comparison of their answers in different questions or in a combination of questions we observe the following:

- The answers show that despite the fact that the educators were users of the same educational software, their answers vary. Therefore either its use is occasional or it is used in particular subjects without further exploring its possibilities or simple the educator has observed the course of the software as this is presented by a specialised user or finally he is not able to use the extra possibilities offered by the software.
- The average evaluation mark of the educational software by women-educators (152) clearly exceed the average mark of the evaluators men-educators (119).
- The average marks of the evaluators educators whose school belongs to an urban area (198) exceed the average marks of the evaluator educators, whose school belongs in a semi-rural (80.5) and rural area (66).
- The average marks (80) of the evaluator educators whose years in service are less than 10 is clearly smaller than the average marks of the evaluator educators whose years in service are more than 10 (153).
- The average marks of the evaluator educators who are well disposed to the use of computer in the school environment is greater (135) than the average marks of the evaluator educators who do not believe that the use of the computer should be expanded in all the lessons or that their professional recognition is influenced by the use of the computer (119).

From the answers of the multimedia and computer science experts (In the research there participate 5 multimedia and Computer science experts) and from the comparison of their answers in various questions or in a combination of questions, we observe the following:

- There is observed a relatively homogeneous concentration of the marks in the various evaluated characteristics, something that shows the homogeneous judgement of the evaluators regardless of the fact that they have worked in the development of the specific software or not.
- Comparing the average marks (159) of the multimedia and computer science experts that have worked in the development of the specific software with the average marks of the evaluators multimedia and computer science experts who have worked in the development of a similar or generally educational software, the results of the research show that there is only a small variation of the marks (143), from which fact it is concluded that those who have worked in the development of the specific software are also credible evaluators.

From the answers of the pedagogues and specialists in didactic methodology and from the comparison of their answers in various questions or in a combination of questions we observe the following:

- There is observed a relatively homogeneous concentration of the marks (114-115) set by the evaluator pedagogues of various specialisation and specialists in didactic methodology in the various evaluated characteristics, something that shows the homogeneous judgement of the evaluators regardless of their specific specialisation.
- Some marks in the various evaluated characteristics are in the limits of neutrality, something that shows that the exclusive interest of this specialisation of evaluators is only the pedagogical approach.

From the answers of the students (60 students participated in the research) and the comparison of their answers in various questions or in a combination of questions we observe the following:

BEST COPY AVAILABLE
The average marks of all the evaluators students (142.3) is very close to the average marks of the evaluator educators (135.5), as well as to the general average of all the categories of evaluators of quantitative formal evaluation (149.7), something that certifies them as evaluators category.

The average marks of the male student-evaluator (138) is smaller than the average of the girl (147.92).

The average marks of the evaluators – students who use a computer outside school as a game (124.84) is smaller than the average marks of the other students, which shows that they are more strict judges than the other categories of evaluators – students.

The average marks of the student-evaluators who have a positive attitude towards the use of the computer or its contribution to their professional career is greater (151.59) than the average mark of all the categories of evaluators of quantitative formal evaluation (149.7).

The average marks of the student-evaluators who believe that the use of the computer does not contribute to the improvement of the educational process (53.66) is by far smaller than the average of all the categories of evaluators of quantitative formal evaluation. The same stands but less intensely (105.6) for those that do not believe that the computers will be necessary in their professional career.

The average marks of evaluation of the students whose mark in the respective lesson is less than 13 or greater than 18 (150.78 and 145.22 respectively) is smaller than the average of all the categories of evaluators of quantitative formal evaluation and the average marks of evaluation of the students whose mark in the respective lesson is from 13 up to 15 and from 15.1 up to 18 (132.41 and 135.87 respectively) is near to the average of all the categories of evaluators of quantitative formal evaluation. The same stands proportionally for the students with their respective mark limits in their previous class and not in the respective lesson, as above.

The average marks of evaluation of the evaluators – students whose school belongs to an urban area exceeds (167.76) the average marks of the students whose school belongs to a semi-urban and rural area (110.26 and 121.35 respectively).

From the answers of the evaluators educators who participated in the formal qualitative evaluation and from the comparison of their answers in various questions or in a combination of questions we observe the following:

The average marks of the women-evaluators (919) is less than the ones of the men-evaluators (939).

The average marks of the evaluators – educators who are well disposed to the use of computer in the school environment is greater (939) than the average marks of the evaluators educators who do not believe that the use of the computer should be expanded in all the lessons or that their professional recognition is influenced by the use of the computer (919).

By modifying the significance percentages per evaluation type and per evaluators' category the final marks are respectively formed as follows:

Table 2: Qualitative Evaluation

Taking into consideration each mark that results in the quantitative formal evaluation with the significance percentages for every evaluators category, that we have stated for each case and the mark of the qualitative evaluation as pair of prices, we can have the following tables by modifying the significance percentages for the quantitative and the qualitative evaluation.
Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 157,4 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 642 | 561,2 480 399,7 318,9 238,1

Table 3: Final Evaluation (1)

Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 153 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 640,2 | 559 477,8 396,6 315,4 234,2

Table 4: Final Evaluation (2)

Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 149,7 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 638,9 | 557,4 475,8 394,3 312,8 231,3

Table 5: Final Evaluation (3)

Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 148,6 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 638,5 | 556,8 475,2 393,5 311,9 230,3

Table 6: Final Evaluation (4)

Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 144,9 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 637 | 555 473 391 308,9 226,9

Table 7: Final Evaluation (5)

Evaluators Category | Mark | Significance %
--- | --- | ---
Quantitative evaluation | 144,3 | 40 50 60 70 80 90
Qualitative evaluation | 965 | 60 50 40 30 20 10
Final mark | 636,7 | 554,6 472,6 390,5 308,4 226,3

Table 8: Final Evaluation (6)

CONCLUSIONS

After the submission of all the results and the elaboration of the particular characteristics of the subjects that were researched the conclusions can be submitted as follows:

- The number of evaluators per category should be at least three in the quantitative formal evaluation and at most three students for the evaluation of each action of one process in the qualitative formal evaluation. (see Finding Usability Problems through Heuristic Evaluation 1992) (see Nielsen J. 1993) The students who participate in the process of the qualitative evaluation must have been taught the cognitive object in their class and constitute an average sample regarding their attitude towards the use of the computer, their didactic performance and the cognitive object and their school performance from the previous class. Also the students should originate from schools that constitute an average origin sample regarding the financial
level of their municipality (Rich – Urban – Downgraded) and regarding the characterisation of their area (Rural – Urban – Semi-urban).

- The number of the actions in the processes of the educational software that will be evaluated should be at least five. The procedures to be evaluated depend on their number in the whole educational software that also refers to the number of the educational hours that are provided to cover. In an educational software of ten didactic hours at least two processes with five actions each should be evaluated.

By evaluating the tables of the results of the marks with different evaluation significance per category of evaluators and type of evaluation, as they are stated above we observe the following:

- The marks for the evaluated software and for the specific evaluation, by modifying the significance percentages per evaluators’ category of quantitative evaluation, have a small variation between them. It is obvious that in the evaluation of other educational software there will result different marks and their variations between the evaluators’ categories will be different.

- The marks that are more close to each other appear in the significance percentages allocations in the cases of the Tab. 3 and Tab. 4. This is also confirmed by the documentation that has been submitted about the significance of the participating evaluators’ categories in the quantitative evaluation per order of importance in the evaluation. With this data it is ascertained that the most important allocation of significance percentages is the one of Tab. 3, where significance percentages vary respectively for the educators, students, multimedia experts and specialists in the didactic methodology and are: 40-25-20-10.

- In the present evaluation and regarding the evaluated software, as it has been already mentioned, the variations in the marks of the quantitative evaluation with different significance of the various evaluators’ categories are very small. As a result, evaluating in turn the tables of the final evaluation with different significance for each pair of marks of quantitative and qualitative evaluation, the variations are also small. However having documented the reasons for which we feel that the quantitative evaluation is by far more important than the qualitative one, and observing that the marks with coefficients the pairs 80-20, 70-30, 60-40 present the smallest variation between, we conclude that the significance percentages 70-30 respectively should be the ones that correspond the most to the objectivity of the proposed evaluation method.

The aforementioned show us that the evaluation model that was planned, according to significance percentages that have been described, can be considered as responding to the evaluation demands. However further research work of more educational software is necessary, when the use of educational software is incorporated in our educational system and it is disposed respectively in the school for use by the educators and students.

Breaking with Tradition: 
Constructivist Development Methodologies for the Web

Marvin E. Howard
Center for Technology in Learning and Teaching
Iowa State University
United States
beowulf@iastate.edu

Abstract: Constructivist instructors who attempt to develop a curriculum that uses browser-based multimedia technologies using traditional instructional design methodologies may find themselves dissatisfied with the results. In developing for the web the traditional ID model is not the appropriate development methodology. This paper discusses the instructional development techniques used in the creation of Iowa State University’s browser-based Masters of Agronomy program. Topics such as rapid prototyping, being mindful of student needs, iterative evaluation, and versatility and reusability of development tools are discussed. By sharing our experiences in developing this program is our hope that others who are developing instruction in this still relatively new medium can gain from what we have encountered.

Introduction

Iowa State University has a long history of providing off-campus instruction and training, dating back to the mid-nineteenth century. After the need for a Masters of Science in Agronomy professional degree was perceived in 1996, it was determined that one of the goals of the instructional designer group was to provide a way for professionals working in industry and the government to gain an advanced degree in Agronomy without having to attend the campus in person. Various ways of delivering the program were examined and the Internet was chosen as the primary communication medium, with multimedia lessons distributed on CD-ROM.

Program Description

The curriculum consists of 12 classes, a 1-credit workshop, and a 3-credit creative component, totaling 30 semester credits. Development of the first three courses began in 1997 and completed in the summer of 1998. After the initial development period, the time required for course creation decreased and the program became available for admission in the fall of 1999.

Each course varies slightly in its manner of assessment, but they generally involve the submission of assignments, discussion postings, and midterm/final exams. The exams are offered off-campus by approved proctors.

The program is loosely synchronous in nature. Students are expected to make satisfactory weekly or biweekly progress within the time allotted for each course, generally a semester in length. Although the majority of the program can be completed remotely, the orientation session, Agronomy 593: Workshop in Agronomy, and a Creative Component seminar require students to travel to the ISU campus.

The project staff consists of three groups that came together over time: first, faculty from the Iowa State University College of Agriculture and College of Education laid out the overall goals and needs of the project; next, an instructional development group was recruited; and lastly, a panel made up of industry leaders in agronomy was formed in an advisory capacity. In addition, a pilot group of agronomy students have been using the courseware since the fall of 1998.

Students access the courseware by computer from their home or place of business via the Internet and CD-ROM. The courseware integrates interactive material on CD-ROM with a Student Notebook.
System (SNS) on an ISU server. The SNS allows students to communicate electronically with their instructors and fellow students by using a calendar, discussion board, chat room, and several other tools.

The recommended minimum computer requirements are: a PC using Windows 95 or greater, a 150 MHz or faster processor, video, audio, and graphics capable, 32 MB RAM, 8X CD-ROM and an Internet connection.

How Our Development Process differs from the Traditional Model

The traditional model of instructional development as described by Dick & Carey (1996) is composed of several sequential steps:
1. determining the instructional goal,
2. analyzing the instructional goal,
3. analyzing learners and context,
4. writing performance objectives,
5. developing assessment instruments,
6. developing an instructional strategy,
7. developing instructional materials,
8. conducting formative evaluation,
9. revising instruction.

Each step has a clearly defined process to be followed and clearly defined boundaries separating one step from another. When we on the development team began this project, this was the process that we were most familiar with and were planning to use. However, three things led us to move away from this model.

First was our emphasis on student-centered instruction. In the traditional model, student input may not be taken into account until the formative evaluation step. As this program was conceived as a way to serve the needs of the students, we felt it was important that student voices be heard from the very beginning.

Second was the nature of the medium. Internet-based courseware allows for a higher degree of interaction than does traditional distance education media, not just between student and teacher but also between the students and their peers.

Finally, creating interactive multimedia is markedly different from conventional course development. HTML tools allowed for the rapid prototyping and revision of the instructional product. As each course was created, revisions were included in previous courses as applicable.

What has grown out of this is a development process that is student-centered, iterative in nature, and has a high degree of reusability. By sharing our experiences in developing this program is our hope that others who are developing instruction in this still relatively new medium can gain from what we have encountered.

Student-centered Development

The concept of student-centered instruction is not new. One of the tenets of constructivist ID is that the focus is on authentic tasks, authentic instruction, and authentic assessment that is meaningful to the students (Willis, 1995). What differs in our project from many other student-centered learning environments is the way in which students were involved. Our original development group consisted of instructional designers and media specialists from the College of Education. We soon added students to the group that either had or were working toward a traditional graduate degree in Agronomy. Their input and co-ownership of the project quickly proved to be invaluable, simply because of their inside perspective. As they graduated, we recruited other Agronomy students as replacements and gained fresh insights as they worked with the group.

Next, as the new program is meant for professionals, we enlisted the aid of the advisory panel mentioned earlier. While they wouldn’t be taking the courses themselves, they are or potentially could be the employers of the students. Their comments gave a good counter-point to the content created by the Agronomy faculty and allowed us to develop authentic tasks performed by professional agronomists.
The last step was to gain as clear an understanding of the target students as we could. After the first three courses were completed, a pilot group of students was selected. A preliminary focus group and orientation was held where they told us what they wanted and expected from the program. They stayed in contact not only with the faculty but also with the development group, giving feedback and finding bugs that we had missed. At the end of the first semester, questionnaires were sent out to gain input their overall impressions on each course and the program in general. Their responses were used to make further improvements and revisions.

Iterative Prototyping

Prototyping has long been used in instructional design, usually taking place during the development of instructional materials (Tripp & Bichelmeier, 1990). Prototypes at this stage reflect the nearly final form of the design, and tend to be difficult to modify in any significant way. In a more flexible environment, such as the web, developing what is called a rapid prototype at an early stage aids in the design process. Development of an instructional unit can be sped up by building and using a prototype that models the unit. Rapid prototyping differs from conventional modeling in that content is minimal at first, what is important is concept. As students use the prototype, developers get feedback from the students early on and discover exactly what does work and what doesn't. Changes are incorporated based on the feedback, and the prototype is re-evaluated.

In a medium other than the web, rapid prototypes can be as simple as a storyboard drawn on paper or a chalkboard. Using modern HTML development tools, a working prototype of a web-based instructional unit can be built and evaluated quite easily. Content is added to the prototype and it becomes, over time, not only the product but also a model for instructional units yet to be developed. The greatest perceived drawback that we saw to iterative development is the difficulty in tracking progress or counting milestones without stepping back and seeing the "big picture". There were times, during the first few months, that it seemed like we weren't getting very far. After the first courses were ready for the pilot group, however, the advantages to this method became readily apparent as course after course fell into place. We also found that this method kept in check what some have called "creeping featurism", or the bells-and-whistles syndrome. Additions that were considered unnecessary or overly complicated became readily apparent and little time was wasted on them.

Versatility and Reusability

Our selection of a development environment was based in part on the skills of the development team and in part on the software that was most available to the students. As a web browser we chose Netscape Communicator, as Microsoft had not yet integrated Internet Explorer into its operating system. Communicator incorporates some advanced HTML features, not the least of which are style sheets and JavaScript. For those unfamiliar with them, style sheets are essentially a way to externally control the look and feel of a web page without having to duplicate the HTML code in each page. If a change to the look and feel needs is needed, it can be made in one place and the changes take effect across the entire site.

The most important use we made of JavaScript was to write self-assessing study problems. When the format of the study problems was finalized, the various pieces of JavaScript code were placed in a common folder. By changing the arguments that are passed to a function from a particular page, the code became reusable. Again, if changes needed to be made, they could be made in one place.

In our choice of development environment, we also tried to look to the future and computer platform compatibility. Although our students, and the industry in which they work, use almost exclusively Windows-based PCs, the development platform with which we are most familiar for multimedia authoring is the Macintosh. Rather than retrain the development group to use a different operating system, we chose software, such as Apple's QuickTime and Macromedia's Authorware that could produce files that are usable by either computer platform. As the College of Agriculture at Iowa State does have a mix of PCs and Macintoshes in its classrooms, the content that has been created could be used again for other classes.
Conclusion

The program that we have developed may not be typical in size or scope to what many educators have developed as they turn to the web as a medium for instruction. What is typical is that we found developing for the web took us to a different place than we had been before. Rather than try to apply old rules to a new situation, we attempted to exploit the advantages that browser-based instruction could give us as developers just as we hope students can use it as a new medium for learning.

Abstract: This paper provides an account of the instructional design and development process used by a team of students enrolled in a graduate level course in Distance Education as the team members conceptualized and created two prototype web-based instructional modules for the Lunar and Planetary Institute's (LPI) Mars Millennium web site and CD-ROM project to support the National Aeronautic and Space Administration's (NASA) Jet Propulsion Laboratory (JPL). It is intended that this paper serve as an instructional design blueprint for other curriculum designers and educators to use, should they encounter a similar need for interactive web-based curriculum based on scientific theory and data, which incorporates a variety of emerging technologies, Internet tools, and innovative instructional strategies.

Introduction

The Mars Millennium Project, an official White House Millennium Council Youth Initiative, is a national art, science and technology initiative created to encourage students to design a community for 100 people arriving on Mars in the year 2030 (see http://www.mars2030.org/). Each educational team participating in the Mars Millennium Project has been given the goal to design a livable life-sustaining community on Mars that is culturally and artistically rich. The Mars Millennium Project is spearheaded by the U.S. Department of Education, the National Aeronautics and Space Administration (NASA) and its Jet Propulsion Laboratory (JPL), the National Endowment for the Arts, and the J. Paul Getty Trust. NASA's Lunar and Planetary Institute (LPI) is contributing to the project by developing web-based curriculum for the Mars Millennium Project and piloting the curriculum in Houston-area schools, libraries, youth and arts centers (see http://www.lpi.usra.edu).

In support of LPI's goal to provide educators and students access to on-line interactive activities as a part of it's educational mission for NASA's Office of Space Science and the Mars Millennium White House Initiative, the Institute's education staff is working with graduate students in the University of Houston-Clear Lake's (UHCL) Instructional Technology (INST) Program to design and develop a series of on-line multimedia activities. Utilizing the scientific research, data, theories and expertise of the planetary scientists at the Lunar and Planetary Institute, two prototype interactive web-based instructional units have been developed focusing on the planet Mars. The units will be featured as part of the education programs available for K-12 educators and students accessing the LPI web page. The Mars curriculum will be targeted to students in middle and high school (grades 5-12) and will be presented as part of LPI's support of the White House Mars Millennium Initiative which challenges students to imagine a human colony on Mars in the year 2030. The web-based materials will be tested with the LPI gifted and talented 5th grade students who attend a weekly "Exploring the
This paper outlines the process used by the instructional design team as they began to systematically design and develop this web-based curriculum. The curriculum designers will explain how the team members used learner and context analysis data to guide them as they identified the most appropriate instructional theory to use as a basis for their curriculum development. The designers will illustrate how an instructional analysis of the subject matter impacted their selection of instructional strategies. And, the design team will describe their development of the web interface and page layout. It is intended that this paper will serve as an instructional design blueprint for other curriculum designers and educators to use, should they encounter a similar need for an interactive web-based curriculum, based on scientific theory and data, which incorporates a variety of emerging technologies, Internet tools, and innovative instructional strategies.

The Instructional Design Process

Given the fact that all members of the instructional design team had experience using the Dick and Carey model (Dick & Carey, 1996), the team agreed to base the project's instructional design process on these steps and processes as they created the curriculum. Although the UHCL designers were involved only with the design and development phases of the instructional design process, all decisions regarding instructional strategies were based on LPI instructional analysis data. A list of the process steps followed by the team are outlined in sequential order below:

- Review LPI data on Mars Millennium Project purpose statement and goals
- Review LPI data on LPI's preferences regarding instructional context
- Review LPI data on LPI's content analysis for specific modules of instruction
- Review LPI data on target learners
- Create instructional goals for each module of instruction
- Identify philosophical foundation upon which instruction will be based
- Break each module of instruction into requisite number of lessons
- Create instructional objectives for each lesson
- Select instructional strategies for each objective
- Design web interface for the curriculum
- Flow chart each module
- Storyboard each lesson
- Identify LPI digital resources to be used for each lesson
- Write lesson content and activities
- Import content, activities and digital images into the web interface
- Proof content and check links

The instructional design team consisted of a group of six instructional technology graduate students who were interested in providing a prototype distance education project for the Lunar and Planetary Institute's Mars Millennium web site and CD-ROM project. One of the members serves on the educational staff at LPI and secured approval for the team to undertake the assignment. This group member was also the team's contact for all LPI Mars Millennium resources, such as scientists (also referred to as subject matter experts), digital images, animation, logos, and instructional analysis data already compiled.

Under direction from the LPI staffer, the design team reviewed the current proposal for a curriculum design for the national program aimed at grade 5 through 12 that had already been developed by the LPI Education Staff. From this extensive listing of proposed curriculum, the team decided on two instructional modules: Mars of the Mind and Ocean on Mars. Two separate groups of three team members each were formed with each three-person subgroup assuming responsibility for one module. Although the subgroups would be creating instructional strategies and content independent of the main group, other decisions, such as the selection of the philosophical foundation for the curriculum and the web interface design would still be coordinated with all six team members to maintain alignment between the modules.
Analysis

LPI's Education Staff presented the UHCL instructional design team with instructional analysis information that was critical to the development of sound, systematically-design curriculum. This information included the purpose statement for LPI's Mars Millennium curriculum project, which is:

"To create a curriculum that is suitable for use in 5-12th grade classrooms with the goal of impacting students and teachers at a national level through the Mars Millennium project, our gifted student program, Alpha, and through a variety of outreach endeavors, including Liftoff and Explore (National Educator Training Workshops) by addressing the following goals:

- To address issues relating to the history of the planet Mars and it's current geologic condition through a series of Earth-Mars analogues, hands-on activities, modeling, 3-D imagery, and other presentation materials, and

- To help support the teaching of the scientific issues facing mission planners designing robotic and manned exploration missions to Mars via a distance learning venue such as the web or CD-ROMs." (Karl & Clifford, 1999)

In addition, the Institute provided the following guidance regarding its preferences for the instructional context and content:

- "We will develop a distance learning venue for the curriculum in order to reach students and teachers nationwide in the Mars Millennium project, by using a web-based format and CD-ROM format. This will include video interviews of a Mars scientist, graphics depicting the possible ocean on Mars, and animated sequences illustrating current missions to Mars that are searching for evidence of water (i.e. the Deep Space Microprobes). The site will also include ways to e-mail with Mars scientists (Ask-a-Mars-scientist), links to Mars activities, images, presentations, posters and resources.

- We will prepare lessons and activities that will address the historical issues of Schiaparelli's 'seas on Mars' and Percival Lowell's 'canals on Mars', and how man's view of the red planet has changed with improvements in technology by using modeling and Earth analogues.

- We will gather NASA (and other) materials suitable for including in this curriculum including, for example, the Surveyor '98 poster which illustrates Mars in the past with oceans and Mars in the present without running water (and also examples of chaotic terrain)." (Karl & Clifford, 1999)

And, lastly, a description of the target learners stated, "We will beta test the activities and materials developed with the pilot Mars Millennium sites this year in Houston and with the Alpha (gifted and talented) students (5th graders) here at the Institute. We will present the material to the teachers at next year's Liftoff 2000, which will focus on Mars, and to the librarians who participate in the Explore Program, Fun with Science." (Karl & Clifford, 1999)

Based on a review of this information, the instructional design team was able to construct goal statements for each of the instructional modules. The Ocean on Mars module goal became: "To present an integrated interactive site for distance education serving the Mars Millennium high school students by using chemistry, scientific theory and mission data in order to design new missions to Mars." And, the Mars of the
Mind module goal translated into: "Gifted fifth and sixth grade students will hypothesize as to what Mars might look like in 2005 with improved technology. Students will accomplish this by navigating the Mars of the Mind web site to (1) review examples of well-known inventions and discoveries which hold a prominent place in history due to the way mankind’s views of reality and truth were altered by them, (2) view historical pictures of Mars from different time periods and study the then available technologies used to form those pictures, (3) use this information to form opinions concerning the accuracy of technology and its effect on man’s view of the universe at any given time, and (4) use these opinions to imagine what technology will be available five years from now and what man’s view of Mars will be because of it."

With these instructional goals and the instructional analysis data from LPI before them, the team decided to use a constructivist approach as the philosophical foundation for their module and lesson designs. Designers of constructivist learning environments subscribe to instructional methods which provide students with experience in the knowledge construction process and appreciation for multiple perspectives, embed learning in realistic and relevant contexts, encourage ownership and voice in the learning process, embed learning in social experiences, encourage use of multiple modes of representation, and encourage self-awareness of the knowledge construction process (Wilson, 1996, pp. 11-12). Constructivism seemed an excellent approach given the exploration- and discovery-based theme of these instructional goals, the inquisitive nature of the gifted and talented students, and the web-based delivery method.

Design

Each instructional module was broken up into three lessons, with the first lesson supplying an introduction to the unit or some background information that students would need in order to proceed with the instruction. The second lessons provided the heart of the instruction where students engaged in web-based interactivities. Students were then asked to construct new meaning out of their experiences in the last lessons and provide some type of evidence of their new knowledge. Instructional objectives were then written for each of these lessons and are presented in Table 1.

<table>

<td>Students will use this information to form opinions concerning the accuracy of technology and its effect on man’s view of the universe at any given time and imagine what technology will be available five years from now and what man’s view of Mars will be because of it.</td>
<td>Students will develop a rudimentary knowledge of the chemical processes needed to sustain life on Mars using in situ resources.</td>
</tr>
</tbody>
</table>

Table 1: Instructional Objectives for Mars of the Mind and Ocean on Mars
With the instructional objectives in hand, the design team began to formulate the instructional strategies, which would ensure that learning occurs as students move through the modules. The Ocean on Mars group decided to present the scientist's theory that an ocean may have existed on Mars and to provide students with a glimpse of a current mission sent to find this water. Students would engage in an on-line interactive chemistry lab in order to understand what an impact the presence of water on Mars would have for human exploration and colonization. Students would then be encouraged to be a part of this developing exploration program by designing a mission to be published on the site and by interacting with scientists through e-mail.

The Mars of the Mind group began by providing students with an example of how the evolution of a different type of technology (other than telescopes) changed man's view of reality and truth throughout history. Students would be taken on a web voyage to explore how the technological improvements in the telescope changed man's view of Mars. Students would then be challenged to hypothesize about the new technology that may be available to them in the year 2030 that would facilitate establishment of a colony on Mars and then write an essay or draw a picture of this technology for an on-line student gallery.

Now that the design was complete, the team set out to develop the web-based modules.

Development

The curriculum interface consists of the module logos and the navigation bars. Module logos, found on each site's home page, were based on the NASA mission patch for the Mars Surveyor '98 mission. PhotoShop was used to create the majority of the logo and then each subgroup customized the three points of the triangle to correspond to the titles of each subgroup's three lessons. After imposing an image map over the customized logos, "launching pads" were established for the students to access the lessons. The navigation bars were constructed in a similar fashion. Generic "Home" and "Lesson" buttons were established and then customized for each module.

Each subgroup flowcharted its sites and then drew up storyboards for each lesson. The next step, identifying and selecting digital enhancements for each web page, was easy given the vast repository of LPI resources. LPI is one of the world's largest Regional Planetary Image Facilities (RPIFs) which catalogues and stores all of the planetary mission imagery on-site, much of it in digital formats. Narrative content was then written and instructional activities detailed.

The Ocean on Mars web pages were authored with Dreamweaver, while the Mars of the Mind web pages were created with HTML. The team believed that it was important to demonstrate that instructionally sound web-based instruction could be created using both high end and basic web authoring tools.

The result of this work on both web sites can be found in prototype format at http://www.ghg.net/ritakarl/MOMMain.html (Mars of the Mind) and http://www.ghg.net/ritakarl/main.html (Ocean on Mars).

Assessment

If accepted by the Lunar and Planetary Institute as a prototype web-site, testing will occur via the Institute's involvement with the fourteen Houston beta-testing sites for the Mars Millennium project. Fourteen at-risk, underserved, and low socio-economic schools and youth groups in Houston are piloting the White House Youth Initiative over the course of the next school year. In addition, the Lunar and Planetary Institute teaches a 5th grade gifted and talented program for the Clear Creek Independent School District called 'Exploring the Planets'. Both of these groups would test the actual curriculum and be asked to evaluate the students' experiences. Students will submit questions to the scientists and also submit mission designs, as well as essays and drawings hypothesizing technological advancements that could permit colonization of the planet, to the web sites. Especially with the LPI Alpha students this could be done in conjunction with other Mars Mission planning activities that have previously developed by the institute. With the Mars Millennium sites, the material would be tested in a fashion more closely resembling what the final interactive web-based class
would be like. Student questions and the scientists' answers will be compiled and evaluated along with student submitted missions.

The Institute will also host a summer teachers' workshop, Liftoff, at the LPI. These educators, a selection of master middle and high school astronomy teachers, will be studying the planet Mars for one week at the Institute. They will as a part of their studies be asked to preview and comment on the material. LPI also has a group of former Liftoff teachers who are interesting in evaluating new products, they will be asked to review this curriculum. Hopefully, by next summer, these two web sites will be one part of a larger curriculum including Mars of the Past, Mars of the Present, and Mars of the Future.

Acknowledgements

The authors, Leslie Hunt and Rita Karl, would like to acknowledge each member of the University of Houston - Clear Lake's Summer 1999 Distance Education design team for his or her contribution to the design and development of either the *Mars of the Mind* or *Oceans on Mars* instructional web sites. Thanks go out to Brigid Dixon, Brent Goucher, Amy Riley, and Deborah Sanders. Congratulations on a job well done! And, last but not least, thanks so much to our Summer 1999 Distance Education professor, Dr. Ruth Cook.
Different Storyboarding Methods in Multimedia Courseware Design

Leping Liu, Ph.D.
Assistant Professor of Instructional Technology
Department of Reading, Special Education, and Instructional Technology
Towson University, U.S.A.
Email: liu@towson.edu

Abstract: When we use multimedia-authoring tools, such as ToolBook, or Hyperstudio, to develop courseware or course segment, we usually go through the major phases of systems development. One of the phases is systems design, in which output, inputs, and navigation are determined and blueprinted, which, technically, are detailed in storyboards. Traditionally, storyboards can be 5 by 7 index cards, or certain paper forms. The current paper will present another means of storyboarding—using PowerPoint as a storyboarding tool. The components and procedures of storyboarding will be introduced. In six undergraduate and four graduate teacher-education technology classes, students designed multimedia courseware using HyperStudio/ToolBook with three different storyboarding methods—index cards, paper forms, and PowerPoint. The evaluation scores on four criteria—screen display, interaction possibilities, orientation and navigation—were compared. Repeated measures were used for data analysis. Differences were found among the groups with different storyboarding methods.

Background

Multimedia courseware development is a process of system development (Liu, 1999). Yourdon (1988) and Burch (1992) described a traditional system development life cycle (SDLC) that consisted of seven phases and was widely applied in commercial and industrial fields. The seven phases are: (1) systems planning, (2) systems analysis, (3) General (or conceptual) systems design, (4) systems evaluation and selection, (5) detailed (or functional) system design (6) systems implementation, and (7) systems maintenance. In the field of education, especially for the purpose of developing interactive multimedia instructional applications for classroom teaching/learning, Beasley (1998-99) modified the traditional SDLC into four major phases: (1) systems analysis, (2) systems design, (3) systems implementation, and (4) systems maintenance. In the systems analysis phase, the major problems are identified (Grabowski & Droms, 1994; Henderson, Gold & Tindall, 1996; McDeniel & Liu, 1996), the scope of the system is determined (Burch, 1992; Beasley, 1998-99), and task/concept analysis is performed (Fankhauser & Lopaczuk, 1996; Vrasidas & Harris, 1995). In the system design phase, output layouts are designed for all screens, special forms, and printed reports. All inputs are specified and formats, both screen and paper forms, are also approved. Based on the output and input designs, specific processes are designed to convert the input to outputs (Burch, 1992; Henderson, Gold & Tindall, 1996). According to these designs, detailed tasks of the system are implemented. The system is developed and converted to operation (Burch, 1992). Then the system is maintained until next life cycle.

In developing interactive multimedia application, the designers go through all these phases, and accomplish all designed tasks in all the phases. One task in the system design phase of developing a multimedia application is storyboarding (Ivers & Barron, 1998). There are several methods of creating storyboards, this study examined the effectiveness of three storyboarding methods: using index cards, using paper forms, or using PowerPoint to create storyboards.

Storyboarding in Multimedia Courseware Design

In the system analysis phase, What To Do has been determined, and all the requested tasks of the courseware have been listed (Liu, 1999). In the system design phase, How To Do will be detailed. For example, screen template and functional areas need to be designed. Multimedia programs, such as HyperStudio or ToolBook, usually contain at least three screen types: instructional screens, menu screens, and question screens (Ivers & Barron, 1998). The primary functional areas include title, informational/instructional text, graphics, directions,
feedback, icons or navigation options. Screen templates show the exact positions of these functional areas that vary based on the purpose of each screen. The next is to write storyboards.

Storyboards contain all the information that will be placed on the screens (in the screen templates), in addition to information that will assist the programmer and production specialists in development of the media components. Storyboards serve as the blueprint for the program. The detailed storyboards contain all the descriptive information required to produce the text, graphics, animations, audio, and video. Also, the links for each button or interaction are specified.

Traditionally, storyboards are written on 5 by 7 index cards. One card is one screen, all the elements designed for that screen should be on the card. Figure 1 is an example of an index card storyboard before detailed information is put in. In this template, the exact information should be displayed. For example, the screen number, the text content, and questions. The Graphic should be in the right position. The background colors and designs should be specified...

Figure 1. Screen Template Written in an Index Card

![Screen Template Written in an Index Card](image)

Another traditional method of writing storyboards is using some paper forms. This is similar to index card except the size of the paper. In the screen component form/table, all elements are listed and there left the space for detailed explanation. For example, navigation, text and audio can be detailed as:

Figure 2. Paper Form Storyboarding

<td>Description:</td>
</tr>
</tbody>
</table>

With more and more multimedia applications available for the courseware applications, evidently, neither index-card nor paper-form storyboarding can "tell" all the detailed information to the designer. Therefore, some methods, based on the idea of taking the advantage of technology to solve problems, should be adapted. Considering the format, properties and purposes of storyboarding, we found PowerPoint has the potential to be a useful tool for creating storyboards. PowerPoint slides can contain the same components as in index cards or paper forms, as well as many visual components, such as graphic object, colors, and so on. However, there is no evidence in the literature to show the use of PowerPoint as a storyboarding tool. There is no other experience to show either positive or negative of this method. In our technology courses, our students are the designers of multimedia applications. The issues are whether our students could learn multimedia design more effectively with this tool, whether this method...
would work well, whether using PowerPoint as a storyboarding tool would be better than the traditional storyboarding methods.

**Purposes and Research Questions**

The purpose of current study was to determine a better storyboarding method among the three methods: index card, paper form, and PowerPoint, so that our students could effectively learn multimedia instructional designs. Considering the different learning experiences, styles, and knowledge background between undergraduate students and graduate students, we examined two research questions in this study:

1. Are there any differences among the evaluation scores of multimedia designs created by undergraduate teacher education students who used different storyboarding methods (index card, paper form, and PowerPoint), regarding to the quality of screen design, interaction, orientation, and navigation?
2. Are there any differences between the evaluation scores of multimedia designs created by graduate teacher education students who used different storyboarding methods (index card and PowerPoint), regarding to the quality of screen design, interaction, orientation, and navigation?

**Methods**

**Subject and Sampling**

This study was undertaken from two dimensions with two groups of students: undergraduate and graduate teacher education students. The subjects were from the College of Education in an eastern state university, including 87 undergraduates from six technology classes, and 72 graduates from four technology classes. The undergraduate classes used HyperStudio to create a multimedia instruction segment, and the graduate classes used Toolbook and HyperStudio.

**Instrument**

Instrument used to evaluate students multimedia instructional design was a criteria list consisted of 10 items that have been used in many studies (Ivers & Barron, 1998):

1. Content
2. Language
3. Screen displays
4. Visual images
5. Interactions
6. Orientation
7. Navigation
8. Input, response analysis and feedback
9. Help, evaluation & record keeping
10. Technical consideration

Under each item, there was a detailed checklist. Each quality item was scored from 1 to 10, where the score of 10 was the best. We selected four quality items—screen displays, interactions, orientation and navigation—for the purpose of this study. Because, the quality of storyboarding would directly influence these four design qualities.

**Design and Data Analysis**

In this study, we used existing classes as the convenient sample. However, in each of the six undergraduate classes, students are randomly assigned into three groups using different methods (Index card, paper forms, and PowerPoint); and in each of the four graduate classes, students were randomly assigned into two groups using different methods (Index card and PowerPoint). We sorted the undergraduate students' scores of the three groups cross six classes, and the graduate students' scores of the two groups cross the four classes. This was not a completely random design; we only focused on the interested levels of the quality criteria—screen display,
interaction, orientation, and navigation. According the purpose of the study, repeated measures were employed for data analysis. For each group, the four quality criteria were repeatedly measured (see Table 1, and Table 2):

### Table 1. Repeated Measures (Undergraduate Groups)

<table>
<thead>
<tr>
<th>Screen</th>
<th>Interaction</th>
<th>Orientation</th>
<th>Navigation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Card</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Paper Forms</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PowerPoint</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Table 2. Repeated Measures (Graduate Groups)

<table>
<thead>
<tr>
<th>Screen</th>
<th>Interaction</th>
<th>Orientation</th>
<th>Navigation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Card</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PowerPoint</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SAS system was used for the data analysis, and assumptions for repeated measures were checked. The two sets of data did not violate the assumptions of equal variance, normality, and extreme outliers. Therefore, we consider that the statistics results of the repeated measures explain the situation of the data well.

### Results

The results of the data analysis shows that significant differences were found among the three groups of undergraduate students' multimedia application design quality scores (see Table 3):

### Table 3. Test of Fixed Effects (Undergraduate Groups)

<table>
<thead>
<tr>
<th>Source</th>
<th>NDF</th>

</tr>
<tr>
<td>Method* Score</td>
<td>6</td>
<td>264</td>
<td>30.66</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

As shown in Table 3, the differences are significant among the quality scores of multimedia application design created with different storyboarding methods ($F = 452.72$). Figure 3 shows where the differences are:

### Figure 3. Interaction Mean Plot (Undergraduate Groups)

As shown in figure 3, quality scores of PowerPoint method group is significantly higher than that of paper forms group ($t = 25.70, p < 0.0001$), and that of index card group ($t = 26.41, p < 0.0001$). There is no difference between
the paper form group and index card group ($t = 0.71, p < 0.4784$). From the mean score plot, we can see the quality scores of the four criteria in PowerPoint group are higher than those in paper form group and index card group.

The results of the data analysis shows that significant differences were found among the two groups of graduate students’ multimedia application design quality scores (see Table 4):

**Table 4. Test of Fixed Effects (Graduate Groups)**

<table>
<thead>
<tr>
<th>Source</th>
<th>NDF</th>

<td>56.65</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

As shown in Table 4, the differences are significant among the quality scores of multimedia application design created with different storyboarding methods ($F = 607.07$). Figure 4 shows where the differences are:

**Figure 3. Interaction Mean Plot (Graduate Groups)**

As shown in figure 4, quality scores of PowerPoint method group is significantly higher than that of index card group ($t = 24.64, p < 0.0001$). From the mean score plot, we can see the quality scores of the four criteria in PowerPoint group are higher than those in index card group. Other detailed results comparing the four criteria will be presented as SITE.

**Conclusions and Discussions**

In conclusion, as the answers to the two research questions, for both undergraduate and graduate teacher education students, using PowerPoint as the storyboarding tool will produce better design in a multimedia application. The screen display, interaction, orientation, and navigation designs were significantly different (higher scores) from the designs using index card or paper forms in storyboarding. The PowerPoint group showed the high quality of design in the four area: (1) The screen frames were properly designed to achieve balance, harmony and simplicity; color and text styles were used appropriately; and special effects were used properly. (2) Interaction possibilities were maximized and properly designed. (3) A natural sense of dialogue was created with the user; users could control the pace or sequence; screens were properly labeled so users could easily find out where they were—orientation. And (4) Users could easily get where they wanted to go—navigation.

The findings of this study also suggested that although undergraduate and graduate students are different in their learning experience, knowledge background, and thinking skills, the results of the two groups are similar. Figure 3 and 4 showed the same pattern of the differences. This indicated that this method worked well for both groups, and could be used in the technology courses for both groups.
One interesting question was why this method made the differences. When students used index card or paper forms, they only could imagine and put in something that was to be created. However, when using PowerPoint, the storyboarding process is a pre-design process. They could visually arrange the screen, for example, they could put the exact object (buttons, cliparts, or pictures) on the right position. This made the implementation process much easier and they could sense visually. The author of this paper ever conducted a study (Liu, 1999), using a visual tool—Inspiration—to structure multimedia application that enabled students to create flowchart that visually showed the structure of the courseware. That study found out it was more effective using Inspiration than using paper flowchart in designing the interactions across several layers of the structure.

The findings from the two studies alerted the idea that technology can be used as a tool not only for improving our daily work but also for developing other technology applications. More and more new technologies are available now. We would not only think about how to use them to solve old problems, but also think how to use them to create new applications.

LEARNING THROUGH DIGNITY:
PARTICIPATORY COMMUNICATION THEORY

Dennis Maxey
Instructional Technology Program
Bridgewater State College
United States
dmaxey@bridgew.edu

Abstract: This paper describes an alternative approach to traditional instructional design models by suggesting that participatory communication theory (PCT) creates a process which values the learner's voice. As a student develops a critical awareness of his/her environment, participatory media becomes a catalyst for cognition. Learners use media tools to influence their own lives. PCT suggests that learning is political as well as psychological and that dignity is a fundamental component of learning.

Introduction

Education and dignity should not be mutually exclusive phenomena. Dignity involves taking control over one's own life. As an educational process, participatory communication theory (PCT) holds as its cornerstone everyone's fundamental right to self-volition. PCT values the learner's knowledge and perspective. PCT allows the learner to fully participate in educational decisions. PCT offers a rich educational framework within which instructional design issues can be addressed with and through dignity.

This paper will first define participatory communication and its theoretical constructs. Second, an explanation of how it works will be given. Third, several examples of participatory communication projects will be presented. Fourth, a rationale for employing PCT will be suggested, a rationale anchored in self-efficacy research as well as socio-constructivist approaches to learning theory. Finally, this paper will explore the uses and ramifications of participatory communication theory in an instructional design model. Education should be about liberation and humanness and dignity. Our teaching and instructional design processes should support such an approach.

What is Meant by Participatory Communication?

Participatory Communication is a field of communications theory that focuses on the political aspect of the communication process (Servaes, 1996) by combining critical analysis with an understanding of the structure of media. Much of the theory is involved with communities who struggle to become democratic entities; however, many attributes of participatory communications provide guidelines for all communities including established first world nations such as the United States.

Two working philosophies helped create and shape participatory communications: emancipatory pedagogy and communication structure. Paulo Freire's work in emancipatory pedagogy (Freire, 1978, 1995) provides a rich philosophical approach as to how education should be imagined. Education is not, as he calls it, based on the banking principle with a teacher depositing knowledge into a student account. Rather, education is the right of all people to have a voice, a voice not filtered through another. To a certain degree, equating voice with education establishes the precious link between communication and learning that is both different from and akin to many of the socio-constructivist theories of learning. Development of voice with respect for the voice of others is one of the key components within Freire's emancipatory pedagogy.
Another theoretical construct of participatory communication is the concept of dual communication channels within a society. On one hand there are official communication channels. These generally support the power structure and quite often are controlled by them (UNESCO, 1980). "Uniform, high-cost, highly professionalized, state-controlled media" (Servaes, 1996 p. 34) are found in most societies. A second channel is generally local, multi-viewpointed and lower cost, and blurs the actor/audience roles. Both communication channels are responsible for the dissemination, development and sustenance of cultural, social and political goals. But is has been suggested that the highly centralized communication channels dominate all communication (Chenyholmes, 1988).

Much of pedagogical critique has revolved around the conflict between these two communication channels, the hegemony of the dominant channel and the dependency of alternative viewpoints. Domination of the center by economic, cultural, and political elements results in control over minority ideas on the outskirts. Minority viewpoints become marginalized. The critical theorists of the 1950s (Marcuse, et al) decried the role of mass culture and its ability to drown out the voices of dissent. Mass culture was ubiquitous and omniscient. Mass culture was the tool of the ruling elite to legitimize its position; mass culture was the tool of the ruling elite to sustain and increase its power. However, during the 1980s critical studies began to look at popular culture (the name change establishes the paradigm shift) as a liberating communication channel because of its ironic elements (Giroux & McLaren, 1986). As a new medium replaces an older one, the content of the old medium becomes the new (McLuhan, 1964). Popular culture may still have been ubiquitous but through self-reference and irony, the difference between what is and what is said becomes the medium through which minority voices can be heard again.

Participatory Communications recognizes the power of the official communication channels to co-opt all viewpoints; but unlike critical theory and critical pedagogy which primarily contribute to a critique of society and culture, it provides a positive, action-oriented method in which minority viewpoints have a place in discourse and it recognizes minority modes of communication, minority media, as alternative yet valued voices. Minority viewpoints become both a frame of reference for official viewpoints and provide “texts” for discussion, discussions which have the potential to seed change.

**How Does it Work?**

Fundamental to the understanding of Participatory Communications is its deep, underlying belief in the fundamental dignity of men and women. Freire (1970, 1995) suggests that in order to be participatory all communication must follow a dialogic model. Individuals must seriously consider the perspectives and viewpoints of others (similar to Habermas’ ideal speech situation). Freire also puts forth his concept of conscientização and problem posing, whereby people learn “to perceive social, political, and economic contradictions, and to take action” (Freire, 1970, p. 19). Finally, Freire’s idea of praxis combines theory building and theory testing, action and reflection as a key component in the understanding and reading of the world (Wink, 1997).

Participatory communication creates a process which:

- a) promotes community identification of needs and problems,
- b) develops cogniscence of the skills and talents within the community allowing self-direction in acting in its best interests,
- c) develops decision-making skills,
- d) creates a climate in which a community can make decisions,
- e) values and strengthens local knowledge systems,
- f) develops group process skills which bring consensus through negotiation and conflict resolution,
- g) creates a direct channel of communication between the community citizens and the decision-makers, and
- h) molds a vision of the future through commitment and ownership by the community (Rajasunderam, 1998).

It is with the blend of emancipatory pedagogy and the study and employment of media that PCT finds its voice.
Examples of Participatory Communication

In Bangladesh grassroots women’s organizations such as Banchte Shirkha and Proshika have used video projects to combat exploitation (Stuart and Bery, 1995). Interviewing politicians as they made promises and documenting their statements through video recordings provided the pressure needed to have leaders fulfill the promises heretofore broken. Video projects also raised awareness of women’s rights issues and spousal abuse.

Popular theatre in India by such groups as the Association for the Rural Poor (ARP) used popular theatre as a single component of larger scale development (Thomas, 1995). In dealing with a fishing crisis between large mechanized trawling operations and smaller fishermen, ARP used local fisher folk as actors in their play. The play was stopped several times during its staging as the audience clarified the social reality as portrayed. The play became the catalyst for the people’s political action against the mechanized trawling forces.

Folk songs, skits, and tape recorders, citizen-band radio, public-access television and copiers compete with state controlled large media for the hearts and minds of each country’s citizens. A recent Boston Globe article (October 30, 1999) describes the use of electronic communication via e-mail and the Internet as a tool by the Falun Gong movement in the People’s Republic of China. Small, participatory media struggles but is not subsumed by the larger, state-owned mass media.

Why Does it Work?

The link between political empowerment and learning is the basis of participatory communications. Situated cognition and self-efficacy are not mere psychological buzzwords but become the mechanisms by which participatory communications theory functions.

A student’s belief about his/her own abilities, or self-efficacy (Bandura 1997), influences students’ motivation and goals for academic work. Freire has shown that an approach to learning that stimulates awareness of a student’s social conscience and that promotes an awareness of possibilities for social transformation through action improves learning (Freire and Faundez, 1989).

Duguid and Brown (1992) suggest that learning takes place at the intersection of task and cognition. Realizing that teaching and learning are not one and the same thing (they quote Rabindra Tagore about stealing knowledge from his teacher--after not being taught anything by his teacher), they provide a new context within which to think about how students learn. First and foremost, a student must be engaged within an authentic situation in order to learn. Problem posing and problem solving focus on what the situation is really like. It’s as authentic as one can conceive.

Vygotsky suggests that students first learn through their relationship with others and only later internalize knowledge. In participatory communication research the rich relationship between participants and researcher becomes part of the research process (White, 1995). Jointly, researcher and participant, define the nature of their shared reality. Jointly, their knowledge base converges.

Implications for Instructional Design

In traditional ISD approaches three phases define curriculum development: 1) A front-end analysis defines the learner, the context, and the task. The task is then operationalized through a performance objective. 2) Material is developed to support the performance objective(s). 3) Assessment provides the feedback with which the materials are reevaluated and/or the front-end analysis is redefined.

To a certain extent the concept of an instructional systems design (ISD) model, any ISD model, might seem outside the frame of reference of participatory communication theory. Indeed, the very idea of knowledge transmission, objective (versus subjective) analysis, and a structural (context-free) design system is antithetical to the
participatory model. But PCT can offer a framework wherein education can be developed albeit with the twin caveats of no dogma, no system (Sullivan and Harper, 1996). It begins with Friere’s problem posing.

A problem posing design model begins by asking the learner to define a) the problem, b) the context, and c) the learner and his/her strengths and potentials. A major difference between the traditional and the PCT model is that within the PCT model the learner identifies the problem. What is to be learned, the skills, the media used, and the curriculum are all products of the problem posing process which is defined by the participants, not an external instructor. The role of the instructor is that of consultant providing only those resources that are requested. The instructor is a co-learner yet he/she must avoid at all times the inclination to dominate the learning process. And during the course of the process the instructor’s role is reduced until he/she is no longer needed.

Historically, both in communication theory and in ISD models, the role of the expert overseer cultivated and inevitably developed the model of what was to be leaned. The teacher’s perspective defined the process. The teacher knew best. The learner was marginalized, becoming the object of the process rather than the subject. Participatory Communications, however, values the learner’s knowledge.

Tilakaratna (1991) provides a two-step process that moves between reflection and action and back again. Beginning with critical awareness of societal forces, a problem is defined. The group determines a strategy that will solve the problem. Self-assessment and action plans move the group towards the solution. Freire (1995) was adamant that a reflection on the action must take place that asked how the action addressed, solved, or changed the problem. This reflection on the action is important to renew the group’s efforts, to revitalize the approach and to avoid the creation of a single viewpoint, the creation of a structure that co-opts the problem posing/problem solving process.

The instructor or ISD designer may better be thought of as an animator (Tilakaratna, 1989). The teacher’s first role is to enable the students to become aware of the problem (animator). Secondly, the teacher is vital to group formation (facilitator). His/her responsibilities include group identification of the strengths and weaknesses of its members as well as the mobilization of resources within the confines of the problem. Finally, the teacher must leave the students to carry out their own learning. Tilakaratna calls this the progressively redundant phase, insuring that the students can continue to learn, to assess, define, and develop their skills.

Participatory Communications Theory also focuses on the media of communication, using the interplay between mass media and small media in both the problem posing and problem solving aspects of the learning model. Mass Media perpetuates and/or develops values and social structures of the power elite. Small Media develops new social structures and new values. The interaction of the media becomes the text to be read.

It is important that the Mass Media not be painted as being diabolical nor to either deify or belittle Small Media. Each is a cultural phenomenon. Mass Media is not omnipotent. While Small Media is not a substitute for Mass Media, it can fill information gaps that Mass Media cannot. And above all Small Media and Mass Media provide the questions, the problems, and the tools to read the world.

Conclusion

I have been concerned that educational intervention, teaching or curriculum development, has focused on the teacher rather than the learner. I have also been concerned with an almost patronizing attitude that comes with such a focus. Dignity involves taking control over one’s own life. Ahmed Kathrada (1999) wrote that a life “without dignity is not worth living.” By valuing the learner’s knowledge and perspective, by allowing him or her to fully participate in educational decisions, and to employ minority media as both a text and a tool, participatory communication theory provides an educational framework for liberation, humanness and dignity.

Teachers Under Construction—Incorporating Principles of Engaged and Brain Based Learning into a Constructivist “Technology in Education” Program

Lee Montgomery, Ph.D.
College of Education
Southern Utah University
montgomery@suu.edu

David Whiting
College of Education
Southern Utah University
whiting@suu.edu

Abstract: This paper is a report on the findings of an action research project conducted during an undergraduate “Technology in Education” class for preservice teachers. The course was structured using a Constructivist approach and designed to incorporate principles of brain based and engaged learning. Technology competencies of students participating in the course were accessed using quantitative and qualitative analysis techniques. Findings indicate that students in the Constructivist course acquired proficiency in the use of technology and developed knowledge structures essential to the successful integration of technology into classroom practice.

Rationale and Problem Statement

Trends in pedagogy and technology are converging to significantly alter the learning environment of the coming millennium. Shifts in theory brought about by findings of cognitive psychology and brain based learning research challenge the traditional lecture-exam model of learning and indicate that learning is best facilitated by activities that actively engage learners in the creation of knowledge. The emerging paradigm supports the theory that learning is best achieved by interaction between learners and teachers and between learners and their peers.

Traditionally, educators have attempted to employ technologies to teach students directly. In the lecture/direct instruction model so common in higher education, technologies may be used to deliver and communicate messages to students who, it is assumed, will comprehend these messages and learn from them. The underlying assumption of this old paradigm is that students learn from technology in much the same way they learn from teachers: through the transmission of information. Thus, for many years, technology savvy educators have sought to embed information in technology-based lessons to be transmitted to the learner who becomes little more than a passive recipient of that information. In this fashion, students learn from technology what the technology “knows” just as they learn from the teacher what the teacher knows.

Constructivists, on the other hand, argue that students cannot directly learn from either teachers or technologies. Rather, they maintain, students learn from
thinking, and thinking, not teachers or technologies, mediates learning. To the Constructivist, thinking can be engaged only through activity. Teachers and technologies can present and support thinking activities, but they cannot directly cause thinking, just as they cannot directly cause learning. Since students learn from thinking about what they are doing, both teachers and technologies can support learning only if they are used as intellectual partners and tools that help learners to think (Jonassen, 1997).

A Constructivist approach to teacher education is essential if the next generation of teachers are to encourage students in their classrooms to apply, analyze, synthesize evaluate and construct knowledge from the massive flow of information available in today's society. White (1996) and other teacher educators have long recognized the importance of engaging preservice teachers in these processes throughout the teacher education program. But in spite of a growing body of research supporting the benefits of Constructivist pedagogy, most technology in education courses continue to follow the transmission model of instruction.

The "Technology in Education" course required of preservice teachers at many institutions typically follows a direct instruction model which emphasizes rote learning of computing skills rather than the integration of those skills in meaningful instructional contexts. Consequently, students often emerge from traditional programs knowing how to perform basic tasks such as using the Internet or constructing a database but lacking the conceptual understanding necessary to know how, when and where to integrate these technologies into their own professional practice. The dilemma facing educators charged with providing technology education to future teachers is how to restructure traditional skills-based courses so that students not only acquire the requisite skills but also construct the knowledge base necessary to apply those skills to support engaged learning in their own classrooms with their own students.

Program Description

In response to this dilemma, Montgomery and Whiting, both professors of teacher education at Southern Utah University, have attempted to develop a technology in education program informed by Constructivist principles and grounded in brain based and engaged learning theory. In developing a pilot program for undergraduate and graduate students, the researchers adopted a framework suggested by Brooks and Brooks (1993) which incorporates a set of twelve Constructivist teaching behaviors. This set of descriptors outlined below presents teachers as mediators of students and environments rather than as providers of information and managers of behavior.

1. Constructivist teachers encourage and accept student autonomy and initiative.

2. Constructivist teachers use raw data and primary sources, along with manipulative, interactive and physical materials.
3. When framing tasks, Constructivist teachers use cognitive terminology such as "classify," "analyze," "predict," and "create."

4. Constructivist teachers allow student responses to drive lessons, shift instructional strategies, and alter content.

5. Constructivist teachers inquire about students' understanding of concepts before sharing their own understandings of those concepts.

6. Constructivist teachers encourage students to engage in dialogue, both with the teacher and with one another.

7. Constructivist teachers encourage student inquiry by asking thoughtful, open-ended questions and encouraging students to ask questions of each other.

8. Constructivist teachers seek elaboration of students' initial responses.

9. Constructivist teachers engage students in experiences that might engender contradictions to their initial hypotheses and then encourage discussion.

10. Constructivist teachers allow wait time after posing questions.

11. Constructivist teachers provide time for students to construct relationships and create metaphors.

12. Constructivist teachers nurture students' natural curiosity through frequent use of the learning cycle model.

Atkin and Karplus (1962) described the process of curriculum development and instruction as a three step cycle. First, the instructor provides an open-ended opportunity for students to interact with purposefully selected materials. The primary goal of this initial "discovery" lesson is for students to generate questions and hypotheses from working with the materials. Next, the teacher provides the "concept introduction" lesson aimed at focusing the students' questions, providing related new vocabulary, framing with students their proposed laboratory experiences, and so forth. The third step, "concept application," completes the cycle. During this phase, students work on new problems with the potential for evoking a fresh look at the concepts previously studied.

The learning cycle represents a significant departure from the ways in which most teachers are taught to teach. In the traditional model, emphasized in traditional approaches to curriculum and instruction, concept introduction comes first, followed by concept application activities. Discovery, if addressed at all, usually occurs after introduction and application activities, and includes only the more capable students who finish their application tasks before the rest of the class.
To facilitate a learning environment consistent with the principles outlined above, Montgomery and Whiting developed a series of experiences which emphasize collaborative and project-based learning. To provide an authentic context for learning, students work collaboratively in small groups to develop a detailed plan for a technology-rich charter school. Students employ a variety of "mind tools" (Jonassen, 1996) including modeling and interactive multimedia software to develop plans which emphasize engaged learning and the appropriate integration of instructional technologies. In the course of completing the project, learners utilize the Internet and other resources to explore the literature of educational reform and the effectiveness of instructional technologies and to expand their knowledge of curriculum and instruction. The groups use spreadsheets and databases to analyze information and produce model curriculum materials using multimedia and desktop publishing tools. During the last two weeks of class, each group presents its plan using appropriate technologies and participates in a self and peer assessment process. Conclusions and reflections on experiences are published on a student-produced web site.

Because knowledge construction is facilitated by collaboration, the formation of collaborative "pods" or groups was an important dimension of the restructured program. To create a learning environment which emphasizes multiple perspectives, peer support and cognitive apprenticeship, the researchers adapted a model of collaborative learning suggested by Kagan (1990). A five-step sequence of activities was employed to facilitate the successful operation of the collaborative pods.

1. **Formation of the groups.** Students were asked to group themselves into pods of three to five on the basis of a shared vision for the proposed charter school. Since the school was to represent an integrated approach to curriculum, the composition of each group was interdisciplinary. In addition to developing a charter school proposal, student subject area specialists were given the task of working together to plan cross-discipline instructional units which would facilitate engaged learning through the appropriate use of various instructional technologies.

2. **Clarification of the group goal.** The common thread of the content to be explored was the creation of a hypothetical charter school based on the principles of Constructivism, and consistent with the latest research findings on brain-based and engaged learning. Each pod was given the task of utilizing various mind tools to create a portfolio representing their school and its curriculum. An integral part of the portfolio was a Unit of Practice and a model lesson based on Constructivist principles. Each group was also assigned the responsibility of conducting a whole group learning experience near the end of the course designed to bring closure to the research process and to share constructed knowledge.
3. **Negotiation of tasks and sub tasks to be completed.** Students were asked to break down the required tasks and to delegate them to various pod members. An important dimension of this process was the determination by the group of which tasks should be delegated to individuals and which should be accomplished in group brainstorming and problem-solving settings. In addition, each group member was asked to master one of the "mind tools" (Inspiration, Avid Cinema, ClarisWorks, Claris Home page, Powerpoint and Hyperstudio) and assume responsibility for teaching others in the pod to use it.

4. **Monitoring of individual and group performance.** Individual and group progress was monitored using process rubrics and periodic reports. Each pod was asked to share research findings and works in progress on a weekly basis with members of other groups and with the instructor. Pod members were also asked to complete weekly self-assessments designed to track mastery of technology competencies related to the use of the various mind tools. These assessments were compared to benchmarks established in individual skills development plans completed by each pod member at the beginning of the course.

5. **Reconciliation of differences in approaches to the goal.** Disagreements in approaches to and interpretations of group tasks and goals sometimes arose, giving pod members opportunities to articulate their unique perspectives and to negotiate differences in understanding. Interpersonal communication skills including providing and receiving feedback, paraphrasing without evaluating, negotiating meaning, and accepting the needs of others were introduced by the instructors and presented as an integral part of the cooperative process.

**Findings and Conclusions**

Qualitative and quantitative data were gathered during and at the conclusion of the course. These measures included concept maps of content knowledge, self-assessment forms related to skills acquisition, group process forms and self and peer ratings of final presentations. In addition, a course evaluation was completed by all students participating in the program.

Analysis of the various measures yielded a number of positive results. All students participating in the course demonstrated mastery of the various "mind tools" and responded positively to the processes of collaborative, project-based learning. A significant number of students indicated that participation in the course helped them to develop problem solving and critical thinking skills. In addition, they reported gains in understanding of the collaborative research process and in their perceived ability to facilitate and teach in a constructivist environment.

On the basis of these results, the researchers conclude that students in constructivist environments can effectively learn the same technical skills emphasized in transmissive approaches to technology education. Further, the introduction of collaborative learning and an inquiry driven curriculum can greatly enhance and
accelerate the acquisition of these technical skills while increasing student interest and motivation.

The new paradigm brings with it an innovative model of teaching and learning that emphasizes the construction rather than the transmission of knowledge. The use of technology and collaboration needs to be encouraged more than ever in higher education in order to prepare teachers for the paradigm shift they will experience as more and more schools embrace the principles of brain based and engaged learning. Consequently, educators at the college and university level must model new approaches which emphasize the role of teacher as facilitator of learning rather than dispenser of information. Only through this approach will prospective teachers acquire the competencies which will be the mainstay of the educator in the new millennium.

PCA - A Digitally Manipulative Software Development Environment for Physically Challenged Participatory Design

Dr. Warren Moseley
St. Andrews Presbyterian College
Laurinburg, NC

Abstract: This research involves creating a context for design and a support environment to create applications for the physically challenged (PC). This research explores direct manipulative user interfaces that are specially enhanced for the PC. PCA (The Physically Challenged Assistant) focuses on the modeling of computer processes and the facilitating support environment that will allow the physically challenged individual to engage in time-dependent activities which need coordination with other tasks, other computers, other individuals, and even other physically challenged individuals. PC and non-PC persons working in coordination with each other do the applications produced from PCA.

The Americans with Disabilities Act of 1990
The Americans with Disabilities Act (ADA) of 1990 stipulates that employers must make reasonable accommodations for those with disabilities (ADA 1990). Reasonable accommodation is any modification or adjustment to a job or work environment that will enable a qualified applicant or employee with a disability to participate in the application process or to perform essential job functions. Examples of reasonable accommodation include making existing facilities used by employees readily accessible to and usable by an individual with a disability; restructuring a job; modifying work schedules; acquiring or modifying equipment; providing qualified readers or interpreters; or appropriately modifying examinations, training, or other programs.

It is not easy to determine just how a physically challenged person will interact with an environment, and hence employers have focused their attention to jobs that require only one person to accomplish, and usually ones that are not time critical. It is the purpose of PCA to expand the capability of the employer to cover situations that are time-dependent, and ones that include user interaction and task coordination. The PCA context allows employers to more readily conform to the ADA, and to mainstream valuable assets.

Challenges for the PC
The computer is now, and will continue to be an essential part of the toolkit for the physically challenged. It offers New Hope of extended independence to those who previously had little hope. These rapid technological advances translate to increases in system complexity. The ability to study and to manipulate complex computing environments is critical to the creation of working and meaningful environments for the physically challenged. An important part of the cooperative environment is the communication devices for the PC individual. Using these devices as a means to a solution creates a distributed application because these interface devices are in themselves powerful and complex computers with very sophisticated application software, some of these already operate as distributed systems. Following are some of the devices that make PCA a reality.

The Liberator
The Liberator is a specially modified computer adapted to the needs of the PC. The extended demands for multi-user coordination in PCA make it necessary to encapsulate the functionality of the Liberator into a larger distributed computational model. Liberator's capabilities can be extended to contain powerful programming tools to augment the communication capability of the PC.
Figure 1 - The Liberator

Liberator’s clock and calendar serve as organizers that are particularly useful in the software development process and in research associated with the development process. In this study we used this device as one of the interfaces to the software test environment. But of greater significance a slight modification provides a non-intrusive monitoring and data acquisition mechanism to help determine just exactly what the PC person was doing. In the initial findings time was a factor that impacted the overall software development, and hinders the PC participant from being an immediate asset to the development team.

Though it is possible to derive some of the cognitive task data from the Liberator interface, we found it limited when trying to track exactly what the participant was doing at a fine-grained micro level. For instance we could tell that the person was working on debugging a segment of code, but it was difficult to determine just what cognitive activity was activated. Coordination of chronological elements with other parts of the environment produced task sequences at a coarse grain level. Often a shift of attention to an associated document, diagram, or piece of test equipment alluded the Liberator. The Liberator allows for other assisting devices to be added to enhance and monitor the software development interface.

The Eye Tracker

The IONTM Eye Controlled Cursor Control System is an access device that operates completely through head and eye motion giving the PC person total access to the computing environment.

Figure 5 - The IONTM Eye Tracking Mechanism

Software adds eye control to basic software for head control, and allows full control of a computer with only the eyes. Two tiny cameras in the headset observe both the user’s eye and the beacon on your monitor, allowing the computer and the IONTM Eye Control Software to determine where the PC Person is looking on or off the screen. The IONTM can also sense intentional blinking, and uses that for clicking and dragging. Eye tracking mechanisms give us insight into the cognitive tasks for PCA. This will provide a focal point for future studies into the cognitive aspects of the software testing process.

Computational Construction Kits

The MIT Media Lab developed a new generation of "computational construction kits" to enable people to express themselves in ever-more complex ways, deepening their relationships with new domains of knowledge. To guide the development of these computational construction kits, a theory of constructional design evolved. Whereas the traditional field of instructional design focuses on strategies and materials to help teachers instruct, constructional design theory focuses on strategies and materials to help students construct and learn.

Essentially there has been much of a parallel effort in the area of the construction efforts for distributed object systems. The architectural foundation provided by the OMG in the CORBA 2.0 specification and the toolkits such as ORBIX, Visibroker, etc. have given rise to a constructional approach to designing complex distributed object systems.

Software architecture serves as a framework for understanding system components and their interrelationships, especially those attributes that are consistent across time and implementations. This understanding is necessary for the analysis of existing systems and the synthesis of future systems. In support of
analysis, architectures capture domain knowledge and community consensus, facilitate evaluation of design and implementation of components, and ease simulation and prototyping. In support of synthesis, architectures provide a basis for establishing product lines and using domain knowledge to construct and maintain modules, subsystems, and systems in a predictable manner. As systems grow in complexity reuse becomes more critical.

Constructional design is a type of meta-design much like the concepts found in building today's software frameworks such as SEMATECH Computer Integrated Manufacturing (CIM) Framework Architecture (Sematech Report 1995) built at SEMATECH in Austin, Texas. Constructional design involves the design of new tools and activities to support students in their own design activities. In short, constructional design involves designing for designers. (Resnick 1996) This is the cognitive foundation for the construction of PCA.

Digital Manipulatives for the PC Person

In many educational settings, manipulative materials (such as Cuisenaire Rods and Pattern Blocks) play an important role in learning and enabling the exploration of mathematical and scientific concepts through direct manipulation of physical objects. A new generation of "digital manipulatives" -- computationally enhanced versions of traditional children's toys have been developed by the Media Lab at MIT. These new manipulatives enable exploration of design concepts. PCA uses digital manipulatives such as computationally augmented versions of blocks and a tube to help create a construction environment that is mentally challenging and physically useful to those who are physically challenged.

Resnick (Resnick 1996) sees the use of digital manipulatives as part of a broader trend within the computer interface research community. Objects to manipulate have traditionally been virtual objects. An example would be object-oriented languages and direct-manipulation graphical interfaces. PCA builds on these virtual objects with the introduction of physical objects. In research efforts variously described as "ubiquitous computing," "computer-augmented environments," and "things that think," (Resnick 1996) researchers are now exploring ways of adding computational capabilities to everyday objects ranging from notepads, desktops, and eyeglasses, to a new version of an ION™ Eye Controlled Cursor Control System 2000.

Resnick and the MIT Media Lab researcher have by choice focused attention to direct manipulative learning aspects, and in particular the use of the physical devices as a part of the learning environment for young children. PCA switches the focus of their attention to the use of directive manipulatives as a means of adding functionality to the participatory software development environment.

Programmable LEGO® Bricks

The MIT Programmable Brick is a tiny, portable computer embedded inside a LEGO® brick, capable of Interacting with the physical world through sensors and motors. The Programmable Brick extends the child's construction kit, enabling students to build not only structures and mechanisms, but also to add behaviors to these structures. With Programmable Bricks, students can spread computation throughout their worlds. They can build distributed systems, and even autonomous distributed systems (real-time embedded systems). They can use Programmable Bricks to build autonomous robots and "creatures"; to create "active rooms" (for example, making the lights turn on whenever anyone enters the room); and to organize "personal science experiments" (for example, counting the number of steps they take in a day).

The physically challenged interact through the use of the eye-track special computer interface which psychomotor skills from the neck commands directly from the ION
and other interface apparatus that allowed computer controlled operation. The project we chose to test PCA was a light sensing robot built with the Mindstorms Robotic Invention Kit.

Figure 6 - Light seeking Robot with attached RCX Lego™ Bricks

We attached the infrared sensors and transmitters to designated portions of the light seeking robot and likewise modified the user interface devices to use the infrared sensors and transmitters of the LEGO™ Brick. In addition we modified the user interface to the computer to be operated by screen representation of the physical devices from computer interface, but also from embedded processors in devices such the ION™.

The Software Development Processes

A quality product depends on a quality process (Humphrey 1989)⁶. This is a tried and tested premise of mature manufacturing and engineering quality circles for years However it is just beginning to become a trait of a mature software development process. A software process can best be defined as a set of activities, methods, practices, and transformations that people use to develop and maintain software and the associated artifacts (i.e. project plans, design documents, code, test cases, and user manuals). As an organization matures, the software process becomes better defined and more consistently implemented throughout the organization. As the process matures, it will be passed between projects, project personnel, and project managers. It is important to consider the impact to the software development process that comes from having a PC participant. It should in no way alter the defined process, but can easily impact the process enactment when going from one person to another.

There is the need to represent as a first class object. The object coordination is first class object. These objects can be fragments of a software product under development or a fragment of the development process to generate that software product. Jacobson introduced the concept of Object Interaction Diagrams (OID). The problem with Object Interaction Diagrams is the lack of a formal representation, and in the PCA instance the lack of a formal representation for the coordination of process, whether product processes, or development processes.

Figure 6 represents a simple message trace diagram of messages between objects in an object application represented as an Object Interaction Diagram. This could represent steps in a development process, or a sequence of steps in a manufacturing process, or a sequence of tasks in a message-passing program. Message diagrams revolve around the main threads of execution and there is a lack of any synchronization mechanism that enables coordination of concurrent execution interactions. To adequately include the PC into the software development process, the process must be able to represent multi-user, multi-process coordinated interactions.

Vondrak introduced Interaction Coordination Nets (Vondrak 1995) (IC-Nets) to represent a tool that provides for concurrent threads for coordinated process management and control. He originally used these to represent steps in the development process, but has since extended these to include process interactions and coordination in actual programs. IC-Nets are an extended form of Petri Net. The processes modeled using IC Nets are inherently concurrent and often distributed. Synchronization of object interactions is simplified by the visual nature of IC-Nets.
Summary

In addition to the exploration of digital manipulatives, PCA provides a solid theoretical foundation for the construction of software products and software processes. Not only did PCA provide a means for the PC person to participate in the design of distributed object systems; it also provided a new way of thinking about distributed problem spaces. In retrospect it was also a lot of fun. Playing with LEGO© Blocks is a lot more fun than programming a distributed test environment.

Graphic Design Software and Creativity Development

Rosa Miriam Ponce Meza
Research Center
La Salle University
Mexico City Campus
mponce@aldebaran.ci.ulsa.mx

Eduardo Martínez Marín
High School
La Salle University
emarin@spin.com.mx

Abstract This paper explores the possibilities to develop the creativity skills originality, flexibility and elaboration of graphic ideas through the use of a locally developed software applied in a sample of 112 Mexican high school male students. The software consists of three main parts: theoretical information on graphic design techniques, links to different websites related with graphic design and a locally developed software for drawing and graphic design and its tutorial. The results were obtained comparing the works in two control and experimental groups. A group of experts evaluated the works by their originality, flexibility and elaboration of ideas, and the experimental groups works were more creative than the control groups.

Creativity in the Design
Creativity is the ability to produce work that is both novel and appropriate (Lubart, 1994; Ochsae, 1990; Sternberg, 1988; Sternberg & Lubart, 1991, 1995). Creativity in design can be developed using specific software. The present paper explores creativity development in graphic design in Mexican high school students who had no previous experience in drawing and graphic design. The creative criteria evaluated in the works of the students were elaboration, flexibility, color composition and generation of multiple ideas. The subjects were assigned to control or experimental groups randomly. The works from each student were evaluated for a group of design experts by the creative criteria established. The main purpose of this paper is to show that the creative potential in graphic design can be developed by using appropriate objectives, tools and evaluation criteria.

The possibilities of using software for different human activities have been not completely explored. The computer and the software for graphic design can demonstrate their usefulness in the development of creative works in graphic design.

Method
Subjects
Mexican males from the first year high school at La Salle University, Mexico City Campus. (N=112) from 14-15 years old, without previous knowledge in design.

Experimental Design
The students belonged to four different groups, assigned randomly in two control and two experimental groups. In the experimental groups the software was applied.
In the design course II, with 72 sessions, in the experimental groups was used a locally developed design software. Students were asked to develop special design works in both groups. The only difference was that the students in the control groups did not use the software, and the experimental groups did use it. The works were evaluated by design experts, after a special selection of the more creative works. The experts agreed on the criteria to evaluate the works: elaboration, color, and creative design.

The works developed in the experimental groups were more creative than the works developed in the control groups. This was explained by the following reasons:

Students in the control groups only worked with the traditional possibilities in design (limited colors, limited tools, limited skills), usually in two hours session they can work one or two design simple concepts and ideas.

In the experimental groups, the time was completely dedicated to practice with the software two hours in each session. Students in the experimental group could work two or three ideas at the same time.

Results
From the first sessions the quality of the works was better in the experimental groups. Specially by elaboration, originality and creative design.

The final designs in the control group were better in the quality of the techniques. It was explained by the possibility these students had to use each session to practice different techniques. Experts evaluated by elaboration, more works from the control group than from the experimental groups. In the experimental groups, students were focused on developing ideas in the software, than developing their own designs by hand.

Implications of the results
The designing software demonstrated to be a useful tool in accelerating the creative process in the conceptualization of design ideas.

The software improved the edition and the final design. At the same time improved the creative skills in the students in the experimental group.

According with the results, the creative students in the experimental groups performed increasingly better in each session. At the end of the course, they showed an excellent performance by the creative criteria.

The potential showed by the students was more evident in the experimental groups. The software helped them to demonstrate and arrived to more creative ideas, and at the same time they improved the process of conceptualization of creative design ideas.

Creative students developed more creative ideas in less time than the students in the control groups. The experimental students used more resources to develop more elaborated, original and complex design ideas.

Cognitive processes involved in Creative Design
The use of the software let the students to design with more freedom their own ideas, which at the end of the process were more creative, according with the opinion of the experts in design.

Concentration of the attention process
The students in the control groups, gave less time to the development of their design ideas. In the experimental groups, the students were completely focused, some times for almost two hours, each session, working and reworking new designs.

Elaboration of ideas
Students in the experimental group dedicated more time and effort to edit different alternatives in their designs. The software was very useful to elaborate more ideas, and more complex designs than in the control groups works.

**Part-Whole interaction**
In the works, the relation and interaction between the part- and the whole was an important element to consider the originality in the designs. The students in the control groups showed limited possibilities in the originality of their designs compared with the results obtained in the experimental groups. The most creative compositions were found in the experimental groups, where students decided a more original and unexpected creative designs.

**Working with simultaneous design concepts**
In the experimental groups, the students used the software to generate and explore different concepts, two, three or more design concepts were worked by almost all the students in the experimental groups. The experimental groups worked simultaneously by hand and with the software. This condition improved the process of generation and elaboration of concept designs.

**Work in two environments**
Students in the experimental groups worked simultaneously with the software or without it. At the end of the course, these students demonstrated more creative designs than the control students.

Approaches for Generating Animations for Lectures

Guido Rößling and Bernd Freisleben

Abstract: Many software tools try to address the growing interest in supplementing course materials with animations. In this paper, we give a short review of the basic approaches for generating animations. Thus, teachers can determine the way best suited for them and are then better prepared to select a tool addressing their needs. For each basic approach, several example tools are cited. All selected tools are available for free use or download, so that interested teachers can test them.

Introduction

The number of teachers who want to integrate animations into their lectures to illustrate dynamic behavior has grown over the last few years. By now, a large selection of tools for generating or presenting animations are available. However, these tools differ in how animations are generated or edited, the offered animation features, portability and cost factors. Many people interested in using animations may find themselves confused by the profusion of different offers. This situation may lead to deciding on a tool not well suited to the intended animation content, resulting in increased time spent on animation generation and possibly frustration on the teacher’s part.

In this paper, we try to help teachers wanting to use animations for supplementing their courses by outlining the general approaches of how animations can be generated. We give some examples of how generation efforts may typically look like, and contrast strengths and weaknesses of the approaches. For each general approach described, we also mention some of the tools supporting this approach.

Our interpretation of the very broad term animation is focused on instructional usage for computer science. Thus, typical animation areas contain the dynamic display of the effect commands or operations have on algorithms or data structures. We are not concerned with animations as seen in movies, like "Antz" or "A Bug’s Life". However, we include animations taken from other fields, such as physics, mathematics or economics.

The paper is organized as follows. In the next section, we mention some of the basic restrictions placed on animations tools. The following section discusses the presented basic approaches for generating animations and gives short examples for each approach. The last section concludes the paper and outlines areas for future research.

General Considerations and Restrictions

Apart from the generation process itself, some other issues should be taken into account before deciding on a tool. These issues are of general nature and not directly linked to a given tool or generation approach. However, they can have a large impact on the usability of the tool and the generated animations, and should therefore be considered first.

The foremost issue from our point of view is platform independence. While the majority of students may own a PC and are most likely using Windows 95/98, this may not be the case for a significant portion of potentially interested clients. This is most especially true for universities, where Unix operating systems are very popular, as well as for the increasing number of Linux users. Furthermore, not everybody uses Intel-
compatible hardware – think, for example, of the iMac platform. Thus, using a proprietary tool based on Windows 95/98 may limit the number of potential clients for your software. Furthermore, the visibility and accessibility of the animations when propagated over the World-Wide Web may be reduced due to security concerns regarding ActiveX controls and JavaScript.

The same is true for formats that “only” require a plugin for Web browsers. Teachers should be aware that while the plugin download itself is usually free, plugins are not necessarily available for all platforms! Unix-based platforms and Linux are not supported by many tools. For maximum platform independence and the greatest possible audience, the chosen tool should provide a Java applet for displaying generated animations, as most modern Web browsers come with built-in Java support.

Furthermore, several of the commonly used tools are commercial software. Teachers should make sure that a player or viewer component is also included and may be freely passed along, so that students can study the animation at home whenever they want.

**Basic Approaches for Animation Generation**

The following basic approaches for animation generation are discussed in this paper:

- Using “classical” presentation tools such as PowerPoint,
- Visual editing using drag and drop or selection of options,
- Direct animation of source code,
- Generating animations by function calls implemented in a function library (API),
- Animations generated by a scripting language or text commands.

Some of the tools available support more than a single way of generating animations, or use a special combination of the basic approaches. In the following, we discuss the individual approaches, mention some of the tools concerned and outline typical strengths and weaknesses.

**Using “Classical” Presentation Tools**

Some classical presentation tools like PowerPoint have lately been enhanced to support animation effects to a certain extent. Classically, many animation effects are concerned with modifying the appearance of new elements or the repositioning of visible components. The programs are not intended to be used for animating dynamic structures, like sorting algorithms or molecular movements. Thus, presentation tools are well suited for making presentations on slides more lively, but also restrict the teacher's creativity in generating animations.

The strengths of using presentation tools for animations include the comparative ease of using the presentation tools, as they typically offer visual editing and thus directly show the effects of a given action. Furthermore, they allow the integration of animations in lectures without having to switch media or presentation programs, as several courses are already presented in PowerPoint. However, the extent of possible animation effects supported by the tool limits their usage. Before spending a lot of time on trying to generate an animation, it is therefore reasonable to determine whether the effects offered are sufficient for the intended animation. If this is not the case, one can better spend the time otherwise wasted on trying out animation effects by using a tool better suited for the targeted animation.

**Visual Editing Using Drag and Drop or Selection of Options**

Probably the easiest way to generate animations is visual editing, where the teacher can directly see what the animation looks like at a given point in time. This approach is very similar to the way presentations are
generated in presentation tools such as PowerPoint. However, most animation tools offer special object
types for certain contexts, such as arrays or list elements (Rößling & Freisleben 1999).

Object drawing is usually accomplished by one of the following approaches:

- dragging predefined objects on a drawing area, where they can be rotated or scaled,
- or by placement of individual points of a given object by a simple series of clicks.

Tools supporting this approach include *Macromedia Dreamweaver* (Macromedia 1999), *Flash* (Flash 1999) and *Animal* (Rößling & Freisleben 1999). The main advantage of this approach includes the direct visualization of effects already mentioned. Teachers can also learn much about animation generation by experimenting, as this can be accomplished by simply drawing objects to see whether they “fit” into the animation. Finally, only very modest computer experience and no programming experience is required for either animation generation or editing.

The main drawback of the approach is that, due to being forced to do everything manually, animation
generation is very time-consuming. This becomes most obvious when more than a single animation for a
given topic is wanted. Furthermore, there may be differences in what a given algorithm does and what is
shown in the animation, as the animation depends on the author’s understanding and interpretation of the
algorithm, which may differ from the actual algorithm’s behavior.

**Direct Animation of Source Code**

In some cases, teachers may have source code for the topic to be animated. In this case, an approach that
can directly generate an animation from the source code would be highly helpful.

Tools such as *Jeliot* (Haajanen et al. 1999) and *AlgAE* (Zeil 1999) support direct source code animation.
With these tools, the teacher is completely freed from having to define animation commands or doing extra
work to generate the animation. The animation is also automatically kept consistent with the underlying
source code. By being based directly on the source code, new animations can usually be generated by
simply exchanging algorithm parameters and restarting the algorithm.

However, there are also some drawbacks. First of all, teachers must have access to source code for their
problem in the programming language supported by the animation tool. The tools cited above support Java,
while other tools others support Modula-2, Pascal, C or C++ code. If the teachers wish to use a
programming language not supported by the chosen tool, the tool becomes unusable. Furthermore, some
topics which may profit very much from animation can not easily be specified in source code. This may be
due to the long running time of the problem, as for NP hard problems, or the lack of clarity and brevity of
the code. In these cases, teachers need a way to directly jump to a given point in the animation, as well as a
way to use pseudo code or a textual description replacing the actual source code. However, tools based on
source code animation do not provide these features. Obviously, the teacher also needs to be a rather good
programmer in the underlying language in order to generate animations. Thus, this approach is limited to
rather special circumstances. Finally, the teacher often has no way to determine the way the code is
presented, as the animation effects themselves are usually hard-coded into the underlying source code
interpreter. Thus, teachers are prevented from choosing a different view of a given topic that they consider
more interesting or beneficial.

**Using Functions Calls Implemented in a Function Library**

In order to alleviate the problems resulting from having a direct match between source code and animation,
several tools support the generation of animations by function calls. These tools include *Animal* (Rößling &
Freisleben 1999) and *JAL* (Silicon Graphics 1998). In this approach, animations are generated within a
collection of functions provided in a function library for a specific output tool. The approaches can be
subdivided in two categories: tools which generate and directly display the animation, and tools that
generate and store animation files that may be loaded and run at the teacher’s discretion. JAL belongs to the
first category, while Animal is part of the second category.

The functions are usually assembled in function libraries commonly called APIs (Application Programmers
Interfaces). The API is responsible for providing functions that generate animations or animation files used
by the underlying animation tool.

The main strength of this approach lies in the ease of generating animations “on the fly”: once a given
source code has been enriched with the corresponding API calls, it can be used to generate an arbitrary
number of animations by simple substitution of the algorithm’s parameters. The same is true for generated
animations resulting from direct source code animation. However, API calls also allow teachers to define
how the animation should look. Thus, the teacher need only decide once on a suitable way to present the
animation of a given topic, and can then use this approach for generating animations of the topic whenever
they are needed. Furthermore, the API calls can also be used for skipping “irrelevant” algorithm parts,
allowing the teacher to focus on the main part of the presentation.

The main drawback of this approach lies in the need for teachers to be comfortable with programming. The
API calls are usually embedded directly in the source code, or collected in a special animation generation
class. This may prevent teachers with little or no programming knowledge in the underlying programming
language from using the approach. Furthermore, the approach is only helpful if the teacher uses the same
programming language for the course as used by the API, as calling functions in a library written in a
different programming language remains difficult. Adapting the animation to other requirements or a
slightly different display can become very time-consuming due to having to decide on how to change the
API calls.

Animations Generated by a Scripting Language or Text Commands

Animation tools working with scripting languages try to combine the flexibility of API calls with a modest
amount of programming knowledge. The scripting language may be a proper but “easy” language, or it
may simply be restricted to specific text commands without programming structures such as conditional
statements or loops. Tools supporting animation generation by a scripting language or text commands
include JAWAA (Rodger 1997), JSamba (Stasko 1998) and Animal (Röbling & Freisleben 1999). Usually,
the commands can be generated and edited with any text editor and contain a single command per line.
Commands are usually defined in an “intuitive” way, making the animation definition (almost) self-
explansatory. Thus, most teachers will find it very easy to read animation files defined by this approach even
without having programming knowledge.

The main strength of the approach lies in the fact that the process of generating the animation definition can
also be automated. Doing so yields results similar to the effect of using API calls, but without being forced
to use a certain programming language. Furthermore, due to the normally good readability of the animation
code lines, many teachers may find this approach easier to use than API calls.

However, while each single line of the generated animation may be easily readable, it is often rather
difficult to get a feeling for what the animation might look like. While experimenting with the code lines is
easy, generalizing the desired effects and putting them into algorithm’s source code can be difficult. This is
necessary, however, for allowing the generation of animations “on the fly” by adapting algorithm
parameters.

Conclusions

In this paper, we have outlined several possible general approaches for generating animations. Apart from
the basic considerations such as platform independence and free availability, the approaches mainly differ
in three aspects: (I) the way animations are generated, (II) the extent to which the actual display can be
adapted to the teacher’s wishes, and (III) how easily multiple animations of the same topic can be generated.

Due to limitations inherent in the target use of presentation programs, we cannot recommend them for arbitrary animations. Visual editing offers a very easy way of generating animations and highly flexible display depending on the underlying tool’s abilities, but does not allow for easy adaptation of a given animation to modified input values. Direct animation of source code offers the easiest animation generation, as this is done by the animation system. Generating multiple animations of the same topic is also done without effort. However, the teacher is usually not able to adapt the default display to his or her preferences. Furthermore, the programming language to be used for all examples is determined by the animation tool, and "irrelevant" passages of the code cannot easily be skipped. Function calls in a special animation generation function library, on the other hand, allow teachers to adapt the display and easily generate multiple animation, but also puts demands on their programming ability as well as the underlying programming language. Scripting languages or text commands offer a middle way, combining easy generation and high. However, trying to automate the generation can become difficult, especially for teachers with little programming knowledge.

In general, we want to stress that tailoring the animations to the specific needs is usually a very time-consuming process. Thus, it is of great interest to be able to automate parts of the process, so that the same steps need only be performed once for a given topic, and can then easily be reused with changed parameter values. Most approaches offer some way to automate this process; however, this is not true for the most "intuitive" approaches taken by presentation tools and visual editing.

In the end, it is up to the teacher to decide which type of tool is best suited for the current task, possibly changing the tool used from one week to the next. All major approaches have their specific strengths and weaknesses, so that teachers should study the effects of the tool’s approach before deciding on a given tool. This may well result in the teacher using a different tool each week, though this has severe drawbacks in the form of the preparation time for getting familiar with the tool. Therefore, teachers should select tools supporting more than a single technique of generating or editing animations.

The animation tool Animal (Rößling & Freisleben, 1999) developed by us supports animation generation by visual editing, API calls and a scripting language. It can thus be used by teachers of any background and easily adapted to the current requirements by simply switching the way animations are generated. The basic graphic elements point, polyline, arc, text and list element are supported and can easily be adapted to more specific structures such as circle segments. All objects can be rotated, moved, shown/hidden or change color using a duration and/or offset defined by the teacher. For presentations, snapshots of the current animation state can be generated by the animation player and are stored in a variety of popular graphics formats such as JPEG or PNG. Animal is implemented completely in Java and freely available for all platforms supporting Java at the URL http://www.informatik.uni-siegen.de/~inf/Software/Animal.

Abstract: This paper focuses on the challenge for classroom teachers to design instructionally sound curriculum materials for diverse learners that utilizes effective technology. Web-based curriculum that incorporates instructional design principles and universal design principles may be one solution to creating a classroom in which technology can enhance the learning and account for student diversity. In the current educational structure, teachers often adapt materials to meet the needs of the diverse learners by using the principles of universal design. Teachers create materials that can meet the educational needs of diverse learners without noticeably targeting specific students. Since research indicates that while students with disabilities greatly appreciate adaptations of materials, they also desire receiving the same materials as their general education peers. The process we are going to describe in this paper suggests ways teachers can develop an awareness of universal design principles in creating web-based.

Introduction

As education moves into the 21st century, the instructional goals and methods of teaching are adapting to the massive changes in our society based on technology growth and development (Roblyer, 2000). At the same time, education's mission is to provide access to all students the ability to achieve in the classroom. Schools have been adding computers to their classrooms at a vigorous rate. According to an ABC News report, “in the past 10 years, American schools have spent more than $5 billion on new technology that was designed to improve student performance. But during that same period of time, student test scores for reading and math have remained relatively flat” (Norris, September 29, 1999, p. 2). The challenge of using technology in these classrooms is not having access but rather teachers' development skills in designing instructionally sound curriculum incorporating technology. The integration of technology calls for new thinking in the way we teach.

Within these same classrooms, teachers are being challenged to provide instructionally sound education for a diversity of learners. Teachers are creating materials for students with disabilities in response to a mandate from the 1997 Reauthorization of Individuals with Disabilities Education Act (IDEA). Thus, teachers, in response to the ever-increasing demands of providing universal designed materials, must be proactive in their curriculum development.

To design curriculum alone regardless of diversity and technology can be a daunting task as both are considered as reactive rather than proactive. Web-based curriculum that incorporates instructional design principles and universal design principles may be one solution to creating a classroom in which technology can enhance the learning while accounting for student diversity. In this paper we will be discussing the universal design principles, the creation of web-based curriculum materials based on these principles and the future impact on teacher education.
Universal Design Principles

"As general education classrooms become more inclusive, strategies for providing access to the general education curriculum are needed so that students with disabilities are actively involved and progress within the curriculum of these classrooms," according to Lou Danielson, director of the Research to Practice Division in the Office of Special Education Programs (U.S. Office of Special Education Programs, 1999). It has been long recognized that the general curriculum may need to provide various accommodations to enable access by these students. In the past, the typical solution has been for teachers to customize already prepared materials and presentations to meet individual learning needs. This process has not always been satisfactory for either the teacher or the student.

First, teachers often do not have sufficient time or specific knowledge to redesign these materials or presentations. As the general student population now includes an increasing number of students with diverse learning needs the task of making effective accommodations and modifications can be overwhelming. Today's teachers will encounter students with different developmental levels, learning styles, special needs, motivation to learn, as well as students learning English as a second language (Newby, 2000).

Second, research indicates that while students with disabilities greatly appreciate adaptations of materials, they also desire receiving the same materials as their general education counterparts. In addition, many teachers are uncertain of how to implement assistive technology in their instruction without jeopardizing educational quality. Klinger and Vaugh in their research found that parents, educators and students realized the importance of quality in their educational process because of the impact it plays in their academic and social success.

Web-based curriculum that incorporates instructional design principles and universal design principles may be one solution to creating a classroom in which learners, regardless of diversity, can succeed and technology utilized to its fullest potential. While no one product or method will ever be always applicable for all students, these principles can guide an educator in the initial design of curricular materials so that further customization will be more manageable and provide effective instruction.

Universal design means the design of instructional materials and activities that allows the learning goals to be achievable by individuals with wide differences in their abilities to see, hear, speak, move, read, write understand English attend, organize, engage and remember (Orkwis & McLane, 1998). There has been a growing body of knowledge concerning the potential and actual use of materials using the principles of universal design. While the first four principles originated from the guidelines for accessible design delineated by the Telecommunications Act of 1996, the fifth enhances cognitive access. These principles include:

- Provide all text in digital format,
- Provide captions for all audio,
- Provide educationally relevant descriptions for images and graphical layouts,
- Provide captions and educationally relevant descriptions for video,
- Provide cognitive supports and activities:
  - Summarize big ideas
  - Provide scaffolding for learning and generalization
  - Build fluency through practice
  - Provide assessments for background knowledge
  - Include explicit strategies to make clear the goals and methods of instruction (Orkwis & McLane, 1998).

Universal design implies the use of technology in curriculum materials. Technology allows teachers the ability to meet the universal design principles by providing various mediums to stimulate differences in student's abilities. However, technology should be included only as a media selection - a tool to deliver the planned instruction. Therefore, in terms of instructional design of universal use, teachers need to determine the instructional goals, conduct a need assessment, and design instruction that meets the gaps between the goal and the current status of the students. Technology comes into play during the design, development, and implementation stages of instructional delivery.
Web-based Materials

The integration of technology has provided a change in the educational paradigm. "Because of the diversity in both learners and information, a single approach to all instruction will not work: a number of different methods and media exist for designing and developing learning experiences and the roles of learner and teacher shift based on the situation, the content, and the special needs of the individuals involved." (Newby, Stepich, Lehman, & Russell, 2000, p. 7). With the advent of technology, teachers may need to reexamine the way they construct classroom materials. Perhaps it is time to consider an universal design approach to teaching and learning in our classrooms.

Web-based materials in the classroom is beginning to gain popularity in both higher education and K-12 education. Web-base materials may provide additional access to students because they would be able to access their classroom materials both in the classroom and at home. An additional advantage of web-based materials, if designed correctly, is that students could advance through the materials at their own pace thus allowing teachers the opportunity to work individually with those students who have not yet mastered the relevant concepts.

Web-based materials that incorporate the principles of universal design may be advantageous for teachers to use as a way to provide embedded accommodations for students with disabilities. For example, teachers may design their web-based materials using high contrast backgrounds and text to provide an easier screen to read. Another suggestion provided by Edward Blackhurst is to avoid the use of frames. "Frames pose problems for individuals who use screen readers because the reader reads across the entire page, from left to right." Additionally, text that is chunked using shorter paragraphs, subheads, bullets and block indented paragraphs can assist the reading process and avoid visual fatigue, (U.S. Office of Special Education Programs, 1999). These are already common designing principles in webpage development and general educators need to realize how valuable these principles can be in assisting the learning and reading processes.

Future Impact

Teachers need to have staff development opportunities that focus not so much on the basic skills of technology, but the use of technology in their curriculum. The important factor of integration is the recognition that technology may provide an effective medium to provide learning opportunities to their students. According to Jane L. David, the director of the Bay Area Research Group, "Teachers are the key to whether technology is used appropriately and effectively, and technology increases conversation, sharing, and learning among students and between students and teachers." (Trotter, 1999, p. 4).

As more and more children with special needs are being expected to learn and meet standards in their regular curriculum, teacher education must meet the challenge of providing both preservice and inservice instruction. Current and future teachers need to fully understand the implications and practices of both universal design and technology integration to become proactive in providing quality materials to their students. To achieve this goal, current and future teachers need to be exposed to the principles of universal design and effective web-building within their educational curriculum.

Currently the educational community focuses on the general curriculum development. Information regarding accommodations for diverse learners is typically taught separately. The goals of the authors are to strongly encourage incorporating universal design principles in initial general education curriculum development. We as educators of preservice students should encourage universal design considerations to be embedded into the curriculum process from the very beginning. There have been numerous examples from research and practice that demonstrate how modifications developed for students with special needs have a broader application in the general education classroom. As the examples cited previously, web pages that are developed for the students with special needs actually are beneficial for the general classroom student to use as well.

One possible solution would be to develop a web-based instructional design course that addresses the principles of universal design in the development of curriculum materials. The authors propose to teach such a course during the summer of 2000 targeted toward inservice teachers. The basic concepts and principles will be incorporated into a one-day session along with instruction in the use of our web-based course. Our course will model the principles of universal design embedded in the physical and conceptual
framework of our web pages. Through guidelines and additional information presented via the Internet, students will have the opportunity to develop web-based instructional materials and will present their work in a final in-class session where feedback will be provided.

Conclusion

Using the universal design principles to guide the web-based material design process has the potential to open the accessibility of all students with special needs to course materials. The web environment offers an endless opportunity for all students to learn regardless of their developmental levels, learning styles, or other special needs. As we venture into this new horizon of educational change, we must remember that “materials are only as good as the pedagogy on which they are based and the way they are used by teachers and students,” (Office of Special Education Programs, 1999).

The bottom line is that all of our students must learn the skills, knowledge, and abilities that will help them succeed as they live out their lives in an increasingly changing society. Technology integration and universal design are two issues that will continue to impact education as educators design curriculum to help students succeed. Focusing on these issues as considerations of curriculum design—not add-ons—may be the first step to ensuring the integration of technology, not as the answer to all curriculum problems, but as a useful way to deliver learning based on the diverse needs of the learner.

Abstract: This paper is about designing learning environments based on the Internet seen from a constructivist-/situated learning point of view. First, we'll take a look at some of the main principles of learning theory before we move on to the structuring of virtual learning environments and integrated use of services on the Internet. We will also present tools for developing entirely netbased learning environments, where the resources in the network work together to support the learning process. Last, we'll take a closer look at some models for integrating network-based learning environments and learning organizations/social context. The network-based concept that we're working on does also include administrative tasks, such as student registration, course-base, salary, exam, etc. This will not be further dealt with here.

Background

The universities are being criticized for creating passive students and for teacher managed methods, based on old behavioristic learning theories. When Information- and Communication Technology (ICT) now makes it's entry, there is a risk that teacher managed models will be copied into network-based learning.

The last few years, The Norwegian University of Technology and Science (NTNU) in collaboration with other universities/colleges and companies, both nationally and internationally, has been working actively towards the development of a more flexible, problem- and project-based learning, in which network-based learning creates the foundation. Constructivistic learning-theory and situated learning, have formed the pedagogical background, not least in order to be capable of offering flexible learning possibilities when it comes to lifelong learning and the need for continuing vocational training in trade and industry.

Constructivistic learning theory/situated learning

From a historical perspective the design of the first computer-based training programs was based on behavioristic learning theory, where learning is thought of as passive acquirement, or absorption, of an already existing and often rigidly defined amount of information. The main role of the teacher is to gather formal knowledge, to find efficient ways of distributing this knowledge, and to control that the students have acquired the taught material. Then cognitive learning theory followed, focusing on how the material is presented, and development of computer-based ways of teaching which emphasized the presentational form and intelligent guidance systems.

Even though we can’t find the same enthusiasm within learning theory today when it comes to the effect of
such managed and organized teaching, we witness the international education market explode with offers concerning manage-based teaching, especially when these are directed towards continuing vocational training. From our own schooldays we carry with us the knowledge that learning means to be quite, to watch and listen, and then, finally, a test of what we remembered. Thus, it doesn't seem too strange that this model is copied into network-based learning environments, especially not when the Internet as a medium is extremely suitable for fast and comprehensive management and distribution of information, and flexible both in terms of time and place.

However, research on learning theory has for the last few years been increasingly focusing on the fact that learning comes through active participation and collaboration in entire social-/cultural environments. Constructivism was rooted in the perspective that knowledge is acquired through personal construction of knowledge and arose in connection with Piaget's research on developmental psychology. Piaget introduced a theory on learning where new information act together with old knowledge through a process of assimilation and accommodation (Piaget, 1985). Papert (1980) further claims that the activity of programming computers could play an important role in constructivistic learning and related this to his work on the programming language, Logo. Here, the learner plays the role as "teacher" in relation to the computer.

In the 1970s, based on Piaget's theories, a group of psychologists, the so-called Genevan School, carried on research on how social interaction affects each individual's cognitive development. The main-thesis claims that each individual is capable of handling new knowledge by interacting with others. Individual cognition is seen as a spiral of causal connection.

The other theoretical main influence was the research carried on by Russian psychologists who were interested in the cultural basis for human intellect and researchers from the social-cultural perspective. The best known of these Russian researchers is Vygotsky (1978) who formulated the theory on cultural historical psychology. Vygotsky general genetic law of cultural development stipulates that learning always is a two-level process: first as an interpersonal act in a social community and then as an internal/personal process. Internalization refers to the genetic link between the social and the internal plans. Social speech is used for interacting with others, inner speech is used for talking to oneself, for reflection and thought. The social-cultural approach focuses on causal connection and connection between social interaction and individual cognitive change. Vygotsky's theory on "The Zone of Proximal Development" (ZDP) has been interpreted in various directions. One interpretation claims that ZDP is the difference between a person's ability to solve a problem on his/her own, and what the same person is capable of when collaborating with others. Another interpretation of Vygotsky's ZDP is the distance between an individual's personal knowledge and the knowledge that exists in social situations. In both these interpretations learning happens through social interaction which inspires to individual acquisition and internalization of knowledge.

A related school represented by the Russian researcher Leont'ev (1974) et al., focuses on the role of active participation for human development, the so-called "Activity theory". The basis for analysis is social activity, from which individual mental functions are developed. This one focuses on signs, symbols, rules, methods, instruments and other artifacts which serves to mediate this activity. Vygoysky's cultural-historical psychology, and later on the work of the activity theorists have again developed successors both in relation to educational research and in the specialized area of computer science directed towards human/machine interaction.

In theories on situated learning is seen as a process for entering a practical society. "To learn to use tools as practitioners use them, a student, like an apprentice must enter that community and its culture. Thus in a significant way, learning is, we believe, a process of enculturation" (Brown, Collins, & Duguid, 1989). Within this perspective, the learning context (both social and cultural) is under heavy investigation, from a view which states "that agent, activity, and the world mutually constitute each other" and that knowledge must be presented in an authentic context, in which this knowledge normally is integrated (Lave & Wenger, 1991). For these researchers the environment is a complete part of cognitive activity, and not just a set of relation through which context-dependent cognitive processes are expressed. Collaboration is seen as the process in which a common understanding of a problem is created and maintained. While the earlier approaches focused on the inter-individual levels, common-cognition and situated learning are now focusing on the social level where new concepts are being analyzed as a group-product.

From constructivistic-/situated learning theory we have decided to emphasize three main principles of learning and to look upon these in relation to design of internet-based learning environments:
1. Focus on active actors with intentions and creativity, searching for knowledge and collaborators.

2. Focus on collaboration and communication between the actors

3. Focus on learning in a total context/environment

So, how is it possible to design internet-based learning environments on these main principles?

**Structuring a virtual competence environment**

Based on these learning theoretical principles, we have tried to find out how available services on the Internet can be structured and used in order to promote a learning environment with active actors genuinely collaborating in a total context. The resources/services that are available in a virtual competence network can be structured in relation to tasks and activities to be emphasized. We have chosen to structure the services into five areas, according to which tasks/theories that are to be dealt with: A presentation-arena for presenting and receiving scientific literature/theories, a knowledge arena for accessing library services/on-line services and other accumulated knowledge, a working arena to manage collected material/information and produce new material, a private arena to make personal notes and reflections, and last a communication arena which, together with the working arena, make up the main core of a learning process based on constructivism and situated learning.

**Presentation-/lecture area**

The criticism against behavioristic learning theory is especially directed towards the belief that "someone can teach someone something" and that learning can be managed by the teacher. Thus, the possibility of spreading huge amounts of science material in a simple and flexible way by using network-based systems, shouldn't be confused with learning. Science material can be presented and mixed together via network-based systems through different kinds of media, such as text, drawings, pictures, animation, video, and audio. It all depends on the one(s) having the knowledge how this knowledge can be made available to others. The activities related to this arena are on one side to present information and on the other side to receive information. And, vice versa, if the communicating parts are equal. Based on cognitivistic principles, this arena will be important if the material is organized properly.

How great the activity related to this arena will be, depends on the amount of information to be mediated. For example, there will be relatively much more activity on this arena if the system is being used in relation to a defined
material/course (reproductive learning), than in relation to creation, e.g. related to learning organizations.

**Competence area for accessing library services and other accumulated knowledge**

This area is also an information area. However, it's main emphasis is to actively search for information/answers for the topical questions. Thus, accessing databases and libraries will be in the form of searching in relation to accumulated and stored information, while requests made to an oracle service may either be contact with resource persons and/or with accumulated information, e.g. stored answers in "Frequently Asked Questions" (FAQ). The services in both the presentation area and the knowledge area must first of all be seen as resources in relation to the actors learning process.

**Working area for organizing and producing science material**

Area for personal organizing of material. This is the real learning area, if based on constructivist learning theory. The learning take place through the actors treatment of information and production of new material. The tools available in this area are the same as those in the presentation/lecture arena, but now as tools for organizing and producing your own material. Group-ware tools are included also here in relation to personal work but communication with others is done in the communication arena. The workbook is also here when working with personal material but the storage of this one is in the private arena.

**Private area for personal notes and reflections**

Basically, the private arena is supposed to be used for storing personal material. The private workbook is stored here.

**Communication area for interaction and collaboration**

Area for communication and organizing in relation to others. Together with the working arena, this is the most important learning arena if based on situated learning. Here, together with group-ware tools, e-mail and the World Wide Web (WWW) create the communicative foundation.

**Tools and help services to realize Learning Environments in Internet - Interactive learning system, (ILS)**

In order to realize this new network-based learning environment it has been necessary to develop a number of tools and help services in order to increase the smoothness of the layout and the production of network-based scientific literature, and support for the learning co-operation. This tools consist of an infrastructure tool based on the Internet and includes tools for hyper-/multimedia-systems, video on demand, animation, object-orientated design based on constructivist learning principles, info-search in free text, a knowledge test based on free text, an oracle-/help service, a workbook, and a plan for student administration. We have also developed specifications for necessary services in group-ware, but this tool is not realized yet.

The Infrastructure tool creates the complete frame for the learning area and ties the areas/functions together. Consequently, the areas are able to communicate and use the resources across the borders.

The tool for creating Hyper-/multimediastystem on Internet make it possible to use media such as video, navigation, lecture-paths, personal paths, lectures on video synchronized with information in the hyper-system, and the possibility of making personal notes for each node, personal working arena, choosing language, fonts, colors,
The Video on demand tool edits video (e.g. a lecture) and makes it possible to synchronize events in order to find the desired picture/sequence. By using this tool it also becomes possible to edit overheads and animations in relation to a video sequence. This is useful if one wants to use several media in order to strengthen a message. Video on demand is available from 28.8 kb and up to a few hundred, or a few mb if needed. We have chosen to connect the main service for video to Video On Demand instead of Multi Cast. The reason for this is i.a. to be able to reuse already produced material without conflicting the law, copyright. Multi Cast is to be considered as broadcasting and thus it doesn’t allow for such an opportunity.

The Animation tool makes it possible to create animations which doesn’t demand much band-with. It is also possible to control the animations step-by-step from a video-lecture. For example, this may be desirable if one wants to illustrate a process and explain what’s going on simultaneously.

The Object-oriented design tool makes it possible for a teacher or a student to build a set of objects by using their own knowledge about a subject. Based on the objects one may easily construct systems in which the system and the work progress are visualized and animated during the execution.

By use of the tool for Info-search in free text one may search for information in free text; the information and the search are compared by use of vectors. Nonsense-answers can be rejected, answers with a touch of reason can be guided. Here, the teacher can decide where to draw the line between nonsense and reason.

The Oracle service/help service tool structures and creates a connection with an on-line help service. Questions and answers are stored for later use in an automatic service for "Frequently Asked Questions".

The Digital workbook structure tool gives possibility to make sure that learning is done through one’s own activity and production, activities in an electronic workbook are very important. The workbook is a frame into which the users are supposed to put their own product, and not a book where you fill in the correct answers, or where you practice defined tasks. This workbook is also available to course administrators/tutors in the period of study, so that course-related discussions are connected to the work of the learner and which they show through the product that the workbook will become. It is also possible to share and develop a workbook in collaboration with other students/partners. Connected to the workbook, there are tools for editing, asking for help and possibilities for tutor/colleges to add comments. It is possible to divide the workbook into chapters. Which tasks that are connected to each chapter will depend on whether there is a special course to be completed or whether the workbook is being used as a public domain for documenting the work in progress. If the workbook is to be used in connection to a specific course content, it is up to the course administrator and those participating how to proceed. One example of how to structure the workbook:

- Preface, where the participant presents himself/herself:
  - A chapter where a group of persons, single or together, creates an overhead series in order to present a part of the material to each other. That is, the participants function as "teachers" for the rest of the group. They do this in turn so that everyone gets the opportunity to present course material to the others in the group.
  - A chapter for writing a summary of lectures/presented material.
  - A chapter for practicing exercises. These are solved through discussions and by working in groups.
  - A chapter for a project assignment.
  - A chapter for miscellaneous.

From a learning theoretical perspective, based on active creative actors in genuine collaboration, we think that the working area and the collaboration area, can create the foundation for such an active collaborative learning process, while the presentation area and the knowledge area can be considered more as resources for the actors work and production. A well-designed network-based learning environment can, as we see it, create the foundation for
active, creative collaborative learning.

Network-based learning environments and learning organizations/social context

According to the principle that learning takes place, and is closely connected to social context/environment, the network-based environment may either be seen as the total learning environment, separated from the social reality where people belong, or as an integrated part of a bigger social context. When collaborating with companies, municipal services, regions, we have tried to see virtual competence networks as integrated parts of an organizational context representation. However, such an integration demands focusing on internal learning processes and organizational development at the collaborative parts. That is, at both the knowledge institution/university and the company/service. From our point of view, it is through the possibility of collaborating and communicating through network-based environments we enable the possibility of collaboration between environments that genuinely seek each other’s competence without considering time and place. However, this requires good effort and a conscious mind, if not, the network-based environment will operate outside the institutions, both from the universities and the companies, and will not be an integrated part of the context.

The Rørvik-model

As an example of such an integrated collaboration-model for developing a total learning environment we want to mention the Rørvik-model (OECD, 1999). The model is based on a close Internet-based collaboration between a small coast society (Rørvik), four universities/colleges (NITOL – Norwegian net with IT for Open and distance Learning) and a local upper secondary school (Ytre Namdal Upper Secondary School - YNVS). The local high school plays the role as the worlds best mediator to Internet-based university education and training for the local population in this area. This due to the close collaboration between the local upper secondary school and local industry.

The background to this project was that one of the companies in Rørvik (Telenor Mobil) needed higher education for their employees, and therefore they contacted the local high school (YNVS) to ask for help for such education. YNVS then contacted NTNU/NITOL, which has for the last few years been arranging off- and on-campus learning based on Internet solutions. Later on, this collaboration has grown to concise several companies in the Rørvik area, municipal authorities has joined the project, i.a. many of the teachers in the area have attended continuing vocational training at university level through this collaboration. The results are very good. In 1998, of those who had started a locally mediated Internet-based university-/college course, 96% graduated. There were only 4 out of 350 who failed the exam, and the average grade was 0.2 above the average for other students who took the same courses at universities/colleges.

Conclusion

Based on constructivism and sociocultural approaches we have tried to arrange for a network-based learning
environment that supports active, creative actors in a genuine collaboration within a total context. From our point of view, there is a great challenge in seeing the context as the foundation for integrating network-based learning, this applies not least to lifelong learning and continuing vocational training related to working place/environment. We have up gained some experience in this interesting area by developing tools so that people with competence in one or several specialist areas could be able to express this knowledge in an internet-based competence-network, and to collaborate with others. There is still a lot of work to be done, both with learning theory, methodology and tool development.

Taking ID On-line: Developing an On-line Instructional Design Course

Jennifer B. Summerville
Assistant Professor
Division of Instructional Design and Technology
Emporia State University
Emporia, Kansas, USA
summervj@emporia.edu

Abstract: Educators in higher education are increasingly being called upon to design, develop and deliver courses via the World Wide Web. Although reasons for the strong push to develop on-line courses are varied, it is clear that the perceived need for such courses is steadily increasing. Also needed are prescriptions for creating courses that are dynamic, interactive and timely. The purpose of this article was to explain, in detail, the process of developing a Masters-level instructional design course for delivery on-line. Rationale behind the need for such a course, development procedures, successes/failures, and prescriptions for future developers will be discussed.

Introduction

Increasingly, higher educators may find themselves in a new situation. They may be asked to design and develop courses for delivery via the World Wide Web. The reasons for increased pressure to develop these courses are varied. However, in an article by Gubernick and Ebeling, (1997) the authors suggest that quite possibly, universities will have to change as we know them. According to the authors, in 1994, Peterson’s Guide listed only 93 schools that delivered instruction via the web. Just five years later, there are literally thousands of courses offered via the World Wide Web.

In order for universities to compete for students, administrators recognize the need for change. For example, Cagney (1997) suggests that no type of college or university will be spared from this trend. Even private universities could be threatened if their students can take a significant portion of their courses on-line.

In an article in the Chronicle of Higher Education, the author discusses the fact that even the “more elite” universities may be jumping on the bandwagon. Universities such as Yale, Rice, and Duke are considering offering distance courses ranging from continuing education courses for alumni to distance-based graduate courses to general courses to the public (Blumenstyk, 1997).

Background Information

The state from which the on-line course was delivered is in the top ten in terms of total area yet the population centers are scattered throughout the state. In addition, in order to meet the changing needs of
students, the administration at the university has placed increase importance on the development of courses for delivery via the web. Faculty members who design and develop web-based courses have received grant money, may be able to receive release time in the future and it may have a positive influence on the process of tenure and promotion.

This author used the ADDIE model of Instructional Design to design and develop an Instructional Design course for on-line delivery beginning in the Summer of 1998. This is the first of the core courses in the Masters program to be delivered on-line. The dean of the college as well as the chair of the department were extremely supportive of the design of this course.

Analysis

The students who take courses Instructional Design are usually Masters students in an Instructional Technology program located in the mid-west. The course is also a requirement for certification in a Library and Information Systems program and an increasing number of those students have enrolled in the class. They are usually in-service or former K-12 teachers and have a range of technical expertise. This is a required course yet most students are self-motivated and enjoy learning about the systematic design of instruction. Specific technology to be used by students is not emphasized—students have designed instruction using print-based media, projected media and hypermedia.

This course presents a systematic method for the planning and development of instructional programs. In addition to examining the research supporting contemporary methods of instructional design, students will apply instructional design principles to the development of an instructional lesson.

Upon completion of this course, students will be able to demonstrate skills, which will assist them in becoming professionals who, are critical thinkers, creative planners, and effective practitioners. Each student will be expected to:

- Describe the basic components of instructional design.
- Summarize the research supporting the various elements of systematic instructional design principles.
- Develop an instructional plan that includes learner and task analysis, instructional design, instructional materials development, a strategic plan for the implementation, and a plan for formative analysis (Summer '98)
- Produce an instructional lesson according to the systematic plan developed (Summer '98)
Design

The design of this course took several months. This author began the conceptualization process of creating a web-based course in the fall of 1997. The biggest obstacle to this course was having enough material available on-line without running the risk of violating copyright laws. Fortunately, there were many sources available on-line. It is extremely important to stress that this author also believes it is important to ask permission to use these sites as a part of the class. The URL's for sources are available through the following website: http://www.emporia.edu/idt/id/design.htm.

This course was offered as a traditional class in the fall of 1997. It was important to this author to keep the content in the distance class as close as possible to the content in the traditional class. Although the class used the ADDIE model as the basic model of Instructional Design, many other models were discussed in class. Much of the class time was used to discuss the "pro's and con's" of several traditional and non-traditional methods of designing instruction. Thus, it was important to set up a listserv for the purpose of class discussion. Examples of questions and responses will be included in the presentation and available through the following website: http://www.emporia.edu/idt/id/design.htm.

Development

This author used Adobe Pagemill 3.0 to create the web-site for class. The site itself consists of three frames: a "contact" frame (with e-mail and street address information plus phone numbers), a "menu" frame (with course syllabus, questions of the day, on-line resources, and directions for subscribing to the listserv), and a "main" frame which contains information loaded from the menu.

A listserv was also created to handle the class discussions. These discussions took place on a regular, almost daily basis during both summer and fall semesters (deadlines were emphasized) and were based on the essential elements in Instructional Design, models of Instructional Design, and outside readings.

The students were required to submit projects via e-mail during the summer ’98 semester. There were a total of seven small projects due during the course of the summer session. These projects were designed to represent each of the phases of instructional design from Analysis to Evaluation. "Analysis" was broken down into three separate projects: Needs Assessment, Learner Analysis and Task Analysis.
During the fall semester, in lieu of projects, students were required to analyze cases in small, pre-assigned groups. Students were directed to read the cases posted to the website, develop their own conclusions, and then submit them to the group. From there, the group would try to reach a consensus of opinion regarding the questions posed.

Implementation and Evaluation

This course was delivered in the summer and fall of 1998. Evaluations as a whole were favorable for the summer semester, but it was evident that the process of submitting projects via e-mail was quite frustrating, both for the instructor and the students. Due to the difficulty in sending and receiving projects via attachment, the course was changed to a case-based course for the fall '98 semester.

Using cases for analysis has proven to be quite rewarding. This author chose to create new cases due to the fact that the case study textbook of choice, "The ID casebook" (Ertmer & Quinn, 1999) was not available for review until just prior to the start of the fall semester. There were a few problems with the clarity of directions in the cases; missed links, making assumptions, not asking questions, etc. However, the problems did not seem to interfere with the students' knowledge of the case. The problems will be corrected in time for the summer '99 class.

Results of the evaluations during the fall '99 class were favorable, far exceeding this author's expectations. However, the summer class evaluations were not as good—students cited that there was too much work and not enough time. By the time the summer evaluations were received by this author, it was too late to make the changes necessary to create a better course.

This author elicited feedback on an ongoing basis from the students enrolled in the fall '99 course. The students were extremely helpful and provided feedback on an ongoing basis which will help in the design of the summer 2000 course. Students requested a less formal chapter write-up (choosing personal reflections instead of summaries), more lead time on cases, a better way to know where they stand in terms of their grades, and a more reliable method for contacting group members than e-mail.

In light of this feedback, this author has decided to use a webcourse template system called WebCT. This program will allow for instant grading (as the gradebook can be accessed from any computer), chat rooms (for group work), instant reflection posting, and better methods for self-assessment of progress. As everything is contained on the site and chat room conversations can be recorded, it will be
easier for this author to make certain that students have submitted all of their work in a timely fashion and that group work has been equally shared among members.

Conclusion

The importance of designing web-based instruction is clear. University personnel must prepare for the inevitability that courses delivered traditionally may need to be delivered via the World Wide Web in order for the college or university to remain competitive. What the exact process of conversion looks like for courses such as Instructional Design remains to be seen.

Real-time courseware design: the LAVAC Video Sequencer®

Tony TOMA
Language Research and Teaching Department
Toulouse III University
France
toma@cict.fr

Abstract: Teachers have already acknowledged the richer learning environment and interactivity of multimedia teaching, its flexibility to different learning styles and a learner's control that allows him or her to engage fully in the learning process.
But they still have problems in courseware design because their work is mainly centered on exercises and not on what the machine can do best. This is why a new device has been designed to allow them to use their videos. The video sequencer can complete real-time automatic segmenting of sound and images and automatically insert an answering time span after each sequence.
Coupled to IBM ViaVoice, the teacher can speak during this time span to create the transcript from which the necessary textual help will be derived for an easier aural comprehension. A 5-minute video will then require no more than a few minutes' work from the teacher to produce a two-hour student session.

Introduction

The aim of IT for a language teacher is to provide interactive simulations of language use through individual virtual learning environments. This highlights an important issue: the need for a particular multimedia learning system and courseware that will actually respond to specific user requirements.
Therefore when the first teacher-controlled multimedia computerized language laboratories appeared six years ago, the challenge was to enable teachers to use the built-in authoring system without any previous computer experience. Several easy-to-use programs with user-friendly interface have been developed to help them to digitize and edit sound, attach pictures and sounds to gap-filling or multiple-choice exercises, and achieve a multimedia integration that diminishes the weaknesses of each media used separately.
Such systems allow the design and development of a multimedia-based tutoring through embedded training packages and networked communication applications. They should offer learners' support, assessment tools and the maximum interactivity between teachers and students whether the teacher is present or not.
But if it is essential to know the possibilities of the system, it is even more important to define as accurately as possible the types of learning procedures that need to be implemented to help the teacher produce his own customized courseware and eventually a powerful interface for learning.

Objective

The building-up of knowledge representation and learning will occur through some proposed tasks but these tasks should be appropriate to a maximum number of cognitive learner types (analytic, synthetic, kinesic, etc.).
The problem is then to implement the metalinguistic learning activities that will suit these different cognitive types knowing that each learner more or less belongs to most or all of these types.
Several solutions can be proposed among which a hierarchized list of different deduction techniques for sound recognition and understanding, i.e. wave spectrograms, phonetic transcription, lexical hints, written form of words and translation. Etymology, knowledge of the discourse situation, contextual logic will be put into use to enable the learner to find the meaning of the words or the group of words by him or herself.
Everything should be designed to help and encourage the learner to carry out his or her tasks alone, with imposed hints if necessary for all of them and proposed ones only for those who need them.
Keywords in multimedia teaching are learner's control, hypernavigation, interactivity, and multimodality. But learner's control does not certainly mean no-time limit to answer nor an easy access to the solution. The problem
is that most courseware programs leave the learner free to read the solution just after a mouse click or to read the
transcript on an aural comprehension task. As a cognitive scientist and a linguist, I have therefore designed the implementation of ten fundamental prerequisites for a multimedia language authoring system: 1. multimediatizing or the use of the multimedia language directly from a didactized content of information the teacher will have in mind. Detailed design will be achieved through doing 2. multimedia expression through a coherent semiological code and a multimedia language still to improve and stabilize 3. easy-to-use authoring system for non-programming teachers 4. adaptation of the produced software to different cognitive types 5. adaptation of the produced software to different personality types 6. set of hints that will implement metalinguistic activities based on deduction techniques, so that the mental processes involved can be reused in other linguistic contexts 7. automatic segmenting with answering time and segment visualization 8. personalized access to the solution decided by the teacher in relation with the learner's metacognitive performance 9. presence of the teacher in the room for personalized tutoring while the learners work on the machines and communication activities in small groups still in the same room 10. possibility of real-time modifications for answering time, textual hints, questions or even mistakes ... on the part of the teacher.

Methodology

The implementation of these pre-requisites began in 1992 when I designed the LAVAC® (Toma, 1993). This acronym stands for "Laboratoire Audio-Visuel ActifiComparatif", i.e. Audio-Visual Active-Comparative Laboratory. Its development is still under way with an html version, but the decided objectives are now reached with the latest version (4.03.i). LAVAC has become one of the most popular computerized language laboratories in France since 1993, with around 5 000 software programs used in more than 150 university departments and high schools in France and abroad. The system consists of a complete network of student terminals, plus a courseware-design workstation, all linked to a server. It was the first to use a teacher's console for presential or distance tutoring, which avoids the well-known 'wandering' and twisted paths of a learner lost in a traditional Resource Center. A LAVAC courseware is in fact a set of segments or sequences with an automatically-given number plus a possible name or wording of your choice, linked to sound, images, videos, texts and tutor zones (for proposed hints or exercises), making it up to six different media altogether. This has mainly been designed for oral comprehension and production, i.e. for listening (with 24 listening modes) and recording, but the student can also type in his answers, either in a learning or testing mode, and will be guided by hypertext or hypermedia links in case of mistakes. The problem is that this tool may have been designed too early. Teachers were not ready yet. As Carlson (1998) puts it: "A technology-enabled curriculum should be conceptualized as a dynamic partnership among three agents: the student, the teacher, and the computer-mediated tools". Six years ago, few students knew how to use a computer and a lot of training was needed. Furthermore, the expensive machines (PC 386) were slow in playing the wave files which had to be short especially because these files were provided by a distant server through a Novell network. The network nevertheless was the only solution to overcome the low capacity of disks (540 Mb) and enable discrete or active tutoring. The three agents were not present at that time, but now the situation has changed. Students have become familiar with cheap machines powerful enough to play real-time full-screen videos in a 100 Mbit Windows NT network. Are teachers a problem? Most observers see them as conservative and technophobic. But this so-called negative attitude and the difficulty to educate teachers who, as educators themselves are sometimes the last persons to accept to be educated, should not be overemphasized, simply because teachers, and not the industry, are at the heart of the system. The main problem with teachers is that they see multimedia as a "combination of texts, audio, and pictures on a single platform. At its best, it should recombine the benefits of 'conventional' Computer-Assisted Language Learning (text reconstruction exercises, tests games, etc.) with those of videos, together with the advantage of

---

being able to jump instantly to the desired frame rather than having to rely on the rewind or fast-forward keys" (Eastment, 1999). Eastment synthesizes the problem and its solution in this comment.

The problem is to believe that multimedia courseware design just consists in digitizing different media already edited in a discrete way and in integrating them with an authoring system, even if as with LAVAC no programming is required (for at least 99% of the functions). The question for the teachers is how to integrate the different media. A complete rethink of their pedagogical practices has to be undertaken. Some are ready for it, some are not. The need for bringing "conventional" teachers into computer-literate ones has well been developed in Niederhauser (1996), but few training courses integrate an epistemological thinking on the changes involved in the didactic practices (Toma, 1997).

Few training courses explain as well that integration should not be carried out in the "ancient" way (still in use however) which consisted in giving scripts, audio and video cassettes, exercises on paper to team of developers that usually, because they are not teachers, have difficulties in understanding the specific teachers' requirements and produce a result often far from the one expected.

This is why I imagined the concept of multimediatizing2 which consists in the direct expression of a didactized content into a multimedia form. No storyboard is needed with the LAVAC system since for language teaching the privileged medium is SOUND. The automatic segmenting of the sound track will produce numbered sequences where text, image, exercises can be attached to if needed.

That is why the solution is in the use of what the machine can do best. Sound processing in LAVAC is real-time and the minimum pedagogical work on behalf of the teacher is to write the transcript and analyze the lexical and syntactic difficulties for his or her specific students. Help will be given in the corresponding text zones and images will be linked to the right sound segment as a prop to the discourse situation. Links are created by a simple mouse click.

Exercises are often difficult to implement with an authoring system. Ironically enough the most profitable ones are not the easiest to complete. The first one is note-taking that can be done on a simple sheet of paper or in a text zone very easy to create. This phase can be labeled "content appropriation" phase.

Then in the testing phase exercises will have to be taken and done with the notes (with possible comebacks to the informational content).

The first exercise is a written question one with open answers. An answering text zone has just to be linked to the sequence labeled "Exercise 1" and this zone will open when the student will select "Exercise 1" and click on "Record". The written answers are immediately recorded on the server for an instant retrieval in case of modifications or analysis by the teacher.

The second exercise is a transcription of a passage of the sound track. It is just the same as note-taking but all the words have to be written. A gap filling-exercise could then be easily set up with a blank for all the words or just for some that need to be tested but a transcript on papers that can be given to the teacher proved as effective since the point is not to know that a word has been badly understood, but to understand why. Students really demand the teacher's opinion on their problems just because they can see the teacher has more time for themselves.

The third exercise is a so-called "simple" exercise since it is a repetition of a part of the sound track. It is automatically implemented by LAVAC since a recordable answering time span is set by default after each segment. But this task is not so easy for the learner since he has to discriminate the words, understand them, remember them and pronounce them in a limited time.

The fourth exercise consists in oral questions that have to be answered orally. Here the sequences are manually created by a mouse click, the question is recorded by the teacher and he decides upon the length of the answering time span by entering a number of seconds.

The fifth is a translation exercise, which is from a computer point of view exactly the same as the first. The teacher types the sentence to be translated and creates an answering zone. The students' written answers will then be automatically saved in their respective files.

Most teachers use this model even if gap-filling or multiple-choice questions are also possible.

However the majority of teachers who discover multimedia teaching, who agree to use multimedia on the condition that they produce their own educational software because the available programs on the market are too general and will not satisfy their didactic needs, still do not know what to do since they think they will not have time to learn how to use even simple tools.

For this reason, I designed a new system derived from LAVAC that presents a new student interface of the LAVAC audio-segmenting device that will avoid teachers to link text or images to the sound segment.

This device, called "Virtual Recorder", is an audio-sequencer and appeared in 1998. The problem was even more complex with videos.

Automatic segmenting of the sound AND the images was not easy to achieve for synchronization reasons between these two media. Moreover the sound volume is sometimes kept constant due to music background on some videos. Since automatic segmenting works by the detection of blanks or volume drops in the sound signal, this problem of background music had to be overcome. This video-segmenting device or "Video Sequencer"® appeared then in March 1999.

Training for teachers is thus shorter. An exercise sheet can even be given to each student at the end of their lab session. Exercises can be done at home and the correction will take place in a normal classroom. If students spend less time in the language lab a greater number of them will be able to use it.

The methodology described here can therefore fit different didactic contexts. Three software tools can thus be used: the complete LAVAC software (authoring system, student interface, teacher interface (for distance tutoring), networking tool program for complete multimedia courseware, the audio-sequencer and the video-sequencer both compatible with the LAVAC student interface.

Results

Many teachers have produced several educational programs with this methodology by using the complete LAVAC toolkit (Toma, 1996). Tests have occurred for six years now with an average of 300 students a year.

Students appreciate the possibility of retrieving their recordings (text or sound) more than attractive exercises that are mainly complex to build. They sometimes consider the teacher as a tool when they urgently need him or her in case of a problem, but most of the time as a guide and a confident for their own particular problems.

Experiments are still in progress with the audio and the video sequencer, so I would like to limit the results to the use of the audio segmenting device, the use of the video sequencer alone, and the use of this tool with IBM ViaVoice and the LAVAC courseware station.

The LAVAC segmenting device

The segmenting device needs first to make a distinction between what is language sound and what is not. This can be set on 1-127 scale. A high level will be used if the background noise is important. At a value of 30 segmenting still takes place but the words have to be pronounced loud, if not they might be interpreted as noise. A value of 5 is used in a quiet environment. Under 5 it has to be very quiet. The computer noise may then be interpreted as language and therefore no segmenting will occur since it is continuous!

The normal values will then vary between 5 (quiet) and 15 (rather loud).

Another setting concerns the value of the answering time span created after each segment during the segmentation process. The length of this span will be proportional to the length of each created segment. The proportional value can then be parameterized in a 10 to 999 % range. I usually use a 150 % value for repetitions, which means for instance that there is a 3-second answering time after a created sound segment of 2 seconds. But if this answering time is used as an automatic pause in aural comprehension for a better understanding process (because slower) and for note taking, the value should preferably be set at 3 to 400%.

The digitizing of the audiocassettes of the old cassette labs has also been planned. At a 100% value, the duration of the recorded blanks of the cassettes (corresponding to the answering time spans) are respected. But teachers find it necessary to diminish the values of the blanks simply because the student language level has raised. A complete recording of the cassette would be necessary with a traditional recording system either analog or digital. With this system, the recording of the cassette can be done in real-time in the server with a different value of the time spans. On top of that if the new value proved unsatisfactory, it can be changed while the students are working on the network.

The video segmenting device uses these LAVAC parameters except for the audio cassette settings.

The student videosequencer interface

3 A screen image could have explained more than words these different settings. They cannot be inserted here in a 6 page article. Nevertheless these explanations are available with images on my ftp site: ftp://130.120.112.2/Tomy/San_Diego

4 For more details on the system see http://www.alizes.fr/cp3i
The Video Sequencer uses the whole set of didactic prerequisites this time applied to an analog VHS recording or an analog or digital camcorder recording or a live satellite program.

When the video starts to be digitized, it can immediately be seen on each student monitor. Sound is heard but no student control is possible. Nevertheless, if a student comes late, he will see and hear the video from the beginning and not from the part that is being digitized when he arrives. Or if a weak level student thinks he will not have enough time to understand more than 3 minutes of video, he can stop the visualization for a while and resume it after, when the first part has been completed.

For a better data transfer through the network, the AVI file sent to each student PC is MJPEG compressed (about 7 times).

The interest of the system is that segmenting occurs during this data transfer but is not visible when the video is played for the first time. As soon as digitizing is finished, the system automatically turns itself into the segmenting mode.

The segmented video immediately starts on the recording mode. Experience has shown that a learner will tend to watch the video intuitively as on television, which may induce a passive attitude. On the contrary, the recording mode shows that the machine waits for an action on the part of the learner. The first segment is played with sound waves in green on the "teacher" track, and after the first segment a red line appears which is the sound track of the student when s/he does not speak. As soon as the student speaks, waves appear in red. But if he does not, the video goes on and the second sequence is played. The video will thus be automatically paused, which will favor a better understanding and note taking.

Unexpectedly, most students stop the video after three or four sequences have been played, just to see the "menu" of their work. Each segment is numbered and represented by a square on a line. It is then possible, using the direction keys, to move rightward or leftward on this line, or to go straight to the end or the beginning by pressing the appropriate keys. In fact they want to be aware of the average length of each segment since 60 segments for a 3-minute video will be much easier to listen than 10.

In each square small lines appear in different colors according to the status of the segment: yellow for non-played segment, green for a played segment, red for a recorded one and green under the red when the listening of a recording has been made.

One of the most used trick is to click inside the sound wave to insert an index from which the video starts immediately and tirelessly. After each click of the mouse a vertical black line will come up in the yellow line. These indexes set by the students will help him find back the segments which posed comprehension problems to him. He will not need then to jot their number down for an easier retrieval. A recap key will help him play the segment at the place of the index when necessary.

The pedagogical interest of sound waves were questioned at the beginning. Some teachers even saw them as a gadget. I even had this dubious attitude. But English pronunciation is so stressed compared to French that this first forced students to speak louder in their microphones to make their spectrograms as accentuated as the master track's, and second, their could visualize sounds that they would have noticed otherwise. Even when they still do not understand it, they can make the difference between what is understood and what is not.

Three "working" modes have then been implemented to increase the range of learning tasks: teacher then student (sequential mode) for recording, teacher and student simultaneously (but in the recording mode, this would mean that the student knows the transcript by heart), and role play (in that case, the student can answer freely to questions asked if s/he takes the role of the interviewee, or know them by heart if s/he takes the role of the interviewer. Role play is the favorite activity of the students because they suddenly have the feeling of becoming part of the video (at least their voice)!

Another surprising result concerns the listening of students' recordings in the sequential listening mode. The LAVAC setting reproduces the classical model of the language lab: teacher listening, student recording, teacher's correction, student's repetition of correction. I chose a different option for the video sequencer. After the recording phase, the listening phase starts with the student's recording and not the teacher's one. Tests proved that students were much more attentive to the teacher's production (the master track in that instance) after they have heard their production than in the opposite way. The reason for that still needs further checking, but it seems that the student is first eager to hear his or her recording. If he hears the teacher's track first, he will not listen to all since he is awaiting his production. When he has heard him or herself, he is more prone to listening to the right pronunciation, so that s/he will become more conscious of the distance between both productions and will immediately try to diminish it.

The teacher videossequencer with IBM ViaVoice and the LAVAC courseware station.

After a real time segmenting, the teacher has just to repeat each segmented part of the sound track in the following blank created by the system. Words are then written by Via Voice in a special window with a 90% accuracy but the silence in the recording room must be total.
A LAVAC lesson has first been prepared and copied as a model. Hints can then easily be made from the transcript and pasted in a window of the corresponding LAVAC sequences. Students will therefore be able to type their own transcript using the aids. This transcript can be visualized by the teacher through the network and when sufficient work has been accomplished by the student, the correction can be sent to him or her. All links to a database for vocabulary, grammar, or civilisation purposes can eventually be made, with the necessary connections to the Net.

Conclusion

More than 5 000 LAVAC software programs are being used in French universities. A number of experimental protocols are still in progress mainly carried out by cognitive scientists. The video sequencer seems to be the easier and more efficient tool to use for non-programming teachers. At least this is perhaps the solution to engage them later in a full courseware design process.

References

Abstract: Current online tutorials were limited to one-way distribution. The learner was unable to negotiate what they wanted to learn and how they wanted to learn. A database-driven tutorial was designed to implement learner-centered pedagogy. A web-based database-driven tutorial was used to support pre/in-service teacher education in learning of web page creation. Pros, cons, and revisions are reported in this paper.

Current Problems

Current computer-based tutorials have been constructed with a linear approach; learners go through a long list to select one, or more, tutorial(s). Contrary to the learner-center instruction theory, current tutorial design does not provide an opportunity for the learners to negotiate and reflect on what they need and want to learn. The tutorial "feeds" learners information that is unnecessary mingled with information they need. The tutorial instruction is not individually customized. The current schemas require time-consuming efforts to select the desired tutorial. These maneuvers neither provide the opportunity for learning nor encourage critical thinking during the learning process.

Database-driven Instruction

Database-driven web-based tutorials engage more critical thinking and interaction in the learning process and are proposed to solve the deficits discussed above. This new design for a web based instruction (WBI) tutorial was applied to a graduate level course, EMC 598 Internet for Teachers, to support the creation of web pages. In this class, students learned how to integrate Internet technology into their classrooms. The content of the tutorial is creation of a web page utilizing three different HTML editing applications. Each time tutorial support for web page creation is accessed, a search function is required (Fig. 1) and performed that displays a duplicate of the current tutorial design (Fig. 2). The learner is required to negotiate, specify, and analyze their needs, then conduct a search on the database by specifying different field search criteria. The learner is able to specify the search criteria, subjects, and levels of skills, applications, and search parameters to negotiate the learning process. After the search is conducted, the database will generate the results with multimedia components, text, still images, and an animated demonstration with audio. The learner is not forced to accept all of the components rather the learner can customize their preferred components to engage this learning process. This design demonstrates a true learner-centered instruction.

Querying the tutorial database is the first phase of the Database Instructional Project, while filling in the database and designing the database structure are the second and third phases of the project. This paper focuses its discussion upon querying the tutorial database.
Database Name: tutorials

Displaying records 1 through 1 of 1 records found.

**Step 1** Highlight the text whose size you want to change.

**Step 2**
Click the pull-down menu from the right-top corner. See below:

**Rationale**

Students are engaged in critical, creative, and complex thinking through utilization of learner-centered WBI tutorials. Querying a database requires that learners evaluate the questions and determine a strategy of searching.
and sorting to answer their query. For example, to learn how to insert texts, learners need to search the field of subjects, identify their HTML levels, and evaluate the media format field. Thereby, learners are required to recognize fallacies, verify information, recognize patterns, and identify assumptions, ideas, and sequences of information, while comparing and contrasting information, using logical deductive thinking, and identifying causal relationships.

Fewer creative thinking skills are involved in querying a database. Querying a database requires learners to predict, speculate, visualize, and intuit responses. Answering queries effectively requires that learners develop a “feel” for the database and its contents.

A number of complex thinking skills are required for querying a database. Learners need to sense and formulate problems and apply problem-solving skills. Decision-making requires that learners make a selection and evaluate their choices when the search results are available. If the search results are not satisfactory the learners are required to find alternatives as an element of the problem solving process. These designing, problem solving and decision-making processes engage learners in developing complex thinking skills.

Literature Review

Literature reporting the use of a database to support instruction is scant. A few articles regarding knowledge-oriented database designs and designs producing thinking skills were identified. Rooze (1988-1989) observed that preparing and searching a database would help students analyze, synthesize, and evaluate data, but stressed the need to distinguish between teaching how to process information and how to think. Further, Rooze (1988-1989) appreciates the database as a tool in teaching social studies but maintains that the primary goal is to teach thinking skills. Watson and Strudler (1988-1989) designed a lesson based on Taba’s Inductive Thinking Model that provided a set of strategies to enhance the teaching of higher order thinking skills with the use of databases. Students were expected to analyze, synthesize, and evaluate information to engage in higher order thinking.

Knight and Timmons (1986) discussed the advantages and limitations of database software in meeting the educational objectives of history instruction. Many studies on utilization of databases were conducted in the field of history education. They all concluded that the database helped students to appreciate the content, strengthen critical thinking skills (Little, 1995; Mernit, 1991; Miller, 1995), and produce a higher order of thinking (Pon, 1984).

Database instruction on the Internet is a giant step forward. Student publishing and peer evaluation were used to enhance learning by graduate students on a web-based database-driven system of instruction (Tu, 1999). Tu (1999) concluded that web-based database-driven instruction enhanced students’ critical thinking, and knowledge construction, and provided learner-center environments. More interactions were identified as well. In this class, students post their assignment to the proper web fields, such as the title field, the body text field, keyword fields for the title and the target audience, and submit it. The assignments were converted into an HTML format and a searchable database upon submission because the keyword fields are created at the same time. Students are asked to evaluate each other’s assignments by using an online evaluation form. Evaluations were available immediately after they had been submitted. It was concluded that web-based database-driven student publishing and peer evaluation increase the level of interactions.

Database is used to support instruction in problem solving. Foyle and Yates (1993) supported the use of databases in problem-solving activities. They concluded that when students developed their own databases they acquired significant social study skills and history skills.

Databases can also be used in computer-mediated communication (CMC) and in multimedia and hypermedia knowledge base instructions (Jonassen, 1996). Using a database to support CMC allows information retrieval and manipulation. One who has experience with manipulating data structure will be able to transfer to information-retrieval processes. This transfer will enhance their ability to search for information in any kind of knowledge base on CMC. Databases also provide a structure for developing multimedia and hypermedia knowledge bases. Database creation permits learners an opportunity to structure and manipulate information in a format that positively affects the use of information processes.
Advantages

The process of creating and manipulating a database is inherently constructive, meaning that learners are actively, mentally engaged in learning rather than merely reading or responding to questions. Knowledge construction is fostered through the intentional searching process and by linking information to the learner's own schema. Critical to the knowledge construction process is the articulation of the learner's behavior while performing a database search. This search facilitates and strengthens connections between elements of information and results in higher-order thinking and meaningful learning. This tutorial database, a learning environment that requires learners to reflect upon personal knowledge, and state their learning intentions, produces cumulative, progressive results for the group.

Another advantage of these database-learning strategies lies in the powerful searching and sorting capabilities of the database. The process of comparing concepts and relationships in the database is greatly facilitated by the speed and reporting capabilities of the tutorial database. Learners can search their databases in any number of ways, e.g. to provide an overview of all the subjects in certain HTML editing applications or to compare particular skills between or among different HTML editing applications, to arrange information to make more sense to them, to query all intermediate skills in certain applications or to use logical parameters, and/or to produce customized tutorials. This powerful querying ability allows learners to engage in different approaches to learn different web page creation skills.

WBI tutorial database, unlike other database designs, allows learners to access the Internet where browser access exists. The proprietary application is not required to access the tutorial database. The convenience of accessibility provides more opportunity for learners to engage in critical, creative, and complex thinking.

Disadvantages

The downside for the learner-centered WBI tutorial database was that the animated component required a plug-in for the client web browser. This caused several problems. The plug-in required for LotusCam was not installed on most web browsers. Therefore, it required the students to download and install the plug-in on their web browser. Many of students had difficulties installing the plug-in on their web browsers. Second, the AVI files require a great deal of server memory. With the tutorial growing, it fills the server memory quickly. Third, the web-based database-driven tutorials require a tremendous amount of time from the instructor or the instructional designer.

Software and Hardware

Various computer applications, FileMaker Pro, Claris HomePage, and Lotus ScreenCam, were used to create this tutorial database. FileMaker Pro 4.0 by FileMaker is used to create the database while HomePage by Claris is applied with use of CDML (Claris Dynamic Hypertext Language), a proprietary HTML, to create HTML pages. Collage Capture 1.0 and Lotus ScreenCam are used to create graphical tutorials and multimedia tutorials. The entire program is run on a PowerMac 7300/200 with 32 MB RAM installed as a web server.

Hardware requirement for installation of FileMaker Pro 4.0 is:

MAC
A Macintosh or Mac OS computer with at least 8 MB of RAM (16 MB or more recommended)
A CD-ROM drive
System 7.1 or later, or Mac OS 8 or later

PC
An Intel-compatible 486/33 PC or higher with 8 MB of RAM (16 MB or more recommended)
A CD-ROM drive
Windows 95 or Windows 98, Windows NT 3.51 or later, Windows for Workgroups 3.11, or Windows 3.1
Hardware requirement for installation of LotusCam for Windows 95 is:
- PC
- PCs 386 or higher
- Windows 95
- CD ROM media
- VGA 16-color or higher graphics adapter and monitor
- Parallel port or sound card-enabled device support by Windows 95
- 10 MB free recommended for recording

Hardware requirement for installation of Collage Capture is:
- MS Windows version 3.1 or higher, MS Windows 95/98, or MS Windows NT, hard disk recommended
- An IBM compatible 3-1/2" high density floppy drive (for installation only)
- 2 MB of disk space to hold programs and files. Additional disk space is required to save your own images.
- 4 MB of available memory.

Hardware requirement for installation of Collage Capture is:
- PC
- Windows compatible computer with a 486 processor or better
- Windows 95 or NT 4.0 or later
- 12 MB RAM (16MB for NT)
- CD-ROM drive (for installation)
- Mac
- Mac OS compatible computer with 68020 processor or higher
- System 7.1 or later
- 12 MB RAM
- CD-ROM drive (for installation)

Revisions

Several revisions are to be made after the student trials. First, the server is not robust enough. When a high demand occurs, the server was unable to process queries fast enough. This database is to be moved to a Microsoft Windows NT 4.0 server with a faster processor. Second, the plug-in required to run animated tutorials created downloading and installation difficulties. The file format for animated tutorials should be converted to a non-plug-in required file format or a common plug-in. Third, although FileMaker Pro 4.0 is able to process the tutorial database, it is not an efficient scalable database. During the publishing time, a plan moving from FileMaker Pro 4.0 to ColdFusion with Microsoft Access is planned.

Conclusions

Learner-centered WBI tutorial database empowers and engages learners in higher-order thinking, which results in better understanding. In this learning environment, learners are able to engage in interactivity with more independence, greater competency, and increased support. Querying the database in this tutorial database is the first phase of learning database instruction. The next two phases will engage in contributing, and designing the tutorial database. These two processes will advance learners’ individual critical, creative, and complex thinking skills and engage them in constructive learning environments with collaborative learning and problem solving strategies.

Designing a “Best Practice” Online Course

Bonita L. Wilcox
and
Linda C. Wojnar
Graduate School of Education
Duquesne University
United States
Wilcox@duq.edu
Wojnar0870@duq.edu

Abstract: This paper is a summary of a “how to” workshop, focusing on design guidelines when moving from an onsite course to an online course. Three most basic considerations are content knowledge, pedagogical skill, and higher-order thinking dispositions. Transferring content to an online environment requires technological expertise. Insuring learning in an online environment requires pedagogical expertise, and facilitating growth in a student’s knowledge base through interaction of literacies requires mindfulness. This workshop is intended for teachers of adult learners who are truly concerned with building thinking persons. We will present a model to guide teachers in designing online courses to increase learning through improved teaching.

Introduction

Teachers who are critically literate have explored their own “ways of knowing” through the interaction of all their literacies. Believing that technology is a literacy, as necessary to a teaching and learning life as reading, writing, listening, speaking, thinking and viewing, led to the design of an online model incorporating “best practice” and “higher-order thinking.” Adding technology to the curriculum or teaching it as a skill, is a very different process than integrating technology for lesson enhancement. Beginning with what we know about “Best Practice” and what the audience knows about “Best Practice,” we would like to create some new designs for online courses developed from a model with the intentional integration of all our literacies. Teachers who have had the opportunity to explore and understand the power of writing their own literacy histories, will be better models of critical literacy for adult students.

The model introduced in this workshop depends on strong dispositions toward teaching (modeling) critical and reflective thinking strategies. Guidelines for incorporating critical and reflective thinking strategies are adaptations from Bloom’s Taxonomy of educational objectives (1956). A content rich syllabus is the driving force for a good onsite or online course, but what makes a course exceptional is the concept of “integrating literacies.” This idea comes from whole language and constructivist philosophy where students make their own meaning and deepen their understandings through reading, writing, listening, speaking, viewing, and thinking. Strengthening reading will strengthen writing, strengthening writing will strengthen thinking. Interaction online requires emphasis on communication skills and critical thinking.

From a movement by national curriculum specialty organizations, such as the National Council of Teachers of English, the National Council of Teachers of Mathematics, and the International Reading Association, and many others who recognize the importance of emphasizing standards, the concept of “best practice” was defined. Certain educational activities stood out as most effective methods for teaching, learning, and assessing. In Methods that Matter: Six Structures for Best Practice Classrooms (1998), Daniels and Bizar write, “…there are six basic structures that help to create Best Practice classrooms” (p.5). These six structures are integrative units, small group activities, representing-to-learn, classroom workshop, authentic experiences, and reflective assessment. Daniels and Bizar go on to explain that we “need all six ingredients in order to describe the Best Practice paradigm” (p. 7). In a recent publication, Best Practice:
New Standards for Teaching and Learning in America’s Schools, the authors list 13 Principles of Best Practice Learning (Zemelman, Daniels, and Hyde, 1998, p.8).

Principles of Best Practice Learning

**Student-Centered.** The best starting point for schooling is young people’s interests; all across the curriculum investigating students’ own questions should always take precedence over studying arbitrarily and distantly selected “content.”

**Experiential.** Active, hands-on, concrete experience is the most powerful and natural form of learning. Students should be immersed in the most direct possible experience of the content of every subject.

**Holistic.** Children learn best when they encounter whole ideas, events, and materials in purposeful contexts, not by studying subparts isolated from actual use.

**Authentic.** Real, rich, complex ideas and materials are at the heart of the curriculum. Lessons or textbooks that water-down, control, or oversimplify content ultimately disempower students.

**Expressive.** To fully engage ideas, construct meaning, and remember information, students must regularly employ the whole range of communicative media—speech, writing, drawing, poetry, dance, drama, music, movement, and visual arts.

**Reflective.** Balancing the immersion in experience and expression must be opportunities for learners to reflect, debrief, abstract from their experiences what they have felt and thought and learned.

**Social.** Learning is always socially constructed and often interactional; teachers need to create classroom interactions that “scaffold” learning.

**Collaborative.** Cooperative learning activities tap the social power of learning better than competitive and individualistic approaches.

**Democratic.** The classroom is a model community; students learn what they live as citizens of the school.

**Cognitive.** The most powerful learning comes when children develop true understandings of concepts through higher-order thinking associated with various fields of inquiry and through self-monitoring of their thinking.

**Developmental.** Children grow through a series of definable but not rigid stages, and schooling should fit its activities to the developmental level of students.

**Constructivist.** Children do not just receive content; in a very real sense, they re-create and reinvent every cognitive system they encounter, including language, literacy, and mathematics.

**Challenging.** Students learn best when faced with genuine challenges, choices, and responsibility in their own learning.

Our concern with the “pedagogical potential” of an online course comes from the ease of moving information to a technological landscape and calling it “distance learning.” White and Weight claim that “...effective online instruction requires an interpersonal approach” (2000, p.vii). In their new book, *The Online Teaching Guide*, these authors and other contributors, write about the human side of teaching and
learning online. Content seems to be a given, but concern for active learning, student engagement, ongoing assessment, reflective and critical thinking, student-centeredness, and an outcomes-based approach are central issues. The book incorporates the Principles of Best Practice without specifically referencing them. Those who think of distance learning as a way to increase student-teacher ratios from 1:12 to 1:800, should consider that teaching and learning online demands one-to-one student-teacher instruction, prompt feedback, significant collaborative interaction, authentic assignments, and a comfortable learning community. Extra time for preparing and delivering assignments for teachers and students is dramatically increased online, and increasing the number of students per instructor drastically reduces the quality on online teaching and learning.

Background

The main differences in moving from an online classroom to and onsite classroom are the use of technology and the non-traditional way the students and teachers communicate, interaction without the use of verbal and nonverbal responses, and the mechanics of receiving and sending assignments and feedback. All communication is electronic, including lectures, chats, tasks, assignments, projects, videos, and the portfolio. Gestures and body language in the classroom translates to reading between the lines online. In addition to technological troubleshooting when transferring messages and assignments, the online instructor must be specific regarding acceptable equipment and software.

Status of the class

Whether through written biographies, questionnaires, journal prompts, philosophies, or discussion, it is important to know the backgrounds and prior knowledge of learners when deciding what to teach, how to teach, and to what depth. Teachers who ask students what their goals and objectives are can use this information to make assignments more meaningful. This makes learning more personalized because the teacher values their input.

Objectives

Thinking and sharing in small groups, participants will design their own online courses. Groups will explore possibilities for creating alternative assessments and a community of learners online. Participants will examine their own literacy histories (ways of knowing) in order to understand how authentic experiences can happen in a virtual classroom. Participants will articulate and defend completed projects.

Mini-Lesson

Step one is to set goals, state objectives, and determine outcomes/assessments.

| What do you want the students to know and be able to do? |
| What evidence will be required to show knowledge and skill? |
| How will you assess? |

| Goals: |
| Objectives: |
| Outcomes/Assessments: |
Step two is to consider your audience.

Learning about the assumptions students have coming into class and their current content knowledge relating to the subject matter is essential in developing tasks and assignments. Following are several strategies for audience analysis.

- Questionnaires
- Biography
- Guided discussion
- Oral quiz
- Journal prompt

Step three is to adjust the content.

Having the expertise to decide what content is essential and most beneficial is the instructor’s most important responsibility.

What is really important for the students to know?

What is the most effective way to deliver content?

Step four is to plan for assessment.

Although there are many terms, for different kinds of assessments, the important thing to know is that assessment is a tool for learning. How will you know if your objectives were met? How will you judge what your students are able to do or how well they can do it?

- Responding in writing
- Assessments with rubrics
- Standardized evaluation
- Rank ordering grading

Audience analysis strategy:

List activities, projects, tasks, prompts.

Alternative assessments:
Step five is to consider the tasks and activities needed for exploration, application, or practice.

While most traditional teachers think of themselves as dispensers of knowledge, they must understand that this is not learning. Students have a more important part to play in learning than memorizing and duplicating information on tests. What authentic experiences can be arranged so students could apply new concepts to scaffold deeper understandings?

- Decision making
- Problem solving
- Investigating
- Projects

Step six is finding ways to enhance assignments to engage students.

When the teaching role changes from teller to facilitator, students accept the lead. Teaching students to monitor and manage their own learning increases autonomy and ensures engagement.

- Reflective self assessment
- Student choice
- Student empowerment
- Peer assessment
- Knowledge construction

Share Time

Participants demonstrate evidence of learning by articulating what they have learned. A final poster presentation offers all an opportunity to defend their work and respond to others. Organizing one's work into a visual display gives way to common themes and meaningful connections.
Conclusion

The following documents support this workshop approach: Initial Design of Instructional Techniques – Model 1, Best Practice of Online Teaching and Learning- W-W Model 2, Ways to Include Best Practice Principles in Lessons, Technology Standards, Using Bloom’s Taxonomy in Assignment Design (http://www.umuc.edu/ugp/ewp/blooomtax.html), and a research summary of evidence of best practice and higher order thinking in student work from an online course.

Technology Assists to Create a Structured Learning Environment for Discovery Learning

Yuehua Zhang
Education Department
Washburn University
zzvzhang@washburn.edu

Abstract: This paper intends to report how a group of inservice teachers who were involved in designing interdisciplinary units of instruction used a systems approach in fulfilling the requirement of a graduate course. The paper will also report on the initial resistance to applying the SDI model on the part of several group members, and those changes that took place in the process of understanding the designing principles. After months of guided practice and engagement in active group interaction, all the participants successfully produced their final projects, interdisciplinary instructional units including several technology tools and the web as the delivery tool, thereby contributing to the pool of knowledge for other professionals to use as resources.

Introduction

One of the main purposes of implementing instructional technology is to create a learning environment in which our students can discover, explore and construct their own knowledge with the help of this technology. The classroom teachers should not only have a strong command of basic technological skills, but should also understand how to make the curriculum come alive in their classrooms. “Making the curriculum come alive” means that teachers should have control of the content and the pedagogy, and thereby be able to create the best possible learning environment to enhance the most effective learning. In order to achieve this goal, it is necessary for teachers to perceive themselves as instructional designers. Because of the enrichments made possible by modern technology, interdisciplinary learning can provide the students great opportunities to make connections among all the subjects they are learning, to gain multiple aspects of understanding, therefore to widen their perspectives of the world.

Instructional design is a process that is creative and active, iterative and complex. Dick and Carey (1990) in their book of “The Systematic Design of Instruction” provide detailed steps for designers to follow. Diagrams are used in the designing of instructions, which is a common practice among the designers. However, many teachers are not embraced this model for a variety of reasons. First, classroom teachers usually are given the chosen curriculum, and hence do not view themselves as instructional designers. Secondly, classroom teachers are given more and more daily responsibilities, from the delivering of the instructions to managing classes. In addition, they are expected to deal with all the social problems typical in a given school environment. As a result, there is little to no time for them to dedicate to designing their own instruction. Thus, we see that many forces are present that conspire against the teachers being involved in the instructional design process.

In addition, the complicated and complex process of instructional design is very confusing to new and novice designers, and the many diagrams of SDI (Systematic Design of Instruction) are interpreted as stiff, passive, and too complicated, with a plethora of visual elements, such as rectangles, circles, ovals, lines and arrows, used to model the process. The purpose of applying SDI is to use a systems approach model for the design, development, implementation and evaluation of instruction. In turn, this helps to lay a foundation for the creation of a technology-enriched learning environment for learners to construct their own knowledge and to provide opportunities for authentic learning in the classroom.

Application of SDI

How does SDI fits into the enriched learning environment? With today’s technology, it is possible to provide a “guided” discovery learning experience to individual learners or groups of learners (Rice; Rice; & Lovell,
It is possible to create a technology-based learning environment built loosely on constructivist views augmented with such cognitive tools as modeling, sequencing and corrective feedback (Schwen; Goodrum; & Dorsey, 1993). The goal is to provide an accessible, open environment that challenges each learner to “discover” a predetermined outcome. Although the method is referred to as being based on “discovery,” this is not to suggest an unfocused, disjointed exploration with no instructional goal. As Bruner (1973) states, “as so frequently happens, the concept of discovery ... (has) become detached from its context and made into an end in itself. Discovery (is) being treated by some educators as it were valuable in and of itself, no matter what it was a discovery of or in whose service” (p. XV).

Teachers as Designers

This paper intends to report how a group of inservice teachers enrolled in a graduate course, “Integrating Instructional Technology in Curriculum,” designed interdisciplinary units of instruction using a systems approach. After spending some time in becoming familiarized with the concept, small groups were formed to work to use SDI in creating a unit of instruction with interdisciplinary content and technology as delivery tools. While these inservice teachers did not find the theory difficult to comprehend, they felt that the detailed steps according to Dick and Carey were too complicated and unnecessary, especially since most of them had been classroom teachers for several years and felt confident in their understanding of curriculum and instruction. They openly professed having very little confidence that they would find the SDI model useful or that what they were learning to do would add any valuable experiences to their professional growth.

 Nonetheless, the project began, with the inservice teachers forming groups and jointly exploring the components of the SDI model. One particular group of three teachers, representing history, industrial technology (formerly called “shop”), and science at the same middle school all initially shared the same prejudice toward SDI, but found that as time passed, they began to realize some of its validity and applicability, even for seasoned teachers. The core components of SDI involve the meticulous, even painstaking process of defining instructional goals and meaningful performance objectives, which stratify into several layers of achievable smaller goals. In the final analysis, however, these teachers were able to overcome the prejudices formed through their own experiences and began to realize that while the articulation of the expected outcomes may require a certain degree of “massaging” so as not to pollute a desired discovery process, one should always use performance objectives as a unifying principle of instruction. After a period of fairly intense collaboration, they produced a complete unit, “The Wright Stuff” (after the famous aviators, the Wright brothers), which integrated a historical background, scientific experiments and development, as well as components of industrial technology. So designed, this unit provided learners with the opportunity to explore, to make choices along the way, and finally to discover the information needed to construct their own knowledge on this particular topic. The project utilized the Internet as a delivery tool providing middle school students with structured learning. In so doing, not only was relevant information presented, but also the tools needed to solve a particular problem were given to the learner. The learner was to decide which tool to use, and what information to apply in solving a particular problem in the instructional unit.

Other groups produced units emphasizing music and history, art and social studies, mathematics skills and reading comprehension. The most valuable lesson they learned through the practice of the SDI model was that they started to see the relationships among the steps. The steps involving the conducting of instructional goals provide a conceptual roadmap for any instructional activity. Even in a discovery-learning environment, an instructional goal should be clearly stated to tailor all the possible events of instruction toward meaningful learning outcomes. The steps of writing performance objectives can facilitate the learning process and provide clear directions of the learning activities toward desirable outcomes.

The End of the Process

After months of guided practice and engagement in active group interaction, all the participants successfully produced final projects, interdisciplinary instructional units including several technology tools and the web as the delivery tool, therefore contributing to the pool of knowledge for other professionals to use as resources. Through this process, they learned a great deal of designing principles and practice strategies. The clarity with which the instructional goals could be stated and the specificity with which the performance objectives could be
identified, made them better able to create an enriched environment within which to better produce predetermined learning outcomes for their students. Thus, these graduate students were afforded an opportunity explore how using SDI can significantly assist them in the development of instruction (even for the experienced inservice teachers) and to discover more efficient ways of implementing instructional technology.

In conclusion, “While some may argue that such tedious and careful design takes the “discovery” out of discovery learning, one should never lose sight of the importance of solidly designed instruction.” (Rice; Rice; & Lovell, 1996, p. 45.) Discovery learning can provide students interaction with enriched environments and active learning experience, but it should not be seen as an all-encompassing approach to all instruction. Based on the experiences of the above-mentioned project, the SDI model certainly appears to validate this assertion.

Abstract: This paper points to the teacher professional development practices in a networked classroom that become reality with the use of advanced telecollaboration tools such as Virtual-U and KnowledgeForum. Those tools support, extend, and strengthen the establishment of teacher learning communities and their collaborative inquiries. Those inquiries are part of larger design experiments aiming at studying teacher learning when deep understanding is the goal of the knowledge-building activities that pre-service, in-service, and teacher educators engage in. The practices at two of the TL-NCE sites illustrate the transformative processes underway in teacher education when collaborative use of information and communication technology is made in networked classrooms.

Introduction

The practice of Internet-based activities is transforming teaching and learning in the classroom as well as it is transforming learning to teach. Interactive learning materials and activities are being developed, and computer-mediated communication tools support the classroom conversation beyond usual limits. Educators of educators are faced with a new challenge, one which is at once risky and compelling given the window of opportunity that is now opened: at the one end of the spectrum, network-based learning is viewed as a means to increase choice (modules and courses) and, sometimes, academic results or performance, and at the other end, as the essential activity for maintaining our scholastic cultures through knowledge-building communities. And then again, teachers are engaged in learning about the technology even as they are to help their students work with it.

Teacher educators involved in the TeleLearning Network of Centres of Excellence (TL-NCE) share the belief that educators must have a say in the orientation and the conduct of emerging on-line learning and teaching practices. The TeleLearning research program, funded under Canada’s National Centres of Excellence, contains an important teacher education component that seeks to develop a model of integrating technology into teacher education. The model identifies a) under what conditions teachers can become thoughtful and reflective utilizers of educational technologies that support, extend, and strengthen their work as educators, b) how those conditions are achieved in a variety of situations and c) the consequences of such achievements. The research program is aimed at assisting pre-service and in-service teachers as well as teacher educators while gaining knowledge and skills of a practical or intellectual nature which they are called upon to master, in order to accomplish the tasks and functions expected of them now or in the not too distant future.

The objectives of this paper are 1) to describe the on-line information and communication practices of teacher learning communities that are emerging at two of the TL-NCE sites, and 2) to point to the early converging results of collaborative inquiries that have been carried out into both Anglophone and Francophone networked classrooms.
The changing parameters of learning

There is ample evidence that important determinants of learning are time-on-task and active learning strategies (Ewell & Jones, 1996). Cooperative and collaborative learning strategies engage students in constructive, reacculturative conversations with one another, helping them achieve better academic grades (Springer, Stanne, and Donovan, 1999). Computer-mediated communication research (Fjermedal, 1986; Cooper & Selly, 1990; Hiltz, 1992; Harasim, 1993; Lévy, 1994) points to the potentials of on-line communication for collaborative and emancipative learning. What is learned is not only about what students read but what is said to one another about what they read (Pence, 1993).

However, the most adequate ways of educating educators not for instruction per se, but for every student to learn by whatever means work best are not always applicable on campus. The lecture-discussion classroom format remains, including in schools of Education, the primary means of producing instruction in North American colleges and universities today because it does in fact produce a lower cost of instruction than the use of individualized active and or collaborative learning strategies. Schools of Education are criticized by preservice and inservice teachers for their lack of coherence between what they espoused theoretically, and what they practice on campus.

Many schools of Education in North America have redesigned their curricula over the last decade, most especially their practice curricula (the Professional Development School Model), to be amenable to research on learning and teacher education research. Many teacher educators have adopted the constructivist view of learning. But campus-based learning coupled with field experience in school setting continues to be the primary mode in professional teacher education. Changes in educational paradigms and the evolving nature of an ever growing information society, create new opportunities and challenges for educators in all sectors and at all levels. And the emergence of networked communities of learners is leading the way toward the development of viable alternative educational models.

The emerging practice of computer-supported collaborative inquiry

On-line resources and tools are usually understood to mean the information and communications technology (ICT) applied to teaching and learning for the purpose of providing: 1) the flexible delivery of educational material (technology for the instructor), 2) the guidance and facilitation of the experience of the student (technology for the learner), and 3) the support of communities of learners (collaborative learning). Thoughtful and effective use of on-line resources and tools is understood to encompass those pedagogies that take advantage of "applications that engage students with the material, illustrate complex systems or relationships, and encourage interaction with other individuals or teams. Ultimately, the technology tools should become transparent as they integrate the user in the process, enabling immersion in the learning level, and that, on an individual or community basis." (NSF, 1998, p. V)

The virtual community of communication and support for teachers working in networked classrooms, established in Phase I of the research program (TL-NCE), is now moving toward curriculum-oriented collaborative knowledge building activities. Participants are encouraged to co-construct their knowledge of thoughtful and effective use of online resources and tools in a networked classroom. Collaborative inquiry is central to the knowledge-building process, and participants are enabling one another as they seek to understand how information and communication technologies can best support student learning. One strand of collaborative inquiries is dealing with the contribution of new information technologies to learning and teaching in elementary, secondary, and post-secondary classrooms, and involves school teachers, university researchers and graduate students from McGill University (Montreal, Canada) and Laval University (Quebec, Canada). The "community of practice" model is applied (Lave & Wenger 1991), and participants share a common set of purposes, practices, and perspectives. The networked classroom generate a whole new set of problems for novice as well as for expert teachers. Collaborative inquiries on specific questions, issues and challenges are conducted, for instance, in VGroups (a key component of the Virtual-U platform) at local sites or between sites. Access to and appropriation of valid and relevant knowledge for teaching in the networked classroom somewhat depend on their success to learn with one another. Key themes being discussed are the following ones: 1) learning and teaching for understanding, 2) cooperative learning and telecollaboration tools, 3) collaborative learning activities and projects using online resources and tools, and 4) the changing role of the teacher and of the learner. Novice teachers and expert teachers co-construct valid understandings of the thoughtful and effective use of on-line
resources and tools in face-to-face and on-line discussions. As they negotiate the meaning of their emerging practices, they develop identity relationships that enable them to increasingly think of themselves as true members of interconnected communities of learners (teachers-as-learners). This strand of collaborative inquiry has led to documentary reviews (1996, 1998, 1999) that condense for practitioners and policy makers articles, reports, papers, and book chapters addressing the question of the contribution of ICT to learning and teaching (see Bracewell, Laferrière, Breuleux, Benoit, and Abdous, 1998). Some of the trends identified are the following ones: 1) the emergence of a mixed mode of learning: face-to-face and on-line learning activities; 2) the unresolved debate over the nature of information access as being or not more direct, interactive, and flexible; 3) the renewed interest in classroom social interaction.

Another strand of collaborative inquiries focuses on the nature of the activities and processes that on-line discussion forums (or dynamic databases) may support when it comes to teacher professional development. Pre-service, in-service teachers, and teacher educators are involved, at times jointly, at times in distinct forums. Depending on the circumstances, pre-service teachers may engage in either collaborative journal writing, collaborative inquiry projects or other forms of knowledge-building activities using Virtual-U VGroups, eGroups, or FirstClass. The V-Groups are, for instance, supporting pre-service teachers' collaborative journal writing, an activity commonly known for its private nature: a conversation occurring between the student teacher and the university supervisor, one sometimes inclusive of the school cooperative teacher. What a student teacher is interested in and what he or she is willing to share becomes visible to all other student teachers and, at times, to those of another cohort (same-year cohort or next-year cohort). Those discussion forums provide views into learning and teaching for those engaging in early field experiences, or preparing for their student teaching. Permissions are granted on a reciprocity basis. Some messages may be deleted in order to respect confidentiality. The platform used becomes an on-line collaborative space, that is, a place for teacher knowledge exchange. It is an evolving space, as incoming student teachers not only benefit from previous online discussions, but add to the content of what is being shared. Reflective teaching activities such as problem setting and problem solving are found to be enhanced, and Laval University student teachers are nearly unanimous in recognizing the value of using a telecollaboration tool such as Virtual-U VGroups to these ends (Legault, in press). As they graduate, they keep their identification code and password to this virtual community.

In-service teachers who use telecollaboration tools such as VGroups, eGroups or Knowledge Forum to gain, or advance, their understanding of effective use of on-line resources and tools, make transparent their engagement in on-line practice for themselves and for the school learners they work with. They deal with dilemmas and problems, create artefacts (templates for use in the classroom, links with the curriculum through concept maps, lists of suitable websites, on-line problem-solving activities, etc.), and share ways of doing things, and creative products. They are inclined to create their own school or personal webpage. Given the opportunity, they link those to a message in a discussion forum (VGroup or eGroup). Many-to-many communication for collaborative inquiry purposes are found to be an advanced use of information and communication technologies. A few inquiries of that sort have been conducted using WebKnowledge Forum, and most resulted in educational materials being created for classroom use (dynamic databases). Some of those inquiries involved only teachers, and others elementary or secondary school learners.

The above findings are part of larger design experiments. At the Laval University / Quebec City Site, the attempt is to enable a large network of associated schools to make adequate use of ICT through the building of a capacity for collaborative teacher learning and teaching in the networked classroom. It is in this context that discussion forums and dynamic databases are emphasized. This is to say that face-to-face and on-line activities are being combined. The collaborative on-line places are analyzed on an ongoing basis in order to identify recurring and evolving thematic content and patterns of communication. At the McGill Network of Professional Development Schools (PDSs), researchers are attentive to the socio-cognitive discourse that is being displayed in on-line conversations (see Breuleux, Bracewell, and Renaud, 1995). Their focus is on the different sources of knowledge required of participants to engage in successful knowledge-building communities. What knowledge results from participation in networked communities of learners remains the central question under investigation in the research project as a whole. Educators in the McGill TL+PDS Net are developing a practical understanding of on-line discussion and information tools. For example, 70 student-teachers and practicing teachers in the McGill TL+PDS Net have used actively the web-based eGroup environment during, and following, the 1999 Summer Institute: they have exchanged close to 500 messages starting in August and up to November 1999. The messages served a variety of purposes such as information sharing, interpersonal support, team building, and knowledge
These educators also are learning in practical and experiential ways how on-line knowledge-building communities are formed, and what purposes can be achieved by such communities. For example, teachers in three schools of the McGill TL-PDS Net have formed, and are monitoring, their own on-line groups for students and/or colleagues. Therefore, there is an emerging practice of on-line collaboration that extends learning in powerful ways, but most importantly there is a growing ownership of the tools, with an associated sense of efficacy on the part of the teachers.

**Early converging results**

As elementary, secondary, and university classrooms get networked, teachers are grasping the potentials of telecollaboration tools. The many-to-many communication patterns enable by tools such as VGroups and KnowledgeForum are seen as ways to enrich, extend, expand, and deepen the conversation in the classroom, be it at the elementary, secondary, or post-secondary level. However, in order for those tools to lead to successful collaborative inquiries in the networked classroom, a reframing of one's understanding of what learning and teaching are all about is often found to be necessary. The implications of the socio-constructivist perspective on learning requires not only a shift of thinking, but in doing as well. Tools that catalyze, support and enable such a change are found to be necessary.

After experiencing an initial shock when being presented with the possibility of using VGroups (Virtual-U), Laval pre-service teachers use of this tool confirms their interest in collaborative learning and teaching. As demonstrated by their readings of the writings of more advance pre-service teachers, they manifest openness and respect for, and recognize the relevance of the writings of more advanced pre-service teachers that have gained expertise in the use of online resources and tools. Their trust in the value of such materials is key to the development of a collaborative knowledge-building capacity in the whole Quebec City Region since 80% of the graduates are likely to teach in that area. They also manifest a positive attitude in looking into in-service teachers collaboratively built data bases (Web Knowledge Forum). However, only a few demonstrate confidence in their capacity to successfully use that tool in their own upcoming classrooms.

The design of the McGill Institute confirms that developing a thoughtful and reflective practice of educational technologies that supports learning can be achieved under conditions that include the following: a) a willingness and a capacity on the part of the practicing teacher to mentor student-teachers, and in doing so to open her practice as a model for inspection by someone else (an essential capacity to be reflective). This capacity is found to be a pre-requisite for successful on-line discussions to include substantial discourse about practice and about its development; b) a school climate that supports (or is conducive to) collaborative knowledge building among the teaching staff; c) guided discovery activities for teachers allowing them to develop technology practices and tools that have two attributes: they are connected to the practice as it currently exist, or to the practice that is aimed by the group, and allow connections between the two practices.

The consequences of an emerging, thoughtful, and reflective practice of educational technologies that support and extend learning include the establishment of new relationships between the members of the teaching staff within a school, the establishment of relations between teachers in different locations, and increased connections between student teachers and teachers.

This design experiment is now entering a phase where issues of leadership are crucial. We are examining leadership practices that support the participation of teachers in on-line learning communities, how leaders can develop their own learning communities, and how teachers can become leaders in their school or school board about the use of ICT to support advanced pedagogies such as collaborative knowledge-building.

Forms of support and communication among the participants may vary while learning takes place in learning networks pertaining to teacher professional development. The different range of learning outcomes entailed in teaching and working with these new technologies, is found to be highly dependent of the level of access to online resources and tools, the support of the local context, the nature of the curriculum, and the teacher’s pedagogy. Those process-related converging findings are found to support the cohabitation of educators at different levels of technology practice, and to promote collaboration in design, implementation, and inquiry.

Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with technology. This purpose is accomplished through the encouragement of scholarly work related to technology in education and the dissemination of research results and through AACE sponsored publications, conferences, and other opportunities for professional development.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high-quality peer-reviewed publications, and conferences.

Membership Benefit Highlights

- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

# TABLE OF CONTENTS

## CONCEPTS AND PROCEDURES

Section Editors: Deborah Bauder, Rome City School District (NY); Rosemary Mullick, SUNY Institute of Technology at Utica/Rome; Ronald Sarner, SUNY Institute of Technology at Utica/Rome

The Role of An Educational Software Clearinghouse in Undergraduate Teacher Education

Programs

- Michael Shaughnessy, Eastern New Mexico University, USA; Randy Seever, University of Houston, USA

Technology For Critical Pedagogy: Beyond Self-Reflection With Video

- David McCurry, Monmouth University, USA

Model Technology Classrooms In Teacher Education

- Kathryn Matthew, Louisiana Tech University, USA; Kimberly Kimbell-Lopez, Louisiana Tech University, USA

Defining a Distant Environment for Teacher Education

- Gertrude (Trudy) Abramson, NSU/SCIS, USA; Timothy (Tim) Ellis, NSU/SCIS, USA

Course Portfolio: A Tool for Online Teaching

- Lissa Pollacia, Northwestern State University, USA; Richard Tarver, Northwestern State University, USA

Student Digital Portfolios on CD-ROM: Assessing Ability-Based Projects

- Terry Corwin, Valley City State University, USA

An evaluation methodology for computer mediated teletraining systems

- Francoise, Sandoz-Guermond, Insa-20, Avenue Albert Einstein - Bat 401 - Ictt, France; Gerard, Beuchot, Insa-20, Avenue Albert Einstein - Bat 401 - Ictt, France

Developing an On-line Ethics Policy

- Jennifer Summerville, Emporia State University, USA

Ethics and the Internet

- Stig R Rask, The Foundation for Knowledge and Competence Development, Sweden

CBT: The Past, Present and, Hopefully, the Future

- Daniela Marghitu, Auburn University, U.S.A.; Roland Hubscher, Auburn University, U.S.A.

Staff Development, Distant and Direct: The Middle School Initiative at Northwestern State University

- Bob Gillan, Northwestern State University, USA; Frank Fuller, Northwestern State University, USA; Karen McFerrin, Northwestern State University, USA

A University Design Team Approach: Developing Courses for On-line Distance Education

- Timothy Youngman, University of Houston-Clear Lake, United States; Lee Gotcher, University of Houston-Clear Lake, United States; Shahrzad Vafa, University of Houston-Clear Lake, United States; Sharon Dinsmore, University of Houston-Clear Lake, United States; Orval B. Goucher, University of Houston-Clear Lake, United States

Interactive Television: The Planning Process

- Kay Allen, University of Central Florida, U.S.A.

The Value Of Information Technology (As Difficult To Assess As The Value Of Education!)

- Alexandre Graeml, CEFET-PR/UNICENP, Brazil; Pierre Ehrlich, EAESP-FGV, Brazil

Then and Now: Technology and the Changing Face of Higher Education

- Eric Seemann, Louisiana Tech University, USA; Walter Buboltz, Louisiana Tech University, USA; Lamar Wilkinson, Louisiana Tech University, USA

Higher Level Thinking Skills and Individual Differences: Bridging Gaps with Technology

- Barbara Moore, University of South Florida, USA

Technology for Teachers: Another Perspective of the Implementation

- John R. Ouyang, Kennesaw State University, USA; James E. Yao, Texas A & M University – Commerce, USA
A Farewell to the Traditional Instructional Media and Technologies in the New Millennium

The Technology Facade
Lawrence Tomei, Duquesne University, USA

Technology Planning and Technology Integration: A Case Study
Linda Espey, Heartland Area Education Agency and Drake University, Iowa, USA

Effective Curricular Software Selection for K-12 Educators
James Marshall, San Diego State University, USA; Marguerite Hillman, Hillman Consulting, USA

Using Concept Mapping in the Classroom
F. Thomas Scappaticci, King’s College, USA

Proving Competence: Integrative Assessment and Web-based Portfolio System In a Dynamic Curriculum
Douwe Wielenga, Amsterdam Faculty of Education, Netherlands; Rene Melisse, Amsterdam Faculty of Education, Netherlands

DISTANCE EDUCATION
Section Editors: Frank Fuller, Northwestern State University of Louisiana; Ron McBride, Northwestern State University of Louisiana

Role Modeling Critical Thinking Strategies in an Online Course for Nurse Educators
Gary Loving, University of Oklahoma Health Sciences Center, USA

Problems and Practical Solutions of Web Based Courses: Lessons learned from three educational institutions
Marios Miltiadou, Arizona State University, USA; Marina McIsaac, Arizona State University, USA

Evaluating new ICT-based models for teacher training
Svein Ove Lysne, Stord/Haugesund College, Norway; Jostein Tvedte, Stord/Haugesund College, Norway

Improving Collaborative Learning by Supporting Casual Encounters in Distance Learning
Juan Contreras, Centro de Investigación Científica y Educación Superior de Ensenada, México; Rafael Llamas, Centro de Investigación Científica y Educación Superior de Ensenada, México; Aurora Vizcaino, Universidad de Castilla la Mancha, España; Jesús Favela, Centro de Investigación Científica y Educación Superior de Ensenada, México

Group learning through Internet
Antonio Vit, UFRGS, Brazil; Tarouco Liane, UFRGS, Brazil

Challenges of Using CSCL in Open Distributed Learning
Anders Grov Nilsen, Stord/Haugesund College, Norway; Elen Instefjord, Stord/Haugesund College, Norway

Remote Labs!
Khalid Hamza, Florida Atlantic University, USA; Bassem Athalabi, Florida Atlantic University, USA; David Marcovitz, Loyola College in Maryland, USA

Online interactive Learning: An Innovative Project of the Inter American University, Bayamón Campus, Developed with the Integration of Students, Faculty and Administrative Staff
Yolanda Serrano, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.; José Guillermo Santiago, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.; Reinaldo Medina, Inter American University of Puerto Rico, Bayamón Campus, U.S.A.

An Overview of Online Educational Delivery Applications
George Marsh, II, The University of Alabama, USA; Anna McFadden, The University of Alabama, USA; Barrie Jo Price, The University of Alabama, USA

Teaching and Learning in an Anytime/Anyplace Classroom
Gertrude (Trudy) Abramson, NSU/SCIS, USA; Maxine Cohen, NSU/SCIS, USA; Timothy (Tim) Ellis, NSU/SCIS, USA; Cordelia Twomey, NJCU, USA; Mitchell Pratt, Alpine School District, USA

DEP WEB: A concept mapping based on web distance education process
Apuna Gomes, Universidade Federal do Rio Grande do Norte, Brasil; Márcia Gottgtroy, Universidade Federal do Rio Grande do Norte, Brasil
More than Having a Connection: Qualitative Factors that Affect Learning in a Web-based University Course

Laura E. Sujo de Montes, Northern Arizona University, USA; Carmen L. Gonzales, New Mexico State University,

Content Analizing as a Tool in Evaluating the Effectiveness of Distance Learning System

Baruch Offir, Bar-Ilan University, Israel; Y. Lev, Bar-Ilan University, Israel

Evaluation of World Wide Web Delivered University Courseware: Creating an Instrument Appropriate For A New Course Delivery Medium

James Izat, West Texas A&M University, USA; LeAnn McKinzie, West Texas A&M University, USA; Charles Mize, West Texas A&M University, USA; Trey McCallie, West Texas A&M University, USA

Trickle Down Technology: A Distance Education Approach

Angie Parker, Gonzaga University, USA

Shifting focus from teaching to learning - ICT as an incentive to reform teacher education

Harald Haugen, Stord/Haugesund College, Norway; Svein Ove Lysne, Stord/Haugesund College, Norway; Lars Vavik, Stord/Haugesund College, Norway; Bodil Ask, Agder College, Norway; Birgit Braathen, Stord/Haugesund College, Norway

New Horizons in Distance Education: Re-mapping the Pedagogical Terrain

Jeannine Hirtle, Sam Houston State University, USA; Robin McGrew-Zoubi, Sam Houston State University, USA; Christopher Scofield, St. Martin's University, USA

Three community building strategies and their Impacts in an on-line course: A case study

Joy Egbert, Indiana University, USA; Chin-Chi Chao, Indiana University, USA; Karen Ngeow, Indiana University, USA

Technology In the classroom: Implications for Teacher Education

Warren Wessel, University of Regina, Canada

Introducing ODL In Teacher Education - on on-line course on how to create on-line learning environments

Harald Haugen, Stord/Haugesund College, Norway; Bodil Ask, Agder College, Norway

A new program for the inservice training of Computer studies teachers through distance education

Elsa Naude, University of South Africa, South Africa

Meeting the needs of Distant Learning through the use of PowerPoint and RealPresenter

David Cary, CSU Northridge, USA; Wayne Smith, CSU Northridge, USA

New tools for assessment in distance education

Luciano Hack, Universidade da Santa Catarina, Brazil; Liane Tarouco, Universidade Federal do Rio Grande do Sul, Brazil

Distance education insights from eight case studies in TESOL teacher preparation

Lynn Henrichsen, Brigham Young University, USA

DIVERSITY & INTERNATIONAL

Section Editor: Madeline Justice, Texas A&M University-Commerce

"At-Risk" Learners and the "Digital Divide": Exploring the Equity In Access Issue

Jeanne Foster, Texas Woman's University, USA; Sharla Snider, Texas Woman's University, USA

Integrating Standards-Based Instructional Technology

Nicole Snow, Northern Arizona University, USA

Technology and the Navajo - Its Time Has Come

Jerry A. Bennett, Navajo Education Technology Consortium, USA

A Multifaceted Approach to Integrating Computers In Multicultural Preservice Teaching

Inês Márquez Chisholm, Arizona State University West, USA

"From Tatters to Tapestry": Technology and the Weaving of Cultural Education In the Mainstream Classroom

Debra A. Suarez, The University of Alabama, USA

Gender Representation In Visuals on School Web Pages

Wendy Maboudian, University of Houston, USA
Within Student Comparison of ESL Acquisition-Through Content Between Virtual F/F Seminar for ESL and Native Speakers' Negotiated Meaning
Stephen Carey, University of British Columbia, Canada

Virtual Interactive Workshop: a pedagogical art education view into the computer lab
Maria Cristina V. Biazus, Universidade de Caxias do Sul, Brazil

Fostering Equity In Pre-College Computing Classrooms
Sandra Madison, University of Wisconsin-Stevens Point, USA; James Gifford, University of Wisconsin-Stevens Point, USA; Min Deng, University of Wisconsin-Stevens Point, USA

EDUCATIONAL COMPUTING COURSE
Section Editor: Wren Bump, Texas Southern University

Insuring the Future: Development of an Exemption Exam for an Introductory
William Wiencke, State University of West Georgia, USA; Leticia Ekhaml, State University of West Georgia, USA

How Can We Help Johnny Compute?
Gail Ring, University of Florida, USA; Sebastian Foti, University of Florida, USA

Technology for Preservice teachers: What is it?
John Bailey, Brigham Young University - Hawaii Campus, USA

Preparing Pre Service Teachers to Use Technology to Teach the Content Areas In Elementary Schools
Maria Bhattacharjee, University of Houston Downtown, USA; Lin Lin "Irene" Chen, University of Houston Downtown, USA

The Impact of Theory on Technology Use In the Classroom
Alec Couros, University of Regina, Canada; Carol Fulton, University of Regina, Canada; Vi Maeers, University of Regina, Canada

Constructing Technology-based Constructivism: A New Approach to the Educational Computing Course
Edwin J. George, Florida Gulf Coast University, Fort Myers, FL, USA; Jennifer Sparrow, Florida Gulf Coast University, Fort Myers, FL, USA

Collaborative Team Teaching Approach In a Technology Course
Seung Jin, Cleveland State University, USA; Abu Nasara, Cleveland State University, USA

Beyond Applications to the Essential Processes of Technology Integration: Designing an Educational Technology Course to Reflect ISTE Standards and to Model Best Practices for the Future
Margaret Ropp, University of New Mexico, USA; Jill R Brown, University of New Mexico, USA

Integrating Electronic Portfolios Into Undergraduate and Graduate Educational Technology Courses at the University of Florida
Colleen Swain, University of Florida, USA; Gail Ring, University of Florida, USA;

Teachers' Comfort Level, Confidence, and Attitude toward Technology at a Technology Course
Amy S. C. Leh, California State University San Bernardino, USA

A Comparison Of Student-Teachers' Attitudes Toward Computers In On-Line And Traditional Computer Literacy Courses: A Case Study
Tarkan Gurbuz, Middle East Technical University, Turkey; Soner Yildirim, Middle East Technical University, Turkey; M. Yasar Ozden, Middle East Technical University, Turkey

What are we talking about? The Impact of Computer-mediated Communication on Student Learning in an Educational Technology course
Sarah Irvine, American University, USA

Information System Design of Undergraduate Education: Combining Lectures with Practice
Yoshinori Fujio, Prefectural University of Kumamoto, JAPAN
EDUCATIONAL LEADERSHIP

Technology Standards for School Administrators: Implications for Administrator Preparation Programs .......................................................... 366
Warren Hope, Florida A&M University, USA; Bernadette Kelley, Florida A&M University, USA; Janet Guyden, Florida A&M University, USA
Information Technology and the transformation of leadership preparation programs: A response to calls for reform in educational practice. .......................................................... 371
Ian Gibson, Wichita State University, USA
Graduate Technology Coursework In a Framework of Professional Leadership .......................................................... 378
Perry Rettig, University of Wisconsin Oshkosh, USA; Penny Garcia, University of Wisconsin Oshkosh, USA; Scherie Lampe, University of Wisconsin Oshkosh, USA
Professional Development for Systemic Change: A Strategic Approach to Scaling Educational Reform Through Professional Development Programs .......................................................... 385
Stephen Best, University of Michigan, USA; Ronald Marx, University of Michigan, USA; Barry Fishman, University of Michigan, USA; Deborah Peek-Brown, Detroit Public Schools, USA
TLI: Recreating University Programs to Meet School District Needs .......................................................... 391
Carolyn R. Parkins, University of Louisville, USA
"The Usual Suspects": Explaining Success and Failure In Instructional Technology Consortia .......................................................... 396
Steven Jackson, Indiana University of Pennsylvania, USA; Dolores Brzycki, Indiana University of Pennsylvania, USA; Mary Ann Cessna, Indiana University of Pennsylvania, USA
ICT Training and Implementation : Inseparable activities .......................................................... 402
Reg North, University of Ulster, U.K.
Attitudes Towards Using Computers In Administration Among School Administrator .......................................................... 408
A. Rafee C. Kassm, Universiti Utara Malaysia, Malaysia; Hatim M. Tahir, University Utara Malaysia, Malaysia

FACULTY DEVELOPMENT

Involving Faculty In Faculty Development: A Recursive Model .......................................................... 418
Kristine Blair, Bowling Green State University, USA; Dan Madigan, Bowling Green State University, USA
Technology Use In Higher Education: A faculty development model .......................................................... 424
Jessica Kahn, Chestnut Hill College, USA; Robert Pred, Chestnut Hill College, USA
A Faculty of Education as a Community of Learners: Growing to Meet the Demands of Instruction and Technology .......................................................... 430
Nancy Browne, University of Regina, Canada; Mhairi (Vi) Maeers, University of Regina, Canada; Elizabeth Cooper, University of Regina, Canada
Faculty Development: From Computer Skills to Technology Integration .......................................................... 436
Karen Milligan, Carson-Newman College, USA; Stephanie Robinson, Carson-Newman College, USA
Technology Mentorships in Higher Education: An Optimal Match for Expanding Educational Computing Skills .......................................................... 441
Sally R. Beisser, Drake University, USA
Constructivist Learning: Also For Faculty! .......................................................... 448
Simone Terwindt, Amsterdam Faculty of Education, Netherlands
Building a Vision for Technology Integration .......................................................... 451
Ann McCoy, University of Alaska Anchorage, USA
Teaching Well With Technology: An Educators Guide to Wise and Time-Efficient Use of Instructional Technology .......................................................... 457
Kevin Barry, University of Notre Dame, USA; Thomas Laughner, University of Notre Dame, USA; Barbara Walvoord, University of Notre Dame, USA
Ten Years of Technology Training for Faculty .................................................. 463
Neal Topp, University of Nebraska at Omaha, US; Robert Mortenson, University of Nebraska at Omaha, US

Teachers' Distance Professional Development And Support Model ................................ 469
Peter Serdiukov, University of Utah Reading Center, USA; Dale Niederhauser, University of Utah Reading Center, USA; Ralph Reynolds, University of Utah Reading Center, USA

Teaching the Teachers: Faculty Development institutes at Two Universities ............... 474
Marc Childress, Old Dominion University, USA; Ray Braswell, Auburn University Montgomery, USA

The Evangelist and the Conscientious Objector - Lessons Learned from Faculty Development .......................................................... 479
Lawrence Baines, Berry College, USA; Lynnwood Belvin, Berry College, USA

Puzzled by Technology Professional Development? Which Pieces Fit In Higher Education? ......................................................... 483
Ellen Newcombe, West Chester University, USA; John Kinslow, West Chester University, USA

Alds and Cautions for Developers of Web Pages to Supplement Courses in Higher Education .......................................................... 487
Cleborne Maddux, University of Nevada, Reno, USA

Power Web Searching Techniques for Teacher Educators ...................................... 492
Judi Repman, Georgia Southern University, USA; Randal Carlson, Georgia Southern University, USA; Elizabeth Downs, Georgia Southern University, USA; Ken Clark, Georgia Southern University, USA

Interactive PowerPoint for Teachers and Students .................................................. 496
Terence Cavanaugh, University of South Florida, USA; Catherine Cavanaugh, University of South Florida, USA

Networked Software Support of Staff Development .................................................. 500
David Baty, University of Dundee, Scotland; Raymond Moir, University of Dundee, Scotland

Teacher Educators' Reflections on Using Group Response Technology .................. 502
Connie Hargrave, Iowa State University, USA; Anne Poegen, Iowa State University, USA; Denise Schmidt, Iowa State University, USA

Understanding Graphics for Effective Communication ............................................. 509
Jerry P. Galloway, Indiana University Northwest, USA

A study of two online learning innovations: implications for teacher education and professional development .................................................. 515
Herbert H. Wideman, Centre for the Study of Computers in Education, York University, Canada; Ronald D. Owston, Centre for the Study of Computers in Education, York University, Canada

Teaching an Old Dog New Tricks .......................................................... 520
Merylann "Mimi" J. Schutloffel, Catholic University of America, USA

Frustration among educators about IT use .......................................................... 526
Charlotte Bohrn, Viktoria Institute, Sweden; Urban Nulden, Viktoria Institute, Sweden

The Impact of Information and Communication Technology (ICT) on Job Characteristics of South African University Academics .................................................. 530
Andy Igonor, University of Fort Hare, South Africa; Yolisa Soul, University of Fort Hare, South Africa

Building the Capacity for Systematic Integration of Technology in Teacher Education .................................................. 537
Rachel Vannatta, Bowling Green State University, USA; Blanche O'Bannon, Bowling Green State University, USA

Integrating Technology Into Preservice Teacher Education Method Courses: A Unique Business/University Partnership for Staff Development .................................................. 540
Ellen Hoffman, Eastern Michigan University, US; Laura Rosenzweig, Apple Computer, US; Joyce Morris, The University of Vermont, US; Christy Faison, Rowan University, US

The Unified Elementary ProTeach Program: Impacting UF and Beyond .................. 548
Colleen Swain, University of Florida, USA

Faculty Development and Preservice Teachers as Agents of Change ....................... 553
Charles M. Savitt, Virginia Commonwealth University, USA; Edward W. Hootstein, Virginia Commonwealth University, USA; Richard J. Rezba, Virginia Commonwealth University, USA
Faculty Development In Technology for Teachers of English for Special Purposes (ESP)
Course........................................................................................................... 555
Tatiana Slobodina, Northern International University, Magadan, Russia, Russia

To Teach How Or To Teach With: Four University's Approaches To Technology Integration For Teacher Preparation.................................................. 561
Kimberly A. Lawless & Louanne Ione Smolin, University of Illinois at Chicago, USA; Neal Strudler, University of Nevada, Las Vegas, USA; Scott W. Brown, University of Connecticut, USA; Steve Soulier, Utah State University, USA

GRADUATE & INSERVICE ............................................................................. 566
Section Editor: Caroline M. Crawford, University of Houston – Clear Lake
Teaching Practice and the Design of Professional Development Activities .............................................. 569
Ronald Abate, Cleveland State University, USA

Merits of Mentoring and Modeling in Internet Technology Integration: Overcoming operational obstacles ........................................................................ 575
Deborah Y, Bauder, Rome City School District, USA; Elizabeth Rossi, SUNY Institute of Technology at Utica/Rome, USA; Rosemary Mullick, SUNY Institute of Technology at Utica/Rome, USA

Educating the Educators: Reflections from the a Mature Public Sector ISP .................................................. 581
Mary Beam, Education Network of Ontario, Canada; Paul Beam, University of Waterloo, Canada

Preparing Teachers to Investigate the Effects of Technology-Supported
Teaching Practice and the Design of Professional Development Activities .............................................. 587
Isabel Borrás, San Diego State University, USA

Media/Digital Literacy in an M.Ed. in Classroom Technology ........................................................................ 593
Gregg Brownell, Bowling Green State University, USA; Nancy Brownell, Bowling Green State University, USA

Empowering Minds by Taking Control: Developing Teachers' Technological Fluency with Lego Mindstorms ........................................................................ 598
Deirdre Butler, St. Patrick's College, Ireland; Fred Martin, MIT Media Lab United States; Wanda Gleason, Gleason Research, United States;

Practical Ways to Improve Instructional Effectiveness Using Internet-Based Course Supplements ........................................................................ 604
Randal D. Carlson, Georgia Southern University, USA; Judi Repman, Georgia Southern University, USA; Elizabeth Downs, Georgia Southern University, USA; Kenneth Clark, Georgia Southern University, USA;

Reflective Judgment And Cognitive Interaction In An Electronically Distributed Astronomy Course For Educators .............................................. 609
Kevin Carr, George Fox University, USA

Technology education: A synergistic approach ........................................................................ 615
Dominic Congno, Chestnut Hill College, USA; Jessica Kahn, Chestnut Hill College, USA

Using The Internet AS A Teaching Tool To Find Statistics For Use In Graduate Education...... 620
Fannie Cox, University of Louisville ,

A Hero's Journey: Introducing modular In-service diploma courses in IT at Trinity College Dublin ........................................................................ 626
Ann FitzGibbon, Trinity College Dublin, Republic of Ireland; Cyril Drury, Trinity College Dublin, Republic of Ireland; Elizabeth Oldham, Trinity College Dublin, Republic of Ireland; Brendan Tangney, Trinity College Dublin, Republic of Ireland

Classroom-based Technology Training for Inservice Teachers........................................................................ 633
Susan Gallagher, University of Nebraska at Kearney, USA

Transforming teaching practice with technology: Incorporating ISTE standards and performance assessment in a constructivist approach to graduate teacher education .............................................. 636
Kay Gibson, Wichita State University, USA; Dennis Kear, Wichita State University, USA

Computer Technology In Foreign Language Teacher Training ........................................................................ 641
Lawrence Glatz, Metropolitan State College of Denver, USA

Implementing The Virtual Campus Learning Community for Teacher Education at George Fox University........................................................................ 647
Scot Headley, George Fox University, USA; Kevin Carr, George Fox University, USA
Active Learning Environments Prepare Teachers for Technology ........................................... 653
Marilyn J. Heath, Southwest Educational Development Laboratory, USA

Modeling Technology Use in Special Education Teacher Training ........................................... 657
Marie Hegwer-Di Vita, California State University, Long Beach

An Effective Model for Professional Development in Using Technology to Learn ...................... 661
Robert E. Hollon, University of Wisconsin - Eau Claire, USA; Susan R. McIntyre, University of
Wisconsin - Eau Claire, USA; Mona C. Majdalani, University of Wisconsin - Eau Claire,

Using Virtual Learning Communities to Enhance Collaboration and Communication .............. 666
Cynthia J. Hutchinson, University of Central Florida, USA; Lynda A. Delius, Sweetwater Episcopal
Academy, USA

Metaphoric scaffolding: Using digital video techniques to overcome teacher apprehension about
new approaches to learning ........................................................................................................ 670
David Keeffe, Curry School of Education, University of Virginia, USA; Linda Tsantis, Johns Hopkins
University, USA

The Alliance for Catholic Education (ACE): Integrating Technology Into a Holistic Teacher
Education Program ............................................................................................................... 674
Valerie Larsen, Indiana University South Bend and the University of Notre Dame, U.S.A.; Kevin
Barry, University of Notre Dame, U.S.A.; John Stack, University of Notre Dame, U.S.A.

CTER Online: Providing Highly Interactive and Effective Online Learning Environments ............ 680
Sandra R. Levin, UIUC, USA; Gregory L. Waddoups, UIUC, USA

Using WebCT to Extend Learning in Graduate Educational Technology Courses ..................... 686
Mhairi (Vi) Maers, University of Regina, Canada

Targeted Instructional Staff Development Project: An Evaluation ............................................. 692
Rosemary J. Mullick, SUNY Institute of Technology at Utica/Rome, USA; Deborah Y. Bauder, Rome
School District, USA; Ron Sarner, SUNY Institute of Technology at Utica/Rome, USA; David L. Carr,
Richard Stockton College of New Jersey, USA

Designing Learning Practices as professional development for teachers .................................. 698
Linda Odenthal, University of Twente, Netherlands; Joke Voogt, University of Twente, Netherlands

We Have the Equipment—We Need the Teachers to Run It .................................................... 704
Davenport Plumer, New York Institute of Technology, USA

Technology Autobiographies in Teacher Education ................................................................. 709
Carole S. Rhodes, Adelphi University, USA

TUTORPEA for Adults’ Teachers Lifelong Learning ............................................................... 714
Blanca Rodriguez, University of Valladolid, Spain; Maria Angeles Perez, University of Valladolid,
Spain; Angel Garcia, University of Salamanca, Spain; Rafael Mompó, University of Valladolid, Spain

Integrating Technology into the School Curriculum with Thematic Units ................................ 719
Mary Stephen, Harris-Stowe State College, USA; Nancy Gammon, Lincoln University, USA; Ann
Podelski, Harris-Stowe State College, USA

Helping Teachers Enhance Lessons with Technology .............................................................. 723
Neal Topp, University of Nebraska at Omaha, US; Marla Dowse, North Platte Schools, US; Tami
Eshleman, North Platte High School, US

The Computer Mediated Communication Environment as It Fosters Collaborative Ways of
Knowing, Teaching, and Learning ...................................................................................... 726
Mary Wildner-Bassett, University of Arizona, USA

Developing A Contract For Learning: A Constructivist Approach For Professional
Development ..................................................................................................................... 732
Linda Stanley Wilson, University of British Columbia, Canada; Patty Phillips, Pitt Meadows
Elementary School, Canada; Jeff Spence, Lord Byng Secondary School, Canada; Adam Gibbons,
University of British Columbia, Canada

Minds on, hands on: The linear-nonlinear problem-solving approach on a multimedia and
Internet course .................................................................................................................. 738
Harrison Yang, State University of New York at Oswego, USA; John Shindler, State University of New
York at Oswego, USA; Ann Keen, State University of New York at Oswego, USA;

Staff Development: Task-Oriented Training ......................................................................... 744
Yuehua Zhang, Washburn University, USA; Carol Stacks, Topeka Collegiate School, USA
Learning to Teach, Teaching to Learn: a constructivist view of how post graduate students on initial teacher training courses develop their information technology skills

John Chatterton, Sheffield Hallam University, England; Moira Monteith, Sheffield Hallam University, England

INSTRUCTIONAL DESIGN

Section Editor: Stephanie Boger, University of Houston

Setting course for the new millennium: planning for IT in a new bachelor degree program

Peter Albion, University of Southern Queensland, Australia

Learning about Information Technology in Education Using Multimedia

B Aris, Universiti Teknologi Malaysia, Malaysia; M Abu, Universiti Teknologi Malaysia, Malaysia; H Ellington, The Robert Gordon University, Scotland; M Dhamotharan, Universiti Malaya, Malaysia

Information model for evaluation Educational Software

Preface to the Millennium Edition!

Now that we have had our celebrations about the coming of a new century and a new millennium, purists are pointing out that we are not really in the first year of the new millennium but in the last year of the old one! "What?", you say. I vacationed in Turkey this Christmas (thanks to Dee Anna Willis being willing to shoulder most of the load for getting the section leaders' comments in and organized) and the English language paper in Turkey ran an article about the way the monk who organized the calendar we use today started it. Instead of making the first year, 0, he made it year 1. Thus, the year 2000 is actually not the two thousandth year, it is the 1999th year. So, if we want to do the whole thing over again next year, we can.

What about the Annual? Is this the 9th or the 10th year of the Annual? That too is a bit complicated. The first conference was held in 1990 which means this is the 11th conference. (We did not think far enough ahead to hold the first conference in 1991 instead of 1990 so it would be easy to keep up with.) Everything being equal this should be the 11th Annual, right? Well, not quite. The papers presented at the first conference were not published in an Annual. Instead, they were Issues 1, 2, and 3 of the 1990 volume of the journal, Computers in the Schools. So, when it comes to Annuals, the year and the number of the Annual is consistent. This is the tenth Annual.

Ten years! For the Annual. And eleven for the conference! Not long in the grand scheme of things but a long time when it comes to conferences. I would estimate that there are 80% more "First Annual" conferences than "Second Annual." And, if we extrapolate a bit my guess is that less than 5% of the academic conferences are around for an eleventh incarnation. SITE is a survivor for several reasons. One is that it does a good job of meeting a need. There is a growing community of scholars and professionals who have a strong interest in technology and teacher education. SITE is THE conference if that is your interest. A country singer whose name eludes me had a popular song a few years ago that had the lyric, "I was country before country was in." SITE was here, with a focus on teacher education before that was an "in thing."

Today, technology and teacher education is an in thing. The U.S. Department of Education's $75 million dollar grant program on preparing teachers to use technology has raised the interest level and attention of teacher education, as have a number of other activities such as the AACTE report on technology in teacher education. Technology was not always in the limelight of teacher education, however. In introducing the special issue of Educational Technology Research and Development on technology and teacher education, Bob Hannafin (1999) commented that in the past teacher education and instructional technology "lived quite happily in separate worlds, neither really knowing - or caring to know - what the other was doing" (p. 27). Hannafin edited the special issue of ETR&D on technology and teacher education because he felt this was an emerging field that deserved the attention of the IT community. I am happy to say that of the seven authors involved in writing articles for that special issue, all except one are regular participants in SITE. Two have been or are presidents of the organization and several others have won awards for their papers at SITE.

The USDOE grants program, the work of NCATE, ISTE, and AACTE; and special issues of journals like ETR&D, are all indicators of the changing landscape of technology and teacher education. SITE and its membership has many opportunities to form collaborative relationships with other organizations. The time is right for that, thus the theme of the conference, Bridges Among Professional Associations. I hope you have a productive and enjoyable conference and that you become an active and energetic part of the process of building bridges in this time of high interest and attractive possibilities.

As an editor one of the joys of doing everything online is not having the long delay for papers to arrive from distant authors. On the other hand one of the disappointments is not receiving mail with beautiful and intriguing stamps in wonderfully scented paper from far away places (I treasure one received years ago from India that is lined with red silk and still smells of sandalwood). Perhaps we should add simulated national stamps to our e-mail; e-scent I suspect, will be a long time coming.

In the past I have tried to take the reader on a round-the-world trip with me, organizing the papers in the International section as if I were a tour guide. Although that yearly tour was dear to my heart, it has become increasingly more difficult to do as this section becomes less a collection of papers from around the world and more a group of reports telling of international collaboration among teacher educators from a number of countries. As I have helped process the proposals for every conference (see the preface to this Annual and last year’s) since our beginning I’ve had an inside view of this growth. No longer can I see this section’s articles in a linear model, but rather as an interconnected, three dimensional matrix—first a bundle of a few twigs gathered together for mutual support, then more, adding strength, and finally building a structure—a home/house if you will, growing a community. At some point even paper books will have ‘hot links’ with articles arranged in 3-D, but until then I fall back on a somewhat linear path, linear but convoluted, like following a rabbit warren hither and yon. So come with me; our path will twist and turn and skip, but it will be worth the journey.

This year I am pleased to begin the International section with a paper from our invited International Panel organized by our Vice President for International Affairs, Professor Niki Davis, formerly UK, now, US. The other panelists are Therese Laferriere, Canada; Bridget Somekh, UK; Wim Veen, the Netherlands; and Jerry Willis, US. The panel examines the international dimension in teacher education and technology, noting that the context for education is becoming global through communication and other technologies. This provides a rich and continually expanding context for critical reflection and growth.

Crossing the Atlantic Roger Austin and Jane Smyth of Northern Ireland describe a case study of the Irish ‘North South’ Project.” Several more papers from the UK, authored by Bruce Elson & Alan Phelan and D.J. Clare & J.L. Blackwell respectively, provide insight into IT from their perspectives.

The fifth report, from Brian Hudson, David Owen, and Alison Hudson, UK, together with Eila Jeronen, Finland, and Peter Schütz, Austria, move us to the European continent in “Promoting collaboration in a European context using multimedia and the World Wide Web.” While there we visit the Netherlands for a response to the challenge of the Information Age from Marco Snoek, Douwe Wielenga, Karel Aardse, and Joke Voogt.

A short flight from the Netherlands and we’re in Switzerland reviewing the work of Wilfrid Kuster and Fortunat Schmid in the development of a preservice ICT course for student teachers to use at secondary schools.

Heading northeast from the Alps we enter Poland where Jacek Gornikiewicz writes of an Internet dialogue of teachers and students. Moving southeast to Romania we nonetheless retain ties to Germany and the UK, building an international community of experts on learning in the Internet as reported by Nicolae Nistor, Germany, Mihai Jalobeanu, Romania, and Susan English, UK. Looping back to the west we explore teacher’s attitudes towards computers in the education of young children as presented by Tamara Pribisev and Sanja Cvijic Vuckovic, Yugoslavia.

Sailing from Yugoslavia through the Adriatic, Ionian, and Aegean seas we arrive at Turkey where four papers take us through a number of aspects of Turkish education and IT. The reports by the respective authors, Selçuk Özdemir, Ömer Delâyalıoğlu, Sozer Yıldırım, and Ashym Asan give us a number of windows through which to look at their IT and teacher education programs.

Crossing the Black Sea to the Ukraine, we are presented with a question, posed by Valentyna Kolomiisets, that we all have to face, one way or another, i.e., “What role can technology play?” The Ukraine, as are all former components of the old USSR, is in a state of extreme transition. Ludmila Gombozhaban writes of how Russia, too, is going through transition and its impact on teacher education.
Leaving Europe and northwestern Asia we cross the land mass of China to Hong Kong where Wing-mui Winnie So, Hing-keung Vincent Hung, and Wai-cheong Jacky Pow, provide us with a case study of a teacher educator using IT in primary classrooms. From the mainland we cruise to the Republic of China for two papers. The first, by Shwu-yong L. Huang and Yeon-Chaw Liu, look at gender-related differences in computer anxiety while the second, by Min-Jin Lin and Ching-Dar Lin, looks at IT training for primary teachers in Taiwan and in Australia.

Malaysia is our next stop where two papers, by Haryani Haron & Sharifah Muzlia Syed Mustafa and by Soo-Lin Teh & Fiti Suraya Mohamad report on different aspects of IT and teacher preparation in their country.

From Malaysia take the Internet (planes take so long to cross the Pacific) to Chile and learn about distance education based on networks there with Jose Duran Reyes and Maria Ines Solar Rodriguez as guides. Crossing the great ridge of the Andes, Earth’s longest mountain chain not covered by ocean waters, and skipping to the eastern side of South America we learn from Airton Cattani, of Brazil, about the new horizons and possibilities provided by telematics in professional training.

On the last leg of our trip we head north to Panamá where Gisela E. T. de Clunie, Damaris González, and Zenith Hernández write of their collaborative projects through the Internet. Panamá is a good ending for our odyssey; Yankees have had practice leaving there recently. While I am in a geographical mind, I am reminded of a fact I have always found curious, that the Atlantic opening of the Panamá Canal is northwest of its Pacific mouth, a good example of perception versus reality. For those who might doubt, see the map, brought to you through ICT, specifically: http://geography.about.com/

Dee Anna Willis is an Associate Professor of Language Arts and Reading in the College of Education, Northwestern State University of Louisiana. She also teaches Instructional Technology courses. Her specialties include field based teacher education, integration of information technology in teacher education, publishing in the IT field, and the diagnosis and remediation of reading difficulties. Her address is Northwestern State University, 118C Teacher Education Center, Natchitoches, LA 71497. Phone: 318/357-5551, Fax: 318/357-6275; E-mail: dawillis@cp-tel.net or willisd@alpha.nsula.edu

Abstract
SITE’00’s theme is building bridges among professional associations so it is only right that one the panels should look at the joys and challenges of developing and researching an international dimension in teacher education. The panelists come from both sides of the Atlantic and will stimulate the discussion through their experiences of collaborating across communities, cultures and languages. Niki Davis and Wim Veen have been developing and researching European teacher training enhanced through information and communications technologies. Bridget Somekh has been working with teacher educators in Europe to inform a view on pedagogy with new technologies. Therese Laferriere’s focus has been the development of teacher education across borders and cultures in North America. Jerry Willis has recently been focusing on curriculum reform in the Ukraine.

Background
The theme of this year’s SITE conference is bridges among professional associations. This panel will consider the growing importance of international collaboration for teacher educators. International collaboration between two associations also brought the panel together led by the first and last authors. Niki Davis was the current chair, or president, of
the UK Association for IT in Teacher Education in the year that the Society of IT in Teacher Education formed in the USA. She met Jerry Willis, the founding president of SITE, at an international conference in Belgium and as a result of expressing the challenges of developing IT for teacher education was invited to give the Keynote speech for SITE'91 in Greenville North Carolina (Davis, 1991). The Associations formed close collaboration to the benefit of both. As the older but smaller organization, which aims to promote both good teacher preparation and scholarship, ITTE struggled to support the international community. However, ITTE was happy to support the growth of SITE and certainly has grown both in numbers and in participation across the world.

Why does the society need a panel on international collaboration?

The Society for IT in Teacher Education is an international Society that actively promotes collaboration for the benefit of its membership and the scholarly field. The current Vice President for International liaison is Niki Davis, the leader of this panel. In addition, there are at least three reasons to incorporate a global dimension in teacher education:
1. The context for education is becoming global
2. Communication and other technologies are being used to increase access to education on a global scale
3. Taking a global view can enhance teacher education through the provision of stimulating rich contexts for critical reflection.

At last year's SITE'99 conference Niki Davis argued this in some detail (Davis, 1999) referring firstly to the commercial situation, which is now possibly more influential that national politics:

As teacher education moves towards more complex organizational arrangements of collaboration and competition at different levels, we are following similar trends in commerce and industry pushed and pulled by Globalization. Dauphainais & Price (1998) edited together the views of prominent chief executives under six themes, with the first as Globalization. The others were radical change, leadership, culture, innovation and customer service. The five latter themes are already challenges in teacher education and this paper suggests that we must also face up to our role in the globalizing of our cultures as workers across the world struggle for job retention and standard of living enhancements made possible through the "uncoupling of the corporation from the nation state. Rapid free flows of technology, capital, and employment contribute to this 'global village' effect." (p21)

In that SITE'99 paper provided suggestions of exemplary technology resources linked to SITE's Principles for technology in teacher education as well as a framework for curriculum development created by the international T3 project working across Europe (Davis and Tearle, 1999). Both Wim Veen and Niki Davis may use T3 Core Curriculum within the panel discussion, see Figure 1 for the holistic treatment of the three main dimensions bound together by lifelong learning, globalization and management of change:
1. collaboration & networking
For the international dimension it is particularly important to pay structured attention to collaboration and networking. However perhaps as other panelists explore the socio-cultural dimension we will together suggest that all these dimensions are important to all programs of teacher education across the globe.

Educating for Agency across the globe

Bridget Somekh's view of developing and researching the international dimension in teacher education and technology will draw upon two major scholarly activities. She has led the Community of Action Research Network and its international journal since its inception with John Elliott and colleagues. More recently the work of the REPRESENTATION Project, sponsored by the European Union, which is using concept mapping as a tool to capture children's mental schema for new technology, has informed her views (see for example Baron, Bruillard & Dansac, 1999). Representation is a research and development project funded by the European Union through the Multimedia Task Force. Kathy Kikis-Papadakis, FORTH, Institute of Applied and Computational Mathematics, Greece, coordinates the project. The partners are INRP, France; Orfeus, Denmark; MAC, Ireland; University of Crete, Greece; University of Amsterdam, The Netherlands; Open University of Catalunya, Spain; and University of Huddersfield, UK. Associated partners are IU FM de Creteil, France; and the University of Mons-Hainaut, Belgium.
The project has led Bridget to question to what extent existing education systems are capable of meeting the needs of today's young children, given the rapid infiltration of new technology into their lives. Bridget may clarify how the comparison across different countries and educational systems has enabled her to better argue that it is imperative to change some of the structural factors in education systems that currently prevent teachers from meeting children's needs. Her argument is that changes are possible that would enable us to use the capabilities offered by new technology tools to meet the socio-cultural needs of local communities. Bridget will end by arguing that we should educate for agency, to produce teachers and young people who believe that they are capable of making a difference to existing systems and enjoy the challenge of change.

TeleLearning Professional Development schools

The North American experience of professional development through communications technologies also holds valuable insights into the collaboration across institutions and countries to create new professional communities. These communities "reach far beyond a school or university by including among their active participants teachers, students, undergraduates, and various other experts from a number of schools, universities and associations." Therese Laferriere and her colleagues in the TeleLearning Network of Centers of Excellence are researching and developing models of time and information management between and within sites (Laferriere, 1999). In this research they note the importance of providing opportunities for 'the construction of shared understandings of teaching and learning'. The panel may explore how close these are to the European T3 projects' core curriculum that includes a dimension for both 'pedagogy' and 'collaboration & networking'.

Central and Eastern European challenge

In addition to the fast moving changes of technology some countries are also experiencing enormous changes in their educational systems. Jerry Willis will reflect on the challenges of providing support through international collaboration from the USA to the Ukraine. Where colleagues are under such stress it can be difficult to avoid cultural imperialism. Yet there is no doubt that the challenges of a centrally imposed curriculum that has now been swept away, led to a reaction in education. At times there is evidence of a much richer appreciation of literature and culture than might have been expected plus an extraordinary appetite for study. Support for Ukrainians redeveloping their curriculum can have benefits for their supporters in promoting reflection of the important value for education across the globe. Such challenges to pedagogical and curricular change have also been evident in international collaborations between Western and Central Europe as in the MATEN project for example, which is developing on-line multimedia courses with colleagues in four central and eastern European countries including the Ukraine (Dovgiallo et al, 1998).
The panels' discussion questions

- What added value does an international dimension provide for teacher education?
- What are the keys points for implementing international collaboration?
- What are the important research questions relating to international teacher education?
- Should all courses of teacher education strive for an international dimension, or is only important for some? e.g. advanced postgraduate courses
- What can SITE do to promote international collaboration and support in teacher education?

Integrating ICT into the Curriculum: A Case Study of the Irish 'North South' Project

Roger Austin, School of Education, University of Ulster, Northern Ireland
rs.austin@ulst.ac.uk

Jane Smyth, School of Education, University of Ulster, Northern Ireland
fcfd@aran.ulst.ac.uk

Abstract: Government Departments of Education in Northern Ireland and the Republic of Ireland emphasise the need to integrate ICT into the schools' curriculum. The training of teachers and student teachers is vital to the success of this integration. This paper reports on the North South ICT Project which was set up to contribute to these aims by involving teacher training in ICT in several areas of the curricula on both sides of the Irish border. The paper also reports on the Project's efforts to promote mutual understanding through ICT between pupils from two divided communities in Northern Ireland and pupils in the Republic of Ireland.

Introduction

Ensuring that pupils keep pace with the Information Society has been exercising the minds of policy makers in the departments of Education in Northern Ireland and the Republic of Ireland for several years. Agencies have been set up by both departments to implement quality ICT initiatives in schools. (Northern Ireland Network for Education http://www.nine.org.uk/ and National Centre for Technology in Education http://www.ncte.ie/index.htm). The integration of ICT into the curriculum is considered essential in these initiatives. The training of teachers and student teachers in the use of ICT in the classroom is also seen as imperative.

One initiative, the North South ICT Project, funded by both government departments of education and co-ordinated by the University of Ulster (UU) and National University of Ireland Maynooth (NUIM) was carried out during the academic year 1998-1999. The Project used a web-based computer conferencing system, Web Crossing and videoconferencing to link 20 student teachers from both universities, 26 teachers and 300 pupils in post primary schools in Northern Ireland and the Republic of Ireland. The pupils were in the age group 15 - 17 years. The collaboration led to a range of twelve cross-border curriculum-based projects on the theme of "This Island we live on", published as part of a website, www.ulst.ac.uk/thisisland/

The aims of these links were to increase ICT competence of student teachers, teachers and pupils in schools, to produce curricular resources through collaborative ICT school projects and to use ICT to foster collaboration and mutual understanding on both sides of the Irish border.

The term ICT is a wide one and whilst many aspects of it were included in the North South Project, the emphasis was on the ‘C’ element of ICT, namely communication. It was a key factor of the Project that this subset of ICT remained inside the curriculum (Misanchuk et al 1997; Austin 1995; Riel, 1992; Teles and Duxbury, 1991).

Data Sources

This paper evaluates the North South Project from the perspective of practice and attitude towards the integration of ICT into the curriculum. Evidence was gathered by use of questionnaires, pre and post Project, issued to all participating teachers and student teachers. Focus group interviews were carried out with teachers and pupils in 4 schools and with teachers only in 4 other schools. An external report was incorporated into the final internal evaluation. In addition, all student teachers in Northern Ireland who were involved in the Project produced evaluation reports on the North South Project as part of their final assessment.

Also, as part of the overall evaluation, student teachers and teachers were encouraged to contribute short progress reports to a specially created discussion, called Reflections, in the computer conference served by Web
Crossing. These and all other messages to conferences were regularly examined, as this was considered a valuable source of information. (Kaye, 1991; Harrington and Hathaway 1994; Marttunen, 1997).

Training in ICT

Integrating ICT into the curriculum at schools obviously needs the full co-operation of teaching staff, and training is essential. Government strategy emphasises the training of student teachers and teachers. The strategy adopted by the North South Project was to place student teachers in Project schools to work alongside subject specialist teachers and to provide them all with the necessary technical skills to enable them to fully participate in the project.

At the outset of the project one of the main concerns registered by teachers was their lack of technical skills. In January 1999, separate training workshops were organised in UU and NUIM to give participants hands-on experience of using both computer conferencing and videoconferencing technologies. These workshops were attended by student teachers, teachers and other school staff including ICT coordinators and in some cases vice-principals and principals. Project staff visited the schools in the following weeks to ensure the equipment was working properly and the appropriate settings were being used. Schools were also able to test the new equipment by carrying out trial videoconferences with NUIM and UU.

It was also noted that student teachers at both universities were taught ICT skills in different ways. At NUI Maynooth all Education students were obliged to participate in a basic course in ICT. A small number elected to take an additional course in ICT. The student teachers involved in the North South Project belonged to this latter group. Neither ICT course had a connection to students' subject specialism. For student teachers at UU, integrating ICT into their classroom activities ran parallel to their own subject specialist training, where computers formed an integral part of their learning at the university.

Strategy for Planning Projects

In early February 1999, a two-day residential meeting was held in Belfast to organise curricular projects. This was attended by teachers and student teachers from the 13 participating schools from both sides of the border, with representatives from the Department of Education Northern Ireland (DENI) Inspectorate, and academic staff from UU and NUIM. At this first planning conference in Belfast it was observed that teachers still seemed apprehensive about the new technologies despite the initial training they had received in January.

Teachers and student teachers were initially divided into subject groups to discuss areas of the two curricula where collaborative projects could be developed. Since the curricula in both jurisdictions differ significantly, this was quite a challenge. As common ground was established, clusters of two to three schools agreed to produce projects in Art, Design and Technology, English, Geography, History, Home Economics and Music.

Before the conference concluded, each project group was asked to complete a Project Agreement Form which outlined the details of the proposed project including the contribution of each school, a draft project timetable and agreed modes of communication within the project group. A prototype of the project website was presented at this inaugural meeting, showing where the curricular resources produced by the projects would ultimately be published. The potential use of digital cameras to complement project work was also demonstrated.

After 6-8 weeks work, a second meeting, to evaluate progress, was held in NUI Maynooth in April 1999. At this meeting teachers were encouraged to take more responsibility for the projects rather than depending too much on student teachers. This was in recognition of the fact that student teachers would soon leave the schools and that teachers should feel confident to continue with ICT without their support.

Integrating ICT into the Curriculum

Schools showed a lot of imagination in their choice of study and topics were chosen with care in order to accommodate the demands of the curriculum in both Northern Ireland and the Republic of Ireland. Projects all had a North South dimension in keeping with the theme "This Island we Live on". One history project, 'Ireland in World War One - Heroes and Traitors' gave schools the opportunity of studying Irish Nationalism from a
southern and northern perspective. It also allowed pupils to examine in detail some of the historic figures of that era who had connections to both parts of the island of Ireland.

One teacher, who was involved in a second history project, called 'Ireland in World War Two', found that integrating ICT into her subject area had acted as a 'strong motivational factor' for the pupils. It had given the subject, 'a clear, immediate and relevant purpose', making them see 'history as a living subject'. Again, the cross-border perspective was very valuable in enabling pupils to see a fuller picture, e.g. the effects of World War Two on one part of the country that was a combatant and another that was neutral.

A student teacher involved in one of the schools commented: "Through the exchange of ideas pupils agreed that their learning was heightened and accelerated. The diversity of ideas also presented the pupils with further stimuli."

The choice of a Yeats poem as an area of study was an example of a compromise. In Northern Ireland, schools were happy to incorporate it as a practice for unseen poetry for the Advanced Level Examination in English Literature while Yeats's poetry features on the Leaving Certificate syllabus in the Republic of Ireland.

Another English project, My Place Your Place, put the emphasis on creative writing, relevant to both curricula, while at the same time exploring local areas and presenting a flavour of each. One geography project consisted of a comparison of urban renewal in two cities, Dublin and Derry.

In another English project, The Pity of War, background information was presented on the 1916 battle of the Somme. This was connected to two World War One poets, and in turn to evaluations of their poetry, enabling pupils to see how the poetry could not be separated from the war. Information on Irishmen who fought in the war was connected to a creative writing exercise, thus bringing the whole experience of the poetry and its context to life.

The most rewarding experience for one of the Music teachers was when her pupils joined their counterparts across the border for a series of live musical performances via videoconferencing. On one occasion, the pupils had written a poem based on the theme of peace and reconciliation, and then set it to music. The song was performed live in a videoconference, with the two schools, north and south, taking turns to sing a verse.

For older pupils in particular, curriculum relevance was an important aspect of the North South project. Comments from pupils themselves, as they embarked on the project, indicated that their aspirations included increasing their understanding of subject. "...Another reason why I got involved was that I am looking forward to getting other peoples opinions about Nationalism and World War 1." Dialogue with distant collaborators led to new insights into the area of study. In general, adding to the body of knowledge of the pupils came in the form of another perspective. One teacher commented: "The pupils have gained ICT skills and a deeper knowledge of history, with the added advantage of seeing events from other perspectives and gaining research and improved literacy skills".

The importance of learning through relating to others by computer is emphasised by researchers (Kaye 1991; Austin and Mendlick, 1993; Harasim et al, 1995; Marttunen, 1997). The North South Project is an instance where different perspectives on a topic coming from Northern and Southern pupils enabled such collaborative learning. Many pupils highlighted the importance of another perspective, especially in the study of history.

ICT in Cross-Curricular Themes: Education for Mutual Understanding

Evidence showed that the North South Project involved both 'intentional' and 'experiential' learning, (Lewis, 1997) the latter often taking the form of cultural awareness. Because the schools chosen included those from within the Catholic sector and State sector (mainly Protestant pupils) in Northern Ireland as well as schools from the South, this cultural awareness was a three-way process. The need for increasing cultural awareness was reflected in the following comment by one Northern pupil: 'Forming links with other schools is needed especially with the way our country is at the moment'.

Broadening horizons was very much a part of the North South project as pupils engaged in voyages of discovery of their own and others' areas. The 'My Place Your Place' English project provided many opportunities to investigate locality (Riel, 1992) under several headings, including local personalities, local writers, colloquialisms and more. In a sociology/home economics project called The Family the study of two social security systems gave a valuable insight into the similarities and differences that exist on both sides of the Irish border. The Transport project, which drew in pupils from Design and Technology and Geography involved surveys of modes of transport used by pupils coming to school, concentrating on traffic congestion, a problem experienced both in Dublin and Belfast. Investigation of urban renewal in Derry and Dublin in another Geography project allowed pupils the opportunity of witnessing many similarities in city life on both sides of the border.
The different perspectives of pupils on both sides of the border were an integral part of the history projects. All of the projects were designed to open up pupils' minds and make them aware of life in two divided communities in Northern Ireland and also life on the other side of the Irish border. This filled the need of pupils as expressed by one teacher, “to find common culture in their daily lives.”

Robinson (1995) warns of the danger of stereotyping caused by passive use of media. However, active use of media can present a different picture. Research has shown that impressions of Northern Ireland change when young people from other countries have direct contact, using electronic communications, with young Northern Irish people (Austin, 1997; Austin and Mendlick, 1993; Smyth, 1999). In the North South Project, pupils from the South were introduced to “ordinary” pupils from both communities in Northern Ireland who live normal lives not dominated by “the Troubles”.

The Process of Learning using ICT

The use of video conferencing and Web Crossing enhanced interaction within and between project groups. Pupils were able to share ideas and experiences as well as text and image files. Video conferencing was new to the majority of pupils, student teachers and teachers involved in the project. While this proved to be an exciting experience for most, it also needed at least one attempt before student teachers and teachers felt competent with it. Student teachers felt that structured video conferencing, with a maximum of six pupils worked best and various strategies were used to put pupils at their ease. Video conferencing proved to be the highlight of the North South Project for pupils who were excited by the prospect of “seeing and talking to people over a hundred miles away”. Most project groups took part in at least two videoconferences.

Teamwork

Teamwork in the North South project existed on two levels, within each school and inter-school. Access to different perspectives because of the different backgrounds of participating schools was one of the main benefits accrued from this teamwork. The benefits of co-operation and collaboration made possible by computer and video conferencing (Robinson, 1995; Lewis, 1997) were evident in all projects to varying degrees. Working as part of a team was one of the most important skills acquired, according to pupils interviewed.

Collaboration was, however, impeded at times because of difficulty of access to computers. There were not enough opportunities to gain a lot of practice with video conferencing, as these synchronous conferences were notoriously difficult to arrange between schools. Findings also suggest that better collaboration might have occurred if access by pupils to Web Crossing had been more frequent. Also in order to increase academic interaction, more guidance from teachers and student teachers would be needed, as this type of academic debate was a new experience for pupils. There is evidence of better social interaction between pupils than academic interaction in Web Crossing. This is in contrast to the interaction using video-conferencing, where pupils were more relaxed when the focus was on work rather than on themselves.

ICT without the ‘C’

All aspects of ICT, not just the communications element were utilised during the project. Student teachers found the North South Project gave them more confidence in putting computer packages demonstrated in their Education courses into use in a school environment. The majority of pupils got the opportunity of using a digital camera. In some cases, self-portraits were posted into Web Crossing accompanied by a digital photo. Others used the camera to take photos for inclusion in the finished product. Apart from using the Internet for communication purposes between schools, research was carried out using the World Wide Web and maps, diagrams and graphics were also cut and pasted from the Internet. Pupils also scanned pictures from textbooks to illustrate the project and used the computer for planning, drafting, editing and designing a layout for their publication; a minority of pupils used desktop publishing to present their project.
The Product

The collaboration on the North South Project culminated in the production of a total of twelve projects in seven areas of the curriculum. These were presented in the form of pages in the main website called “This Island we live on”. This was seen as crucial in the integration of ICT into the subject area. Pupils had a tangible goal at which to aim. They looked forward to seeing their work on the World Wide Web presented as learning resources for other pupils to access. This was the “pay-off” recommended by Teles and Duxbury (1991) in the form of an electronic anthology. Evidence coincides with findings of Cohen and Riel (1986) and Austin (1995) that writing for an audience produced higher quality work. However, findings suggest that pupils should have been more involved in the completion of the project for the website, allowing them to engage in development of higher order critical thinking skills.

Student Teacher and Teacher Collaboration in ICT

One aim of the North South Project was training student teachers in the integration of ICT into their chosen subject while at the same time being “ambassadors” for ICT in the schools in which they did teaching practice. A recent UK study into the effectiveness of ICT in schools shows that teachers are still quite sceptical about ICT improving the quality of learning. In particular, teachers felt that their perceptions of the value of ICT differ from those of the policy makers (Cohen, 1999). In the North South Project, incorporating ICT into the curriculum was seen as a problem by some of the older teachers, whose teacher training took place before the widespread use of technology. Evidence shows that the student teachers played a very active role and often took the lead in promoting ICT in schools. Even though many of them had very little experience of ICT, their enthusiasm was very evident from comments such as:

“Nine months ago I didn’t know how to word process, never mind send electronic mail or videoconference, so this year has been one great, enjoyable introduction to ICT.”

According to informal feedback obtained from school visits, one of the key issues which seemed to impede progress in projects was an over-reliance by teachers on the student teacher’s technical skills. In the last term, as examinations approached, the student teachers felt the strain of this responsibility.

Because the student teachers were often seen as the local expert in the school, it was very important that they felt supported by the universities when technical issues arose. The importance of quick responses in Web Crossing was emphasised by all student teachers. Heflich (1996) draws attention to the role of outside agents, such as universities, in the successful implementation of online computer technology in schools. The link to the universities in the North South Project provided a ‘comfort zone’ as assistance with technological problems was always at hand. Although this assistance was, in theory, available to all participants in the Project, it was only the student teachers that took advantage of it.

However, it emerged in many of the teacher interviews that as the project progressed the teachers gained more confidence and practically all of them believed the project had given them a real appreciation of the potential of ICT as a valuable teaching tool.

While projects such as North South motivate staff, it is important that this energy and motivation is sustained in order to support the strategies of the Departments of Education in both jurisdictions to equip teachers and student teachers with the skills necessary to integrate ICT into the curriculum. The North South Project recognised that student teachers were only temporary members of staff in their practice schools and the duration of the Project may not have been long enough for ICT skills to be assimilated by full-time teachers. The strategy adopted therefore at the second face-to-face meeting in April was to put more focus on teachers’ input and to invite schools to continue the work the following year, even without student teacher support.

Conclusions and Recommendations

The North South Project attempted to implement some of the ICT aims of the Departments of Education in Northern Ireland and the Republic of Ireland in its overall framework. Improved confidence and competence of student teachers, teachers and pupils in the use of ICT, its integration into the curriculum and as a vehicle for
cultural awareness were outcomes of the Project. Technical support from the co-ordinators at the universities and also, in some cases, assistance from ICT technicians in the schools resulted in much greater awareness of the potential of ICT. As well as academic interaction, there was evidence of social interaction, particularly visible in Web Crossing. Access to different perspectives was considered to be very valuable.

The greatest challenge to the use of ICT, from the teachers' perspective, appeared to be restricted access to the Internet. Better online facilities in schools would facilitate more regular pupil involvement, resulting in more frequent communication. Increased training of teachers in the use of ICT would lead to a better 'comfort zone' around computers and hence more confidence in using them. Correct timing for the Project was another factor determining its success. All schools interviewed considered that the first term would be more suitable for such projects because teachers are less busy with examination classes, and student teachers are less busy with their own studies.

Opportunities to follow through these issues will arise in a new project entitled "Dissolving Boundaries through Technology" which will involve 25 schools on each side of the Irish border and will run from 2000-2001.

Abstract: A range of pedagogic, administrative, socio-economic, structural and resource issues surround the establishment of a global campus. This paper identifies and discusses such issues, and suggests that pedagogic aspects are paramount. The limitations of conventional subject-based approaches are considered, and local experience in curriculum design and module integration is discussed in the context of flexible learning, wider access and participation. The need for a range of learner support mechanisms is indicated, and our implementation (together with others) is described. The concept of a global campus is underpinned by appropriate technological developments. Internet- and Web-based experience is discussed, as is the need for more radical approaches such as Virtual Reality techniques.

Introduction

The nature of higher education (H.E.) is changing globally: the convergence of wider access demands, greater emphasis on vocational preparation, new teaching and learning delivery mechanisms, and the emergence of globalised economies is propelling forward-looking H.E. institutions into careful self-analysis. At the same time, many countries (for example, U.K., Australia, U.S.) are witnessing a withdrawal from state-funding for both H.E. institutions and for student maintenance costs. With other but equally significant structural and resource difficulties, developing nations also share these problems (Koul, 1995).

As well as financial challenges, certain global trends are beginning to emerge. Valcke and Vuist (1995) describe experiences in the Netherlands that matches our local experience in the UK. Demographic changes mean that the profile of the traditional student is becoming older, often working or balancing the requirements of other family/career commitments: this implies a growing demand for increased part-time and more flexible learning provision. An increasing number of UK institutions have adopted a modular approach to course design and delivery – see, for example, George, Murfin, and White (1992). At the same time, there are many pressures for more effective teaching and learning delivery mechanisms. Active learning, student-centred and case-led methods are now accepted parts of the educator's canon (Rogers [1991]), and such changes have been growing in influence since the late 1980s. What is now emerging as a radically different and (potentially) revolutionary change is the use of Internet- and Web-based delivery channels.

Open Learning and emancipation

Before discussing such issues, it is worth recalling that one of the strengths of an open learning approach is what Reid (1995) refers to as an 'emancipatory tradition' - the barrier-dissolving aspects of such learning. Such emancipatory aspects are principally associated with learners previously denied access to education and assume a much wider relevance within the context of a global campus. Reid (1995) directs our attention to 'structural constraints' relating to institutional, social, cultural, and political/economic factors. While the cost of commissioning and building new higher education institutions may stretch the financial resources of the developing countries, the ability to 'tap' into such programmes of study offered via the Web may be of great emancipatory, as well as economic, potential.
This implies fundamental challenges for the future of higher education. Dolence (1995) suggests that these challenges stem from the use of an educational model developed from and for an industrial model of society. Is this appropriate in what Dolence calls an ‘information model’ of society? Is the cost model of such a paradigm still valid given the nature of such an “Information age”? Can the higher education sector ignore the potential of technologies such as Web-based ‘push’ technology, ‘click-thru’ mechanisms, video-conferencing, and virtual reality models?

In a wide-ranging survey of current thinking about pedagogical issues facing H.E. Diana Laurillard articulates the necessity of ‘situation-learning’ (Laurillard, 1993). Such learning implies that “the acquisition of inert concepts (e.g. algorithms, routines, decontextualised definitions - i.e. the stuff of many university courses) is of no use if the student cannot apply them...[We] have to use our knowledge in authentic activity, i.e. genuine application of the knowledge; this allows us to build an increasingly rich understanding of the tool itself and how it operates” (page 17). Here, the application of Virtual Reality models and techniques offers potential for implementation of ‘authentic activity’ and ‘situated learning’.

Globalised education

The idea of a globalised higher education sector - a ‘global campus’ - implies administrative, pedagogic, operational, and technical issues, and the Virtual Online University (www.tcet.unt.edu) offers an interesting metaphor for the learning ‘cyberspace’. It is structured around a virtual campus, designated as a ‘MOO’ (an Object-Oriented Multi-User Dimension), around which students can wander as they would around a physical campus. At the same time, the range of courses offered remains very traditionally ‘subject-based’. Is this appropriate to such a new learning environment?

Such an environment may well present a lack of unified focus for learners. Laurillard (1993) draws attention to the decentralising effect of new technology. She argues that this can push forward a very fragmented view of knowledge. This is opposed to, what she typifies as, ‘academic knowledge’, which has an integrative function different from simply ‘knowledge’. It is this reflective aspect which is likely to prove difficult to deliver in the information model described by Dolence (1995). Learners in a virtual campus may well require a much stronger structural identity. It is, therefore, important that there is a strong conceptual platform that integrates and preserves a sense of intellectual and discipline consistency.

Local implementation

At a local level, we have attempted to incorporate such issues and challenges within a conceptual and pedagogic framework for the education of information engineers. A set of modules has been implemented within a conceptual framework entitled Systems, Techniques, Implementation, and Integration (STIMI). An outline of this is shown in figure 1 (The STIMI Progression). In stage 1, the concept of systems and systems thinking is introduced to students. This theme is elaborated in separate semesters in stage 2. The first emphasises the usual systems analysis techniques of process, data, and event modelling. Implementation within the context of Computer-Aided Production Management (CAPM) is combined in the second semester. By stage 3, management and management-information related issues are addressed by examination of strategic and operational planning aspects. The integration of ‘islands of automation’ within the context of manufacturing businesses is the prime concern of the postgraduate programme. This module is designed to enhance the learning experience of those continuing students who wish to pursue their studies at this level, together with providing a firm base for external students entering the programme from a wide range of industrial and educational backgrounds.
The basis of delivery for the modules is illustrated in figure 2 (Support for Module Teaching programmes). A body of structured teaching material (linked and sustained by four pillars that rest on the STIMI conceptual foundation) has been developed to minimise duplication of content and to provide a common platform for delivery. Following Race (1989), this incorporates a range of techniques developed from Open and Distance Learning models, such as self-assessment questions and other developmental questions and activities consolidated within the text.

The particular problems of part-time students, those students beginning their studies at differing entry points, and students who require extra support are recognised, and are of especial relevance within the context of this paper. Such students have significant demands placed upon them by work and family pressures so such students can also access this material via the University web site. Open and distance learning material may appeal to university management because of its apparent cheapness, but such students are likely to require significant support mechanisms. They may be unfamiliar with the nature of independent learning implied by a higher education programme of study. How are such mechanisms to be implemented and managed given an electronic local campus, let alone a ‘global campus’? Learner support in the global campus will rest upon two pre-requisites: learner support and technological delivery mechanisms. We will address the latter aspect later in this paper. For now, we wish to describe briefly some of the issues involved in supporting widely-dispersed learners. Such learners may well be dispersed temporally as well as geographically. The use of packaged material (CD-Rom, text-based and other resources) is the conventional means of handling knowledge content. But how can learners benefit from a shared learning experience? Romiszowski (1995) describes how a co-operative programme can be established, and can be extended by various Internet and Web-based technologies - bulletin-board conference facilities, email, links to resource materials (virtual museums, virtual libraries). All of these offer significant potential as an integrated collaborative platform.

**Distributed learning**

Such initiatives still, however, rest upon a traditional view of teaching and learning. The support of Distributed Learning paradigms should now be considered. Distributed learning is founded on the belief that the personal needs of the student are paramount. Academic institutions can evolve courses based upon modules (STIMI), that can expand choices for students whilst maintaining educational quality across location and time-bound constraints, as well as providing the student with a more self-paced, self directed, career-biased learning experience. A distributed learning environment can essentially be stand-alone with a single subject/operator or can be linked via with a common database and/or other systems into a distributed system/servers. The common database may either be held centrally (and modified if required by each system/server) or local copies can be used with changes highlighted to the other components of the system/network. For example, for a design engineer a distributed learning environment is desirable, but design engineers can be trained individually. For other learning contexts, it is mandatory, especially where teams of operators interact in command and control of resources. An example where a distributed environment would be mandatory is in Air Traffic Control where visualisation of air space needs to be accessed and controlled by many operatives.

**Technological aspects**
One of the potential problems with distributed learning is data transmission rates over networks. Optical Fibre technology has developed such that within the near future transmission rates of 10 Gigabits per second will be possible over broadband optical networks (Chan, 1995). A current or near term technology is the so-called "DVD" CD-ROM (Bell, 1996) where data is written to a multi-layer CD. This technology gives the CD-ROM the capacity to store up to 17 gigabytes on a single disc with a data rate capacity of 11 Mbits per second.

Such technologies (given development) are of direct relevance to Distributed Learning and its application, by affording a platform for the development of such teaching aids as Virtual Reality (VR). Given the inherent ability of VR to display three or multi-dimensional properties of objects to an operator its uses in teaching and training are virtually endless. It must, however, be remembered that VR is essentially only a display tool and therefore cannot fully substitute for other forms of learning. It is also important, given the growing importance and development of VR technology, that VR itself should be taught as a module at core level (STIMI). Being a multi-disciplinary subject it can only be taught at a relatively high level. It should however become a mandatory subject in all information technology courses even if minimum time is devoted to it (Elson, Sims [1997]).

Table 1 below lists some potential applications for VR in teaching. This list is not meant to be complete and many other applications may occur to the reader.

For basic tutorial type work the basic technology already exists with PCs and CD-ROM's. For more extensive use lightweight cheap helmet-type displays need to be available along with the appropriate computer technology (fast networks delivering M-Bytes per second).

In conclusion then, the Global Campus is a rapidly developing field with many potential applications. It has direct application to teaching and training at many levels. Educators should be made aware of the capabilities and limitations of the technology. Distributed systems are required for its effective use. The concept of a Global Campus offers a useful metaphor for the delivery of a new mode of education, supported by fast and flexible delivery mechanisms.

Information and Communications Technology: Teachers' and Students' Preconceptions and the Implications for Teacher Education

D. J. Clare, Department of Design, Goldsmiths College, University of London, UK, d.clare@gold.ac.uk

J.L. Backwell, Independent ICT Consultant, JB Consulting, UK, john.backwell@mono.edex.co.uk

Abstract: The authors have for some time been concerned with notions about information and communications technology (ICT). The term has only recently come into use in the UK, where information technology (IT), had been previously used. Elsewhere IT is still common as is Telematics or Informatics, even when the term is agreed there seems little consensus as to its meaning. Although there might be some agreement between teachers, the authors are not sure this extends to their students. Within the constructivist tradition, it is considered vital that teachers understand and take account of the preconceptions of students for successful learning to take place. Where no shared understanding exists, planned learning is unlikely to happen. This paper introduces a research project investigating the preconceptions of teachers and their students and, with reference to initial findings, identifies possible implications for teaching, particularly in the context of teacher education.

Definitions of ICT

The development of integrated circuits and in particular very large scale integration and microprocessors in the 1970s led to what has been widely called the second industrial revolution. In the early 1980s, the term information technology (IT) was being used to describe the resulting microelectronics-based computers and associated technologies. At this time, the newly developed microcomputers started appearing in schools, with peripherals and software. In the UK, in response to perceived challenges to competitiveness in microelectronics industries, government initiatives to support IT in industry and in education were launched. It was generally assumed that IT included computer hardware and software artefacts and functions but no single definition was dominant. In the UK a number of organisations and individuals gave their own definitions including, IT:

is 'the technology associated with the communication, storage and retrieval of data' (Chandler, D. 1984)

'includes matters concerned with the furtherance of computer science and technology, design, development, installation and implementation of information systems and applications' (San Diego State University 1998)

There are many more, but in particular from the UK central government education department, IT is:

'the technology associated with the handling of information: its storage, processing and transmission in a variety of forms by electronic means, and its use in controlling the operation of machines and other devices' (Her Majesty's Inspectorate, Department of Education and Science 1989)

'the use of technology to process information by the use of computers or electronic telecommunications' (Her Majesty's Inspectorate, Department of Education and Science 1991)

'the acquisition, production, transformation, storage, and transfer of data (information) by electronic means – in forms such as vocal, pictorial, textual, and numeric – so as to facilitate interactions between people and between people and machines. It also includes the applications and implications (social, economic and cultural) of these processes' (Mansell, J. et al 1987)

Even where definitions are published by the same organisation, then, there is not necessarily an agreement. Most definitions do include reference to microelectronic technology and its use in dealing with information...
(rarely differentiated from data), with varying degrees of detail. Since there is then no authoritative definition of ICT, for the purpose of this research the authors have taken the Further Education Unit (Mansell 1987) definition as a convenient starting point.

In UK education, in 1988 the National Curriculum for England and Wales was enacted. This included statutory Programmes of Study for IT Capability for all school students in maintained schools from 5 to 16 years, and Statements of Attainment for assessment and reporting learners’ progression in IT Capability, which were published in 1990. The IT elements have been revised since (1995 and 1999) and now, termed ICT, include the definition:

‘ICT is used to refer to the range of tools and techniques relating to computer-based hardware and software; to communications including both directed and broadcast; to information sources such as CD-ROM and the Internet, and to associated technologies such as robots, video conferencing and digital TV’ (Department for Education and Employment 1999)

It is worth noting that the UK government has also introduced the statutory Initial Teacher Training National Curriculum for the use of Information and Communications Technology in Subject Teaching (Department for Education and Employment 1998a), relating to this definition of ICT. This includes discrete and compulsory Expected Outcomes in ICT for all students graduating after 1998. To accomplish the government’s targets that ‘serving teachers should generally feel confident, and be competent to teach, using ICT within the curriculum’ and ‘most school-leavers would have a good understanding of ICT’ by 2002 (Department for Education and Employment 1998b), a major programme of continuing teacher education has also been established for practising teachers. This is based on published competencies by the Department for Education and Employment reflecting the initial teacher education expected outcomes and the published definition of ICT.

### Meaningful learning

Ausubel (1968) used the term meaningful for learning that related to a learner’s own constructed knowledge, indeed he considered ‘the most important single factor influencing learning is what the learner already knows’. This sentiment certainly relates to classroom experience where teachers will generally agree it is much more effective to start ‘where the student is’ then move to new knowledge, skills and understanding than making inappropriate assumptions and see little learning. Driver (1983) undertook her highly regarded research in science education on this theme identifying the alternative frameworks students construct and, when in conflict with the framework the teacher intends communicating, prove a barrier to learning. She fully concurs with Ausubel’s (1968) statement that ‘preconceptions are amazingly tenacious and resistant to extinction’, recognising the importance of the teacher understanding those preconceptions and designing learning experiences accordingly.

The authors see this as relating to teaching and learning in ICT. Although the issue of knowledge acquisition is less significant than developing skills and gaining understanding, it is as important that these are meaningfully developed, through a clear understanding of students’ preconceptions. To gain some insight into the issue of alternative preconceptions a research programme was set up to discover what students (15-16 years old) understand by ICT. In addition, the same was attempted with teachers and initial teacher training students, for whom the research was extended to also find out what their expectations were of their students’ preconceptions.

### Methodology

It was considered inappropriate to ask subjects to define ICT since initial work indicated this would at best result in rote-learned definitions, students being well practised in giving teachers the ‘right responses’, that is those that the teacher wants to hear. This is no less true of teachers and student teachers. For the initial research then, a questionnaire was prepared asking subjects to identify items listed as examples of ICT by choosing yes, no or not sure. The items were chosen to reflect the preferred definition and to include examples of audio, graphical, textual and numerical media; acquisition, production, transformation, storage and transmission...
functions. The items for each included what the authors considered to be strongly, weakly and unlikely examples of ICT. For example, for audio transmission:

Megaphone
Radio
Mobile phone

were listed. In addition, items that did not fit into any one category were included, such as:

Internet
Automatic doors
Air-cushion trainers
Books

In all 90 items were listed, in alphabetical order. For teachers and student teachers, two lists were given one for their own responses, the other for their expectations of the response of a typical 15-16 year old. In addition, teachers and student teachers were asked to identify their own Gender, Main teaching subject, Age band (five bands).

The initial results discussed below come from:

314 student returns, 48 teacher returns, 36 student teacher returns

The students and teachers were asked to complete questionnaires in the autumn of 1999, the range of schools was selected to approximately represent the comprehensive education of males and females between 14 and 16 years old and in London, and includes single sex and co-educational schools. Approximately 20% of dispatched questionnaires were returned completed. Very few items were not responded to, blank returns being considered insignificant. The data received represents the first phase of a bigger project targeting receipts from up to 5000 students and 1000 teachers, and from that quantitative survey follow-up interviews will be undertaken.

The student teachers were post-graduates following subject-based programmes for teaching students of secondary school age (11-16 years). All attend one University in South London and were mixed in terms of age, gender and main teaching subject. This data was also collected in autumn, 1999. These represent limited samples for quantitative research, yielding only indicative results to which further, more substantial data sets will be added as the project progresses.

The initial analysis determined the degree of confidence each group demonstrated in choosing yes for each item, that is in considering the item was an example of ICT. This was calculated by comparing the proportion of yes responses to no and not sure responses giving a value of between +1.0 and -1.0 for each item. A band of confidence measures between +0.33 and -0.33 was considered adequate to cover confidences calculated from non-significant data, that is responses that could have occurred by chance alone. Values above +0.33 were identified as having high confidence as examples of ICT and probably representing a tacit understanding of ICT.

The data for each subject group was formatted as ranked lists of items (Tab. 1), although there was some clumping of rankings and the size of the differences in confidence varied the ranked lists are useful indicators of these tacit ICT definitions.

Table 2: The number of items identified as examples of ICT with a high degree of confidence

Results

The numbers of items confidently chosen as examples of ICT varies considerably with a clear indication that teachers and student teachers include a wide range of items in their own definition of ICT while including a much smaller range in predicting student responses (Tab. 2).

Within the items identified by the data from each subject group there are fourteen items common to all data sets, these largely represent visual media with only one example each of sound (mobile 'phone) and numerical types (spreadsheet). The extent of this difference is not as marked in individual subject groups.

Conclusions

The data sets used are small and to some extent lack reliability, particularly in terms of validity, however they do indicate possible trends. The expectations of teachers' and student teachers' definitions of ICT thought to be held by students were very different from their own in terms of scope. In addition, they differ considerably from the students' actual choices that represent approximately, what one might expect (about 1/3 of items confidently identified as examples of ICT). There is some indication of underestimating students' understanding of the range and variety of ICT, and at the same time maintaining the very broad definition apparently held by their teachers. Although there is a core of common items selected, many more within students', student teachers' and teachers' definitions are not common across all groups, however mapping this core onto the selected definition shows all aspects to be covered in terms of examples. This does not in any way suggest the definition could be derived from the examples:

'...the acquisition [digital camera], production [laser printer], transformation [scanner], storage [electronic mail], and transfer [internet] of data [information] by electronic means – in forms such as vocal [mobile 'phone], pictorial [satellite TV], textual [wordprocessor], and numeric [spreadsheet] – so as to facilitate interactions between people [fax] and between people and machines [teletext]. It also includes the applications and implications (social, economic and cultural) of these processes' (Mansell, J. et al 1987)

A survey of items largely categorised as not ICT or unsure includes games console, lottery terminal (National Lottery device used to electronically enter the draw and transmit data which is held centrally), lottery lucky dip (generates random lottery numbers) and cyberpets. These are all relatively high profile applications and might have been expected to be chosen. Synthesiser and plotter were also largely in the not ICT choices. These lead to speculation about the subjects' knowledge of the named technologies or perhaps the fact that questionnaires were completed in educational environments led subjects to ignore ICT outside that context. This condition is reflected in published case studies where traditional ICT applications are related, almost exclusively, as examples of good practice.

Despite these speculations, the ranges of items included in subjects' choices indicate a generally broad perspective on ICT although this also includes a great deal of uncertainty. This indication of uncertainty causes some concern, not only regarding the points made above about the need to understand the students' preconceptions to engage them in effective, planned learning but also in terms of clarity in the planning itself when intentions are unclear.
The indications outlined above emphasise the good practice of diagnosing the starting points of students, to inform planning for teaching and learning. This is perhaps less obvious in ICT education than in other, traditional and more knowledge-based subjects. Many of the definitions, particularly those promulgated by government departments, describe ICT largely in terms of tools to be applied elsewhere. It would be easy for a teacher to make assumptions about students’ understanding while focussing on the application, possibly missing opportunities for students to also progress in their understanding of ICT. The other side of this is having inappropriate expectations of understandings and skills, obviating the achievement of any objectives or limiting the appropriate exploitation of ICT. For student teachers, these issues are compounded by their need to monitor and exploit their own uses of ICT. A first step in this might be to encourage student teachers to determine their own definition of ICT. By necessity, this will need to be flexible since the technology is continuously developing, as are individual relationships with ICT resources. Student teachers should also take advantage of time in schools to explore students’ preconceptions, aspirations and situations in order to identify their needs and celebrate achievement. To understand their learners and to recognise the potential, both positive and negative, of ICT in their education, teachers and student teachers will need to share in students’ perspectives on ICT and use or challenge preconceptions in a planned, considered approach.

Abstract: This paper is a report on developments arising from the collaboration between a number of institutions and departments of teacher education under the European Commission SOCRATES programme. The background and aims of the developments involve the building of the "European dimension" through the use of multimedia and the World Wide Web into schools and teacher education institutions. In reflecting upon these developments in general terms, the role of telematics has played a crucial part in promoting communication, fostering the development of social relationships across the project team and facilitating the effects of synergy arising from this collaboration. Sustained and effective communication is seen to be the key to the success of such collaboration at all levels. A collaborative goal-oriented approach leading to purposeful activity can be seen as a common feature of the successful working of the project team, groups of student teachers and also pupils in schools.

Background and aims of the development

The EUROLAND project (1996-99) has been supported as an In-service training project under the Comenius 3.1 Action of the SOCRATES programme of the European Commission. It brings together partners from Austria, England, Finland and the Netherlands, in building the European Dimension into the curriculum of schools and teacher education courses (see also Hudson et al. 1997 and Hudson et al. 1999). The aim of the project is to develop the curriculum through the production of resources and teaching approaches with a cross-curricular focus at the upper primary/lower secondary school age range (8-14). The classroom resources are built around the use of a CD-ROM with simulations of and links to the World Wide Web. Teacher education institutions and departments lead the project in close collaboration with partner schools and teachers in each...
country. The resources that have been produced by the project have been used as the basis for the development of pedagogical approaches with teachers on intensive in-service training courses, which have been supported under the Comenius 3.2 Action of SOCRATES. They have also been used with students in initial teacher education via the SOCRATES European Module ECOSCHOOL (1997-2000). This project has been supported under the ERASMUS Action of SOCRATES that focuses on development in Higher Education. The content of the EUROLAND project involves the geography, history, economics, sights of interest and aspects of day to day life of the participating countries. Further it includes opportunities for the development of literacy, numeracy and ICT skills in problem solving contexts relevant to real life.

Nature of the resources and tools

The CD-ROM resources are used in an integrated way within the classroom with an emphasis on group work and discussion. Through this activity, it is intended that pupils gain increased knowledge of the capital cities and countryside of Austria, Finland, the Netherlands and England. It is further intended to provide opportunities to develop:

- information skills in the use of maps, charts, timetables and tourist information literature;
- skills of numeracy, literacy and ICT through problem solving activities in a European context;
- decision making skills in real life contexts and
- a wider awareness, appreciation and understanding of other countries and cultures in Europe.

Full use of the resources is intended to address the three aspects of Information, Activity and Communication. Students use their ICT skills to access Information from the CD-ROM and the WWW. They engage in problem solving Activities through the activities section on the CD-ROM. Further they develop their Communication skills through group discussion and also their wider communication skills by utilising possibilities to link to the World Wide Web and to make use of the EUROLAND Discussion Forum for example.

Users

Currently the resources are being used in a number of schools in Austria, England and Finland. The materials have been used also by groups of teachers from across Europe as the basis for development and evaluation as part of the Comenius 3.2 In-Service training action. Courses have been held in Linz in April 1997, in Sheffield in July 1999 and a further course will be held in Sheffield in February 2000. As a result of the recent course in Sheffield, a EUROLAND “chat day” is planned for January 2000 involving school students from Austria, Finland and the UK, with further participants expected from the other countries. In addition a videoconference was held in November 1999 between Oulu, Linz and Sheffield as part of the European Commission Netd@ys Europe initiative. The main objective of this initiative has been to familiarise participants with the possibilities of new media such as multimedia and video-conferencing, with priority given to supporting projects based upon educational content rather than to technology. The focus of this videoconference was a comparison of prices of different shopping items in the three different countries, which took its initial motivation from the EUROLAND section on “shopping”.

The ECOSCHOOL project leads on from EUROLAND developments by focusing on web-based learning and communication. It is a potential means of students and teachers discussing their use of EUROLAND although the project is not entirely dependent on the use of the CD-ROM resources. Accordingly the ECOSCHOOL project has two aims:

- to develop learning by using the WWW and email across Europe, and
- to learn about the social and economic aspects of the participant’s home city.

The resources and tools being used are university email communications and the resources provided by the ProTo environment at the University of Oulu – Project Learning Tools on the Web. This is an open learning environment that has been developed at the University of Oulu. Students can access the ProTo system via the World Wide Web. They have a password that allows them to create simple web pages and enter messages on a bulletin board.

The participants are primary teacher education students from Linz and Sheffield together with students on an international teacher education course at Oulu. A more recent partner to this development is the University of Darlana in Sweden. This has led to the participation of a group of social studies student teachers from Falun in Sweden.
Theoretical framework

The pedagogical approach underpinning the EUROLAND development is strongly influenced by a socio-cultural communicative perspective, as outlined in Hudson (1998, 1999). This approach is underpinned by the notion of Activity whereby students are engaged in purposeful tasks that can involve group work, discussion, problem solving and the use of ICT. Some of the activity is computer-based whilst some is away from the computer. A full and active role for the teacher is envisaged that involves the introduction and structuring whole class activities, monitoring group activities, intervening with individuals and small groups and drawing the class together in whole group discussion where appropriate. The role of the teacher in a technology rich classroom is discussed more fully in Hudson (1997). The open-ended nature of the resources enables use by students across a wide range of capabilities.

The European Dimension

A key aim of the project has been to promote the European dimension and the use of ICT in teacher education across Europe. The design of the material and the pedagogical approach has, therefore, been developed to accommodate implementation and wider development. Phase one developed the foundation for the project by focusing on resources for Austria. At the time of writing, the Finland section is practically completed and work is ongoing on the UK section. The CD-ROM contains content-based information with Web links, teacher’s notes and classroom activities. The Web site provides information about the project and is the basis for evaluation activity and further development of the communicative aspects of the project. The first version includes multilingual audio tracks on the CD-ROM (English, Finnish, German and Dutch) and corresponding versions of the evaluation forms. The final phase of the project will involve the implementation of appropriate sections of the material in the languages of the partner countries.

Example of use

Links to the Web have been incorporated and a Web site for the project has been established. The Web site includes both EUROLAND and ECOSCHOOL forums. The former has been used mainly by teachers and pupils in participating schools whilst student teachers have been the primary users of the latter. This section of the paper gives an account of how the ECOSCHOOL project has developed in particular.

Initially students in each country worked in collaborative groups to produce a short illustrated report on one of the following aspects of their home city. This involved:

- a general description of the city;
- the environmental situation of the city;
- the employment structure and opportunities within the city;
- the regional or national education system.

Subsequently they presented these reports as web pages by writing them in to the ProTo learning environment. Figure 1 shows a page produced by the Sheffield students.

They also emailed their work to other students in the partner countries who were presenting the same topic. Once all web pages were complete, they read their partner’s pages, asked questions and made comments about them on the bulletin board.

Each group evaluated their work using the same criteria designed by the tutors in each country. The tutors then read each group’s pages, assessed the pages and provided feedback to the each group. The students’ work was assessed against the criteria and graded A to C. The tutors posted written feedback on the bulletin board.

Three cycles of the ECOSCHOOL project have been completed; one is in progress at the time of writing. Figure 1 illustrates an example from the first cycle in which each group of students presented their own home city.

Figure 2 is an illustration of the activity in the second cycle. The aim of this round of co-operation was for students to share lesson plans and teaching ideas. Each group of students planned lessons with the aim of children learning more about their local town or city.
Figure 1: Work from the Sheffield students posted to the ProTo learning environment.

Figure 2: Teaching and learning about Sheffield
Evaluation

Evaluation has been an ongoing aspect of this development and has been built in as an integral part of the developmental process. Feedback has been gained from teachers involved in the in-service courses; teachers and pupils involved in classroom trials in the pilot schools and students on initial teacher education courses. The project Web site has been designed specifically to facilitate on-line evaluation. The evaluation of the use of the EUROLAND CD-ROM can be carried out in English, German, Finnish or Dutch.

With specific regard to the ECOSCHOOL project, the analysis of evaluation data for the first cycle shows that the students developed their ICT (Information and Communications Technology) skills and confidence during the project. The majority of students in all counties reported that they had linked well with their partner students by email and by using ProTo. A key issue was the demand for academic credit for their work, as this project was not assessed as part of their degree programme. The students who took part were motivated and enjoyed the process. This is significant and positive point as all the students had limited ICT skills at the start of the co-operation and many students viewed the creation of Web pages with some anxiety.

Evaluation of the second cycle revealed that communication between the students was not as frequent as in the first cycle. Reasons given for this lack of communication included the 'interruption' of the project by school teaching practice in the UK and Finland, and that students spent more time on constructing their own pages than communicating with their partner groups. This time the work formed part of an assignment at Sheffield Hallam University so the students received credit for the design of their Web pages and for the production of a report concerning the project. This pressure of assessment had two effects; it satisfied the students in the demand for academic credit, but it also reduced the importance of informal communication between the groups.

The ECOSCHOOL project has involved the use of ICT appropriately to support environmental and social learning. It has been successful in terms of developing ICT skills, subject knowledge and has provided the opportunity to compare different approaches to teaching and learning across the European Union. Sustained and effective communication is the key to such a project. This can be elusive and an important finding from the evaluation process is that placing too much focus on producing the resources can hamper communication.

Primary and secondary schools in the UK are now being connected to the National Grid for Learning and students need the skills and pedagogic understanding to use ICT as a medium for European and global communication. The ECOSCHOOL project has prepared teacher education students for developing communication projects when in school. One student has already set up a similar project whilst on teaching practice. In this example infant school children communicated via email with children in Bermuda and compared their localities, hobbies and homes as part of English and geography learning.

Discussion

The ECOSCHOOL project is running during the autumn 1999 with several new developments. The students are in internationally composed groups rather than from one single country; the focus of the project will be to choose an educational problem and present a solution to this by co-operating and communicating using ICT. The students can use email, create their own web pages, use ProTo2 (a more sophisticated version), or use the EUROLAND bulletin board at http://www.shu.ac.uk/services/cnweb/euroland/digroups.htm.

It is timely to reflect upon the overall aims and objectives of the SOCRATES II programme of the European Commission which is the programme that is currently being phased in to replace SOCRATES I. This places the emphasis on lifelong learning as a means of fostering active citizenship and enhancing employability. The objectives contain many elements that can be seen to be very relevant to the experience of the project team with regard to the developments outlined in this paper:

- To strengthen the European dimension in education at all levels and to facilitate wide transnational access to educational resources in Europe while promoting equal opportunities throughout all fields of education;
- To promote a quantitative and qualitative improvement in knowledge of the languages of the European Union, in particular those languages which are less widely used and less widely taught, so as to lead to greater understanding and solidarity between the peoples of the European Union and promote the intercultural dimension of education.
- To promote co-operation and mobility in the field of education, in particular by: encouraging exchanges between educational institutions,
- promoting open and distance learning
- encouraging improvements in the recognition of diplomas and study periods,
- developing the exchange of information,
and to help remove obstacles in this regard.

- To encourage innovation in the development of educational practices and materials and to explore matters of common policy interest in the field of education.

In reflecting upon these developments in general terms, the role of ICT, multimedia and the WWW or (more concisely) telematics has played a crucial part in fostering communication, facilitating the development of social relationships across the project team and also the effects of synergy arising from this collaboration. A core group of partners involved in these developments began their collaboration in the autumn of 1994 around a shared interest in environmental education and supported by the European Commission as a network, which met just twice a year. The communication between meetings consisted of fax only at that time. The transformation that has taken place since then owes much to the effects of telematics in fostering communication between project members and facilitating the current level of collaboration which has the potential to develop much further.

The successful synergy effects can be seen in the level of teacher and student exchanges between the partners and the level of joint teaching, curriculum development and evaluation and increasing levels of research and international dissemination activity.

Sustained and effective communication is seen to be the key to the success of such collaboration at all levels. A collaborative goal-oriented approach leading to purposeful activity can be seen as a common feature of the successful working of the project team, groups of student teachers and also pupils in schools. The role of telematics has been crucial to achieving this stage of development.

We believe that we have learned a great deal collectively from our experience and that there is enormous potential for further development. We hope that we have something to offer others who are interested in learning from our experience and look forward to benefiting from wider responses to our dissemination activities.

Abstract: The information age challenges pre-service teacher education to change rapidly. This is the result of the catalytic impact of technology on the changes in society at large, and consequently on the changes in the role of learning and teaching in society. Therefore the challenge is not only that prospective teachers need to acquire the knowledge and skills to use Information and Communication Technologies (ICT) in education, they also need to learn a new approach to teaching and learning. In 1997 a national contest in the Netherlands challenged all Colleges of Education to put forward a proposal for the development and implementation of a new approach to teacher education, reflecting the needs of the information age. As a result two Colleges attained the status of 'Experimental College of Teacher Education'. In the four contributions of this panel the vision on education and the implementation after two years of experience are shared.

Curriculum Innovation between Care and Courage: National Curricula and Innovation Strategies in the Netherlands

In November 1996 a Dutch ministerial committee published a report about the transformation needed in education to meet the demands of the 21st century. The changes that are taking place in society are

963
characterized as a transformation from an industrial society to an information society. This transformation
influences all levels of society and will have enormous impact on education. However, the consequences
of this transformation can not be predicted, because the future is yet unforeseen. It is fundamentally
impossible to foretell what new ways of education there will be in the future and the only senses we have
are for today. This transformation requires a process of change in education of which the outcomes are
unknown. According to the committee two parallel strategies are necessary to move from the old, present-
day situation to the new situation. These strategies are characterized by the words 'CARE' and
'COURAGE':
- CARE for the existing system: how can we make innovations in the existing system, taking care of the
  present-day students and schools.
- COURAGE to start experiments that will give some outlook into the future: exploring new ways, new
technologies, new methodologies.

A crucial factor in the dilemma of the combination of CARE and COURAGE is the extend to which the
innovation of teacher education is based on explicit ideas about the future of teacher education. Often, the
changes in the policy and regulations from the government are brought forth by problems in the present-
day system and not explicitly by ideas about how society is changing and what the consequences of these
changes are for education. These two approaches of the innovation process should be really complementary: together they create a
change process that is both realistic and innovative and in which teacher education institutions are able to
innovate their curriculum along different routes at different speed according to the local situation and their
potential for innovation.

Since 1996 both the CARE-line and the COURAGE-line have been present in two major developments
concerning curriculum innovation in teacher education in The Netherlands:
1. The Minister of Education started a process to develop a 'national curriculum' for teacher education;
2. The Minister started a program on the implementation of information and communication technology in
teacher education.

CARE: A National Curriculum

A national Process Management developed a project plan, in which they described their main aims to
improve teacher education: Curriculum innovation: development of common curriculum guidelines and
teaching goals for primary teacher education and secondary teacher education; Regional co-operation
between the institutions for teacher education; Professional development of teacher educators.
In March 1998 the national curricula for primary teacher education and that for secondary teacher
education were published. The underlying assumptions in the national curricula about 'good' teaching and
learning and teacher education are that teaching is a pedagogical process and that good teachers are able to
reflect upon themselves and the teaching situation in order to improve teaching and learning.
The curricula exist in three parts. The first part is the introduction to the national curriculum. The second
part consists of quality standards that each institution for teacher education has to meet. These standards
give an indication about the quality of the curriculum that must be developed on an institutional level, and
give institutions a lot of freedom and responsibility in the actual translation of a national curriculum into a
institutional curriculum. The third part of each of the national curricula contains the teaching goals for the
general pedagogical part of the curriculum and for each school subject.
The national curricula mirror the existing views on teacher education in The Netherlands. They are
important tools in the discussion about teacher education because they present a general view on teacher
education, quality standards for all institutions for teacher education and general and subject related
teaching goals that can be used to assure the quality of teacher education in The Netherlands. In this respect
the national curricula represent the CARE-line.

COURAGE: Innovative projects, the experimental teacher education program and research

In answer to the committee-report the Minister of Education started a program on the implementation of
multimedia and ICT in teacher education in June 1997. The main aim was to stimulate the integration of the
use of ICT in the curricula of teacher education. This was done by challenging the institutions to start projects and experiments based on new teaching methods, combining CARE for the existing practice and COURAGE for new way of educating teachers. In this way new ‘emergent practices’ evolved. These emergent practices in which ICT is used, will fit with the new ideas on education, in which concepts like active and self-responsible learning, problem-based learning and learning strategies play a central role. The program contained several elements: Institutional projects, Experimental teacher education program, Development of new educational software, Research on and monitoring of the use of ICT in (teacher) education, Regional centers of learning technology. After a contest two institutes were designated to host an experimental teacher education program. The Ichthus Hogeschool Rotterdam conducts an experiment on a restricted base (elementary schol level, with each year an increasing number of students involved). The Amsterdam Faculty of Education, on the other hand, is transforming a whole large faculty that provides for 4000 students. In this SITE-panel both experimental teacher education programs are represented, together with people who conducted academic research during the development and implementation of the new programs.

The Courage-line and the Care-line have been separate developments in the period 1996-1998. The most important difference is the perspective: while the Care-line focuses on the system of today, the Courage-line focuses on the demands that the rapid changes in society place on education. This separation between both lines can be seen as a necessary phase in the innovation of teacher education. To start a transformation from present-day teacher education to teacher education for the future, it is necessary to have consensus about what good present-day teacher education is. By taking the initiative to develop a national curriculum for teacher education the government has defined the starting point of the transformation of teacher education towards the demands of the information society. The simultaneous implementation of the national curricula and the Courage-program also has its problems. If emerging practices and experiments on new ways in teacher education have to fit in the national curriculum, within today’s system of teacher education, the innovation is limited. When the experiments have to exist within the boundaries of the existing system, the existing educational model and the existing practices of assessment, it is impossible to really discover the possibilities the future has to offer. This is the challenge where the two experimental teacher education colleges have to cope with in implementing their visions and ideas of a new curriculum. After all, Care for the existing must lead to Courage for the new.

The Education of Teachers: A Change in the Concept of Curriculum is Needed

The Amsterdam Faculty of Education, which attained the status of “experimental teacher education” in the Netherlands through a national contest in 1997, is developing and testing a new curriculum concept for professional education, focused on meaningful learning. Education should reflect the way a professional works. This means that students, like professionals, work together on complex authentic tasks, and take control and responsibility with respect to their work, their learning processes and the way they will prove competence. In this concept, nicknamed “learning through producing”, we integrate ideas on authentic learning practices, first-order and second-order learning, integrative assessment and electronic web-based portfolio systems. ICT is not used as an add-on technology, but the technology plays a role as catalyst of the curriculum transformation in the same way it induces changes in society. In our view, this new type of “dynamic” curriculum meets the needs of professional education in the information age.

Core Characteristics of the Experimental Teacher Education Program

**Capable of managing change:** Teacher Education should adequately prepare students for their profession in a largely unknown future. We cannot predict what that future will be like. However, what we do know is that in the decades to come there will be an increasing demand for professionals who are capable of coping with change and who can shape education in the information society – not only because teachers must be able to react quickly to changing circumstances in their teaching, but also because learning paths, in part due to rapid developments in information and communication technology, are becoming increasingly individualized. This does not necessarily mean, however, that learning is an individual activity. For teachers, this means that they, above all, as experts in guiding learning processes, must be able to shape their own learning processes.
Responsible Students: The program should offer students an environment in which they are indeed given the opportunity to shape their own learning processes. For this, students need to be given responsibility and they need to accept it - responsibility not only for the way in which they acquire the (constantly changing) competencies they will need in professional practice, but also for the way in which they demonstrate to the outside world that they have indeed acquired these competencies. To this end, at an early stage, the program offers students an environment that mirrors professional practice. In that environment, acting responsibly is related to real working situations. We view the program as a collection of facilities which students use to take responsibility for realizing their learning processes.

Freedom: In this environment, students have a considerable degree of freedom in filling in the details of their own learning processes. Our program operates in a context in which the requirements for newly qualified teachers are stipulated by law. This means that, although students should be given the opportunity to create their own learning paths toward becoming adequately qualified, we wish students to demonstrate to us, through integrative moments of assessment at three points in the program, that they have acquired the competencies they need to be admitted to the next phase. This view is in contradiction with the dominant view in education, namely that under the direction of the institution offering the program, the road to becoming a competent and qualified teacher consists of parts of a curriculum that have been determined in advance, and that evidence of competence is synonymous with the successful completion of those parts of the curriculum.

Dynamic Curriculum: Given the goal of our experiment and our view of teacher training, the current static curriculum needs to be made more dynamic. This is necessary because:

- Students must have the freedom, in consultation with their mentor, to shape the learning processes they feel are necessary to acquire the required competencies;
- Students must have the freedom themselves to organize the evidence they wish to present at the integrative moments of assessment;
- The program must have the freedom to be able to anticipate and react quickly to changing circumstances in society. In fact: the program itself must also be capable of quickly coping with change.

Authentic Learning in Professional Education: At as early a stage as possible, the program should create an environment for students which mirrors professional practices. Learning during the program must be linked as far as possible to useful and responsible work resembling work in the profession for which one is being trained. In professional practice, teachers have to carry out relatively complex tasks that fit in with the objectives of the school. To be able to do this useful work well, they must be able to use ‘two kinds of learning’. They should not only be able to acquire on their own initiative the knowledge and skills they need to do their job well (learning of the first kind), but they should also be able to continue to learn from the experience gained and to experiment systematically with actions leading to improvement or change (learning of the second kind).

Both kinds of learning are important in the concept of ‘lifelong learning’. Both are ‘guided’ by the competencies, which the competent and qualified teacher must have. The program offers an environment in which students can (and indeed should) put these two kinds of learning into practice in order to acquire the skills required for the profession.

Each learning process the student goes through in that environment consists of the phases of orientation, planning, execution and evaluation, and is guided by the competencies derived from the professional profile.

Assessment: For students this means that, in their orientation with respect to the learning and working process, they take the competencies they need to acquire as their point of departure. In doing so, they are aware of the fact that at a later stage, during the assessment, they will have to demonstrate that they have actually acquired the required competencies using their portfolio. On the basis of that orientation, they formulate concrete learning goals and activities (plans), subsequently work on useful products in a learning environment created by the program (execution), and, finally, they evaluate the degree to which those activities have contributed to the realization of their learning goals and the acquisition of competencies. The assessment of a teacher’s work is – if all is well – based on the degree to which the teacher’s work has been useful in aiding the achievement of the school’s objectives, and on the teacher’s ability to make
improvements and cope with change. This assessment is therefore not based on disconnected knowledge and skills. Since the program is intended to mirror professional practice, it includes at three points in about four years time an integrative assessment based on competencies. During these assessments, students must show that they are qualified to take the next step: first to be admitted to the main phase, then to enter the assistant teacher phase, and, finally, they need to show that they are competent and qualified to start a professional career. The student’s admission to each phase depends on the outcome of these integrative moments of assessment, which are in that sense decisive and final. During these integrative moments of assessment, students demonstrate individually to a small committee (consisting of people from within the institution and from outside) that they have reached a level of development which is at least that required. They also show how their growth in acquiring competencies has progressed so far. As proof of their growth, students must compile a ‘showcase’ from their portfolio containing results of their work and studies, including judgements made by others. In principle, students are thus made responsible for proving their own level of competence, measured against externally specified criteria. This is also in accordance with the procedures followed in professional organizations and professional practice. Our traditional, static curriculum only offers students sufficient freedom to take responsibility in the execution phase of learning processes. In the educational environment we have in mind, students will be expected to take responsibility in all phases.

Program facilities in relation to learning processes: The program environment consists of a number of facilities which students may use in taking responsibility for achieving their processes of learning and gathering evidence of competence. It is this change in the concept of "curriculum" that is meant in the title of this contribution.

The facilities can be categorized along the circle of orientation, planning, execution and evaluation. They consist of a set of competencies, an assessment procedure, a web-based portfolio system, lots of authentic learning practices, a continuous line of metacognitive work and a demand driven set of resources of knowledge and skills. More about these facilities can be learned about at other SITE 2000 contributions, e.g. on Integrated Assessment, Learning Practices and Web-based Portfolio System. Also the Website of the Amsterdam Faculty of Education is a source of information for this purpose: www.efa.nl

Realizing New Educational Concepts Using New Technological Possibilities

The Explo project of Ichthus University - Department of Education aims to train elementary-school teachers who have both vision and skill in handling ICT. Explo is a new, experimental teacher-training program, related to the Dutch government’s Prommitt program (Program on Multimedia in Teacher-Training). Reflecting the program’s experimental nature, the name Explo stands for Exploration, particularly the exploration of new educational concepts combined with new technological possibilities.

The curriculum’s educational principles

Explo’s objective is to train learning professionals. Thus, it is important for the program to train students to learn-as-they-work. We achieve this through both the in-school and outside-of-school curriculum. An important aid here is the multimedia portfolio, helping students to learn how to react to their working and learning experiences.

Learning how to think, learn and work independently: Students engage in learning activities to achieve certain learning objectives. They decide for themselves which learning activities to undertake. Nobody can take a student’s place in learning, and there will be no learning results without learning. That is why, in Explo, we expect students to actively control their learning guided by their learning styles, learning concepts, knowledge, learning motivation and learning abilities, likewise guided by their experiences in interacting with education. Two consequences result from this view. First, we endeavor to teach students how to learn, think, and work independently. Hence, we see to it that students’ learning, which initially is more program-controlled, gradually becomes more student-controlled. Tasks that were initially performed by lecturers are gradually taken over by students, such as selecting learning objectives, planning learning activities, the application of knowledge, monitoring progress and even evaluating the results. Secondly,
learning to think, learn and work independently means a change in the tasks and roles of lecturers. They now pay rather more attention to the way students learn, they challenge students to start controlling their own learning process and help them to develop their "meta cognitive skills". The entire learning process is recorded as much as possible in a (multimedia) portfolio, in which students report their experiences in images, sounds, products and statements. Moreover, the study program is arranged so as to allow students to set their own speed in following their own learning routes.

View of learning: Increasing self-control in learning

View of teaching Emphasis on guiding the learning process

Learning how to think, learn and work independently

Links between theory and practice: Explo's system of instruction is determined by the link between theory and practice. The world of employment is the principal standard for the selection of learning objectives and program contents. Here, we are guided not only by the world of work and by theory, but also by individual students' subjective concepts. They consist of the values, opinions, convictions, ideas, principles, rules, guidelines and expectations that students have regarding education and those developed during the course of the program.

Practical work: In a professionally oriented program, students are prepared for work through internships as well. In Explo, we use the following lines of development to learn how to work as professionals:

a) From observation to education;
b) From working with a few children to working in a combined class;
c) From standard education to special education;
d) From performing a single teaching skill to giving a series of connected lessons;
e) From giving a lesson to a whole class to developing differentiation within a class;
f) From performing internship assignments set by lecturers to performing tasks based on students' learning questions and planning;
g) From teaching a single subject or several subjects under the guidance of a mentor to functioning independently as a class instructor for a few days a week.

Both in the internship school and in the learning environment of the program students are expected to learn from each other. We encourage this through the joint preparation of internship assignments, attending each other's lessons in the internship school and offering practical examples from internships during lessons and modules.

Links between subject areas and fields of training: The program's point of departure is the professional qualifications for novice teachers. We distinguish the teacher as: (a) a professional, (b) a didactician, (c) an educationalist, and (d) as a team member and colleague. Since the teaching skills of novice teachers require a subject-related content, we start from the subjects that must be taught under the Elementary Education Act. In addition, we base the program on the starting-level requirements and the recommendations of the Process Management in Elementary-Education Teacher-Training Programs memorandum. Since we also assume that elementary-school teachers must be generalists, each program term has its central theme matching the students' development as much as possible. This theme forms the framework for all multidisciplinary and discipline-related tasks that students work on.

Study counselling and student counselling: Study counselling involves the development of students into learning professionals. Here, lecturers pay special attention to the way the students structure, regulate and assess their own learning processes. Student counselling involves a student's personality development and his or her cultural and social performance. One important object of counselling is that students develop a personal work concept. Several persons provide counselling: a) the phase-coordinator provides information about the program structure, b) the tutor provides counselling regarding the learning process students go through in their in-school and outside-of-school curriculum and c) the internship school mentor deals with
day-to-day student counselling, in particular students' practicing of skills and the performance of assignments.

**ICT in education: vision and skill:** In Explo, the development of views and skills is not an isolated activity, limited to any one subject, component or theme. It is an integral part for all components of the curriculum. In Explo, we wish to train teachers who: learn-as-they-work and are innovative, function in a multi-cultural and international environment and in doing so use ICT with vision and skill. In Explo, five uses of ICT derive from this mission. ICT serves as:

1. A link between learning-as-you-work in practice and learning-as-you-work during coursework (the Internet);
2. An aid in providing adaptive education in elementary schools in a multicultural and international context (multimedia software, the Internet);
3. A means for students to develop vision and skill in the use of ICT in education: "being digital" (a laptop as a mobile toolbox for daily use);
4. A motor for lecturers and students to be innovative colleagues in designing (digital) learning environments (the Intranet to share knowledge);
5. A hub for the exchange of knowledge (website, electronic discussion platform) and to maintain the organization's external contacts (e-mail).

**Technology Rich Learning Environments in Pre-Service Teacher Education:**
**Implementing Ideas in Practice**

One of the core characteristics in the changes towards a new curriculum for pre-service teacher education deal with the notion that prospective teachers need to be able to design learning environments in which learners are able to accomplish authentic tasks. In pre-service teacher education programs these authentic tasks often consist of the realization of concrete products which could be used in educational practice. Important features of such learning environments are that a) curriculum content is not offered separately but derived from the authentic tasks and attuned to students' needs, b) students get responsibility for their own learning and c) teachers guide and facilitate the learning process of students. In short these characteristics reflect present ideas in education such as constructivism and situated learning.

Technology can facilitate the realization of these learning environments in several ways. It can serve as means of communication between students and teachers (e.g. e-mail, CSCL) and as source of information (WWW). Technology can support the curriculum organization and learning process (e.g. digital learning environments, electronic portfolio). Finally students can develop digital products as an authentic task.

In the two experimental colleges of teacher education in the Netherlands a variety of such learning environments are part of the pre-service teacher curriculum. In the Amsterdam Faculty of Education these learning environments are referred to as Learning Practices. Learning Practices are one of the main parts that constitute the dynamic curriculum. The Ichthus' Faculty of Education has realized a cooperative project with elementary schools. Within this setting elementary schools implement innovative projects using ICT and pre-service students support the elementary schools in the realization of their project. The following examples represent two typical innovative learning environments.

**A multimedia database for history teachers (Amsterdam Faculty of Education):** The toolbox of a history teacher is a database of resources (video- and audiotapes, pictures, texts) on historical events together with student activity sheets and lesson plans. Pre-service history students are jointly developing such a toolbox in a digital format. The toolbox will be used in their internship program. Each student has to prepare 25 contributions to the database, share them with peer students and teachers and evaluate as a group the quality of the contributions. The students apply a number of ICT skills in realizing the database.

**'A view on the world' in the Kindergarten class (Ichthus'Faculty of Education):** Pre-service students in the elementary teacher training program cooperate with elementary school teachers in a project for the Kindergarten. With the help of a digital camera and PowerPoint children, teachers and pre-service students are jointly developing an interactive picture book about the process of milk production. The pre-service students have the expertise on the use of technology, the teachers have their didactic experience and the kindergarten students put their curiosity and creativity in the project.
The role of formative evaluation

Formative evaluation activities are being conducted to guide the process of development and implementation of these new learning environments in both experimental teacher education colleges. The starting point of the evaluation is a conceptual framework, which reflects characteristics of innovative practices using technology in education (Voogt and Odenthal, 1999). This framework has been fine-tuned to the specific characteristics of the innovative learning environments as they are defined in the two experimental colleges of teacher education respectively. In both sites the formative evaluation aims at 1) sharpening the educational concepts and ideas which the learning environment intend to reflect, 2) contribute to a sound implementation of the learning environment in practice and c) description of the learning environment with a view to transfer of experiences. In the evaluation data (document analysis, interviews, observation) are collected to trace discrepancies between the intended curriculum (the educational concepts and their translation into curriculum materials) and the implemented curriculum (the realization in practice).

The formative evaluation points to the following concerns in the implementation of innovative learning environments:

- Educational concepts, such as ‘self responsible learners’ are not yet clearly elaborated in the learning environments. Students’ are not always ready to take their responsibility and the instructors’ repertoire is often insufficient to guide students in their learning process.
- The use of technology is not yet part of the routine of instructors and students and is therefore time consuming.
- The development of learning practices often starts from creative ideas of the teaching staff of the colleges of education. However, the organization of a curriculum through well defined learning environments cannot be based on creative ideas only, but requires also an appropriate blend between the competencies that students’ need to acquire and the competencies that are dealt with in the learning practices.
- Pre-service students supporting schools in realizing examples of innovative use of technology have to deal with the outdated technological infrastructure in many schools.
- The elementary schools involved in the cooperation with the teacher education colleges have a very different experience in the use of and vision on technology. It implies that pre-service students cooperating with the elementary schools need not only to bring their expertise to the schools, but also need to become sensitive to the innovation process itself.

In the presentation these results will be presented and the implications for the further development and implementation of learning environments will be discussed.

Abstract: Our two-semester course has been developed over several years. We specifically 
try to prepare student teachers to use information and communication technology (ICT) in 
their future work in the classroom. Thereby we are faced with three major difficulties: – the 
broad spectrum of subjects students have studied and will teach, – differences in the pre-knowledge and the pre-skills students bring with them, – most 
students have gained their own learning experience in classic lecture situations which are not 
compatible with a technology-oriented context. This paper will show how we try to overcome 
those difficulties. Our current course design is based on a learner-centered approach and 
combines different learning styles. In the first semester, our students work in independent 
groups following a guideline sheet. During the second semester, students create their own 
projects where they integrate ICT into classroom situations.

Introduction

Compared to America and most European countries Switzerland is very small. It has less than 
3% of the inhabitants of the USA yet is composed of 26 cantons, which are autonomous 
concerning schooling. Hence many different school systems exist. However, we will only 
consider the situation of the canton of Zuerich in the north-eastern German-speaking part of 
the country. Secondary school are of two types. Most students (nearly 80%) attend normal 
secondary schools and after 9th grade leave school and start an apprenticeship. Only the 
remaining 20% go to grammar school and after the 12th grade will pass the final examination 
called "Matura" in German), which is required to enter university. The following paper deals 
only with pre-service education of grammar school teachers. They have to acquire a first 
degree; afterwards they go through teacher education, which also takes place at the university. 
As a result, grammar school teachers teach only one, possibly two, subjects. Our two-
semester course has been developed over several years and we have continued to adapt it to 
correspond to the evolving situation in information and communication technology (ICT). 
Because of restricted resources, our course is not compulsory, but optional to the students.

Concept

The goal of the course is to prepare students to use computers and communication technology 
in their future work in the classroom. This is not an easy task. Reports and our own 
experience show that ICT is not commonly used in grammar schools. For the novice teacher, 
there are many obstacles. Teaching itself is difficult and must be learned through practice. 
Due to their own lack of teaching experience, novice teachers tend to use the experience they
gained in earlier situations as learners. In the technology context, experience from a learner perspective rarely exists. Furthermore, working with computers on a personal basis and embedding technology in a classroom setting are two totally different tasks. There are considerable differences concerning pre-knowledge and the pre-skills in relation to ICT among the participants in our course. The ability to use technology is a pre-requisite but not a guarantee for effective action in the classroom. Experts in this field refer to typical examples, but there is rarely agreement on the best way to apply technology-based teaching. A very important point is the following: The participants of our course have studied, and will teach different subjects: Languages (German, French, English, Italian, Spanish, Latin), History, Mathematics, Physics, Chemistry, Biology and Geography. The questions arising in the teaching of English for example or Mathematics using ICT are really different. All in all, teaching such a course is a well-nigh impossible task. However, a heterogenous audience may also have positive effects (Moser 1999).

Summarizing the facts we have to deal with three major difficulties in designing our course:

- the participants will teach different subjects
- the participants have different pre-skills in the use of ICT
- the participants have no teaching experience, nor can they activate relevant learner experience.

An obvious strategy to overcome the difficulties is to individualize the learning process. This means a decomposition of the course: Students work individually on their own tasks. This is quite natural in a computer context, because this machine is tailored for individual use, having only one keyboard and one mouse. Nowadays however, it is widely accepted that learning also has a social dimension and that the learning process may be influenced positively by cooperation. There is currently interesting research being done on this subject (see for example Dillenbourg P. 1999). Bringing the two concepts together results in groups of learners. The size and the composition of such a group is of course critical. During the first session we normally let the students form learner groups composed of two to four participants teaching the same or a similar subject. The differences in pre-skills may also be evened out in such groups. This difficulty can, however, not be completely resolved. Cooperation in the groups and imposing the focus on didactical reflections reduces this difficulty. The third problem is the most difficult to overcome in a university framework. The best thing would be to give the students the possibility to observe lessons and to conduct their own teaching experiments. We are able do this to a very limited extent; external constraints do not allow more. As mentioned earlier, novice teachers use their learner experience as a resource in their own teaching activity. Therefore, in our course we try to prepare learning arrangements, which build up the experiences of the students, and we try to give concepts which they can copy later in their own classrooms. Our intention is a kind of "hidden curriculum". This may be explained easily by the famous saying: "Teachers teach as they were taught, not as they were taught to teach." By individualizing the learning process, we observe another slogan: "self-directed learning". This is an essential point in every learning process: To what extent is the learner guided from the outside and what part does he manage by himself. There is a continuum of possibilities from leading by the nose to not being guided. It is an art to find the right balance for every audience. Our conviction is that in most cases guidelines are needed to produce an efficient learning environment. Within an carefully fixed framework the participants of our courses have the liberty to create their own learning path.
Basic Course in Detail

In the first semester of our course (called "Grundkurs" in German) the student acquires an overview, basic techniques and basic knowledge. During this semester there are about fourteen sessions. Five of them, spread out over the semester, are plenum events where demonstrations, talks and other input are combined with group activities. The other sessions are arranged by the learner groups. A task sheet (called "Semesterpass" in German) describes the work to be done as structured in the following sections:

A organisation and tools
B telecommunication
C software for learner (tutorials, simulations, etc.)
D application software
E authoring software
F articles, books, videos
G practice
H portfolio

Figure 1: Part of the task sheet

A booklet (called "Arbeitsheft" in German) contains the necessary worksheets, guides and schemes organized in the same sections as the task sheet. Additional information can be found on our webpage (http://www.unizh.ch/hlm/ascifu/index.html) and additional material, for example software or videos, must be ordered by electronic mail. The learner group has to plan its activities at the beginning of the semester and report them to the professor responsible. Most communication is conducted by electronic mail. Search competitions on the internet aim to improve the search skills and the regularity of e-mail use of the participants. A panel discussion with active teachers and visits to schools give an insight into classroom reality. The progress of the group is supervised by the professor responsible in periodical conversations. As an example, let us take a closer look at section C, where a special scheme presents the tasks required. A software tutorial introduces the students to the features of tutorial- and drill programmes. Learning software of their choice, ordered by mail, must be tested and evaluated by the groups. Leading questions are – what are the benefits of this software? – can the task also be fulfilled without technology? The findings and the evaluation must be reported to the supervising professor.
Project Course in Detail

During the second semester of our course (called "Projektkurs" in German) the student applies the knowledge and skills gathered to a classroom situation. The goal is to develop, perform and evaluate lessons in the specific subject whereby ICT must be inbedded. Again students of the same subject work together in groups to carry out this task. Possible interdisciplinary cooperation is encouraged of course. Often groups firmed in the preceeding semester continue working together. The course is arranged as a pedagogical project. There are different definitions of such a project and we will therefore outline our concept, which is based on a description of Bruggmann (1992). The framework is given by the following facts:

- lessons must be designed, performed and evaluated
- at the end of the semester the results must be presented to the plenum
- during the lessons information and communication technology must be used
- milestones and a learner diary will accompany in parallel to the process

Besides these obligatory conditions, the groups are free to design their project. This means that decisions concerning the number of lessons, the topic, the technology used (internet, software, etc), to what extent the technology is used, the pedagogical methods and the social form are made by the group. We have a database with addresses of teachers who have agreed to place a class at our disposal. However, the groups themselves have to arrange the necessary cooperation. The most difficult aspect in projects is time management. As already mentioned, we emphasize the idea of guidelines and we shall now describe how we realized this in the project part of our course. The members of a group have to sign an agreement fixing in advance the topic and plan of realization. This should help to set realistic objectives, and is done in cooperation with the supervising professor. Secondly, each participant writes a learner diary and has to discuss it with the professor responsible. In particular we point out the metacognition aspect. Students dislike writing diaries during the process, but describe it afterwards as a very useful tool. The milestones are the third way in which to guide a project: The group regularly has to present the progress made in the project, the problems encountered, the support needed as well as the modification in project goals.
Conclusion

As the development of technology progresses, course design and teaching material must be continuously adapted. Three years ago, we published a concept for cheap and efficient in-service teacher training (Kuster et al. 1996). We have recently been able to transpose this, starting with teachers of two subjects. There are plans to make connections between these two areas: On the one hand bringing together experienced teachers, and on the other, the less experienced students. There could be mutual benefit in such exchange. Moreover, we have started to use groupware tools, which will be useful in the project part of the course and in in-service teacher training.

Many articles discuss pre-service teacher training in the area of ICT (see for example Murphy and Greenwood 1998). Our efforts to focus on technology and on teaching style, and to offer student teachers excellent learning arrangements to enrich their own experience has proved very successful.

Dialogue of Teachers and Students on the Internet in Poland of the Nineties in the Context of Moulding the Creative Vital Orientations by E. Fromm

Jacek Gornikiewicz
Department of Pedagogics and Psychology
Bialystok University
Poland
jacegor@noc.uwb.edu.pl

Abstract: Based on the latest Polish experience, the report attempts to estimate the validity of the common belief the Internet provides opportunity to create new quality in teacher-student relation and aids the process of moulding creative vital orientations of the two parties involved in the process of educational interaction. The main objectives of the article are determining possible obstacles to widespread distance education, acknowledging first efforts of communication through the Internet administered by educational institutions in Poland, and assessing how the initiatives aid the development of teacher and student creative attitudes.

Introduction

The objective of the paper is estimation - on the basis of the recent Polish experiences - of truth of the common belief the Internet provides opportunity of new partnership quality in teacher-student relation and aids the process of moulding creative vital orientations of both teachers and students. Hence, several questions must be raised on the subject. One issue is how possible is it in Poland? How easy/cheap is the access to the net for a Polish student or teacher? What can be other, non-economical obstacles against the dialogue over the Internet? What possible psychological barriers may underlie teacher and student attitudes to the use of computer in education or to Internet communication? What emotions do they declare? I searched for the answers to those questions in Polish GUS Statistical Yearbook of 1995-1997, in applicable literature and in my own surveys. Other essential question to be answered is where such dialogue occurs by determining first endeavours of Internet communication administered by Polish schools. Where are such schools? How do they use the net for teacher-student communication? How seriously is the Internet used for educational purposes? How helpful for development of creative orientations is it and finally what (first) initiatives in connecting teachers with students are currently emerging in Poland? I tried to find answers in both electronic and printed reference materials, however I based my search particularly on WWW resources.

The condition of computerization in Poland

Statistical data on computerisation in Poland are provided below. The rates are given for various regions of the country and various social status groups. Poland is a country where distance education can be applied more widely, outside the local experiments conducted by educational institutions of different levels for the last few years. There are several economical, financial and psychological reasons for the above statement. Polish Gross Domestic Product is continuously growing. Annual rates of GDP increase place Poland among the most dynamic group of developing countries. There was 125 GDP increase rate in Poland in 1997 (the rate had amounted to 100 the year before), which was more than in most other European countries: the rate was 61 for Russia, 109 for Germany, 99 for Czech Republic, and 64 for Lithuania. USA achieved 110 GDP increase rate in 1997. It has to be certainly remembered GDP per capita in USD is still quite low in Poland and did not exceed 3702 in 1997, while in Germany it was 25754 and in Czech Republic 5184, however it was as little as 2982 in Russia and 2097 in Lithuania. In the USA, the rate was 29187 (Statistical Yearbook 1998). The described financial condition of a country cannot be regarded as unimportant for the idea of the broad use of multimedia communication technology for educational purposes. The rates of computer equipment found in households are as vital for distance education. Unfortunately, the Polish Statistical Yearbook does not quote the number of personal computers used in Poland vs. other countries. However, the source provides information on rates of radio and television sets per 1000 population, which too are potentially important for distance education purposes. The rate here is 311 for Poland, 564 for Germany, 377 for Russia, and 805 for the USA. (Statistical Yearbook 1998) In 1995 there were 148 telephones per 1000 population in Poland, 493 in Germany, 170 in Russia, and 626 in the USA. The rate of telephones in Polish households (which is important for DE since it determines how many computer users can access the Internet via their modem and a phone line) is too small.
however the rates of increase in the number of telephones are truly satisfactory. The rate was 86 in 1990, 102 in 1992, 129 in 1995, 169 in 1996, and 193 in 1997 (Statistical Yearbook 1998). The source provides information on computerisation in Poland, however its relation to other countries in not quoted. Means for automatic production processes and electronic media in industry, and households furnished with selected durable goods are recognised. 88 publishers and printing firms had access to local area networks (LAN). 38 firms had access to external computer networks and 64 used Internet services in 1997. (Statistical Yearbook 1998)

Following table presents rates of computers found in households with specified number of person in 1997.

The above figures show considerable diversity in rates of computers found in Polish households in relation to social and employment status of the families and the amount of children. Self-employed middle class families consisting of 3-5 members (i.e. with 1-3 children) own the most computers and retirees and pensioners own the least. The challenged position of the latter is certainly different from the situation of American retirees and pensioners. On the other hand, even in the wealthiest group computers are found in less than one third of the households and no information is provided about their access to the Internet.

Another question concerns the number of people now educated in relation to the number of population. In other words, the question concerns participation of young people in Poland of the nineties in various forms of education, regardless of its level. The answer will allow rough estimation of how much the educational needs (aspirations) of the residents of Poland, especially young adults and children, are satisfied. It will also make it possible to determine whether the current traditional system meets the needs and requires no changes or it's the opposite. Moreover, the number of foreign students in Poland will make it clear how accessible Polish universities are for foreigners. Thus, the figures will provide an answer to how much the current educational system meets the market demand and how much it should be modernised.

In 1995, primary education in Poland was provided to 130 students per each 1000 population, vocational education to 41 students and high school education to only 18 students per 1000 population. In USA, the figures were relatively 90/781, in Germany 46/28/72, in Russia 53/9/84, in Lithuania 60/14/86, and in Slovakia 62/76/48. The minute percentage of high school students in Poland is striking (Statistical Yearbook 1998). In case of university students, the tendency is less evident. In 1995/96 Poland provided higher education to 248 students per 1000 population while in USA the number of students was 540 per 1000, in Russia it was 300, in Lithuania 202 students, in Germany 264, and in Slovakia 172 students per 1000 population. While analysing the rates, one should remember about radical changes made on the map of Polish universities and colleges during the last several years (Statistical Yearbook 1998).

There have been established nearly 200 new non-state higher education centres in 1990, which offer higher education and thus certainly aid state universities, so while there were 248 university students per 1000 population in Poland in 1995/96, there had been only 134 in 1990/91. Unfortunately, Polish higher educational system provides too few students with opportunity to learn at the more popular courses. Classes are based on the traditional system of lectures, moreover courses consist of mostly obligatory subjects and students cannot chose their teachers. Distance education provides an opportunity to overcome problems of too little space or even lack of classrooms, of Polish university teachers overworking in spring and of under-heated rooms in poorer schools, and it also gives some hope for adding new and more personal quality to the traditional rigid teacher-student relations.

In 1995/96 there were slightly over 5,000 foreign students in Poland; in 1990/91 there were 4,300 of them. That was a small group within the total number of university students: 512,000 in 1990/91 and 956,000 in 1995/96 (Statistical Yearbook 1998; 599). It can be infered the current Polish system of education based mostly on lectures is not attractive for residents of other countries. Distance education, using good system of communication and information technologies, might result in more foreign people studying in Poland. In my
opinion, the motivation might be diversified from sentimental (descendants of Polish immigrants) and therapeutic (e.g. new Polish immigrants not yet adjusted to their new country) to cognitive purposes.

The motivation and emotions supported towards the computers by the Polish teachers and their students

One question that should be asked now is whether Polish teachers and students are ready for distant education employing advanced computer technology. Are they well motivated to communicate e.g. over the Internet? What emotions do they declare on the prospect? What do they feel when they are about to sit behind the computer? Is it trust or fear? Monika Kostka and Irena Pulak conducted their survey in Malopolska region of Poland in 1995-1997 (1998). The survey covered about 306 people: 170 teachers (more than a half of whom were primary school teachers) and 136 students of arts and pedagogics. The teachers declared their practical ability to use tape recorder (96%), video recorder (89%), television (89%), slide projector (85%), computer (44%), writings projector (37%), and less than 20% admitted their ability to use other equipment like episcope, epidiascope and CD player. The teachers most often use tape recorder (80%), video recorder (78%), television (74%), slide projector (63%), computer (44%), writings projector (37%), and less than 20% admitted their access to other equipment like episcope, epidiascope and CD player. The teachers would like to use also computer (75%), video recorder (60%), television (47%), tape recorder and slide projector (44%), CD player (36%), writings projector (25%). Teachers/students would like to use computer (75 / 87%), video recorder (60 / 97%), television (47 / 87%), tape recorder (44 / 89%), slide projector (44 / 72%), CD player (36 / 79%), and writings projector (25 / 79%). Only 19% surveyed teachers had any contact with computers. 7% took a course on using a computer, 3% learned on their own and 81% had not used computers at all. It is interesting to notice nearly one third (29.7%) of 219 surveyed students of political science in Silesian University in Katowice, Poland, declared in January 1998 they had never used computer so far (Gramlewicz 1998; Tab 3 p320).

When I was looking at the title of How teachers use the Internet (Serim & Koch 1997) on teachers’ experiences with internet, it crossed my mind to survey whether, and to what extend, Polish teachers use the internet. My findings are quoted below, based on my survey of emotions studying teachers have toward computers and the internet.

In 1998 I surveyed 200 teachers studying pedagogics in Wszechnica Mazurska in Olecko, Poland on their knowledge of basic terminology connected with the use of computers for educational purposes (Górnikiewicz 1998). The whole surveyed group consisted of 3rd-year students who had done a regular course in computer usage before. The results of the survey show their computer knowledge was minute. The recognised terminology was connected with very rudimentary knowledge, not adequate for practical educational use of computers. The students had theoretical rather than practical knowledge of computer terminology that had been mainly heard of and not experienced. The surveyed teachers seldom use computers and still do not use the Internet almost at all. Nevertheless, the reason is not their fear of computers (they declared positive emotions toward computers). The reason is they did not yet realise how important it may be for their job. Given the opportunity of active participation in computer courses and provided with practical computer skills, they are bound to give up the use of their pens and papers or chalk and blackboards in favour of more sophisticated means of conveying information. On the other hand, even in the most advanced countries (Japan, USA, Sweden) chalk and blackboard still play crucial roles in education (chalk and talk; see Pettersson 1997). Hence, it seems most Polish schools still have a long way to go from traditional handbook to electronic one, regardless of the recognised drawbacks of the former (see Winniewski 1996).

First Polish institutions using the Internet for teacher-student communication

First Polish institutions using the Internet for teacher-student communication are presented below. They comprise schools and other establishments co-operating with their American partners for promotion of the idea of education over the Internet. One of them is PAM Centre in Lodz assisted by University of Maryland; another is Internet for Schools (Ids), which has particularly contributed to promotion of advanced information technologies in education in Poland. The results of Ids actions prove its effective use of American foundations’ financial assistance it is offered. In found the Polish institutions offering distance education mentioned above in the Internet by means of Internet Explorer. I used Polish Infoseek, Polish and English Wirtualna Polska and Alta Vista, and Yahoo search. I also used Webscrawler. I used both Polish and English keywords like distance education, distance learning, or distance teaching. Polish servers provide different amounts of information. Wirtualna Polska provides merely several links, e.g. 2 links to studia na odległości (WSiP publishing house and CKU in Tarnow); 2 links to distance learning (e.g. SITA Learning System) and 1 link to distance education (Doctor Q Cenrum Edukacyjne alias Lotus Authorized Education Center, which runs computer courses). On the
There are several centres for open education in Poland that are interested in distance teaching. Those institutions are often called Continuous Education Centres (Centrum Kształcenia Ustawicznego; CKU) or Distance education Centres (Centrum Edukacji Niestacjonarnej; CEN). They are usually connected with universities or technical universities. The ones whose WWW sites are relatively easy to access are the establishments in Bytom (Regional CKU in CKU), Gdansk (DECTUG and CEN), Cracow (CKU at AGH), Kielce, Krosno (CKU), Wroclaw (CKU), and Zielona Gora (CKU). Below are two examples.

Kielce establishment belongs to Swietokrzyska Technical University. It runs distance courses in computer architecture, AutoCad 13, English, management, economics and finance (http://www.tu.kielce.pl/~cku). Other courses are interpersonal communication (30 hours) and 3-level language courses (80 hours each). The institution provides also post-degree courses (280-290 hours), however they are not available in the distance education system. Students of Management and Marketing have conducted an Internet survey for the institution mentioned here to gather opinions on Internet virtual universities and estimate potential interest in such forms of education.

The centre employs four administrative workers. It is worth mentioning CKU is not operating by itself; it belongs to European Distance Education Network (EDEN).

Distance Education Center at Technology University of Gdansk (DECatTUG) assumed the task of promotion of Open Distance Learning (ODL) methods in its local environment and organisation of ODL training within EU programmes of PHARE, Leonardo, and Socrates. Moreover, the institution partakes in realisation of various Internet-based educational projects like PASCAL, EE-DEC, TTT, ENGTUS, ThinkQuest, 1*EARN, and National Geographic Kids Network. The centre was established in 1997 within Phare Multi-country Programme in Distance Education (Establishment and Operation of Regional Phare Distance Education Study Centre). This is an experimental educational institution conducting educational projects connected with the use of computer networks and multimedia technologies. The project of Join Our English Language Club (http://despina.advanced.org/17844) was admitted to a contest final in Washington in 1997. In 1998, the project of The Ways of Communication (http://despina.advanced.org/17844) was realised.

Distance Education Centre at AGH in Cracow introduces elements of distance education to realisation of chosen regular courses by the use of videocassettes and diskettes, without the need of Internet teacher-student communication. The centre runs various professional courses and ones preparing for university examinations. In 1997 a seminar was held in Dom Goscinny in Cracow, Poland, on Information about Possibilities and Conditions of University Distance Education, which initiated a series of Open Learning seminars.

CKU at Technical University of Wroclaw runs optional courses for students, computer courses, and seasonal "schools" and seminars, however it does not partake in practical promotion of distance education forms and methods. Among the optional subjects, students are offered classes in language culture meant to teach the art. of self-presentation in front of cameras and presentation of a given topic.

International E-mail Tandem Network is a highly interesting form of Internet education, providing opportunities of both teaching (one's partner) and learning a foreign language (from one's partner). The system is based on cooperation of two universities speaking different languages and located anywhere in the world. Helmut Brammerts from Bochun University, Germany established the Network in 1992. Polish Jagiellonian University, Cracow, partakes in Polish-English and Polish-German subnets.

Post-Graduate Distance Education Centre run by Lodz University and Polish American Management Center (PAM Center) and Virtual University at Mila College in Warsaw are two examples of the most interesting projects on application of DE in Poland.

PAM Center located at Department of Educational Science at Lodz University, Poland started enrolment to new Distant Education School in 1997. The course consists of 300 hours conducted partly in the distance teaching system and partly as meetings. The use of modern multimedia communication means of voicemail, email, BBS, online communication via WWW pages and compressed video is assured. The Center is co-operating with University of Maryland University College (UMUC), USA. The course lasts two semesters from October to June, providing its graduates both certificate of completion of the course and PAM Center certificate. The course provides education to people of various professions: the learners are not only teachers but also physicians and office workers. PAM Center also runs MBA and MiniMBA studies, which are MiniMBA Management School and Human Resources Management School. The graduates belong to the Alumni Club. PAM Center web site administrators introduced noteworthy amount of links to WWW sites. Those links are connected e.g. with distance education in Poland and several other countries (the list is reduced to barely a few links among many possible ones) and sites that can be useful for teaching (a relatively long list).

Virtual University (www.universytet-wirtualny.edu.pl) is an educational experiment conducted by Professional Training Institute of Mila College (http://www.mila.edu.pl) in co-operation with several other Polish universities. Mila College offers lower and higher degree studies of computer science, economics, business
management, data processing management, finance and accountancy, and tourism and recreation. Mila College is advertised on its WWW site as "the first Polish Internet school". The college co-operates with De Montfort University, United Kingdom and has been operating for seven years. It is well equipped with computers and has its own 1 Mb line as well as its own Virtual Library that is also described as the first one in Poland. After paying the initial fees, each student is provided their free personal email accounts. Co-operating with Regional Education Centre in Polkowice, Mila College has long experience in distance education, which is currently unique in Poland. This experience was the basis for the establishment of Virtual University, which has broadened its undergraduate computer studies offer by undergraduate and post-graduate studies of European integration. Virtual University currently has approx. 50 students from all parts of Poland living in small towns as well as in big cities and aged between 20 and 43. The university maintains virtual contacts with its 2000 ex-students who still have the right to keep their school email accounts and use the school library resources. University consists of 20 teachers and 5 administrative workers. It is worth mentioning Professional Training Institute applies Virtual University technology to its courses for the disabled in Adult Education Centre of Tczewo and Professional Promotion Agency of Gdansk. The disabled are thus given the opportunity to learn the economic profession.

Institute of Teaching Technology at Department of Pedagogics, Copernicus University in Torun is another vital institution among the pioneers of DE promotion (and promotion of practical use of advanced information technology for educational purposes) in Poland.

There are many new initiatives in Poland on the use of computer technology for distance education purposes. One of the latest is foundation of General Internet Gymnasium by Polish educational reform advocates working in Educational Initiative Centre (C10). Both teachers and promoters of culture assemble in the Centre, which is lead by celebrities of Polish science and culture (e.g. Andrzej Wajda, Henryk Samsonowicz, and Andrzej Janowski). The main objectives of Internet Gymnasium are to present advanced multimedia technology to teachers and help them apply it to their work. Another endeavour to promote distance education is the project of Wszechnica Mazurska, a non-state school of higher education in Olecko, based on the idea of individual Internet studies. The project would comprise high school older students and would enable them to take chosen university courses in advance so that they have less work at university afterwards (provided they choose to study at Wszechnica Mazurska). The initial connection between students and college is highly desirable. Moreover, the project would also cover soldiers in service and any other individuals forced to postpone their education.

The current forms and methods of using the Internet applied by the Polish educational institutions in the light of Fromm's concept

Distance education is merely emerging in Poland: so far it is connected more with providing knowledge rather than creative individual development. In terms of Fromm's creativity concept, DL greatly develops productive rather than destructive orientation. It is also focused on being vs. having mode and develops individual skills (see Fromm 1994). This kind of education provides students the choice of time, place, and frequency of their contacts with tutors and other university staff. It gives them free access to the world's information highway and contact with the whole world, or at least its electronic presentation.

The use of Internet seems particularly important in the light of Fromm's concept. The system of retrieving information is even more important here than its availability as such. Users check various browsers looking for clues where to follow; they try new links uncertain of the result and explore various sites. This is their mental journey. The net users can feel liberated from their bodies and limited only by how much faith in their actions they have or how imaginative they are. The Internet makes them move across continents and through space with the speed of their thoughts. (Or is it the speed of their fingers?) The eternal conflict between the human will and the limitations of the human body seems to vanish.

Surfing the Internet can also be compared to journey within one's dream since the net user experiences a specific kind of logic there. This logic allows travelling through time, recognition of graphic designs as meaningful symbols, and admitting more importance to things that feel more intensely. People use the language defined by Fromm as the only universal human language whose knowledge is the key to learn about oneself (Fromm 1972), which in turn is a necessary condition of personal development. Such journey involves challenge, hope of learning new secrets and finding new solutions, and changes of moods from confidence to uncertainty. This is work and fun, adventure and inspiring or exciting way of spending one's free time. It fuses work with fun and rejects the gap between the "useful work" and "idleness", implied by cultures. It is also worth mentioning that although the Internet employs but two senses of sight and hearing it employs them to a substantial extent.

Success of DL is greatly subject to inventiveness and commitment of tutors, well exemplified by work of Jonathan Dron for and with his students at Brighton University, UK (Dron et al. 1998; 1999).
Conclusion

To sum up: in my opinion it is far too early to estimate how useful specific forms and methods of Polish educational institutions may be for moulding creative vital orientations of involved teachers and students. Nevertheless, theoretical possibilities of the Internet and experiences of more advanced countries in distance education allow optimism on the subject. Thus, we hope to witness similar success in Poland in the near future provided distance education develops in our country and becomes sophisticated enough to serve more purposes apart from delivering information or developing technical skills.

Abstract: In the summer of 1999, the "Romanian Internet Learning Workshop" (RILW) took place for the third time. The main goal of the conference was to build and maintain a community of Romanian and international experts as a framework for exchanging domain knowledge and developing practical, collaborative projects. The presented papers of the workshop were grouped in three sections: (1) Theoretical and practical perspectives of learning on the Internet, (2) The Internet as a learning environment for schools, universities and adult education, (3) Internet tools for teaching. This paper concentrates on the projects and issues discussed at RILW.

The conference has been successfully held for three consecutive years and it is planned to continue and to be extended with other related projects such as a summer school to the same subject area in the context of the European Socrates/Erasmus project.

Why RILW?

This summer (1999), the "Romanian Internet Learning Workshop" (RILW) took place for the third time, organized by the cultural society "Polygon" (NGO). What were the needs which lead to the idea of this conference? What were the goals?

As learning with the Internet is still a new topic in educational science there is a scarcity of literature (i.e. research reports and best practice examples) and not enough to satisfy the needs of researchers and teachers. In addition, the situation in Romania is special, there have been recent changes in the political, social and economic system which has necessitated fundamental changes in the educational system. This is why initial and professional continuing teacher education in Romania must be able to offer teachers a sound technical infrastructure accompanied by up-to-date factual information as well as training in modern didactical methods, including the use of New Media and the Internet. Consequently, there is a large demand and interest in this subject area.

Goals of the RILW Project

In this context, one of the most important goals of RILW is to build and maintain a community of Romanian and international experts as a framework for exchanging domain knowledge and organizing collaborative projects. Further, it is an opportunity for foreign participants to confront their knowledge and practical experience with the particular context of Romanian schools and universities as well as to explore new possibilities of cooperation.
The Nature and Substance of RILW

RILW has taken place annually since the beginning - in July of 1997. At each event, some 20 to 30 papers were presented and 4 to 7 round panel discussions were held. Because the RILW organization team is spread throughout Europe, a large part of the organizational work in preparing the conference has been carried out using the Internet. The conference is represented on the Internet by its homepage (http://www.itim-cj.ro/rilw/, mirrored at http://rilw.emp.paed.uni-muenchen.de and also at Hungarian, Spanish and American sites) as well as by a mailing list.

In the following, we shall outline the most relevant topics discussed at RILW. The accepted papers were grouped in three sections:

1. **Theoretical and practical perspectives of learning on the Internet.** Papers included in this category were engaged in defining a broad theoretical context or practical background of learning on the Internet. According to these authors, new communication technologies will radically change the way people learn. Universities are becoming more flexible in what is being offered to students, the times and frequency of course presentations and the nature of new student cohorts (opening access to a greater diversity in level of ability, age and geographic location). Traditional values are being challenged and a growing global market competition are putting pressures on educational institutions to change. These changes are enabling a way of learning which is not restricted to the time spent in schools and universities, but extends into a life long process (Clayton 1999).

   From a theoretical perspective, knowledge is viewed as actively constructed by the learner. As a consequence of this, learning on the Internet is seen as a process of constructing knowledge cooperatively and at a distance. The design of an Internet-based learning environment should offer learners the opportunity and the resources to support this process (e.g. Gallenberger, Gruber, Harteis & Stamouli 1999).

   The connection between this theoretical position and practical educational work is illustrated among other works in Nistor (1998).

2. **The Internet as a learning environment for schools, universities and adult education.** A large part of the papers presented describe examples and case studies of Internet-based learning environments in schools, universities and further institutions for adult education. In traditional campus-based universities as well as in specialist distance learning universities, the usual courses are being successfully extended by the addition of virtual courses (Berz, Erdelyi & Hoefkens 1997; Ribold & Weber 1998). Besides researchers' interest for virtual learning environments, important reasons for the use of the Internet in education are the need to reach isolated geographical areas (Lindsay, Ion & Murdoch 1997; Yrker & Uzer, 1997) and to enable people to communicate at a distance e.g. as a vehicle for cultural education by interacting with people around the world (Platon 1997; de Fresno 1999; Smith 1999). An important question regarding virtual courses is how are they to be evaluated? This has a dual meaning – what are appropriate assessment procedures? And how can the course as a whole be evaluated with the aim of making improvements for the next presentation. These issues are discussed in several papers (e.g. Harteis, Gruber & Gallenberger 1999).

3. **Internet tools for learning.** Online learning requires special tools adapted to the particular needs of the learners or to special didactical concepts. At RILW, several Internet tools for learning were presented such as tools for automatic generation of educational WWW pages (Trausan-Matu 1999), a tool for cognitive mapping on the WWW (Ertl 1998), or various applications of artificial intelligence in virtual learning environments (Florea 1999; Majumdar, Majumdar & Banerjee 1998).

   Round panel discussions about educational and technical topics have been a regular feature at all the meetings of RILW. In this way issues have been prioritized and problems along with potential solutions have been considered. One particularly valuable proposal under discussion last year involved the task of designing and delivering new courses to be offered on a networked study-center system in Romania. The known existing issues were first acknowledged: local and individual initiatives did not always have support from the authorities; legislation of this form of education is very recent; accreditation is still being defined and developed; quality assurance methods need priority attention to overcome a previous lack of rigor;
strategies are needed for study centres to co-operate with each other and the type of students to be targeted as well as form of media to be used for delivery needed consideration. The outcome of the discussion highlighted issues that are pertinent to anyone who has the task of designing new courses for extensive use:

- Courses are more likely to be successful if there is a perceived need by the student for the subject and if the students are very well motivated and thus highly committed.
- Ease of access to equipment and facilities is very important.
- Preparation may be needed in IT skills training for students and tutors.
- Choice of media for delivery should be based on the required didactic method used in course presentation.
- Regarding a target group - evidence suggests that post-graduate level distance courses have the highest demand and success rate. In which case, existing teachers would be an appropriate group to start with and there was a need for continuing professional development in this area.
- Support from higher authority is not always present but this should not prevent the design of new courses taking shape.

Other round table topics have been: The impact of the Internet on children's civil education; Virtual libraries vs. virtual universities; Universities and international cooperation; Electronic distance education: The development of DE centers in Romanian Universities and Teachers' Houses. A common frustration that has been frequently voiced is how the heavy weight of bureaucracy and the feather-light touch of financial investment has thwarted many creative initiatives in Romania. The continuation of RILW as a platform for inspiration and collegial support is, therefore, all the more essential.

**Results & Perspectives**

The conference, now aged three, is based on the enthusiastic and permanent participation of a core number of specialists from different countries like Germany, Great Britain, New Zealand, Spain, USA, and of course Romania. Other participants have been mostly university professors but has also included undergraduate, graduate and doctoral students from Romania and abroad. The participants found the papers and discussions and the informal exchange of experience and knowledge to be most interesting and fruitful. Though our cultures and contexts are different, many of the difficulties and problems that arise regarding the new methodologies and features of learning on the internet, are familiar. A particularly satisfying outcome of these workshops are the lessons we have learnt, often repeated in different contexts, about internet-based learning. Regular findings include:

- Suitable pedagogic designs involving student-centered learning, problem-based learning and 'real-life' contexts and activities.
- The need for staff development training in an on-line learning environment.
- The need for students to be prepared with ‘learning skills’ training (team skills as well as IT skills).
- The need for constant monitoring, evaluation and improving of virtual courses.

There were many factors that contributed to building the community of experts. Of course, the most important of them was the scientific exchange due to presenting and discussing papers at RILW. A lot of cooperative work between the experts took place before the conference, while intensively communicating via e-mail, reviewing papers, organizing the conference, publishing all the information in the WWW. Also during the conference days, there were many informal discussions between the participants, between experts and students - in the conference rooms as well as while visiting interesting places in Romanian towns and villages or trekking in the Carpathians (involving hill walking and cave exploration).

Social and cultural events during all the conferences have not only given flavor and character to these meetings but have also enabled meaningful professional relationships to develop by sharing real-life experiences (as mentioned above). Together with the opportunities given for the silent sharing of musical and artistic performances, we have learnt far more than words could possibly offer. It is due to the vision and practical help of the Polygon Society (joint organizers) that RILW has been enriched with a mixture of culture, arts and science. This vision stemmed from oppressive earlier days when communication between disciplines and between countries was very limited. Now through the freedom of the Internet, we have organized, traveled and participated in scientific, social and cultural events mutually benefiting from the resulting knowledge and friendship gained.

A very important development that indicates a successful outcome of the RILW is the growing level of attention that Romanian authorities and newspapers are giving to the use of the Internet in education. Since
the beginning of RILW in 1997, communication via the Internet has been included in political decisions and reform proposals of the Ministry of Education. More new distance education centers are continuously opening and Romania is now involved with international educational projects like 1*EARN or KidLink which include many school students.

An additional perspective for the future has recently been developed - starting from 1999, the RILW was extended by a summer school in the same subject area within the context of the European Socrates/Erasmus project. A book is planned to integrate the most relevant theoretical contributions and practical examples presented at RILW. Finally, as a result of RILW, several projects are being initiated in cooperation between Romanian and Western European institutions.

Yugoslavia
rajs@yunord.net

Abstract: The paper presents a research on attitudes towards computers and educational technology in education of young children age from 7 to 11 in few public schools in Subotica (Yugoslavia). The research included over 100 inservice teachers, and was undertaken in September 1999.

The research aimed at:
- the teacher's attitudes towards the usage of computers in education of young children,
- the teacher's computer skills, and
- the teacher's attitudes on implementation of computers in the education.

The research has shown that very few inservice teachers are actually "computer literates"; the teachers don't see the possibilities of applying computer technology in their work, but are very interested and willing to advance in that direction.

Background

By the end of the 60's and during 70's the problem of the computerization especially in the field of education had emerged and has been debated over ever since in the Yugoslavian pedagogy. World tendencies are being followed, foreign and domestic authors related to the issue are being published, articles as well, many debates and courses are organized. The new projects in introducing the newest technology as a way of improving and modernizing the education were at the time: D. Frankovic: Development of technology and contents in SFRY education, 1972; V. Muzic: A computer in contemporary education, 1973; V. Pilic and co-authors: Cybernetics, computers and education, 1975; N. Soljan: Computer assisted education, 1972; Computer assisted programmed education, 1973; M. Bakovljev: Theoretical basics of programmed education, 1972; P. Mandic: Innovation in education and its' pedagogical meaning.

The status of the students and teachers in educational process is being debated over as well as their inter-relations in the student-teacher-education technology triad. Emphasize is put on 'thought activation', problem solving, learning through discovering and the individualization of the learning process. Computers take the important place in the theoretical consideration of modernizing the education. However the theory proved different to the practice, and very few things have changed since then. 20 years ago B. Vlahovic examined attitudes of teachers towards changes in education in sense of modernizing it and involving new techniques, and determined the importance of those attitudes in further development of education. It is interesting to mention that as early as then enthusiasts spontaneously have tried to initiate innovations in the educational process (Kaurin, 1999, p.431). Even in the early 80's the information revolution shock is present and it is openly feared that the gap will enlarge - between the present status in the computer science and the needs that will for sure in the future be developed thanks to computer itself (Nadrljanski, 1986 p. 10). The experiences from abroad are being accepted and the computers are being integrated into schools very intensively. In the republics of former Yugoslavia different projects are developed but based on sole experiments and not on a mass scale. We can set apart some projects as Electronic study-rooms, School mediatheques, SIS – School Information System. Initiatives as 'The Computer in School'-1984, 'Computer Aided Education', 'The Computer on University'- 1981-85. The
possibilities are discussed: Computer education in primary and secondary schools as well as college students and thus related qualification of teachers and staff needed.

Golden Age of pedagogical theory of computerization of schools tends to decline at the time it was supposed to develop even more. In the early 90’s the number of schools equipped with computers, which is a positive trend so far keeps getting bigger, however it is all up to individuals and their pedagogical intuition, ability and creativity. The most common pattern of computer equipment integration into schools are computer study-rooms and cabinets, equipped with several computers which can be used by scholars but in most cases only older scholars (7th grade and upper) may use it, during computer classes. Until that time scholars manage on their own - experimenting if they own a PC or which is the case nowadays – enroll in the specialized private computer schools, because public schools can’t meet extremely high demands for computer literacy among the children of different age.

In such conditions we decided to undertake a research which should help integrate computers in everyday school life and make it possible for all scholars to use them freely. At the same time we take the teachers as the basic carriers of computer literacy. Logically, many questions add to this problem on a multi-level scale; starting from the aims and goals of the education in general, status and the role of schools in acquiring those aims, financial and technical platform in educational technology planning all the way to the capabilities and qualifications of staff needed to realize these programs. However, the readiness to use highly motivational media as a computer, touches the very person of teacher as well as technical capabilities of a school in which one teaches.

What we need to emphasize is that never before a research with this or similar theme was undertaken in this region. This fact has determined this research as a exploration study or a pre-condition to a wider inspection into teachers’ attitudes, but in the time to come, educators’ attitudes, as well, towards computers in the education of younger children.

The Research

The research intended to inspect the attitudes teachers have towards computers in education of children aged 7-11. It related to 3 groups of assignments:

a) data of computer experience of the teachers (self-estimated level of computer skills; type of computer training and years of experience with computers)
b) determine the existence of computer training in schools (evaluation of technical capabilities in schools; level of computer training and the age it starts)
c) determining the level of expression of teachers’ attitudes towards computers in the education of younger children and how they relate to pre-determined perimeters expressed in previous groups of assignments

The basic hypothesis of the research was that teachers already have a positive attitude to begin with towards computers in education and that they can perceive the benefits the computers have being integrated in the process of education. The research can be described as a correlated study helping us acquire data on presence, direction and level of correlation between teachers’ demonstrative attitudes as a dependent variable and independent variables such as gender, age, years of working experience, owning a computer and a computer experience. For the needs of this research an analysis of correlation between certain teachers attitudes and computer experience. The research instrument used was a questionnaire constructed for this purpose, consisting of two parts. The first part is an interview, which gives us basic data of a person examined. This includes gender, age, class the one is teaching and the number of children in class, as well as the information connected to the computers (estimated level of experience, length and type of training, usage of Internet and e-mail, estimated number of colleagues and scholars who own a computer, their willingness to equip the schoolroom with computers, level of school’s technical equipment. The second part of the questionnaire is a scale of a Lickert’s type divided into several sequences:

a) the role of computers in improving society and mankind
b) stereotypes about computers
c) the fear of the computers
d) motivation to use a computer for a personal and professional development
e) the influence computers have on psychophysical development of a child
f) the vision of the role computers have in school reform

Specimen description:
The research was undertaken at the end of 1999 in 12 public primary schools in Subotica (Vojvodina), the city with a long tradition of institutionalized education of the children of all ages, on an intended sample, of an improbable type made up by teachers from 1st to 4th grade (No=135). Gender structure is 120 females and 9 males excluding six examinees who didn’t answer the question, expressed in valid percent 93% females and 7% males. Here is the graphical description of the sample given for some independent variables expressed in valid percentage.

The analysis of the results related to the computer competence of teachers

The analysis of frequencies and percentages of dependent and independent variables gave the following results: A large number of examinees (78.8%) doesn’t own a computer. More than a half doesn’t know whether their colleagues own a computer (58.3%), a small number estimates that a few colleagues (up to 5) own a computer (32.6%), while 9.1% thinks that more than 5 colleagues own one. The global opinion is that it is very rarely spoken about this issue in the school. Somewhat different is the estimation of the number of scholars who own a computer – 72.5% of teacher thinks that up to 5 scholars in the class own a computer, 23.7% doesn’t know while 3.8% thinks that up to 10 scholars own a computer.

Special care was given to a teacher’s computer skill self-estimation – computer competence related to the profession. Only two of the teachers (1.7%) have evaluated their skills as excellent; a small number (14.4%) as good; 24.6% as satisfying while more than a half rate their skills as weak or insufficient. This data is consistent with the other one about length of computer experience. 87 examinees (64.4%) said that has never used a computer, 19 of them (14.1%) uses it for a few months, for a year 11 (8.1%), between 2 and 4 years 10 of them (7.4%), while 8 teachers (5.9%) use it for more than 4 years. The largest number of those who can use computers said they learned the skill through self-improvement, while the number of those who attended courses (whether institutionalized or private) is insignificant. Very few teachers – 12 of them works on computer literacy of their scholars in classes. A group of questions referred to the Internet; more than half (79.2%) has never used any Internet service, and the remaining minority (20.8%) uses it for personal needs. Similar ratio refers to E-mail service as well. At the end of this analysis let us mention two more interesting facts. More than a half of teachers doesn’t know if their school has issue related literature or if the school is subscribed to any specialized magazine, domestic or foreign, about educational technology. The other one is tied to technical equipment of the schools researched. Only one school of 12 has more than 10 computers, and the Computer science there starts in the 3rd grade of primary school at the age of 10 (approx.). In the remaining schools the number of computers in use goes from none to 10, and in most cases the training starts in 7th grade as a non-compulsory subject and is not available to all scholars.

Analysis of teachers' attitudes towards computers

The general attitude, which was calculated as a central value of all attitudes towards computers as a media in education, is positive, which confirms the basic hypothesis of the research. However, the attitude is not extremely strong, as seen from the results (statistic analyse was taken in SPSS for Windows).

</table>

This fact is encouraging, taken previous results, which tell us about a relatively low rate of computer literacy of the examinees. Also, the fact that the research was undertaken in an urban environment has to be taken into account. It is supposed that there was a greater interest for the issue. We inspected the relationship between the self-estimated computer competence and the general attitude towards computers in young children education. With Pearson’s coefficient 0.2544; p<.05 but p<.01 importance as well, we can accept a hypothesis that as the computer competence grows so does the positivity of the general attitude towards computers. Also, the expression
of the attitude is stronger with the persons who have had a bigger computer experience, than with those who have had it little or none. It seems there is a strong causal relation between these two variables.

When a rate of accordance in single attitudes inside every sequence is being observed, the following can be concluded:

- data show that teachers rated very positively attitudes on role of computers in education. Leading attitude would be "Computer competence is very important in the society we live in" (X= 4.60, SD= .52) while the weakest rated "Computers stimulate human productivity" was also very positive (X= 3.77, SD=.89)
- referring to other subsequences given in the description of the research instrument, we can see that teachers have a high rate of accordance with the attitudes concerning the influence computers have on psychophysical development of a child. The rates range from the minimum value for "Children should use computers" attitude (X=3.02, SD=1.03) to the maximum value for "Computers stimulate a child's ability to solve problems" (X=4.08, SD= .69)
- a high rate of accordance is expressed related to the role computers have in education reform. The maximum values regard the following attitudes: "Involvement of computers into schools means a greater possibility for school modernization" (X=4.38, SD= .75); "Computers in class can make education both more interesting and stimulating for scholars" (X=4.31, SD= .73), while the minimum value concerned the attitude: "The number of computers in schools will triple in the next 5 years" (X=2.70, SD=1.07). These results fit in generally accepted situation in our schools, where chalk and the board still represent the most dominant hardware a teacher uses in the process of education
- attitudes from the "motivation of teachers to use computers for professional and personal development" group were rated very high. It seems that teachers, even with the very low financial motivation to do their job, are interested in further improving both professionally and personally, and unavoidable instrument on that way is a computer. It is encouraging to see that they globally think of themselves as persons who need to know how to properly use a computer, and to pass on that knowledge to their scholars. Besides, they consider computers as a mean to get rid of some routine duties, and as a helping hand in thinking of new ways in education and realizing those programs in the classroom. One of the highest rated teachers’ attitudes was: "I think that it is very important for me to know how (better) to use a computer" (X=4.24, SD= .79). "The computer competence is a significant characteristic of an educational worker" (X=3.29, SD=1.26) as seen here was highly rated as well, even though the accordance is more dispersed than in the previous case.
- Attitudes concerning fear of computers (anxiety) weren't specially expressed neither negative nor positive and take up central values. "Computers don't scare me at all" attitude has a highest level of accordance in this group but the highest level of deviation from the central value as well
- A low level of accordance dominates among the attitudes in the group of stereotypes, and it is important that they have sunk down to the bottom of the list of attitudes. The last attitude was rated lowest on the list, but with high deviations between examinees is the attitude: "Men handle computers better than women" (X=1.82, SD=1.07)

Instead of Conclusion

Which characteristics, abilities and skills distinguish our inservice teachers? Which characteristics, abilities and skills are desirable? There are some indications which give the teachers of new era the role of a selfconfident, creative, cooperative, active, innovative...creator. Results have shown that teachers are ready and eager for changes. They need support, a well worked-out integration model of education technology in school as well as material support, since at the turning point into the new millennium, the question of computer literacy is the same importance as basic literacy is in life and work of a modern man. And all these start with the education of the youngest generation.

Abstract: The purpose of this study is to discuss the new skills and knowledge that the students in Turkish primary or secondary schools will be furnished with through the integration of educational technology into the educational system. In order for attainment of the major national intentions listed on the paper by Ministry of National Education (MONE), there is a need of determination of the student learning outcomes in Turkey. The determination of the student learning outcomes will help to define that the students, achieving the national goals, will be like what after passing through the technology integrated educational system.

Introduction

"Education is critical for economic growth and poverty reduction. Changing technology and economic reforms are creating dramatic shifts in the structure of economies, industries, and labor markets throughout the world. The rapid increase in knowledge and the pace of changing technology raise the possibility of sustained economic growth with more frequent job changes during individuals' lives. These developments have created two key priorities for education: it must meet economies' growing demands for adaptable workers who can readily acquire new skills, and it must support the continued expansion of knowledge" (Priorities and Strategies for Education by World Bank, 1995). To respond these priorities, today, most agree on use of technology in education. Industrialized and developing countries around the world allocate a considerable amount of money and energy to integrate educational technology (technology is used interchangeably with computer) into their own educational system so that (Information Literacy Standards for Student Learning, 1998) “the student who is information literate:

- Accesses information efficiently and effectively
- Evaluates information critically and competently
- Uses information effectively and creatively
- Pursues information related to personal interests
- Strives for excellence in information-seeking and knowledge generation
- Contributes positively to the learning community and to society by recognizing the importance of information to a democratic society.
- Contributes positively to the learning community and to society by participating effectively in groups to pursue and generate information.”

The goals, mentioned above, of the integrating technology into education are drawn from a developed country’s –Canada- standards of information literacy for student learning. However, the same intentions can be traced in the policies on the use of technology in education of developing countries where annual per capita income does not exceed US $4,000. Two concrete examples are Chile and Costa Rica. These two Latin American countries (Alvarez et al.) “provide a valuable opportunities to analyze two approaches to introducing computers into developing-countries education systems. Both are democratic, middle-income countries; both have focused their computer-based education programs on schools in low-income urban and rural areas; and both intended that computer use would enhance children’s cognitive abilities and prepare teachers and students to participate more fully in the Information Age... with the intent that the computers could be used to promote cooperative learning, higher level thinking, data management, and communication skills.”
Similar intentions are shown in the countries like Canada and Israel where annual per capita is much higher than the two Latin American countries mentioned above. The main purpose of integrating technology into the Israel's educational system is "to match each individual student to the program of instructional activities appropriate to his/her cognitive development and preferences." In Canada, also, the intention behind the use of technology in education is to (Information Literacy Standards for Student Learning, 1998) "prepare students to locate, analyze, evaluate, interpret, and communicate information and ideas in an information-rich society. Authentic practice of these skills enables students to realize their potential as informed citizens who think critically and solve problems, to observe rights and responsibilities relating to the generation and flow of information and ideas..."

The quotations, taken from different income level countries, on the subject of determination of policy on the integration of educational technology into the education systems show that all nations view technology in education as a tool to prepare the coming generations for the needs of 21st century. This tool will "equip the new generations with the critical thinking, problem solving, self-learning, and communication skills they need to participate fully in the economy and society."

Turkish Case

As a developing country where, also, a great deal of money and energy are reserved for the integration of technology into her educational system, Turkey has almost the same overall intentions with the other nations about the use of technology in education. These intentions (Ministry of National Education, 1999) "are based on three major points:

- Given the widespread use of technology in almost all professional areas in the next century, it is one of the primary tasks of the Ministry of National Education (MONE) to provide individuals with computer skills.
- Since one of the tasks of a school is to prepare the individuals for the community, integration of changing and developing technologies into education not only will improve the quality of education and will also support social and economic development.
- Technology can enrich learning environment and be an effective tool in increasing students' motivation, their retention, and improving their problem solving and critical thinking skills.

To complete these overall national tasks, MONE started the Computer Experimental School (CES) project in 1985. With this project, educational opportunities were opened up to a wider population and accelerating human capital development. Since the beginning of the project, the broad range of knowledge and skills required meeting present-day job market needs have been aimed to give the students in these schools.

The Skills Required by Present-day Job Markets

Present-day job market needs (Information Literacy Standards for Student Learning, 1998) "information literate people who know how to learn. They know how to learn because they know how knowledge is organized, how to find information in such a way that others can learn from them. They are people who are prepared for life-long learning, because they can always find the information needed for any task or decision at hand." So, today's schools should aim to teach the young generations how to access the information, how to evaluate the found knowledge to understand whether it is the proper one, and how to use it to solve the real life problems, to extend their own knowledge on any subject, and to communicate in an "information-rich society."

Accessing Information

As mentioned at the beginning of the discussion, the rapid increase in knowledge and the pace of changing technology force the individuals in all professions to update their own knowledge in short intervals. To satisfy this need, one has to know how to gather the required knowledge in the shortest time. Today, to access various kinds of resources around the world, the cheapest and the fastest tools are computer and Internet technology. Many educational courseware and reference materials are available on diskette, CD-ROM, and Internet in multimedia formats. Only several clicks and pressing keys may put anyone into the center of the biggest library in the world. Therefore, in an educational environment where computers connected to the Internet are installed, the first task should include
teaching the students how to find the required information from different kinds of resources. This practice maybe named as the first step of the "resource-based learning."

"By bringing telecommunications applications into the classrooms, teachers are able to create environments where students can... come in contact with a rich array of information sources that broaden their horizons. Chile currently runs one of the few successful educational wide area networks of any country in the world... It was designed as a computer network project in which participating primary schools were given the opportunity as one of the first in Latin America to use computers for on-line communication" (Alvarez et al.).

On the other hand, in the Computer Experimental Schools in Turkey, information resources related to computer technology are on diskettes or CD-ROM's. Unfortunately, the Internet connections of these schools are very limited due to the economical and geographical constraints. However, connecting these schools to the world using Internet is one of the primary tasks of MONE in coming several years. Today, the students in CES use the educational and instructional software like games, Enigmatic for English and Edunetics for math, biology, physics, and chemistry to find information in a computerized environment.

Evaluating Information

After gathering the information from different resources, the students need taking an evaluation step to understand whether it is the proper one to use. The children will have to filter a great deal of information accumulated from various kinds of resources, because there is no any control on the information gathered from especially Internet. Therefore, the schools, using computer technology in education, have to give the students critical thinking skill so that they can analyze the information at hand, and select the proper ones to use.

In conventional educational systems, one of the important resources for information gathering is teachers, and the students accept what a teacher says as true and sacred without analyzing and criticizing. However, after integration of the technology into the classroom, (Alvarez et al.) "the teacher is no longer the wise man... the teacher's role has changed to one of providing guidance to the groups. It is sort of a consultant's role, advising on how to the work is done and making suggestions when something is missing. The child feels that he/she is creating and originating his/her own work and managing his/her knowledge, and this has changed the mentality of the children to be more responsible and to meet work demands on schedule...they learn much more by navigating alone." The technology in education today does not change only students. The changes in different concepts of education as a result of restructuring schools with technology (Knapp & Glenn, 1996) are:

<table>
<thead>
<tr>
<th></th>
<th>Conventional Schools</th>
<th>Restructured Schools</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Learning</strong></td>
<td>Students learn by absorbing information and skills presented through listening to teachers' lectures and reading textbooks.</td>
<td>Students learn by constructing their own knowledge through inquiry, experience, teachers, textbooks, and other resources.</td>
</tr>
<tr>
<td><strong>Teaching</strong></td>
<td>Teachers introduce information and skills, provide exercises to practice skills and memorize information and check students' ability to remember these lessons.</td>
<td>Teachers engage students in activities that require them to think critically, solve problems, and seek answers to their own questions. Teachers serve as model learners, mentors, coaches, and resources.</td>
</tr>
<tr>
<td><strong>Classrooms</strong></td>
<td>Classrooms are primarily isolated settings where teachers deliver information, and students practice skills and answer questions. The focus is on individual and competition.</td>
<td>Classrooms are multipurpose rooms where learners engage in research and problem-solving activities related to specific topics of study. The focus is on cooperation and team building.</td>
</tr>
<tr>
<td><strong>Technology</strong></td>
<td>Educational “technologies” have traditionally included pencils and paper, chalkboards, textbooks, manipulatives, and other resources that help students develop basic skills, concepts, and generalizations.</td>
<td>A variety of technologies are now available to assist learners in the creation of knowledge and skills. Many of these technologies can support research, analysis, problem-solving, and communication processes more effectively than the traditional resources.</td>
</tr>
</tbody>
</table>
Today’s students must be able to (Information Literacy Standards for Student Learning, 1998):
- “Judge quality and usefulness of resources for the specific task
- Question the messages presented in the mass media
- Adapt and transfer strategies for seeking information among various technologies”

to be functional in the 21st century.
Without having the abilities given above, the children will have been like rubbish bins filled with useless, even harmful information.

Using Information

The last important skill for children is how to use gathered and evaluated information to solve real life problems. To solve real life problems, because (Ministry of National Education, 1999) "one of the tasks of a school is to prepare the individuals for the community."
The schools using computer technology in education teach students (Potashnik & Adkins, 1996) "to use a variety of computer productivity tools widely used in business and commerce" like word-processing, spreadsheets, databases, and Internet tools. The basic reason to teach the children such tools is to furnish them with "marketable skills for employment." Computer laboratories, installed in some developing countries like Mexico, and Belize, serve for "preparing students for employment in private business and government."
Computer related tools provide the children with the ability to:
- Create products using the knowledge accessed also from computer related resources
- Use systematic processes to create products
- Communicate information and ideas through products and presentation.

Conclusion

Related to the incredible advance in technology, information in today’s world is in a various kinds of formats. The educational institutions using information technology aim to give the students skills of accessing, evaluating and using the information. An individual using these skills will be able to:
- think critically,
- solve problems in real life,
- learn himself / herself,
- communicate in an "information-rich" society.
Moreover, (Information Literacy Standards for Student Learning, 1998) "authentic practice of these skills enables students to realize their potential as informed citizens...to observe rights and responsibilities."
To conclude, information technology in education is only a tool to prepare the new generations for the demands of today’s economies and societies. With the use of information technology in the classroom, the students will have the ability to find, to evaluate, and to use information, which is the most valuable means of production required by the modern business world.

delialog@metu.edu.tr

Abstract: The purpose of this study is to examine the students’ perception in a Turkish State University about the mission that the Department of Computer Education and Instructional Technology conveys. This study also investigates the students’ beliefs about the effectiveness of their 4-year curricula to successfully achieve their goals and missions. Data was collected through a questionnaire containing open-ended questions related to the department’s mission, aims and goals and about the meaning of the terms “Instructional Technology” and “Computer Education”. The findings showed that although most of the major goals were stated by the students there was no consistency among the perception of the students with respect to the minor goals. The students also had difficulty in defining the basic terms.

Introduction

Effective use of technology in the classroom has received much attention in education, and teacher-training programs are expected to produce computer literate teachers. As a result of the wide dissemination of computers in Basic Education schools, the Turkish Council of Higher Education has restructured state schools of education in 1998. A new preservice teacher education program named as Computer Education and Instructional Technology (CEIT) was established to meet the national educational needs such as: upgrading the curricula and instructional materials for the Turkish educational system, improving the teacher training process, training high-qualified people with the broad range of knowledge and skills required for the 21st century’s job market. Additionally, these new departments are expected to train computer teachers for K-12 and to furnish those teachers with adequate computer skills and the understanding of instructional technology to help other teachers in enhancing their teaching practice with technology. Even though these two major goals shape the primary mission of these new departments, students of these new departments may have a different perception of their main missions because of that these two terms; “computer education” and “instructional technology” are fairly new concepts for the Turkish preservice teacher training system.

Computer Education & Instructional Technology Department (CEIT)

At the undergraduate level the CEIT Departments aim particularly to equip students with up-to-date knowledge and practical skills required for K12 computer teachers. Computer laboratories are available to enrich the theoretical background of prospective teachers. An important objective given a high priority by these departments is to provide its teacher graduates with relevant contemporary information, training, and prerequisite skills. Graduates
of these departments are qualified to teach in basic education schools and high schools. The graduate program of the Department is designed to prepare graduate students instructional technology experts, and supervisors, curriculum consultants, test and evaluation specialists in instructional technology education. Computer education and instructional technology departments of all universities as well as the Ministry of Education and private schools employ the graduates of these Departments as academicians, teachers, supervisors, inspectors, curriculum consultants, test and evaluation specialists in computer education and instructional technology.

Methods and Data Sources

The target group of the study was a total of 158 students from 1st class to 4th class of the Middle East Technical University CEIT department. As the data source a questionnaire was developed. Qualitative data was collected with the help of the General Expectations and Awareness Questionnaire (GEAQ). The GEAQ, consisting of 5 open-ended questions about the department's missions, goals, curriculum and basic concepts and skills, together with student interviews intended to understand the differences in the expectations of students and the teaching staff from the CEIT Department, and to which extent the students are aware of their professional goals. The students received the questionnaire at their laboratory hours throughout the Spring semester of the 1998-1999 school year. To proof the collected information, 25 randomly chosen students from those who could answer the Questionnaire were interviewed with the same questions. In order to get a clear picture about the ideas of the students about instructional technology and computer education, the data from the GEAQ and the interviews were grouped into categories driven from common answers of students to the questions. The findings showed grade difference in the perception of the students in their understanding of the department’s goals and basic concepts studied (e.g. instructional technology and computer education), were discussed with the faculty members and students with a seminar at the end of the school year.

Results

The findings for each question in the Questionnaire and the interviews can be descriptively summarized as:

1st question: According to your opinion, what are the foundation aim, mission and major goal(s) of your department?

1. % 46 of the 1st grade students, %67 of the 2nd grade students, %53 of the 3rd grade students and % 58 of the 4th grade students are not exactly aware of the major goal of the department.

2nd question: What are the minor or specific goals of your department?

1. %19 of the 1st grade students, %10 of the 2nd grade students and %30 of the 4th grade students can not distinguish the minor and the major goal of the department.

2. % 10 of the 1st grade students, % 8 of the 2nd grade students, % 9 of the 3rd grade students and %22 of the 4th grade students have no idea about the minor goals of the CEIT department.
3rd question: Do you believe that your department's curricula fit its goals? Are there any skills and subjects that are not included in the curriculum but you think should be?

3. % 10 of the 1st grade students, % 17 of the 2nd grade students, %23 of the 3rd grade students and %11 of the 4th grade students believe that the CEIT department fits its goals.

4. Students who don’t believe the CEIT department fits its goals emphasise the following points:
   1. Biology and chemistry courses are not so important (%35 of the 1st grade students, %34 of the 2nd grade students and %29 of the 3rd grade students).
   2. Science and math courses should be in introductory level and should last only one semester (%14 of the 4th grade students).
   3. There should be more computer-related courses (%28 of the 1st grade students, %9 of the 2nd grade students, %23 of the 3rd grade students).
   4. We would like to have some courses that were not offered in the previous curriculum (%19 of the 4th grade student).
   5. There should be more programming languages (%18 of the 1st grade students, %26 of the 2nd grade students, %17 of the 3rd grade students).
   6. There should be more powerful languages like C++, Java or Perl (%11 of the 4th grade students).

7. Students find the computer-related courses as insufficient. %28 of the 1st grade students, %9 of the 2nd grade students, %23 of the 3rd grade students say that there should be more computer-related courses.

4th question: What do you understand from “Instructional Technology”? What do you understand from “Computer Education”?

8. There is a considerable number of students don’t know the meaning of instructional technology. At the 1st grade %29, at the 2nd grade %23, at the 3rd grade %10 and at the 4th grade %10 of the students doesn’t have any idea about what the instructional technology is.

5th question: According to you, which skills and abilities a person graduated from your department should possess?

9. 1st (%39), 2nd (%21), 3rd (%14) grade students believe that their department should possesses programming skills. However when the grade level becomes 4th the percentage decreases to %9.

10. As for the teaching skills, %16 of the 1st grade students, %4 of the 2nd grade students, %12 of the 3rd grade students and %18 of the 4th grade students emphasize that their department should possess this skill.

Conclusion

The variety in the perception of major goals of the department decreases with the increase of the grade level. 3rd and 4th grade students are aware of more specific and realistic goals. Homogeneity in terms of sharing common ideas of the goals of the department increases from 1st to 4th grades. The main goal of the department is shared as “to train teachers for computers in the classroom”. The way they perceive the mission and goals of the department shapes the way they define the minor or specific goals of the department. Although most of the major goals are stated there is no consistency among the perception of the students with respects the minor goals.
Until the 3rd grade the students first concern is the science courses. In the 4th grade they are more concerned with the quality of the instruction. 1st, 4th and especially at the third level there is a great variety of definitions for the instructional technology. On the other hand, at the 2nd level students concentrated on only two different types of definition. Some students cannot distinguish the difference between instructional technology and computer education.

At the 1st and 2nd grade the programming skills are perceived as the most important skills while at the 3rd and 4th grade computer literacy and computer using skills have the greatest percentage. Students at different grade levels emphasize the great variety of skills that should be possessed by a person graduated from their department.

Observations in the environment of the department it was seen that some of the CEIT students were trying to define the identity of their department. They were trying to find an answer for the question "What am I going to be when I graduate from this department?" From interviews with students it was seen that the computer (hardware and software) and Instructional technology sides of the department were favorite to educational side of the department by the students. There was a spontaneous interaction among students towards searching the identity of their department.

In the light of this finding it would not be wrong to say that there is a need for the formulation and dissemination of the departmental goals and mission. This will help the students in finding answers the question "who am I" and "what am I going to be". There might be an orientation program for the 1st grade students.

The orientation program might include the information about

- Major goals of the department
- Minor goals of the department
- Meaning of the computer education
- Meaning of the instructional technology

For further research interviews may be done with the department head and related instructors about the rationale of the courses, which are perceived as irrelevant by the students.

Furnishing Turkish Preservice Teachers with IT Skills: Hope or Hype?

Soner Yildirim
Department of Computer Education & Instructional Technology
Middle East Technical University
Faculty of Education
06531 Ankara, Turkey
soner@metu.edu.tr

Abstract: There is a growing demand from the schools that prospective teachers be computer literate. New teachers are expected not only to have necessary skills for using computers but also to use computers effectively to enrich their classroom teaching. These expectations have pressured teacher education institutions in Turkey to redesign their teacher education curricula. In order to respond to these pressures, the Turkish Council of Higher Education (YOK) has developed a new teacher-training curriculum for schools of education in Turkey. According to the new curriculum, a computer literacy course became a must course for all preservice teachers to fulfill the requirements for teaching credential. The main purpose of this study is to introduce and to discuss the efficaciousness of the new preservice technology-training program in Turkey.

Introduction:

Existence of high expectations from the application of new technologies is not new. Ever since people first began to use new tools and innovative methods to extend their own limited abilities, they have been confronted with the need to adapt themselves to create effective working and living environments. Especially, with the advancement of new information technologies, the way people communicate and perform at work has changed dramatically. Not only have the emerging technologies of information made possible new forms of communication and interaction in every aspect of our lives, they have also unleashed strong forces for educational reform. Now, educational institutions are primary responsible for preparing individuals for the new millennium in which IT skills will evidently have a decisive role.

Many researchers in such diverse fields as economics, sociology, organizational psychology, and education have long recognized the importance of information technology for national and institutional development. However, the term “IT” has different meanings and functions for different areas of study. For example, IT in education is perceived as not only a tool to be used for enhancing teaching and learning but may be a change paradigm in the classroom or in the educational system. Over the last three decades, instructional technology has progressed from its early emphasis on the protection and use of media and instruments of communication technology to its current concentration on the systematic approach to solving instructional problems based on theories of learning and instruction (Seels & Richey, 1994). As a result, provision of information technology in education is assessed on the bases of its efficaciousness in providing new ways of learning for both teachers and students. For instance, Means & Olson (1993) reviewed research related to use of technology in the classroom and concluded that technology:

- Often stimulates teachers to present more complex tasks and materials
- Tends to support teachers in becoming coaches rather than dispensers of knowledge
- Provides a safe context for teachers to become learners again and to share their ideas about curriculum and method
- Can motivate students to attempt harder tasks and to take more care in crafting their work
- Adds significance and cultural value to school tasks

Computer Literacy Courses for Teachers:

A number of institutions, organizations and state agencies have attempted to create sets of guidelines to determine what computer skills are necessary (or should be required) for prospective teachers. As a result of these extensive attempts, now a number of different guidelines exists.
Luehrmann, for example claimed that, "One who is truly computer literate must be able to do computing to conceptualize programs algorithmically, to present them in the syntax of a computer language, to identify conceptual bugs, and to express computational ideas with a high degree of organization and readability" (Luehrmann, cited in Troyer, 1988, p.144).

At the other end of the continuum are those who are not in favor of including computer languages and programming into the content of computer literacy courses. Berger & Carlson (1988) criticized current computer literacy courses for heavy concentration on technical information rather than focusing on learning and instructional design theories and methods to integrate computers into the curriculum. They propose a pre-service course that is aimed at teaching the connection between instructional strategies of computer assisted instruction and the theories of learning and instructional design. Similarly, Martorella (1984) predicted that teachers do not need to know computer programming to use computers effectively as an educational tool. That view is shared by Rundall who expressed his opposition to those who are at the other end of the continuum by using the automobile analogy: “We can run a computer, just as we can run an automobile, without knowing how it works” (Rundall, 1985).

Davis (1992) developed a list of outcomes for teacher training that focuses on how to utilize technology in the classroom. Davis believed that a teacher training program should focus on increasing teachers’ competencies to utilize technology effectively rather than promoting their programming skills. He further proposed that pre-service teachers should be able to:

1) make confident use of a range of software packages and information technology devices appropriate to their subject specialism and age range;
2) review critically the relevance of software packages and information technology devices appropriate to their subject specialism and age range and judge the potential value of these in the classroom;
3) make constructive use of information technology in their teaching and in particular prepare and put into effect schemes of work incorporating appropriate uses of information technology;
4) evaluate the ways in which the use of information technology changes the nature of teaching and learning (Davis, 1992).

Finally, there is an emerging perspective, which tends to view technology as a way of promoting innovations emerging from other fields of education such as curriculum development, instructional design or the theory of learning and teaching. Willis & Mehlinger (1996) think this perspective will frame the decisions and debates of the 1990s because this approach reflects a maturing perspective on educational computing.

It does not treat all uses of computers in the classroom as equal as did so many of the research reviews published in 1980s. In addition, it does not treat educational computing as something separate from other aspects of the classroom such as the curriculum, lesson plans, and instructional design...Although this is very desirable, it will make discussions about computers in the classroom much more complex. (p. 1006)

In light of these different approaches, it is evident that the term “computer literacy” remains an ambiguous term because it means different things to different people. Tremendous development in the computer industry is also making the issue become much more complex. Even though outpacing of technology in teacher education programs has been too slow, the computer industry has been promising and providing more advanced technologies for instructional use simultaneously. Ongoing debate on the definition of “computer literacy” and guidelines for student teachers’ computer competencies creates a serious debate on the contents of computer literacy courses. Each scholar determines the content of such courses based on their view of perceiving the term computer literacy resulting in confusion and lack of agreement.

Troyer (1988) reviewed a number of sources giving recommendations for the content of computer education for teachers. He noted that three topics are most frequently recommended for inclusion in teacher computer literacy training: (a) computer operation and structure, (b) educational applications of computers, and (c) software/courseware evaluation. (p. 145). Troyer (1988) also found that early emphasis on knowledge of the basic elements of programming has been losing its attractiveness among the scholars:

Teacher computer literacy training now directs teachers to consider the methods of utilizing the computer effectively in the classroom, to evaluate available software, to use the computer as a tool in accomplishing record-keeping and managerial tasks, and to consider the larger impact of computer technology on society and education. (p. 146)
There is a number of researchers who firmly believe that computer literacy is a matter of individual organizational need. These scholars claim that we should focus on what is important to student teachers rather than pondering the glut of computer skills available. Moont (1987), for example, criticized that we are spending too much time and effort on the definition of computer literacy rather than teaching. Sheffler (1986) summed up the philosophy of computer literacy when he claimed “the challenge confronting teachers is to adapt whatever advantages computer use may be shown to offer, while holding fast to their independent vision of educational values” (Sheffler, cited in, Kay, 1989).

Higdon (1994) claims that each school for teacher training develops its own criteria of proficiency level in computer literacy and these imposed computer proficiency levels are achieved by pre-service teachers for credit but are not necessarily functionally learned. He further proposes that the pre-service teacher needs to be impressed with the social, economical, and cultural factors along with the empowerment that come with computer literacy. (p. 436).

Constructivist theory defines learning as a dynamic and continues process that must be sustained and strengthened by a multiplicity of experiences from which students then construct their own experiences and explanations (Jonassen, 1994). As constructivist approach receives wider acceptance in the field of teacher education, some teacher education institutions attempt to increase the emphasis on experience in the schools and deacrease the emphasis on lecture/discussion and computer lab components of the course by promoting student teachers’ field experience (Burson, 1995).

Rodriguez (1997), for example, suggested that some of the general guidance in constructivist literature can be applied to technology training for teachers. Rodriguez proposed five constructivist strategies that can be used in technology training. First, he believed that constructivism and cognitivism complement each other and these two approaches should be merged. He further suggested requiring students to exert their mental effort in support of generative learning while providing explicit instructional support to avoid information overload in short-term memory. Second, he emphasized the importance of focusing on learners and their needs. He advocated that keeping students engaged through active participation and maintaining students’ sense of relevance concerning course activities are critical. Focusing on the essence is another strategy that Rodriguez proposed. He argued that grasping the essence, students can then literally accomplish more complex tasks with the instructor’s guidance, thus developing their understanding as they grapple with more complex problems. Fourth, he advocated that learning under the constructivist view is a communal activity. Even though teacher trainees need time to develop their technological skills on an individual basis, they often enjoy providing informal assistance to each other. Finally, the last strategy concerns reflexivity-learners’ awareness of their role in constructing knowledge. He suggested that the instructor’s role is to be one of “...engaging the student via questioning and prompting so that the student assumes responsibility for acting to solve the problem. Reflection and action, then, support construction of new knowledge” (p. 1309-1311).

Keizer and Wright (1997) describe how a basic computer course should be designed by using constructivist strategies, which are proposed in the previous study. First of all, the researches suggest that the course should be redesigned with a shift from whole-class to small-group instruction, from individual to tutorial instruction, from lecture to coaching, from summative evaluation to performance assessment, and from isolation to cooperative learning. The curriculum should be based on major concepts rather than a long list of objectives; it should focus on competencies rather than meeting externally imposed criteria. The classroom is to be more learner-oriented and less teacher-centered. The basic framework for the course should be changed from large group lecture and individual practice to teaching practice based on coherent themes, reflection, and relevant contextual experiences. Finally, faculty should give students guidance but not step-by-step instruction so that students can explore the computer applications through tutorials at individualized speeds and engage in authentic, real-word projects (p. 210).

It is obvious that the term “computer literacy” and “the content of computer literacy courses” have been modified according to developments in the field of technology and teacher training. In its beginnings, computer literacy addressed an understanding of hardware and software development. The student was expected to know the parts of the computer both internal and external. In addition, the student was required to become conversant in programming languages since it was necessary to know the language to get the computer to do many required tasks. As user-friendly computers and software become more available in education, the term computer literacy became more application oriented. Accordingly, an evolutionary change also took place in outlining the content of computer literacy courses. Computer literacy courses became more application oriented and the learners were prepared to use computers and software rather than to learn how to program them. Finally, computer literacy is now perceived as a tool for teachers to reform the way they teach.
Characteristics of Effective Preservice Technology Training:

Teachers will play a decisive role in how successful the integration of technology will be in education. It is evident that the investment in technology cannot be fully effective unless teachers receive necessary training and support to become fully capable of using these technologies.

A large body of research points out that technology should be integrated across the entire teacher education curriculum to be effective. Most teacher educators admit that only required computer literacy course for educators is of limited value if it is isolated from the rest of the teacher education curriculum (Yildirim, 1999; Yildirim & Kiraz, 1999). For example, Novak & Knowles (1991) examined beginning elementary teachers' use of computers in classroom education. They discovered that computer usage was not emphasized in their first year of teaching experiences because new teachers viewed computers as "extra" and "special," not as general tools to enhance the instructional process. This study supports the position that technology training needs to be integrated into the entire pre-service teacher education program so that pre-service teachers accept it as a means to enhance teaching and learning.

Effective technology training has four common characteristics that can be traced in the literature:

(a) educational technology training needs to be integrated into the entire teacher education program so that effective technology integration is modeled for pre-service teachers;
(b) the training should link technology with curriculum;
(c) the training should provide hands-on practice so that teachers become comfortable with them; and
(d) the training needs to be in-depth (Dell & Disdier, 1994).

Integration of IT into Preservice Teacher Education Programs in Turkey:

The Turkish Council of Higher Education (YOK) is responsible for the planning, coordination, and supervision of higher education in Turkey. Parallel to the international practices in reforming preservice teacher education for the new millennium, the Turkish Council of Higher Education has developed a new teacher training curricula for schools of education in Turkey. According to the new curricula, a computer literacy course became a must course for all preservice teachers to fulfill the requirements for teaching credential. This new course is designed to improve and enhance teachers' IT skills.

The main purpose of this course is defined in the new curriculum as to teach basic computer skills and introduce teachers to several commonly used computer applications such as word processing, spreadsheets, databases, telecommunications, and presentation programs. However, as described in the curriculum, preparing teachers for the use of these technologies into their classroom teaching is not among the course goals. Even though earlier practices of preservice technology training clearly ascertained that one computer literacy course is not of a high value unless computers are integrated into the whole teacher education program.

Even though this computer specific course is the first attempt at preparing Turkish preservice teachers to use computer technologies in the classroom, this effort should go beyond only training the teachers on basic computer skills. If the Turkish Council of Higher Education is to prepare teachers for the 21st century, the Council should recognize the need for providing other courses concentrating on instructional strategies to promote teaching with the computer in the classroom. In addition to that the content of “Methods of Teaching” courses can be reorganized to introduce new teaching methods including those incorporating the computer. As a result of this reorganization, schools of education will not only be training preservice teachers on technology but they will also be training preservice teachers on teaching with technology.

It is a fact that teachers teach as they have been taught, and it is unlikely that they will integrate computers into the classroom teaching unless they see their faculty using computers to teach. Therefore, it’s also of the essence for faculty to promote “teaching with technology” in their classrooms.

Conclusion and Recommendations:

It is obvious that requiring a computer literacy course for preservice teachers to fulfill the requirements for teaching credential is an important step for the Turkish Council of Higher Education. It is because this required computer literacy course will make teachers more at ease with using applications, help them gain more confidence in using computers, increase their awareness of computers and its applications. However, the related literature on the preservice technology training indicates that “teaching with technology” is more than “using technology.” Therefore, preservice teacher training programs of Turkey should be reorganized in accordance with the following principles.
technology should be infused to entire teacher education program,
technology should be introduced in context, and
students should experience innovative technology-supported learning environments in their teacher education programs (Davis, 1999).

In order for the Turkish Council of Higher Education to successfully redesign preservice technology training programs, the following recommendations are offered:

1. Even though every preservice teacher is now mandated to take this required computing course, the value of this course is limited unless computers are integrated into the entire teacher education curriculum. Therefore, the Turkish Council of Higher Education should take the initiatives to employ new policies to incorporate technology into teacher education curricula outside of computer literacy or instructional technology courses. One of the most effective policies for incorporating technology into the whole program would be the integration of technology in teaching methods courses.

2. Needless to say, faculty of teacher education programs will play a decisive role in how successful the integration of technology will be in education. Therefore, they should demonstrate their competency and willingness to use technology in teaching. They should be role models for prospective teachers in integrating technology into the classroom teaching.

3. However, faculty of teacher training programs will need constant assistance from the educational technology experts in developing their hardware and software skills. Therefore, the Turkish Council for Higher Education should develop new policies to make this assistance available.

Abstract: The purpose of this study is to determine time dependent computer attitudes of preservice teachers at the College of Education at Karadeniz Technical University, Trabzon, Turkey, in an entry-level computer course. The focus of this study is to determine whether the gender and length of computer usage influence attitude of preservice teacher toward computers. Our results show that gender does not appear to significantly influence attitudes toward computers. However, the length of computer usage does influence attitudes toward computers.

Introduction

One of the great challenges facing today's education system is the computer revolution in education. There is a need for preservice education programs, which emphasize integration of computer use in subject content areas and individual curriculum units. Beginning in 1982, the Turkish government introduced a series of funding initiatives to promote the use of information technology in schools. Applying information technology to effective learning and teaching all keys learning areas is the current Turkish education policy.

Teacher education faculties in Turkey have grappled for years with the challenge of preparing teachers to integrate technology using a variety of different approaches. Some components of the knowledge and skills required for teaching with technology are assessed with reasonable confidence. These include technical skills such as the operation of hardware or software and knowledge of relevant curriculum and policy documents. These teacher education faculties have been giving graduates with these capabilities for several years. However, this capability does not translate into more or better integration of computer technology into teaching. There are factors other than technical knowledge and skill, which contribute to teachers' success at technology integration in their teaching.

Positive teacher attitudes toward computers are recognized by researchers as a necessary condition for effective use of information technology in the classroom. (Poling, 1994) asserted that students feel as if they are dragged, kicking and screaming into the realm of computers. Hakkien evaluated how a computer course affected the anxiety level, computer attitude, and feelings about computers of 29 first year education majors (25 females and 4 males). Sinclair's results indicated that as familiarity with the computer increased, computer anxiety levels decreased and attitudes improved. The other study compared education students in a computer course with a control group. Students who had taken the computer course had lower anxiety scores and higher self-perceived ability than those who had not (McCoy & Baker, 1994).

At the College of Education at Karadeniz Technical University (KTU), Trabzon, Turkey, all education majors take an entry-level computer course entitled as Introduction to Computers. This course covers basic computer concepts, word processing, spreadsheet, and database. The course ensures that all educators can use information technologies to improve student learning, support effective teaching, and enhance overall teacher productivity. Students in all majors of college of education are required to take this course. However, many enter the course with anxiety due to limited use of the computers. Researchers suggest that negative attitudes and unfavorable perceptions of computers adversely affect computer literacy.

The purpose of this study was to investigate preservice teachers' time dependent attitudes and perceptions about computers in an entry-level computer course. This study attempted to address the following questions:

- What are preservice teachers' general attitudes toward computers?
- Do variables such as gender affect preservice teachers' attitudes toward computers?
- Do length of computer usage influence preservice teachers' various attitude domains?
Method and Instruments

Participants were pre-service teachers who were enrolled in undergraduate entry-level computer course in the spring program at the college of education in 1999. The study examined the computer attitudes of 78 preservice teacher majoring in science education in an eight-week computer course. Further, these attitudes were studied in relation to gender and length of computer usage.

The instruments used in this study were a) Interview Questionnaire, and b) Computer Attitude Survey.

a) Interview Questionnaire: Participants were interviewed to gather data and to determine their computer experience and preferences. This survey was given to students at the beginning and at the end of the computer class.

b) Computer Attitude Survey: To determine preservice teachers attitudes toward computers, subscale of Computer Attitude Measure (CAM) (Kay, 1993), was translated to a Turkish version and utilized in this study. These attitudes included personal attitudes and also application of those attitudes to teaching situations. This survey was given to students every week to determine weekly changes in attitudes toward computers. The following is the CAM subscale:

ATTITUDE ABOUT COMPUTERS

Please mark an X on the line, which closest indicates your choice.

Computers are:

1- Unlikable
2- Unhappy
3- Bad
4- Unpleasant
5- Tense
6- Uncomfortable
7- Artificial
8- Empty
9- Dull
10- Suffocating

Likable
Happy
Good
Pleasant
Calm
Comfortable
Natural
Full
Exciting
Fresh

Computer Course

The required computer course was taught in a computer lab by an experienced computer instructor. The content covered in the computer course include basic computer literacy tasks: 1) knowledge about computer hardware and software, 2) skills of using and exploring programs, and 3) ability to apply software features to produce the desired result.

The computer application classes are structured so that participants are engaged in hands-on activities to gain insights about how computers can be used to improve teachers efficiency and productivity.

In the first week students were introduced to basic computer terminology and gained knowledge about computer hardware and software.

In the second and third weeks students are required to demonstrate their skills in several word processing tasks. These included creating a word processed documents, retrieving and editing a file, setting new margins, changing the size, type, and style of fonts, and aligning text. They were instructed to change a document’s line spacing, center a line of text, move text, and insert or delete text where necessary. The final tasks were to print the documents and save them as files on the diskette.

In the fourth and fifth weeks, to demonstrate competence with spreadsheets, students were asked to create a spreadsheet file. After the spreadsheet was created, the students had to increase the width of a column, edit a cell, use a function to calculate the average, and create a bar graph. The students were printing a copy of the spreadsheet and save their work on the diskette.

In the sixth and seventh weeks, in the database section the students were required to create, edit, and sort a database records. Students were directed to create a database using the fields and data that were provided. They
were then instructed to edit a record, delete a record, sort the database according to specific criteria, and print the records. The students were then asked to create and print a report and save their databases on the diskette.

In the last week, students were instructed to use presentation program, Power Point. They were asked to create a new slide, add a color, picture and animation, and apply styles to their slide. The students were then directed to create a slide show. The final tasks were to print slides and save their work on the diskette.

Procedure

At the beginning of the computer course the purpose of the surveys was explained to the students. They were told that their responses would facilitate course revisions as well as provide a measure of the effectiveness of the course. Interview Questionnaire was administrated to participating students prior to and after eight weeks and data about their computer experiences and preferences were collected. Interview questionnaire contained a short survey about basic technology competencies that are needed by educators. The students are asked to give an overall rating of their competency within each of the five domains (1) basic computer operation skills; (2) word processing; (3) spreadsheets; (4) databases; and (5) media communication. Participants are instructed to self-assess using a four-point scale (Very competent to Not competent).

On the computer attitude survey respondents were asked to indicate the degree to which they agreed or disagreed with each statement by circling the appropriate number from 1 to 7 (number 1 indicated negative attitude and number 7 indicated positive attitude toward each statement). This survey was given to students at the end of every week to determine weekly changes in attitudes toward computers.

Results and Discussion

Results revealed that 8 of 78 students owned a computer, 35 of 78 students were female and 45 of 78 were male.

The results of Interview Questionnaire that is administrated at the beginning of the computer course showed that students assessed themselves Not competent. Overall rating of their competency within each of the five domains ranged from 1 to 1.57 as it is shown in Tab. 1.

Table 1. Results of Interview Questionnaire

The results of weekly variations of attitudes about computers are shown in Fig. 1 for both boys and girls. The weekly variation of each attitude is presented from (a) to (j) in Fig. 1. The following general observations can be done about Fig. 1: In general, both boys and girls responded positively for each attitude it is seen from Figure. So, students (boys and girls) think that computers are: likable, happy, good, pleased, calm, comfortable, natural, exciting, fresh and full. There are some weekly variations of these answers as it is seen from Figure. In general, for every week students responded more positively to all attitudes except in the third week and the week before last week (in the seventh week). In these weeks there is a slight decrease in the positive responses. The reasons for this can be attributed to the homework that was assigned to them at the end of the second week and the final exam, which was announced the week before last week. Again the differences between the responses of boys and girls are not significant in general. But Fig. 1 shows that the assigned homework at the end of the second week affected boys more than girls which is seen as a sharp decrease in boys graphics in Fig. 1. On the other hand the Figure shows that the final exam effect affected boys and girls almost the same.

Ukrainian Teacher Education in Transition:
What Role Can Technology Play?

Valentyna Kolomiyets
English and Methodology Department
Gogol State Pedagogical University of Nizhyn
Ukraine
valia@iastate.edu

Abstract: The paper presents a critical analysis of teacher education reform in Ukraine. The author discusses the educational legacy of the Soviet period, major changes in teacher education, which resulted from general educational reform, and current needs of Ukrainian teacher education. The author argues that teacher education reform has so far succeeded in correcting the most obvious vices of the inherited education system. Further development of the reform should be aimed at altering the fundamental ways in which the system is organized. The successful accomplishment of this task is possible only on condition that all central dimensions of the teacher education reform, namely, teaching materials, teaching approaches and belief systems, undergo profound change. The expansion of teacher education reform can be ensured through the use of technology, which has a potential of becoming an important means of altering teaching strategies and beliefs.

Introduction

Like other countries, which emerged after the collapse of the Soviet Union, Ukraine is living through a period of profound transformation. Formerly part of a totalitarian state, it is slowly but steadily acquiring its own identity. A central role in this process belongs to education. The new Ukraine needs people who have been trained in the ways of the new social and political environment. Therefore, creating an educational system, which can help young people meet the challenges of the new, emerging democratic society, is a goal of utmost importance. Success in achieving this goal depends, to a great degree, on the quality and commitment of the teaching force.

This paper will focus on the current state of pre-service and in-service teacher education in Ukraine. Beginning with a brief description of the Soviet period legacy, the paper will shift to examining the major changes in teacher education which resulted from the implementation of the national policy in the field of education. It will then describe current needs in teacher education in Ukraine. Finally, the paper will consider the role, which technology can play in building up teacher education system, which will produce thoughtful, creative, independent specialists, who have clear understanding of inherent values of education for democracy and are willing to participate in the renewal.

The Soviet Period Legacy

A reform is correction of a wrong, of errors. Therefore, we shall start our analysis of changes in teacher education in Ukraine with a description of the Soviet period legacy.

The structure and content of teacher education in the Soviet Union was mainly shaped during the late 20s and underwent but rather insignificant changes during the Soviet period (Webber, Webber, 1994).

Pre-service teacher training in the former USSR was realized in both higher and non-higher, or secondary, educational institutions. Most secondary school teachers were prepared in higher educational institutions: pedagogical institutes and "classical" universities. These institutions also trained teachers for schools for physically and emotionally handicapped children, as well as children with learning disabilities. Most primary school and pre-school teachers received their training in non-higher educational sector, the so-called pedagogical schools and technikums, though a substantial proportion graduated from teacher training...
institutes. Higher educational institutions admitted applicants who had completed secondary education, pedagogical schools and technikums could be entered by people with either complete or incomplete secondary education. In the latter case students received their secondary education along with teacher education.

Most higher educational institutions offered five-year programs, which prepared for teaching two subjects. Many of them also offered courses by correspondence, evening courses or both. Students taking such courses had to take an additional year to study and unlike the full-time students prepared to teach only one subject. Pedagogical schools offered two- or three-year programs for students who had completed secondary education and three- or four-year programs for students with incomplete secondary education.

The curriculum in both higher and non-higher teacher education institutions was fairly standardized. The elementary and pre-school teachers took compulsory courses in Russian language and literature, mathematics, history, natural sciences and teaching methods. Pre-school teachers did language development, singing, sculpting, and drawing. Students of pedagogical schools also learned to play musical instruments.

The curriculum in pedagogical universities consisted of three interrelated components: content area, social disciplines (scientific communism, Marxist-Leninist philosophy, political economy and history of the Communist Party of the Soviet Union) and pedagogical disciplines (pedagogy, history of education, educational psychology, school hygiene and methods of teaching the student's particular content area). Also all student teachers had to take physical education and nursing (female students) or military training (male students).

An integral part of the curriculum in both higher and non-higher teacher education institutions was practical application of what the students learned. In the first years of study students were involved in extra-curricular activities at schools and worked in children summer camps. Later they did full-time student teaching under the guidance and supervision of teacher educators and on-site secondary or primary school teachers. Prospective teachers of biology, chemistry, and physics also had to do an industry practicum.

Upon graduation teachers were assigned to schools where they were required to work for at least three years before they could move to another job.

The in-service teacher training was realized in Institutes for Higher Pedagogical Qualifications and Institutes for Teacher Development, which offered short courses dealing with a specific content area and with certain topics in pedagogy. Teachers were required to have such retraining every five years. The participation in these courses was a necessary prerequisite for improving teaching qualifications.

This system of teacher education ensured significant educational accomplishments, for example very high literacy levels and great successes in the sciences and technical education. However, being designed to serve the needs of an authoritarian state with its command style economy it emphasized the values, which were opposite to those characterizing a democratic society. The major features of the system may be summarized as follows:

- State monopoly in the field of education. There were no private or denominational educational institutions in the USSR.
- "Rigid uniformity" (Webber, Webber, 1994). The system was universal with no diversity in region with markedly different history, culture and traditions.
- Heavy politicization. It was considered that the teacher's primary role was that of ideological educator (Webber, Webber, 1994), which explains, for example, why social sciences carried more weight in teacher education programs than pedagogical disciplines.
- Centralization. It was a hierarchical bureaucratic structure, in which all curricular, methods, objectives were issued by the Ministry of Education.
- Subject-centered approach. Teachers saw their aim in imparting and students in memorizing factual subject matter. Therefore, the system emphasized didactic and expository methods of instruction and paid little attention to building up higher cognitive skills.
- Low quality of philosophical and pedagogical culture. Pedagogy was separated from philosophy completely. This accounts for insufficient attention to the development of student teacher personality. Teacher education was concerned in the first place about preparing students with encyclopedic knowledge of different subjects and emphasized conformity rather than developed independence, leadership, creativity, critical attitude, willingness to take risks, tolerance to different opinions or responsibility.
The political change in 1991 generated fundamental social and economic transformation of the society and stressed the need for a different type of educational system, which could provide young people with the knowledge, attitudes and skills to be flexible, adaptable, and self-reliant.

**Ukrainian National Policy in the Field of Education: Major Outcomes**

Ukrainian national policy in the field of education began taking shape soon after the country proclaimed its independence. Its main directions were first defined in the Education Act of Ukraine adopted in June 1991 and were later instantiated in the Law on Education of Ukraine (1996) and in the Law on Secondary Education (1998). From the very beginning Ukrainian national policy was directed towards improving considerably the quality of education, integrating it with international educational practices, and reviving the people’s national identity. Now, nine years later, we can see concrete results of its implementation.

The most visible aspect of change is a structural reform. The past decade has been marked by the establishment of private education institutions and the development of fee-paying higher education. Many teacher education institutions have changed their status, for example, according to the Law on Education of Ukraine former pedagogical schools now provide basic higher education. A number of pedagogical institutes have been transformed into pedagogical universities. This process was accompanied by considerable course diversification, which was motivated not solely by teacher training considerations but by student demands and needs of local and national economies.

Recent years have also been marked by the development of a multi-level system of pedagogical education. Now teacher education students may receive incomplete or basic higher education at Bachelor's level and complete higher education at Specialist's or Master's level. Pedagogical colleges offer programs which lead to Bachelor's degree, pedagogical institutes run Specialist's degree programs, and pedagogical universities grant Specialist's and Master's degrees.

Although higher education system of Ukraine is still regarded as highly centralized (Savchuk et al., 1997), higher education institutions have been given certain amount of autonomy. Subject matter and course structure are still decided by the Ministry of Education, however, teacher education institutions can now offer courses of their own choice, in accordance with the possibilities, which they have at their disposal, and regional peculiarities. Teacher educators also enjoy more freedom to choose textbooks and teaching materials.

Another result of educational reform is depoliticization of teacher education. Heavy ideological orientation of the system and rigid ideological control were brought to an end. New courses have been introduced, for example, sociology, logic, history of Ukraine. The content of the existing courses has been significantly updated.

National educational policy has also led to a wide spread of complexes, which consist of universities and gymnasiuums or/and colleges, where different phases of teacher education are brought into closer contact with one another.

The scope of changes achieved in a relatively short period of time is impressive. However, this immediate correction of the most obvious faults of the inherited teacher education system is no more than a beginning of educational reform. To ensure its success more comprehensive mechanisms of change are needed, above all, careful strategic planning.

**Have We Learned Our Lessons?**

During the Soviet period there were two attempts to substitute the authoritarian, content-based education system with a humanistic, student-centered one. The first attempt was initiated by the educational authorities under Anatolii Lunacharskii immediately after bolcheviks came to power in 1917. The second one was advocated by the USSR Ministry of Education during the years of Perestroika. Both initiatives were enthusiastically met by broad-minded educators in the former USSR and abroad, but neither brought the desired results. It would be oversimplification to assign the failure of the reforms to a single factor. But it is not an exaggeration to say that an important part in burying these bold initiatives was played by lack of attention to the task of preparing agents of the reforms. In both cases reformers did not understand, did not
take seriously or overlooked the problem of resistance of the teaching force. They obviously acted from naïve
theories of change, believing that long established practices could be altered through sanctions, exhortation or
new courses in the curricular. Reforms were conceived not as multidimensional processes (Fullan, 1991), but
rather as single events. Such an approach explains the choice of strategies of change which neglected
addressing all three dimensions, which M. Fullan considers central to any educational reform, namely,
materials (regulations, curricular, technology), teaching approaches (teaching strategies, activities,
techniques), and beliefs (pedagogical assumptions, theories, which serve as basis for new programs) (Fullan,
1991). Although implementing just one or two of these dimensions, for example, introducing new courses
without altering teaching strategies, or adopting new techniques without understanding the conception which
underlie them, can accomplish certain educational objectives, but it cannot lead to fundamental change of the
education system. Issuing new regulations, developing new materials and providing new resources are the
most visible part of the reform and at the same time the easiest to imply, but they allow no more than
improving the quality of what already exists. Changing teaching approaches and belief systems is much more
difficult and requires continuous application of efforts. However, it is the development of the new teaching
skills and provision of conceptual understanding of reasons for and main objectives of educational reform that
makes the reform irreversible.

The lesson to be learnt from the two unsuccessful attempts of educational reforms mentioned here is that a
precondition of a successful general educational reform is a reform of teacher education. The latter requires
special attention and should be regarded a task of utmost importance if general educational reform is to
have a chance to succeed.

Current Needs

The changes in teacher education achieved so far have resulted from the implementation of the general
educational reform. Although these changes provided correction of the most obvious faults of the educational
system, which Ukraine inherited from the USSR, they have not altered the fundamental ways in which it
works. Therefore, there is a need to back up building a system of teacher education for democracy with a
philosophy of change which would address both the content and the process of teacher education reform. It is
important to ensure that educational change moves beyond issuing new regulations or revising materials. This
does not mean that structural reform has achieved all its objectives. On the contrary, teacher education is in
great need for new textbooks, curricular materials, computer hardware and software. But new laws or modern
technology do not necessarily translate into significant improvements in pedagogy. They work or fail
depending on whether or not they are based on changes in conceptions and teaching strategies. This means,
for instance, that teachers need to be brought to grips with the inherent values of a democratic system and the
nature of the teaching process in a democracy. They need to learn how to develop courses, which would fuse
content learning with the development of student cognitive skills. They need to acquire practical skills in
organizing and running schools in a democracy.

An important characteristic of the present reform is the enthusiasm and willingness to change felt by the
majority of teachers, which is revealed, for example, in increasing numbers of “alternative” schools. This
positive motivation for change needs to be fostered and teachers who struggle to ensure the success of
educational reform should be provided with necessary skills and competencies as well as administrative
support and resources.

The past few years have been marked by the development of a new tendency in teacher education map in
Ukraine, namely, growing importance of provincial universities in pre-service and in-service teacher
education. More and more school graduates who consider teaching as a career and people who already have
higher education but want to be retrained as teachers enter provincial rather than central teacher education
institutions (Gluzman, 1997). The faculty in provincial teacher education institutions also demonstrates
greater commitment to their profession, while teacher education institutions located in big cities are becoming
more like general universities, often dropping the focus on teacher preparation entirely. This brings forward
the need to turn provincial pedagogical universities into regional centers for pre-service and in-service teacher
education. The implementation of this strategy requires careful planning and state funding as unlike the
advanced central higher education institutions most provincial universities have seen very little change
recently as far as modernization of teacher education is concerned.
This list of need is far from being complete. I have just described those, which, in my opinion, require immediate attention.

What Role Can Technology Play in Teacher Education Reform?

Most teacher education institutions, in particular those, which are located in provinces, have but limited technology resources. Nevertheless, these resources could help to achieve an important breakthrough in teacher education reform, provided they are put to good use.

As has already been emphasized, educational reform is a multidimensional process. Change in materials is relatively easy to employ, changes in teaching strategies and belief systems present immense difficulties. However, if fundamental educational change is to be achieved, it is essential that all three dimensions - what teachers use as well as what they do and think - be altered in actual practice. It is in expanding educational change to cover up teaching strategies and beliefs that I see the primary role of technology in teacher education reform. Technology can ensure reform expansion in a number of ways:

- Providing continuous personal access to new ideas, which is a necessary condition for becoming aware and following up on innovations (Fullan, 1991).
- Providing opportunities for open ongoing interaction among teachers focused on educational reform implementation. Interaction is regarded the prime basis for social learning (Fullan, 1991). Expanding the scope of interaction, letting it go beyond one school or district may accelerate the acquisition of new concepts, new behaviors, new skills and new beliefs considerably.
- Letting external facilitators into the educational reform. Educators in Western Europe and in the USA have considerable first-hand experience of education for democracy. They may provide invaluable assistance helping Ukrainian teachers become aware of the existence of new approaches, choosing among a range of new practices, deciding on suitable evaluation. This interaction may provide Ukrainian teachers with important insights into the nature of education for democracy.
- Providing access to innovative educational materials (sample lessons, teaching tips) and resources.

While technology is not the only factor affecting educational change, it may play a key role in its successful implementation.

Conclusion

Analysis of teacher education reform in Ukraine gives reasons for optimism as well as for pessimism. On the one hand, there are obvious successes in dealing with the faults of the inherited education system. On the other hand, we face lack of strategic planning for educational change, which may eventually allow the system to remain essentially untouched. Whether teacher education reform will end up at the structural reform phase or move beyond it depends on a number of factors. One of them is technology. Hopefully, its potential will be used to its fullest.

Abstract: To say that Russian educational system is currently in transition is an understatement. More than ever before higher education in Russia and teacher training as its integral part is responsive to societal changes. The massive pressure of the technology revolution has created conditions that have greatly transformed the nature of academic life, the content of learning, and the roles of educators. The paper presents an effort to analyze the current situation in Russian teacher education considering both external and internal forces affecting the system. It also focuses on the issue of educational technology within the system of teacher training.

Introduction

To speak about changes and transformations the Russian teacher education is facing today is better through examining and analyzing its basic features from historical and contemporary perspectives. The following aims to track both the traditional Soviet and the reformed Russian teacher training system.

Teacher Education in Soviet Russia

Pre-service education

The structure of pre-service teacher education in the former Soviet Union resembles that of systems in many Western European countries. Traditionally a university diploma has been a license to teach. However, teacher training in the Soviet Union was not limited to university level: only 10 percent of teachers were prepared at the universities.

By the early 1990s, pre-service teacher training in the Soviet Union had been provided by three types of educational institutions:
1. specialized pedagogical schools,
2. pedagogical institutes,
3. universities.

Pedagogical schools still function in Russia today, specializing in preparation of preschool and elementary school teachers. The admission to pedagogical schools is based on either nine or eleven years of study in secondary school. The curriculum is mostly focused on methods of teaching and study of education. The course of study varies from four to two years, depending on the educational background of the students. Nearly three fifths of the course is devoted to core subjects and methodology of teaching them Theoretical professional training is combined with practical work during the first years and a teaching practice in the final year.

Pedagogical institutes, which were equivalent to university level institutions, and some departments of universities originally trained the students intended to teach in secondary schools. The course of study in both institutions was five years. The major difference between institutes and universities was in the curriculum, in other words in the existing balance between subject matter and educational studies. Traditionally pedagogical institutes paid greater attention to methodological and educational issues and provided more in-service training than universities did. The emphasis was placed on the preparation of professionals qualified to work as teachers.

The universities focused on preparation of scientists and researchers rather than educators. The common feature for both types of higher educational institutions was that the variety and number of courses taken by students were based on the standard curricula and were mandatory.

In the 1970s departments for training preschool and elementary school teachers were established...
in pedagogical institutes. It was an attempt to provide elementary schools with higher education institutions graduates. This implied that specialized pedagogical schools would be gradually replaced by pedagogical institutes, but it didn’t happen. In spite of the differences between the ways future teachers were trained in pedagogical institutes and in pedagogical schools some school principals believed that elementary school teachers graduating from pedagogical schools were better prepared for their work than those graduating from the institutes. (Holmes et al. 1995). The former had more practical experience in their work than the latter due to the fact that in the institutes theory courses dominated the curriculum. Thus, by the early 1990s the above described institutions provided all Soviet schools with teaching personnel.

**In-service Professional Development**

In-service teacher training has been traditionally a significant part of the entire educational system. Every five years elementary and secondary school teachers had to take refresher courses, provided by teacher development institutes. These courses focused on specialized and advanced study in each core subject, as well as innovative teaching methods. Similar courses were organized by professional development departments for university faculties. School teacher qualification system responded to teachers’ academic background, professional accomplishments and teaching experience. To be promoted to the higher category, which would result in salary raise, they had to pass challenging examinations in educational studies and subject area, present a teaching portfolio and conduct a series of demonstration classes.

**Teacher Education in the Reform Period**

The international trends to raise the status of teacher training to a professional level became one of the decisive external factors in reorganizing and restructuring the existing types of teacher training institutions. Since early 1990s Russian institutes have been gradually reorganized into universities, and pedagogical schools into colleges. Besides, an ever increasing number of new private educational institutions have emerged. Today’s financial crisis in Russia has seriously effected its academic life. All over the country pedagogical institutes merge with technical institutes into classical universities. The main purpose of this reform is to reduce the number of higher education institutions in order to survive in crisis. Thus, by August 1994 among 141 newly established universities, 46 were classical (Lugachyov et al. 1995). A great concern here is that under the crisis and reduced finding from the Federal Government such transformations can lead to teacher education downgrading, due to the introduction of new programs, other than teacher training, but based on student fee. To survive and successfully compete with those, teacher training programs should be significantly reorganized.

Internal forces for change have been equally important. In newly established universities the teaching staff has been given greater freedom to design the curriculum. Having preserved national standards as unified test model, the universities are trying to take complete control over curriculum development and introduce new independent research topics and students’ choice.

**Moving Towards Technological Society**

Russian teacher education system is currently in transition. One major shift that can be already seen is the greater focus given to preparation of educators for the future.

As the 21st century approaches, emphasis on technology has increased. It is known to improve opportunities for learning, to enrich teaching, and to strengthen the society. Unfortunately, teachers’ acceptance of educational technology is not increasing as rapidly. Thus, Russian teacher training system has been slow to respond to the potential of the technology now available. Despite its importance to teacher education, technology has not become a core part of the teacher training programs in most institutions. There is an urgent demand to substantially expand the use of technology in teacher training curriculum, which will help future teachers to become technically literate to be effective in the classroom.

These demands for the broad integration of technology into the teacher training system are increasing throughout the world. Some nations, e.g. the United Kingdom, respond to them by including the use of technology in core subject
teaching within Teacher Training National Curriculum (Davis 1998). Such initiatives tend to emerge everywhere. Also exemplary is the experience of US higher education in incorporating technology in teaching. Such international parallels are a matter of comparative study and might help Russian teacher training.

Technology and Russian Teacher Education

Although no solution for financial and social problems of Russian educational system, technology plays a crucial role in its restructuring and updating.

The integration of technology into Russian teacher training curriculum would allow:
1. to meet the requirements of today’s "information society";
2. to resist in the struggle for surviving with non-teacher training departments;
3. to update currently existing curricula and create a richer learning environment for students;
4. to improve teachers’ professional efficiency.

The challenge to implement these changes into Russian teacher education is great, but so are the advantages.

The expansion of advanced technology of all types in technological universities and departments of sciences and business created favorable conditions for those institutions to compete in fast-changing community. It is no secret that although today’s education students have more access to computers than did their counterparts five years ago, colleges and university departments of education are often behind the rest of the campus in available hardware and faculty expertise. The education institutions have seldom received large equipment donations from federal or local budgets that other institutions have. They can hardly purchase the equipment by their own, as the business departments do, since they have no fee-paying students and as a result of it no financial support from this source. Besides, education faculties have usually not received systematic training in technology use. All these factors suggest that trying to infuse technology into teacher preparation curriculum remains a difficult task.

Another problem is connected with availability of computers in elementary and secondary schools. Although computers in Russian schools are widely distributed and access to them by students has increased, the vast majority of schools still do not have enough of them to make the computer a central element of instruction. Lack of funds continues to be a serious problem, identifying one of the powerful obstacles to increase use of technology in teaching. In fact, Russian public schools experience full computer laboratories and classrooms with no computers. Use of email is also not realistic choice for many students yet.

On the other hand, computer use in most of the schools is limited to a Computer Science course, the main purpose of which is to provide learners with computer skills for general purposes, and for business and vocational training. The teachers in traditional subjects hardly use computers in their instruction. The most popular technology tools used by teachers in the classrooms are videocassette-recorder (VCR), an overhead projector, a slide projector. Such single use of technology doesn’t allow to exploit the enormous potential which it offers. Teachers need a hand to understand this for helping students solve problems, think for themselves and collaborate with each other.

In this sense an increase in the amount and capability of technology in schools will be required once the technology fully realizes its potential. The level of support from regional authorities might be also enhanced by emphasizing and demonstrating the cost-effectiveness of educational technology, applied to all disciplines.

Even so, availability of technology cannot alone solve the problem. According to E. Willis (1997), “Change from the static perspective of knowledge to that of dynamic...cannot come from the technology itself... Change must come from educators ...” (E. Willis 1997). Since computers though powerful are not self-implementing, it is the teacher, who plays the crucial role in the educational technology classroom implementation.

However, the vast majority of Russian teachers have had little or no training at all on how apply technology in teaching. In spite of traditional for educators desire to develop professionally and do their job better, they feel left behind the time, since they are not adequately prepared to integrate technology into their teaching. For this to happen they need special training, which could cover both: technology training (learning how to use computers) and technology education (learning about computer and its capabilities). The focus should be placed on both pre-service training and in-service professional development. Unless teachers receive fair training and support, investments in technology cannot be fully effective.

Pre-Service Technology Education

A Brief History

ERIC
In the Soviet teacher preparation curricula educational technology used to be represented by a course on Technical Aids of Teaching (TSO), comprising one semester either in the first or in the second year of study. The 38 hours of instruction combined both lectures about technology tools and practical training on their use. The subjects of study were the then technologies for classroom use, such as the movie projector, the old type overhead projector, the slide projector, etc.

By now, since most of these artefacts have been out of use, the course became outdated and has been extracted from the curriculum. For some time, it had not been replaced with any other course in educational technology. Recently colleges of education have incorporated a basic computer literacy course into their curricula. Normally, such a course offers 9 hours of lectures and 36 hours of hands-on computer training. Nevertheless, despite the course offerings graduates of teacher training departments do not feel prepared to use computers in their teaching. Since the training is provided by computer science departments or computer centers, the instructors focus on technology issues rather than its applications in education. But teacher training in technology must go beyond learning about formatting disks. It should be authentic and functional.

What Has to Be Done.

There has been considerable research conducted on instructing pre-service teachers how to use technology in classrooms. Many students currently entering the universities have at least minimal experience with the computer. So scholars agree that today's major issues are related to instructional strategies, instructionally appropriate software (J. Willis 1993) and advanced technological pedagogy. Oliver (1994) found that students express a strong need for computer education as an integral part of teacher training, particularly for courses including issues of curriculum and strategies for classroom implementation. Other studies reveal that providing a comfortable learning environment, promoting students participation and supporting them in constructing their own learning enhance their future use of computer technology. Activities facilitated by computer use supply the prospective teachers with the expertise how to enhance creative learning and collaboration in the classroom. With computers students can work on problems individually or in small groups, sharing more responsibility for their own learning. They find that technology is no longer a teaching device, but a learning tool which they can interact. They get convinced that computer skills are very important for successful participation in the educational environment. Furthermore, interaction of the medium requires a shift in the teacher's role from an information presenter to a facilitator of student learning. These need a lot of demonstration and modeling. Unfortunately, undergraduate instruction in most of Russian education schools lacks exemplary teaching models. There is an urgent demand for concrete examples of what technology integration looks like to prepare future educators to teach with technology. The most effective way to get these examples is through teacher educator modeling. In fact, use of computers in teaching requires knowledge of computers as well as that pedagogy to support their use. That is why instructors in computer integration courses need to be experts at teaching with technology. They need to show their trainees how to change their teaching style to incorporate technology, or to demonstrate how technology can meet their pedagogical approaches. Ideally, methods instructors in all core subject areas should introduce computer related activities into existing education courses. This would give pre-service teachers continuous training during the entire course of study.

Another way to model educational technology is through internship or student teaching practice. Here a teacher intern can see technology promise and problems in real settings. That provide collaboration between new and experienced teachers. The teacher who uses technology creatively and regularly could become a good model for a beginning teacher. Conversely, a student teacher can help bring technology to the experienced classroom teacher, who has not worked with computers previously (Power On! 1989).

Thus, training pre-service teachers in how to integrate technology in their teaching is not successful unless three prerequisites are met: computer literacy applications and computer programming, as an option; faculty to model using technology in the course; and field experience with supervising teachers using learning technologies in their classrooms (Wetzel 1993).

Teacher Educators As Change Agents.

Since pre-service teachers' education is focused on learning how to use technology as a teaching tool, it is teacher educators who must be prepared to address that issue. The instructors from computer science departments, currently conducting the courses, tend to use highly technical language in their teaching and focus on sophisticated technological issues. They fail to provide knowledge how to use technology in teaching, due to the lack of expertise in pedagogy and subject matter. In this way teacher educators can become change agents and build bridges between teachers and technology. Since communication is the essence of their job, teacher educators can bridge communication gaps between the highly specialized language of the instruction and that of the learners. However, there are many teacher
educators who lack the skills to model technology uses in their classrooms. The lack of effective training for teacher educators has been a barrier to technology utilization. Therefore, change in technology use must begin with teacher educators.

The research on the use of technology by education faculty comes to the same conclusions as that regarding in-service teachers. Barriers to greater use of technology by both counterparts include lack of equipment, inadequate training, anxiety about technology, and time constraints. To eliminate these barriers faculty and teachers need appropriate preparation, support for experimentation and innovation, and time for learning and practice. The latter is perhaps most valuable of all.

Very often, though proficient in their area of study, faculty feel uncomfortable with technology use. Initial fears about technology need to be overcome by revealing the myth that only “technical people” with large technology expertise can get good results. To achieve this, educators need opportunities to practice with the computer, as well as constant support from instructors, administrators and technology advanced colleagues. Those able to use technology on personal level show best results in implementing it in their teaching. Teaming up with the instructor on identifying topics in the subject matter and then using technology as a teaching aid helps make faculty’ experiences more contextualized and meaningful. An innovative approach described in recent studies (Thompson et al. 1996; Gonzales 1999) is a way to accomplish this. It is based on reciprocal mentoring where students mentor faculty on how to integrate technology into their courses and the faculty mentor students on the academic process and teaching itself.

Teacher educators empowered as change agents can greatly contribute to the adoption of technology innovations at all levels. For this to occur they should be prepared to invest considerable time and efforts, while university departments should provide support and commitment.

In-Service Technology Education

In-service education plays an important role in technology training. While pre-service education is important in giving future teachers facility with the computer, it only serves as an introduction into the field. Teachers need continuous training, as the technology changes and its applications vary widely, and as more is learned about learning with technology. The advanced training, based on teachers’ specific classroom experience and needs can then be provided through in-service and continuing education.

The effective in-service training programs require: first, the system of an ongoing professional growth continued throughout a teacher’s career. School administration in Russia has traditionally encouraged teachers to gain new skills and qualifications by providing higher pay for advanced category. In today’s transition period, Russian teachers need even more encouragement. The environment of support for experimentation and innovation has to be formed in schools. Second, training workshops for teachers should address specific goals and be based on previous experience and knowledge. As a number of studies report, teachers prefer learning about technology from those who understand the settings in which they work. They appreciate and learn from good modeling on the part of the trainers. Third, appropriate balance between lecturing, discussion and hands-on practice during training should be observed. “Doing” an activity or seeing a teaching strategy modeled does not insure understanding of its possibilities” (E. Willis 1997). Fourth, follow-up support and guidance can make a significant impact of training. Teachers would get back together, report on their use of technology applications, and share experiences and ideals.

The use of technology makes teaching more challenging. Very few teachers have adequate time for planning and preparing for using technology in their classes. They need attending conferences and professional meetings after formal courses taken. Isolation is one of the basic problems teachers face. Workshops provided by professional development institutions are scarce and do not meet the needs of all prospective clients. One of the possible solutions might be long distance learning. Among a large number of Russian higher education institutions, only a few provide long distance education programs, and they do not specialize in educational technology. However, they might be a future investment to provide Russian teachers with opportunities they deserve.

Conclusion

As the 21st century approaches, the demands that society makes on teachers have increased. Trying to respond to these, the Russian teacher education system is being modified and restructured. In addressing these drastic changes, technology training is not the only solution, but it can be one piece of it. The teacher education reform provides the opportunity to consider new roles for teachers and ways for technology to fit in.

Abstract: This paper shares the personal experience of a teacher educator in Hong Kong who took the opportunity of lecturer attachment to a local primary school to field-test the application of information technology (IT) in teaching a primary school subject in Hong Kong. This is with the aim to get herself familiar with the application of IT in teaching primary pupils, as well as to initiate more discussion and demonstration in promoting the use of IT to the pre-service teachers. The paper also reports on how the teacher educator planned, implemented and evaluated her teaching, along with the difficulties encountered. The paper concludes with practical suggestions for teacher educators and pre-service teachers in Hong Kong on how to implement IT effectively in primary classrooms.

Background

Computer technology is employed as a tool that supports and extends student's understanding of the pertinent concepts, processes, and themes involved. (Moersch, 1995). In his maiden Policy Address in 1997, the Chief Executive of the Hong Kong Special Administrative Region pledged a five-year strategy to promote the use of information technology (IT) in enhancing the effectiveness of teaching and learning. However, schools in Hong Kong at present vary considerably in terms of their awareness of the need for the paradigm shift, willingness and ability of teachers to teach through use of IT, availability of IT facilities, or even the feasibility of school sites to install computers, and the exposure of their students to IT (Education and Manpower Bureau (EMB), 1998). On the whole, there is a lack of strong IT culture in the school campuses, especially in primary schools. Though it is stipulated in the Five-year Strategy (EMB, 1998) that 60% of the primary schools have each been given 15 computers in 1998, many schools put all these 15 computers in special rooms.
shared by about 20 classes of pupils. Such arrangement does not facilitate pupils’ access to the computers.

Teacher Enablement of IT Use

It is also pledged in the Five-year Strategy to provide various training courses to meet the varying needs of teachers. It is also suggested that in addition to the training provided to serving teachers, pre-service teacher education should take the responsibility to equip the future teaching force with necessary knowledge, skills and attitude.

With the high degree of IT application in the tertiary curriculum, it is believed that pre-service teachers are at least IT literate when they graduate from the teacher education institute. However, it is found that the issue of using IT to enhance the effectiveness of teaching has not yet been fully addressed in the current teacher education programs (EMB, 1998). There is a similar situation in other parts of the world, many of today’s pre-service and in-service school teachers are not adequately prepared to utilize computing, communications, and other technologies to support teacher-facilitated technology-based learning experiences for school students (Handler, Andris, Moran, Bievenue, Waugh, Payne, Levin & Brehm, 1998). It is recommended in the Five -year strategy that “active steps to assist teachers transit to the new mode of teaching” (EMB, 1998). Emphasis should be placed on how the contemporary mode of teaching can diversify to include elements of IT.

It is common that educators are often asked to develop computer-assisted-instruction (CAI) programs out of whole cloth, using secondhand descriptions or sketches developed by universities or consulting firms that have not tested the innovations themselves (Kohl, 1996). To effect the paradigm shift mentioned in the previous paragraphs, teacher educators should take a more active role to demonstrate the effectiveness of teaching using IT, on the one hand, by fully utilizing IT in their lectures, and on the other hand, by trying to expand the pre-service teachers’ knowledge on the application of IT in classroom settings. Moreover, the importance of models of good practice in IT should not be underestimated. It is hard to create new CAI programs if one has not observed relevant examples in action. This is what might be called the paradox of large-scale innovation. Without models, people are left anxious and directionless, innovation fades, and things remain unchanged (Kohl, 1996). Teacher educators’ experience in applying IT in primary teaching provides a very good model for pre-service student teachers.

Methodology

This paper describes my experience as a teacher educator who took part in a lecturer attachment scheme and was allocated to teach in a local primary school. During the attachment period, I conducted a small action learning project. My study aimed to field-test the use of technology in the teaching of a primary school subject, in order to initiate a more convincing discussion and demonstration in promoting the application of IT to pre-service teachers.

In this initiative, there is collaboration between academic staff and supporting staff, including staff from the Instructional Development and Media Production Section of the Centre of Learning, Teaching and Supervision in the Teacher Education Institute, who helped produce a series of CAI programs. A total of thirteen programs in two topics were developed. Six weeks of eight lessons of teaching are videoed and analyzed. I studied the eight videoed lessons to reflect on the interaction between the pupils and me, and activities conducted in the
lessons. The analysis of the present study was based on three data sources: my reflections during the preparation of the computer-assisted teaching program, as well as obstacles and difficulties encountered; and journals of my own teaching with the use of IT during the attachment period.

Findings and Discussions

The level taught was primary four and the topics covered were:
1. *The Earth* which included the topics of “The shape and structure of the earth”, and “Continents and oceans”,
2. *The Geographical Setting and History of Hong Kong* which included the topics “The geographical position of Hong Kong”, “The relief of Hong Kong”, and “History of Hong Kong”.

Since most of these topics were factual information, the teaching could be very dry. It was a great challenge for me to design meaningful teaching to arouse pupils’ interest to learn. The analysis reported below was organized into three major parts and was supported with data (from the transcription of lessons, reflective journals).

Preparing for the Lesson that Incorporate the Use of IT

*Designing Computer-Assisted Instruction (CAI) Programs*

In preparing for the lessons that teaching was supported by CAI program, a detailed lesson planning was the most important point to start with. The followings were some reflections of my journals during lesson planning:

“An extra column “Instructions and resources required for the CAI programs” was included in the lesson plan to illustrate my ideas to design the program. This column recorded the ideas together with a list of information and resources provided for Jacky to design the CAI programs.”

Would the education technology officer be able to read my mind by reading a few lines of descriptions? The written instruction in the extra column did not seem to provide sufficient information for the education technology officer. Face-to-face discussions were then conducted so that I could explain my ideas more explicitly, how I came up with the ideas, and the expected effect of the program. However, I was inexperienced in writing the CAI program, some of my ideas were not practical and feasible. The technological ideas provided by the education technology officer were useful for me to modify my ideas of teaching and for my planning.

“The lesson plan was forwarded to Jacky for action, I hope he could translate what I had written into electronic form”.

“Jacky phoned me this morning and asked me to explain in detail to him what I had written in the column, ........ His suggestions to put into practice of my ideas was wonderful that I had ever thought of.”

Not many Hong Kong schools have started using IT in teaching, the school that I was attached to was no exception. There was a lack of facilities and internet service in the school. The information and photos I got from the world wide web to support teaching had to be put in the CAI program.

“I phoned Jacky this morning and told him that I found some useful information and photos about earthquakes on the www, he told me to download the photos if possible, well, this is my first time to download photos from the web!...”
During the trial stage of the program, I found that the headings and descriptions always came before the pictures/diagrams or videos, and all the labels of a diagram appeared together at one time. Though this was common in most other CAI programs, I found that such design did not match with the constructivist view of teaching.

"...it seemed logical to have the headings before displaying the information and photos, BUT this was NOT my way of teaching, what I believed, the constructivist view of teaching was that pupils should be involved in exploring, observing or studying some phenomena before they are introduced the concepts.....Fortunately, Jacky understood my philosophy of teaching,..."

A thorough discussion during the trial use of the program allowed both the education technology officer and me to have a better understanding of each other's expectations. And it seemed that the design of CAI program by the technical staff alone would probably be a little more than a computerized presentation. In order to have the CAI well articulated with a learner-centred teaching, the involvement of teachers who could provide a clear message of their conception of teaching in the design process was desirable.

**Creating Conditions for Using IT in an Ordinary Primary Classroom**

In using CAI program in the classroom, several facilities were indispensable: a computer, a projector and a screen. The following showed the resource constraints and difficulties I faced in transporting the equipment to and setting it in the classroom.

"Mary, the school head, asked me whether I needed a bigger room for my teaching using IT, if I wanted, she could swap the classrooms by having P.4A moved to P.5B classroom, which was a bigger classroom. In fact, I was very grateful for Mary's arrangement but I preferred to field test the use of IT without causing too much trouble to the pupils and school."

"How clever I was to use a trolley that had all equipment fixed onto it so that I could carry the equipment with ease to the classroom. .....There were only 35 minutes each lesson, including setting up the equipment and teaching....."

An examination of the facilities available in the classroom and a trial of the setting-up of the equipment were the essential step towards a successful implementation. The followings were my feelings about my first visit to the classroom.

"How dense the class of pupils was! Fortunately, there was a screen hanging in front of the blackboard. ....... There was only about a foot of gap between rows of seat, three feet between the screen and the first row of seats,... we needed to move the third and fourth rows of seats further apart so that the trolley of projector could move a little bit further away from the screen to make a bigger projection image on the screen."

"Kin, the supporting staff from the Education Technology Unit, took only a minute to have all items set up on the teacher's bench, but no matter how hard I tried, it took me at least five minutes to complete the task."

**Enhancing the Quality of Teaching and Learning**

*Improving Teaching and Learning with the Incorporation and Assistance of IT Elements*
It seems that the use of IT can help to transform the way in which education is delivered in primary classrooms by breaking down the traditional boundaries of teaching and learning, from a largely textbook-based teacher-centred approach to more interactive and learner-centred approach.

“The program was so powerful that it illustrated very clearly the seven plates on the earth surface. When a pupil moved the cursor around the earth surface, he could identify the different plates by himself.” (Lesson 2)

“The interactive activity for pupils to place each of the historical sites to its exact location served not only help pupils to identify the locations, it also helped pupils to revise previous knowledge of the different districts in Hong Kong” (Lesson 10 and 11)

The use of IT also helped to link up pupils with the vast network world of knowledge and information to enable them to acquire a broad knowledge base and a global view.

“Pupils were able to observe the change and extension of Hong Kong’s coast line by clicking the button, that is fantastic for pupils to make a comparison between the present and the past. The magnifying effect of the scene of the harbour showing how ships entered Hong Kong surprised pupils” (Lesson 8)

“The videos of the different historical sites in Hong Kong provided an eye-opening experience for pupils, like touring around Hong Kong electronically.” (Lesson 10)

“It took me a lot of time to search for photos and pictures about old Hong Kong from about twenty books in the library (some of them were for reference that I could not take them out) and websites. Surprisingly when all these were put together in the program, it presents a very interesting and attractive story of the development of Hong Kong.” (Lesson 12 and 13)

Moreover, there was evidence that IT had the potential to liven up classroom life by making teaching and learning more dynamic, interactive and innovative where pupils could become more motivated and inquisitive, to bringing about more effective teaching and learning.

“The effect produced by the computer assisted teaching was wonderful, when I wanted to talk about “ASIA”, I just needed to move the cursor to the exact place and it automatically flashed, this was very useful to focus pupils' attention” (Lesson 4)

“The animation of a plane flying from Hong Kong to San Francisco aroused pupils' interest to solve the problem of time lag”. (Lesson 5)

“The interactive activities designed in the program provided a very good opportunity for pupils to use the computer, all of them were actively involved in making guesses to the answers.....How strange it was! About half in this class have never touched the computer before this lesson, .... I felt the girl’s hand was shaking when I taught her how to use the mouse to select her answer.” (Lesson 8).

Incorporating with Other Teaching/Learning Activities
There has been government target of having 25% of the school curriculum taught with the support of IT (EMB, 1998). To achieve this 25% target, it is necessary to bring about changes to the current school curriculum and the existing mode of teaching and learning. This can proceed gradually by first enhancing the level of awareness and meaningful use of IT in the existing curriculum with incorporation and assistance of IT to liven up some other learning activities. In other words, this is reconstructing teaching and learning with IT rather than replacement of the existing mode of teaching and learning with IT elements.

"Though the use of the computer program is effective, some demonstration with teaching aids (foam plate and water) to illustrate the floating of plate on the larva is very helpful for pupils to experience it." (Lesson 2)

"The programme gave an introduction to pupils on how earthquakes happened and showed pupils the damages caused by disastrous earthquakes. The group activities are very useful to help pupils to identify the seriousness of earthquakes which are of different scales and to identify places that usually have earthquakes are situated at the edges of plates.” (Lesson 3)

"Though I did not use computer program in this lesson, the use of scanner and colour printer in re-producing the maps for the activities, to me, was also a very effective use of IT.” (Lesson 6)

"Besides having a happy time with observing the videos of different historical sites, the activities requiring pupils to identify the history of the sites helped pupils to have better understanding of the history behind.” (Lesson 10 and 11)

Conclusion

This paper aims at evaluating neither the effectiveness of the teaching and learning process nor the student learning outcome. It is noted by Dwyer, Ringsraff and Sandholtz (1992) that “The use of technology does not guarantee fundamental change in teaching-learning process and consequently in learning outcomes”. It is hoped that the analysis provides a better understanding of the process of planning and implementation process, as well as the issues and concerns in teaching with the use of IT in Hong Kong primary schools.

Moersch (1995) found in the current use of technology that most of them are used for isolated activities unrelated to a central instructional theme, concept or topic. My experience in the present study also suggested that the incorporation and assistance of IT elements and other activities could make teaching and learning more meaningful. Such experience concurred Cuban’s (1997) saying that ‘the overall goal was to create different forms of learning and teaching with the help of technology, not have technology determine what was to be learned or how it was to be taught’ (p.xiii). Hence IT should be incorporated into and complement the conventional instruction. Though the level of technology implementation demonstrated in the present study is only at level 4A - Integration (mechanical) among the six levels suggested by Moersch’s Level of technology implementation framework. My experiences addresses the resource constraints in using IT in schools, it also provides insights to the teething problems in building up an IT culture in schools.

Gender-Related Differences In Computer Anxiety Among Technological College Students In Taiwan

Shwu-yong L. Huang
Center for Teacher Education
National Tsing Hua University
Hsinchu, Taiwan
Syliou@mx.nthu.edu.tw

Yeon-Chaw Liu
Jin Wen Technological Institute
Taipei, Taiwan,

Abstract

This study investigates gender-related differences in computer anxiety and the variables related to male and female students' computer anxiety. Participants were 549 college of technology students, each was administered a revised Computer Attitude Scale. MANOVA results indicate that male students had significantly greater confidence and lower anxiety than female students. Male students' computer anxiety was influenced by their own locus of control and total number of computer courses taken. Female students' computer anxiety was influenced by the same two variables as well as by their subject majors. Age and grade level, however, showed no significant influence on these students' computer anxiety. Standard deviations were relatively large, suggesting there was a great variance among students responses.

Gender as a differentiating variable in college students' computer use has been examined in a number of studies during the past two decades. Most of these studies are centered on students in colleges of liberal arts or teacher colleges. For example, Busch (1995) examined college students and documented gender differences in perceived self-efficacy regarding completion of complex tasks in both word processing and spreadsheet software, but not in simple tasks. Harris & Grandgenett (1996) found that gender is an attributing variable to teachers' anxiety in their use of networked resources. Very few research studies, however, have been specifically focused on students in technological colleges, assuming that these students receive adequate training in computer and technology, and are therefore least fear of using computer. It is important to understand the actual perceptions and needs of technological students and some influencing variables like gender on their computer use. Unrealistic assumptions may interfere the provision of educational programs that address their unique needs. Therefore, the purpose of this study is to investigate gender-related differences in computer anxiety, and to determine the variables related to male and female technological students' computers use.

Methods

The participants of this study were 549 college of technology students. Among them, 100 were male and 449 were female. These students majored in eight subject areas. About 96% of them were age 25 or younger. About 86% of them had computers at home and over 60% of them had been working with computers for more than two years. Nearly 60% of them had taken two or more computer-related courses.

The instrument used in this study is the revised Teacher Computer Attitude Scale (Violato, Marini, & Hunter, 1989). It includes 10 items measuring computer anxiety and confidence on a 5-point Likert type scale. A score of 1 indicates that a student disagrees strongly to the statement and a score of 5 indicates that a student agrees strongly to the statement. The instrument has been found to be reliable and valid in previous studies (Huang, 1997; Huang & Padron, 1995; Liu, 1998). For the present study, the instrument was translated into Chinese for the use of participants in Taiwan. Content validity was verified by reversing the translation of Chinese survey into English by English teachers who had not seen the original English version. No revision was found necessary. The alpha reliability coefficient is adequate at .87. A few questions on students' demographic and computer background were also included in the survey.

The instrument was administered to students in mid of the academic year by experienced researchers. Students answered the questionnaire anonymously. Multivariate analysis of variance
(MANOVA) was used to determine whether there were significant differences in computer anxiety by gender. Follow-up univariate analysis of variance (ANOVA) was performed to determine where the differences were. A series of multiple regression was used to determine the variables related to male and female students’ computer anxiety.

Results

The results indicate that college of technology students generally had above average confidence and below average anxiety in using computers. The item with the lowest score is “Computers make me feel uncomfortable,” followed by “I get a sink feeling when I think of trying to use a computer”. The item with the highest score is “I am able to do as well working with computers as most of my fellow university students”.

MANOVA results indicate an overall significant difference in computer anxiety by gender (F(10, 538) = 2.71, p < .01). Male students had greater confidence and lower anxiety in using computers than female students. Table 1 presents the ANOVA results. Significant differences between male and female students were found in the following items: (a) I feel confident with my ability to learn about computers (p < .05); (b) Working with a computer would make me very nervous (p < .05); (c) I am not the type to do well with computers (p < .05); (d) I feel comfortable using computers (p < .01); and (e) Computers make me feel uneasy and confused (p < .01).

Multiple regression results reveal that students’ locus of control of computer use, age, grade, year(s) of computer experience, computer(s) at home, subject majors, and number of computer courses taken have an overall significant effect on male (F = 9.83, p < .001) and female (F = 30.86, p < .001) students’ computer anxiety. The R square value for male students equals to .43, suggesting that 43% of the variance in male students’ computer anxiety may be explained by the seven independent variables. The R square value for female students equals to .33, suggesting that 33% of the variance in female students’ computer anxiety may be explained by the seven independent variables. Stepwise regression results show that locus of control and total number of computer courses taken have significant effects on male students’ computer anxiety. On the other hand, students’ locus of control of computer use, subject major, and total number of computer courses taken have significant effects on female students’ computer anxiety. Table 2 displays the regression results by gender.

Discussion

The findings of this study indicate that there were significant differences in technological college students' computer anxiety by gender. Male students were more comfortable and had lower anxiety using computers than their female classmates. These findings support previous research on the impact of gender-related perceptions on computer anxiety among college and university students (Brosnan, 1998; Liao, 1999). Plausible explanations include that (1) female students majored in different subject areas than male students; (2) female students had taken fewer computer courses, and (3) social stereotype of computer proficiency. Computer and technology have been portrayed in the society as more appropriate for male than for female and thus influence male and female students' self-efficacy in using computers. Because freedom from anxiety has been found to be an attributing variable to computer achievement (Liu & Johnson, 1998), it is important to reduce computer anxiety among female students. This can be done by identifying the areas and sources of anxiety in computer use by female students, and design instructional technique that can reduce their computer anxiety (Ayersman, 1996; Ayersman & Reed 1995-86; Liu & Johnson, 1998; Presno, 1998). For example, Fitzgerald, Hardin, and Hollingsend (1997) developed a course in hypermedia authoring program and provided instructional strategies to help decrease participating education students' computer anxiety.

Findings of the present study have provided a better understanding of gender-related technological college students' computer anxiety, identifying several related variables, such as locus of control and courses taken. Future research need to examine how these and other variables may be used to enhance equity among technological students' computer confidence and achievement.

Abstract: This paper describes the in-service training programs for primary school teachers to use information technology in Australia and in Taiwan. The advantages and disadvantages of the training programs in these two countries are analyzed and compared. The Taiwanese government has done an excellent job in setting up the Internet infrastructure and different levels of technical support, and its in-service training programs have good supports for the full-scale implementation of web learning in the primary schools. However, the Australian in-service training program has merit in the setup of the full time facilitators and a good record tracking system to reduce the cost. Thus, a combined approach to take advantage of the best parts of these two in-service training programs is recommended in the future. This approach will help primary school teachers to learn and to adapt information technology in the classrooms more quickly.

Introduction

The advance of network, multimedia, communication technology has made a great impact on the way people work and learn. Today, information technology enables teachers to outreach teaching resources on the Internet, communicate with subject domain experts or other school teachers through the World Wide Web (WWW).

In Australia, the Department of Education and Training (DET) in the New South Wales (NSW) has funded public primary schools to purchase at least one modem and some Internet computers under the Computers in School Policy. Moreover, DET began a statewide Technology in Learning and Teaching (TILT) program in 1996 to promote computer and network literacy of primary school teachers (Training and Development Directorate, 1997).

Similarly, the Department of Education (DOE) in Taiwan identified the importance of information technology in education. In the past ten years, money and efforts have been allocated to set up the network infrastructure, computer laboratories and technical support centers in all levels of government schools. Moreover, from 1 October 1998 to 30 June 1999, the Taiwanese Government has spent a total amount NT$647 million (approximately US$20.2 million) dollars to update computer hardware, networking hardware and software in all levels of schools with a special focus on high schools and primary schools. Also, in-service training courses and local network support centers were provided to build up the computer literacy of the primary school teachers (Department of Education in Taiwan, 1999a).
In-Service Teacher Training Programs in Australia

Starting from 1996, DET in NSW had funded many state universities to run a 2-hours Internet workshop for primary school teachers. Each school in NSW selected one teacher as the Internet Contact Person (ICP) to attend the workshop. Moreover, later in 1996, the DET conducted a statewide TILT program. Approximately 150 teachers in NSW were selected as facilitators, and they were trained so as to be able to train other teachers. The facilitators were paid by their schools, but DET allocated extra money for schools to hire substitute teachers, so facilitators could be released from teaching and administrative tasks. Their major task was to train 70 teachers in the school districts each semester every half year. Each semester, the facilitators ran a thirty-hour workshop which contained six components entitled "Powerful tools to enhance teaching and learning", "Beyond the classroom walls", "Computers and related technologies", "Software", "How can I do this in my classroom", and "Future Directions". Each component lasts for five hours. There is a one-hour video program addressing the key issues, a two-hour hands-on activity using computers and related technology, and a two-hour follow-up activity related to the practical application of skills in the classroom (Training and Development Directorate, 1997).

Roughly one-third (15,000) of the primary school teachers in NSW have participated in the TILT program from 1996 to June 1999. The participants attended the workshops of the TILT program every two or three week after school. During the training period, DET allocated funding to each school to release the participants from the normal teaching loads for three single days or six half-days. They can use the free time to practice what they had learnt or ask the facilitator to do one-to-one tutoring. Moreover, the participating teachers are not allowed to take the same TILT program repeatedly in the future (Training and Development Directorate, 1997). The goal of the TILT program is to train 10,000 more teachers (i.e. up to 55% of the primary school teachers in NSW) to participate in the TILT program by Year 2000.

In 1999, DET in NSW also ran a small-scale survey to trace the participating teachers who attended the workshop in 1996-1998 period. The survey showed that 80% of the participants applied the computer technology in the teaching and administrative work at least once a month. Among which, about 63% of the participants used a computer at least once a week (Training and Development Directorate, 1997). However, there was no real application of network technology in classroom teaching and learning activities currently due to the limited numbers of modems to access the Internet.

In-Service Teacher Training Programs in Taiwan

Before 1995, governmental organizations, universities and colleges conducted in-service teacher training programs regarding information technologies. It was very costly for primary school teachers to participate in the training courses because schools have to pay for the substitute teachers and pay the travel and registration fees for the participants. Usually, the training courses were held for half-day or one-day. Occasionally, there were some workshops that lasted for three to five days. Yet, these short-term training courses did not have a good outcome because when the participating teachers returned to their schools, they sometimes did not have the equivalent computer hardware or software to practice what they have learnt in the workshop. As a result, they usually forgot the training content quickly and could not apply what they learned in their classrooms immediately.

As far as the training of facilitators is concerned, there were a few training programs that lasted for three-months or half-year to train some selected teachers to be facilitators. However, the facilitators' teaching loads are usually not waived. Meanwhile, they were also responsible for the maintenance of computer laboratories because primary schools in Taiwan did not have the budget to pay computer companies to maintain the computers, and there are no computer technicians in schools. As a result, the workloads of the facilitators are very heavy, and there are many complaints about it (Roy, 1999).

Before 1997, not many primary school teachers in Taiwan had been trained to use information technology. The reason for the lower outcome is due to the lack of record tracking of the trained teachers. Usually, those who were interested in learning computer technology would take the opportunity to attend different teacher-training courses over and over again.
To improve the shortcoming of the traditional teacher-training model, a new "on-site, full-scale" model had been applied to train all the primary school teachers in their schools from 1 Oct 1998 to June 30 1999. The DOE in Taiwan also selected some schools in each county to be the technical support centers as well as teaching resource distribution center. The DOE in Taiwan allocated funds to conduct the teacher-training courses with an aim to train 70% of teachers in each primary school (Department of Education in Taiwan, 1999b). There are also selected universities that are network centers of Taiwan Academic Network (TANET) which provide higher level technical supports to the county level technical centers, and they may even provide direct supports to primary schools if needed.

Starting from 1 Oct. 1998, many workshops were run for a semester to enhance the learning outcomes of primary school teachers. Every Wednesday afternoon, there were no classes for all the primary school teachers in Taiwan. The experienced facilitators or university professors came to primary schools and gave a four-hour training course to teach a wide range of preliminary computer and network knowledge and skills.

There were nine units of the basic courses including Windows 95, CAI, Internet application, MS Word, The application of WWW in teaching, Network Multimedia, CD ROM, Computer Maintenance, PowerPoint. Each unit was either four-hours or eight-hours depends on the difficulty of the content or the participants' background knowledge and skills. Some schools provided advanced training courses on Saturday every two weeks. The advanced courses included Homepage Construction (18 hours), Excel (12 hours), MS Outlook (12 hours), Word 97 (12 hours). The new "on-site, full-scale" model of teacher-training programs turned out to be more efficient than the traditional teacher-training courses. (Department of Education in Taiwan, 1999c).

Comparison of the training programs in Australia and in Taiwan

Although the TILT program in NSW, Australia has successfully trained more than 1/3 of the K-12 teachers in three years, the real application of the network technology in the classrooms has not become popular due to the limited numbers of modems, network hardware and software. On the other hand, the Taiwanese DOE has spent more than ten years in training teachers and promoted the usage of email and WWW in primary schools. In the past year, the network and hardware/software have been upgraded significantly. Many centers have been set up in each county to distribute teaching materials, software, CD ROM and other teaching resources developed in the past years. In addition, many WWW web sites have been developed to support the real application of information technology in the practical classroom teaching and learning.

There are some advantages in the Australian in-service teacher-training program. Firstly, Australian facilitators are released from teaching loads, so they can concentrate on running the workshops and provide tutoring to assist the participating teachers. On the other hand, Taiwanese facilitators were very much over-loaded by the tasks of training other teachers in their schools and maintaining the computers on top of their ordinary teaching loads. However, starting from 1998, there are remedies. For example, when primary schools purchase hardware from a computer company, it is required that the company takes the responsibility of the hardware maintenance for three years. Moreover, the teaching loads of facilitators are reduced somehow to compensate their time in training other teachers.

Secondly, the Australian in-service training system keeps records on the participants' names and only takes those who have not attended the TILT programs. In contrast, there is no record tracking in the Taiwanese in-service training system. One of the shortcomings is that limited numbers of teachers who are interested information technology may take different training courses repeatedly. However, the Taiwanese government has changed the strategies of in-service teacher training. The newly introduced "on-site, full-scale" training model works quite well to make sure that most teachers in the primary schools have attended the workshops. Yet, it is very costly for the government to do so, and the new model only last for eight months.

Conclusion

The Australian teacher in-service training program is more cost effective. The ways to release facilitators to allow them to concentrate on training, and the record tracking of the participating teachers have proven to be
effective and economical. The next step to take is the setting up of the network infrastructure in the primary schools and the organizing of the technical support centers in school districts, so teachers and students will benefit from the progress in information technology.

The Taiwanese teacher in-service training programs have better support in terms of the network infrastructure, the setup of the county's technical support centers to promote web-learning and to distribute teaching resources, and development of many web sites to enhance the teaching and learning through Internet in the Taiwanese primary schools. However, both the traditional model and the new model of teacher training programs in Taiwan are very expensive to execute.

Apparently, Taiwanese in-service training programs have better supports for the full-scale implementation of web learning in the primary schools. However, the Australian in-service training program has merit in the setup of the full time facilitators and good record tracking system to reduce the cost. It is recommend taking a combined approach to take advantage of the best parts of these two in-service training systems to help primary school teachers to learn information technology.

Abstract: This paper is a report on a pilot study to find out whether the teachers in Malaysia are computer literate and to explore teachers' attitudes towards using computers in the classroom. Questionnaires were distributed to schools and statistical analysis was used to present the results. The findings of this study show that the teachers are computer-literate, using computers for various tasks from administrative work such as recording students' grades and typing assignments for students to leisure such as playing games and Internet surfing at home. The teachers agreed that computers can be a useful tool in the process of learning for schoolchildren in Malaysia. They have a positive attitude that the usage of computers in the classroom can be implemented and are willing to learn the ways to use computers in the classroom. However, the teachers are not too agreeable or certain that computers are not indispensable in teaching since it cannot take the role of teachers.

Introduction

Malaysia is a developing country that emphasises on the development of information technology. In the early eighties, computers were introduced to schools through the establishment of computer clubs. From then onwards, it has attracted interest in schoolchildren. The Malaysian government through her sixth Malaysian Plan has decided to introduce computer studies as a subject in all secondary and primary schools. In October 1993, Prime Minister Datuk Seri Dr. Mahathir Mohamed urged more schools to use computers as part of their teaching and learning process. Therefore, in 1994, the Ministry of Education decided to further enhance computers usage in the learning process in the classroom by introducing computer literacy subjects in the curriculum.

Teachers play an important role in the classroom. For the usage of computers in classroom to be a success, teachers must have the knowledge and the willingness to learn to use computers effectively before imposing the usage on the students. In 1994, a research investigating the attitude of teachers towards Computer Aided Instruction (CAI) found that teachers generally have a negative perspective towards computer (Zulkifli, A.M & Raja Maznah R.H.). However, this perspective might have changed due to several reasons. First, is that the Prime Minister's Vision 2020 to make Malaysia a developed country through industrialization using the latest technology. Together with the Vision 2020, is the development of the Multimedia Super Corridor that emphasises the development of information technology. The information technology program also leads to the development of smart schools, where computers are used extensively and intensively in the process of learning.

With all the recent development in Malaysia, another research should be carried out to find out whether currently teachers have a more positive outlook towards computer. This pilot research aims at
exploring the readiness of teachers in using computers in classroom to enhance the process of learning. Readiness here can be defined as the teachers having the knowledge to use the computer (computer literate) and as the teachers' willingness to learn and use computers in the classroom. With all the preparation and money allocated by the government to introduce computers and information technology in the classroom, are teachers, as the main figure in the classroom, willing to use computers in their work, or in the classroom as a teaching tool?

Demographic Findings

This pilot study is based on questionnaires that were distributed to 122 teachers from five different secondary schools. Malaysian secondary schoolchildren range from the age of 13 to 18 years old, while teachers must have at least a diploma in education, often with additional bachelor or master degree. The respondents in this study ranged from 23 to 55 years old, with the majority in the 26-35 years old group. Majority were Malay (118), and female (112).

Teaching experience of these teachers ranged from as new as less than a year to teaching more than 20 years. A large numbers (51) taught languages, either Malay or English, while smaller numbers taught Sciences, Mathematics, Religion, History, and Living Skills.

Computer Usage Among Teachers

A huge percentage of the respondents (86.1%) claimed to have experiences using computers, either self-learned, taught by friends, or acquired through courses. Slightly more than half of the respondents (63.9%) have personal computer at home which they used for typing (94.3%), playing games (46.7%), surfing Internet (43.4%), and watching CDs (52.5%).

More than fifty percent of the teachers (66.4%) said that they were directly involved in using computer at school, of which 41.8% used computer for clerical work, 67.2% for preparing exams, quizzes or grades, and only 23.8% for teaching and learning in class. From the 122 respondents, only 5 teachers claimed to use computer in classroom, whereas there remaining respondents still use traditional chalk and board method.

In encouraging teachers to utilize the technology in their work, the ministry have allocated computers at schools. Among the five schools surveyed, one school with 118 teachers have 10 computers where 60% of the teachers believed that they have access to only two of the computers. Another school with 90 teachers have 24 computers where many perceived that they could only use from one to about six of the computers. The other three schools have 52, 38 and 48 teachers, each with a total numbers of 20, 14 and 20 computers and majority of the teachers perceiving they have easy access to most of the computers. Table 1 summarizes the utilization of computers in the schools surveyed.

Discussion

This study defines computer literacy as the ability to handle and uses the computers to perform the desired tasks effectively. The findings show that a big percentage of the teachers have experiences using computers. The ability to use computers shows that the teachers are computer literate. The usage of computers is not limited only in their workplace but also at home. Various activities are done through using computers signalling a positive feedback that the teachers are literate enough to manipulate computers to suit their needs. It is very interesting to know that the teachers learn how to use the computers through their own initiatives or through their friends.

Generally the teachers are willing to use and acquire more knowledge on computers but at the same time are quite sceptical about the role of computers in the classroom. Specifically, they don’t think in order to teach effectively, they have to use computer. They also feel that they don’t have time to use computer in their classroom. This findings should not be viewed negatively since teaching is a two way process which requires natural interaction between two humans, more so with school children.

Overall, the teachers agreed that computers could be a useful, but not practical tool in the process of learning for Malaysian schoolchildren. This is due to the factor that the teachers themselves are already burdened by their teaching preparations and extra curriculum activities. In addition, the current numbers of computers in schools are far from sufficient to cater for schoolchildren in a classroom. Apart from the advantages offered by the computer technology, Malaysia still has to get some basic financial and logistic preparations sort out to ensure that the implementation of computers in classroom a success.

Abstract: This paper evaluates the effectiveness of conducting reflective learning in a teacher-training program, which comprises of TESL (Teaching English as a Second Language) undergraduates studying in Universiti Malaysia Sarawak, through web-based instruction. Findings indicate the perception of the undergraduates, who are taking a CALL (Computer-Assisted Language Learning) course, towards the use of web-based instruction as a medium of instruction, collaboration and reflection.

Introduction

Teachers open the door, but you must enter by yourself.
Chinese Proverb

To survive in today's world of Information and Communication Technologies (ICT), learners require aptitudes in self-learning and self-discovery through reflective thinking. Failures to independently build knowledge and adhering to passive learning interaction limit further development of cognition. Seeing these fallacies in classrooms of the present day, educators are inclined to find alternative strategies to empower the learners and enhance the learning experience. Using web-based technology is one.

To empower learners, Neilsen (1999) suggests some guiding principles to become independent thinkers, readers, and learners:

1. Allow learners to be actively involved in the learning process.
2. Provide consequential contexts for learning.
3. Provide a supportive learning environment.
4. Provide opportunities for learners to collaborate.

With the fluidity of the web, these components can be easily integrated into the classroom instruction. With the emergence of the web in the educational technology realm, the trend in classrooms heads converging different approaches in the teaching and learning process. Web-based instruction becomes a tool to maximize the effectiveness of each stakeholder in the entire learning environment.

Why reflective learning? According to Dewey (Gordon, 1998: 34), "...reflective learning involves resolving an indeterminate, problematic situation." Thus, reflective learning, which comprehends issues in problem solving revitalizes the learner to reflect on knowledge and experience. The transformation of an entirely new insight is gained when knowledge is reconstructed (Hullfish & Smith, 1961: 207). The processes of reflective learning consummate through a "conversational framework" simultaneously consist of discursive, adaptive and interactive process of learning. The "conversational framework" defines a structure of an interactive conversation that relates to the content in conditions of a topic goal (Laurillard, 1993:104).

The application of "conversational framework" instead of assisted through verbal conversational dialogue, was conducted on-line in written form. Learners interactively participate in a written form of discussion, done individually or in groups. The flexibility of asynchronous communication promotes reflective thinking when a larger group of interaction requires the retrieval of previous discussion as well as personal views. The capability of computer-mediated communication, which secured group interaction through a security login procedure, gains learners' confidence and builds on their comfort zone to reflect on
ideas and views posted from peers, devoid of temperance of outsiders. In any case, "technology can support and strengthen relationships, but never create or replace them" (Schneiderman et al. 1998).

The Study

A Computer-Assisted Language Learning (CALL) course was conducted for one academic semester (four months) at the Universiti Malaysia Sarawak. The course is one of the core components of a teacher education program (Teaching of English as a Second Language majors). At the initial stages of the course, learners attended face-to-face lecture sessions twice a week (4 hours), complemented with the utilization of a web-based application, made available to all course participants. Course assignments are mostly supervised on-line with asynchronous interaction between the instructor-students and student-student.

![Welcome to PEIT3173 computer assisted learning system](image)

Figure 1: A screen shot of the title page of the web-based application used for the course.

The four processes of learning, which are discursive, adaptive, interactive and reflective, integrated in the "conversational framework" (see Figure 3) encourage the participation of learners in this course to freely and interactively share views and ideas related to the subject matter. The model of the "conversational framework" indicated in Figure 1, shows the process of learning experienced by the instructor and students. The instructor manages and guides the on-line discussions, and questions are posted to stimulate reflective thinking. In the beginning, learners given individual assignments are encouraged to share their opinions based on own readings and personal understanding without any guidance from the instructor or peers. However, later, assignments are distributed to different teams formed in the class, and team members are required to brainstorm and share ideas to improve on the task at hand. Initially, learners begin with a team-based interaction that generates ideas and comments with feedback from each team member. Then, each member eventually learn how to think deeper when asked to reflect on the views of others that differs from their own, and when they are asked to utilize the knowledge and perspective to improve on their own understanding. As put by Andrusyszyn and Davie, "the important strategy for the clarification of their own understanding is based on individual reflection on their own values and learning" (1995).

The achievement of individual understanding requires collaboration on theoretical concepts and practical perception on the topic of discussion. "In order to share, learners must first be clear about their own concepts and understanding" (Andrusyszyn & Davie, 1995). It is then that collaboration would succeed in the quest of diffusing vast knowledge and experience beyond the boundaries of traditional text. Teamwork collaboration through web-based instruction interacts in the search for meaning. "Meaning is central in learning and, hence, is central in thinking; it pervades the learning experience" (Hullfish & Smith, 1961). Thus, collaboration supports the process of learning through reflection of discursion, adaptation and interaction.
Findings

Questionnaires were collected at the end of the course with the return rate of 92.86%. The questionnaire evaluates the perceptions of the participant towards the conduct of an on-line discussion course in relation to the use of reflective learning. There are 8 males and 18 females who participated in the study. The t-test and One-Way ANOVA procedures are applied to determine the significance of selected variables.

![Screen shot of the online discussion room, where reflective thinking skills were put to use throughout the course.](image)

Data from the survey indicated that the group who used the web-based application perceives that it motivates and challenges them in the course development. Most reported that they are able to follow the reflective thinking tasks assigned on the web-based application, and they noted a sense of learner control over the course, as they are able to contribute to the course curriculum through the use of the web-based application. The group also indicated the challenge to master the reflective thinking skills, as they progressed in this course, and the fact that they had to do everything online made the challenge even more consequential, as everyone in the learning environment had access to view each other’s development. However, due to spatial limitations for this paper, details of the data analysis will be presented during the conference paper presentation at a later date.

Conclusions

In the beginning of CALL course, many of these trainees were hesitant about publishing tasks and assignments on the web. However, they gradually performed better in the following tasks, particularly those that involved team-oriented discussions. The responses of the students were overwhelming, and the quality of their contribution to specific tasks was notably better than their performance in previous courses. Some of the factors that were found to influence the success of conducting a web-based instruction learning in the teacher-training program, as such reported in this study, include prior knowledge and skills in ICT. Based on the observations and findings from the questionnaire, the web-based platform used to encourage reflective thinking worked for these teacher trainees – they grew to become more responsive toward the subject matter, and they invested more than what they had predicted from the initial stage of the course. Hopefully they will graduate with a better perspective about teaching and learning, as they become more receptive toward the journey of the mind in its quest for knowledge and education.
Figure 3. The "conversational framework" adapted from Laurillard (1993) that identifies the activities involves in the reflective learning process.

ABSTRACT:

Distance Education based on digital computers has evolved in the last four years in Chile. The main educational institutions who develop experiences in the field are Universities, some public companies and some group of private firms. The technology used to support distance education goes from www sites, to specifically distance education oriented software. The first part of the paper includes a brief summary of the principal experiences in Chile. The second part describes a very interesting case related to Universidad de Concepción who develop a technological platform for distance education in the early 1998, thanks to a grant for educational development given by the "Ministerio de Educación de Chile". The paper describes this experience emphasizing the capabilities of the system to implement important teaching and learning considerations, such as: Education based on learning rather than teaching, Open learning, Personal and group interaction, Flexibility in teaching support, Discussion and Knowledge space to be shared by students and teacher, Autoevaluation, Learning material distribution and many others. Finally the paper discusses the "new" role of the teacher in this type of environment as a key component to improve the quality of education. The presentation includes a real demonstration of distance education of some courses given during 1999.

1.- Introduction.

Distance education born as a need to extend teaching capabilities to students that could not access the regular education system, due to geographic distances or because of the impossibility to perform time schedules. The first expressions of distance were education based on the distribution of learning materials and instructions by mail. Technological advances such as telephone, fax and later television and electronic mail, introduced significant improvements.

The experiences developed at Universidad de Concepción about this topic, considered Distance Education as a teaching – learning environment based on computer networks, in which participants interact through a man-computer interface that facilitates the development of their role as a teacher and as a student.

The first steps were given at the beginning of 1998, strengthened importantly thanks to a grant for Institutional Development (Education Ministry), the project was conducted by María Inés Solar (Education Faculty) together with José Durán (Engineering Faculty) and the technical support of specialists Mónica Salazar and Paola Pizarro.

2.- State of the art of Distance Education based on computer networks in Chile

2.1 Distance education based on computer networks in chilean universities began less than 4 years ago. The first experiences used the www environment to implement virtual classes, less than 8 Universities could be considered as pioneers using this methodology, A few of them are using right now special oriented software for distance education (Learning Space, and in one special case a Proper technological platform : Universidad de Concepción ).

Speaking about organization oriented to develop distance education we find different models, the principals are
- Dirección de Educación a Distancia-Teleduc : Aula continua 2000 and Quinto Campus (Universidad Católica de Chile )
- Universidad Virtual ( Universidad Técnica Federico Santa María )
- Programa académico de Educación a Distancia ( Universidad de Concepción )
- Programa Aula 21 ( Universidad de Chile)
2.2 Distance education based on TV network, the very important experience corresponds to Universidad Catolica de Chile, Teleduc a National organization with 17 Regional offices that operates for more than 15 years.

2.3 Distance education based on video-conference (ATM technology) an important group of 9 National Universities are working together around the project REUNA II Virtual University, the video conference network has been recently inaugurated.

3.- Modeling of Distance Education at Universidad de Concepción, Chile

It could be explained through the following components:

- Technological environment: a set of technical components (information technologies, computer network, personal computers, complementary equipment, internet connectivity) organized in such a way that they facilitate the development of teaching-learning processes.

- Actors or participants of the educational process:
  - Student (as individual or as a group)
  - Professor and/or teaching team (main professor, auxiliary professors, facilitators, other professionals, such as: psychologist, pedagogist, sociologist, etc.)
  - Technical support for students and professors.

- Technological platform or man-computer interface (explained in detail later on)

PICTORIAL MODEL OF DISTANCE EDUCATION BASED ON COMPUTER NETWORK

4.- Working environment using the technological platform

Technically speaking the technological platform is a computer programming system that support teaching-learning processes in a distance education mode based on networks, to help teachers, students, and facilitators.

The system was designed and implemented at Universidad de Concepción and operates under Internet environment.

The building of the system began in January 1998 and started to be used in April of the same year supporting three undergraduate courses of the Engineering Faculty. The use of the platform increased significantly since then, recently was utilized to support a National distance education course for teachers of secondary level (9th year) that are
facing a national education reform. The initial registration of this course was approximately 5000 professors, connected through Internet along with Chile.

The use of the platform is being used partially by Engineering, Medicine, Education, Economy and Agriculture Engineering.

The functionality of the platform satisfy the following needs:

- Display of norms and academic regulations
- Personal data
- Micro design of the activities of the course (academic planning, instructional material organization, etc.)
- Development of the course activities (execution of personal and group activities, evaluations, discussions, etc.)
- Process Statistics
- Methodology evaluation

The teaching-learning environment displayed by the platform for the teacher and students, according with experiences obtained since 1998 for at least 50 courses at undergraduate and professional level (approximately 1200 students in total), shows that it is perfectly possible to integrate the following curriculum components:

- Participants Interaction
- Space to make free questions, privately or public, to one or to many participants
- Space to participate in discussions
- Space to find and retrieve knowledge offered by INTERNET
- Opportunities for the multidisciplinary interaction
- Capacity to get dynamic processes in communications, evaluations, collaborating work, etc.
- Flexibility to introduce changes in the degree of presence or face to face activities
- Resources to introduce adequate students motivation just in time
- Capacity to make decisions permanently about the teaching – learning processes, from the very beginning (microplanning), to the postevaluation

5.- The role of the professor in the new teaching-learning environment

In this learning environment, the professor accomplish in rather different ways the traditional responsibilities assigned to him, due to the introduction of new tools to communicate, to produce, distribute and present learning materials, he has to change the way things were doing.

On the other hand, the nature of digital electronic information, brings with it, new ways to process, distribute, manage, and operate the information, producing benefits and new problems.

Probably the internal learning process of the student in the transition stage does not change but the whole external atmosphere evidently changes.

Practice is showing that the role of the professor changes. Actually the use of the platform during distance classes show that the professor emphasize the following aspect:

- Plan in advance all the activities covered by the course (microdesign)
- Orient, guide, direct, all the educational activities of the students.
- Facilitates the communication processes between students and him, or between students and students, or between students and other participants
- Evaluates the learning processes increasing the scope of evaluation.
  (Co-evaluation, Group evaluation, Autoevaluation, conventional evaluation)

6.- Usability conditions and grade of accomplishment of the platform

The realization of distance education experiences at Universidad de Concepción and the analysis and evaluation of them, validate conclusions about the grade of satisfaction of usability conditions.

- Open, friendly and flexible environment for the participants. Students communicate, ask questions, express their opinions and collaborate efficiently — The following capabilities of the platform help: Asynchronism, Network working environment, Discussions site, IRC chat, and interaction through Internet
- Thinking stimulation, and Creative disposition — Guided and oriented participation of the students during discussions, consults, and assignments using the technological tools provided by the platform
- Open to professor creativeness — Thanks to the new technological resources permanently evolving, the professors have the opportunity to experience new ways to improve teaching (multimedia resources, videoconference, simulation, etc.)
- Apply the best leading style to stimulate participation, develop values, and motivate — Depending on the initiative of the professor the platform itself could help or at least be neutral.
- Promote the collaborative work — Thanks to the facilities of the platform students can develop, coordinate, revise, and build reports or exchange knowledge in benefit of all. (chat, sharing files, compartir archivos, e-mail, etc.)
- Stimulate the metacognitive thinking — The introduction of frequent autoevaluation, the access to the fantastic world of Internet and other resources can influence the personal learning, giving clues to advance, or turn back in the plan of activities.
Telematics in Professional Training: New Horizons and Possibilities

Airton Cattani
PhD Program of Informatic in Education
Federal University of Rio Grande do Sul
Brazil
aacc@vortex.ufrgs.br

Abstract: Today's information and communication technologies have offered many possibilities for activity when applied to education. However, these various applications usually occur in the usual teaching/learning environments (schools, universities, centres of study and research) and are used by operators for whom study is their prime activity. The objective of this paper is to indicate the possibilities offered by telematics as a tool for access to professional training by users for whom access to these resources is not usually easy: civil construction workers. The principle theories and results obtained in the implementation of a website directed at the training of civil construction workers in the reading and interpretation of architectural plans are presented employing an interdisciplinary approach involving architecture, engineering, education, psychology, and information technology.

Introduction

The present conditions of technological development do not always provide the necessary professional qualifications for all those who are involved in the different stages of a productive process. In the civil construction industry, the training of planners and designers is guaranteed in various circumstances (universities, technical courses, trades unions) the same does not apply to the workers entrusted with constructing a building. Due to this, in the specific panorama of the countries of the third world, poles of technological excellence coexist alongside a large contingent of workers who remain at the margin of processes of qualification. In these conditions, the professional training of these workers happens in a large number of cases in an informal manner, as technical knowledge transmitted from one worker to another alongside the construction itself. Due to the precariousness and unsystematic character in which it occurs, this model of training has not been shown to be the most appropriate, principally with regard to new constructive processes and techniques where the capacity of anticipation is one of the demanding requirements.

As a solution for this impasse, providing conditions of access to training and qualification for workers is one of the departures in the search for standards of quality compatible with the requirements of those peculiar situations. In that context, continuing education based on current technological resources, appears to be a possible solution to face the new requirements of qualification. In agreement with Cardona (1995), the training of human resources in obsolete technologies can result in an underutilisation of human potential (and later in unemployment or underemployment), as a result of traditional training processes being out of phase with the path of technological development.

The Role of Graphic Representation
Graphic representation by means of technical drawing has been acquiring a larger importance everyday in the field of new industrial technologies, because of its capacity of allowing elaboration, anticipation, control and the checking of solutions to spatial problems, extending into numerous fields of activity (Bessot and Verillon, 1993). Containing information of a spatial nature, plans, maps, diagrams, technical or geometric drawings become indispensable tools for the realisation of numerous professional tasks: to manufacture a machine part, to locate an object, to find one’s way around a city, to build a house, are tasks which are optimised when accompanied by information about the spatial nature of activity in question.

In architecture and civil construction particularly, this information comes before the stage of the construction of a building, permitting a control over the whole constructive process and informing all those involved of the procedures to be adopted. In this sense, the correct understanding of the graphic codes of preliminary representation of the architectural space is one of the necessary conditions for a professional performance within the standards of quality demanded by industry and consumers, not only on the part of workers charged with the construction stage, but on that of everybody directly or indirectly involved with a building work.

The absence of this knowledge on the part of the workers is reflected in the whole execution of a building, causing them to constantly request further information, resulting in loss of time and several disruptions to the productive process (Rabardel and Weill-Fasina, 1995). This is without speaking of the losses of material due to waste, caused as much by the use of incorrect amounts of materials as by rebuilding.

The establishment of clear concepts, based on norms of representation of universal acceptance defined by the Technical Rules manifested by Technical Drawing requires a formal intervention, a way of guaranteeing unified standards of understanding and identification on the part of the professionals involved. Due to the restricted opportunities of professional training becoming more precarious in post-war periods, allied with the characteristic mobility of workers in the civil construction industry, these interventions occur in an informal way in the working environment, which is not the most appropriate manner for professional qualification. Unlike the techniques of training in the workplace which are planned in advance and have the necessary resources for an activity of educational qualification (training "on the job"), training on the building site is sporadic and unplanned, raising doubts concerning its effectiveness.

In this way a favourable scenario takes shape for experiences which, using new technologies in a more extensive manner may take care of some aspects of professional training, not only in normal conditions, but also in moments of crisis. To this end, a pioneer project, at least on a Brazilian level, is being proposed, for the training of civil construction workers using resources available on the World Wide Web (WWW), where one aspect of this training is addressed: the reading and interpretation of the graphic codes of representation of architecture.

Telematic Networks For Professional Training

The WWW is now the standard interface in telematic communication (telecommunications + computer science), incorporating multimedia resources - text, sound,
animation, videos - and permitting fast and efficient communication between geographically distant users. Its exponential growth -estimated to be one billion people at the turn of the century - leaves no remaining doubts about the importance of this form of communication, when reaching such impressive numbers, although all the effects (cultural, economic, strategic, social, etc.) of this new form of communication are still not all known (Negroponte, 1995). But they will certainly be significant and profound.

The dynamic and diversified character of the Internet, besides its practically limitless reach - in spite of numerous technical/economic even political restrictions - make it an important means of communication and interaction with potential educational implications. The resources offered and supported make the network one of the technological apparatuses which has been most attracting the attention of researchers from all areas, to the point of classifying it as the most explosive communication phenomenon of the century (Galbreath, 1997), or the invention that has most changed the world since the invention of movable type by Gutenberg (Descy, 1997; Maddux and Johnson, 1997).

The technical resources available on the Internet (animation, simulation, virtual reality, etc.), its wide geographical reach, the more and more friendly character of navigation, associated with the possibility of interaction and cooperation among users, show themselves to be important tools for the construction and/or recovery of the knowledge necessary for a good professional role. Besides this, it can provide support for the necessary requirements pointed out by Roca Villa (1994), for general training and, especially, the professional training or requalification of workers in future years: personalised, flexible, based on resources, interactive, accessible when necessary ("just in time learning") training.

But it is in what Levy (1998) calls a “new relationship with the knowledged” that is found one of the most significant differences in relation to conventional pedagogic practices, to the extent that these new technologies amplify, externalise and modify human cognitive functions, providing new forms of access to information and new styles of reasoning and knowledge. The productive processes are modified by emergent paradigms, in the same way that knowledge is, as new models and spaces of knowledge are created, open, continuous, fluid, not linear, reorganised in accordance with objectives or contexts, in contrast with linear and parallel scales, structured by levels and prerequisites, converging on “superior” knowledge (author's quotation marks).

Simulation, virtual reality, communication on a global network, artificial intelligence, multimedia, interactivity, become the new forms by which knowledge is being made available, symbolised and represented, generating new ways of knowing that develop the imagination and intuition much more than previously. According to Moraes (1998), the amplification of the spaces through which knowledge and the changes of knowledge come and go requires that individuals are made literate in the use of electronic/computer equipment and resources, enabling them to produce, store, disseminate and benefit from knowledge through its new forms of digital representation. It is not, therefore, only a new support, but a new form of connection, construction and production which establishes itself far from the monopoly of the institution/teacher, and open for autonomy and wider participation.

Possibilities For Action And Possible Approaches

The activity of the recovery of the professional qualification of workers finds in the Internet a virtual environment of training compatible with the characteristic mobility of workers, at the same time that it adapts to
the new productive paradigms directed towards professional qualification, seeking to reach desirable levels of quality and productivity. The use of educational sites represents one of the most promising resources offered by the Internet, because the possibilities of interaction and cooperation, through consultation, the exchange of messages, etc.

This perspective implies profound changes in the educational system, once aspects such as personal differences, cognitive styles, learning rhythm, affinities, areas of interest, thought strategies, and motivation, which until then have been unconsidered, start to have relevance. It implies, equally, changes on the part of teachers, methodology, curriculum, material and didactic resources, evaluation, physical space and timetables, considerably enlarging the range of possibilities of educational activity, so that they can incorporate the resources offered by new technologies.

Based on these precepts, Jonassen (1998) describes the characteristics that he called "significant learning", or the process of teaching-learning based on the constructivist perspective. Arguing that these new technologies can support thought that deals with these qualities, the author describes them thus:

- Active: taking risks, through experiences and actions, supplies solidity for the learning process. The experience acquired in the activity and the manipulation of the tools of change are essential in this type of approach;
- Constructive: meaning is built by means of previous knowledge;
- Reflective: experience is not enough for learning. It is necessary to reflect and analyse, to articulate the decisions, strategies and answers found. When the student articulates what has been learnt and reflects on the processes of decision adopted, s/he understands more and has more capacity to apply the constructed knowledge;
- Collaborative: explores the abilities of each person, supplying support and approval in the construction of individual and collective knowledge and learning;
- Intentional: the fixing of goals and objectives articulates and directs thinking, action and learning towards attainment;
- Complex: opposing itself to the apparent simplicity and reliability of the contemporary world, it adapts to its complexity, irregularity and lack of structure;
- Contextual: developed through significant activities in the real or simulated world, they acquire more consistent meanings when transferred or applied to other situations;
- Colloquial: the exchange of opinions and ideas becomes a social activity that can be put to the service of the construction of knowledge.

All these characteristics are interrelated, interactive and interdependent, requiring that the educational activities based on these frames of reference conform with the largest possible number of approaches, because these characteristics are synergetic, that is, their combination results in learning processes broader than the individual characteristics used separately (Jonassen, 1998).

Furthermore, according to the author, the potential of the various technologies mediated by the computer is favourable to the development of new pedagogic focuses that prioritise constructivist frames of reference, in distance learning, as well as the classroom mode. Teaching and working collaboratively, contextually, with interaction, simulation, and virtual engagement with the object have been permitting the development of new pedagogic focuses towards an approach to instruction centred on the subject, no longer emphasising the teacher as the source and arbiter of all knowledge.

The Site
Taking these presuppositions as a base, the site ‘The Reading and Interpretation of Plans’ is being developed, available at the http://www.ufrgs.br/des/plantas/index (access password available on request from aacc@vortex.ufrgs.br) designed specifically to respond to the needs of civil construction workers. Its aim is to be a virtual space of information, exploration and construction of knowledge, where the basic principles of the graphic representation of constructed space are formalised. Furthermore it becomes an environment for familiarising these users with the possibilities offered by information technology, and the Internet in particular.

Constructed around four thematic axes - drawing, design, the reading of plans, and civil construction - the site employs simple language arranged in short paragraphs, seeking to adapt itself to the characteristic of the subjects. Its structure is based on frames as a way of permitting rapid access to all the contents in an order defined by the user him/herself. Furthermore, animations, and applications in dynamic html and JavaScript are other resources employed.

But the principal difference of the site is not the use of the latest generation of technological resources, but the simple manner in which the resources are employed in an approach directed towards users who are interacting with technological resources. Instead of presenting all the content with ready answers, situations are presented in which the user him/herself has to construct his/her hypothesis from situations experienced in the routine procedures of working alongside the construction itself, and reproduced on the screen. A space is also anticipated for the resolution of doubts and exchange of information between participants. The construction of a glossary of words and technical terms employed in civil construction will be made incorporating contributions from the participants. In this way, by recording their contributions, they will be formalising these contents.

These characteristics, allied with the dynamism of the Internet, make the site a place of constant change and up-dating, since each participation can lead to reformations and redirections, permitting a constant updating of contents and/or approaches.

Results

The first results obtained from pilot use give an account of the appropriateness of the means of information technology and telematics in the forming/recovery of knowledge necessary for the professional activities of civil construction workers. Workers invited to interact with the site in an experimental way confirmed data obtained in previous research (Cattani, 1998) which gave an account of the existence of potentially favourable conditions for the employment of the resources of information technology in the training and qualification of these workers. There are indications that the difficulties of use of computer resources on the part of adult subjects with little formal schooling are due more to material conditions (the concrete difficulty of access to equipment) than to cognitive limitations. The fears, suspicions, doubts and insecurities demonstrated by workers were no different from those of educated adults on their first interaction with a computer.

These data permit deductions upon the viability of experiences which employ this technology directed to these specific users, as well as confirming the course followed in the theoretical frames of reference of the development and refinement of the site.

Abstract: The first experience of the Universidad Tecnológica de Panamá and the Instituto Episcopal San Cristóbal, in the development of educative projects collaboration through Internet, go back from the year 1994, with the creation of the project “Enviroment and Contaminated Atmosphere”, with the fulfillment between educational institutes from Panama and Brasil, with the mediation of the Universidad Federal of Rio de Janeiro and the Universidad Tecnologica de Panama.

The results obtained in the entirely development with the various projects, in addition to strengthen the relation between University – School permit the identification of the group of aspects to consider in the planning and execution of educational projects with the mediator of the netting.

This potential relate the integration University – School on the development of educational projects with the collaboration through Internet, and presents identified aspects, as a priority to consider in the development of such projects.

Introduction

With the arrival of the Internet Netting to Panama in June 1994, revealed a common reality in the educational system of the region; this is; the use and access of the netting marked on the activities of higher level. The communciation and the facilities introduced with the arrival of Internet emerge out of reach of the scholar institutions of basic and middle teaching. The public schools were in disidvantage because they didn’t have the necessary conditions for establishing the use of a net in their installation, since there wasn’t a national policy that could supervise the installation of a net in the educational system.

The Instituto Episcopal San Cristóbal, a private school in the Republic of Panama which attends to students from Pre-School up 12Th grade, in 1994 showed interest in the developing experiences with the Universidad Tecnológica, UTP, with the enclosure of works applied to the process of teaching learning. Due to the fact that the Universidad Tecnológica attends hihger studies and the fact that the time, equipped with Internet, the need to work with school, here or abroad, interested in participating in the project with Panamanian schools, based on the agreement of cooperation between the Universidad Tecnológica de Panamá and the Universidad Federal de Rio de Janeiro, we were able to contact a school, in Brasil, which presented the profile needed in order to develop the work.

The experiences began with the project “The Environment and Its Contamination” inteded to develop the practice of distance investigations taking advantage of the use of the e-mail and other resources available through the net of Internet. The general objective that oriented the definition and the development of the project was: to establish the communication and cooperative work, via Internet, between students of different cultural environment, with a present day topic of world interest (Clunie, 1996), with the participation of students from
the 9th grade of high school, between the ages of 13 and 15. The communications were sent in the languages of each country, Portuguese and Spanish.

After the first year of work, the coordinating teams of Panama and Brasil concluded that: (i) the experience was intellectually rich, allowing the exchange of information in both languages and the preparation of the conclusion in relation to topic worked on; (ii) in the social aspect new relationships were established with inter and intra working groups, this is within the working groups of each country and with the colleagues of the invited country: and (iii) the possibility to work with a new technique stimulated, the students work in a spontaneous way. why the integration of University- Schools.

Why the integration of University – School?

Actually it’s common to encounter with teaching institute who posses Informatic Laboratory, most of them well equipped and with access to Internet; where the machines “have eternal rest”. This situation due to the fact that the faculty and others public employees were not prepared on the adequate use of the New Technology and it’s respective application in the educational process and in the educational administration activities (Clunie, 1992). The truth that is frequently found in the institutions is that the resources are installed in the laboratories and abandoned to self-learning of the users, subtracting importance to the process of updating and incentivating the board of educators.

In the process of the university activities, the task of investigations prevail, and it is a necessary condition to continuously update the board educators. This premise was extensive to all the activities and projects that develops the university, at an intern level or with the participation of outward collaborators. The agreement of cooperation between the Instituto Episcopal San Cristobal and the Universidad Tecnologica of Panama, is based on this last object, on which we emahzise: (I) To promote and to impel the scientific exchange, technology and cultural with the foreign or national institution and cooperates with these last in the solution of the technological problem at a high level, of their ability and, (II) to bond enlargement of the acton of educational system to the production process, through the investigation of educational technology to fce the problem of the country.

To have as a mark of reference the university political, expressed before and considering that in the university there are specialist in technique appliance, it’s fundamental for the exit of all experience that entail with the new technology to the educational process, to count with the participation of personal specialized with a mastery knowledge and qualification of the fculty of the educational center in the use and application of the technique. The agreement of cooperation between the Universidad Tecnologica of Panama and the Instituto Episcopal San Cristobal, in this present case, vialize and guarantee the fulfillment of these objectives planned.

Team Work

Through the collaboration, a model in which the social and the self-esteem coexistence are increased, is being built, with the academic success which can rely on tools that make the communication and motivation of the participants easier, basing the individual learning through the communication and the search to reach the common objective. The conscencious ness of groups is the catalyst agent that makes the construction of the collective knowledge through knowledge and individual learning possible.

Team work lays the foundation of peer learning, resulting in an alternate way to the traditional teaching process that creates rivalry between the students. Instead of rivalry there is mutual help.

Investigations made with children between the ages of 7 and 8 who were studying in the 2nd grade of elementary concluded that (Lucena, 1997):

- To group children in pairs resulted of great importance and motivation for the development of writing and recognition.
- Peer work, along with the existing facilities, drove the children to acquire mor confidence to: (i) change their thoughts into comprehensible writting; (ii) to write with more freedom, without been scared of making mistakes and (iii) increase then self esteem in the presentation of the works.
Without subtracting from the importance of maturity (operation) as a determiner of the process of human development, Barbosa Goulart calls the attention to cooperation, this is the process of development. Of the operations of the social coexistence confirming that “in the exchange of their equals, individuals acquire autonomy” (Goulart, 1991)

Collaborative Projects through Internet

Investigations in educational technology suggest the use of new sociopedagogical approaches integrated to the technology of the computer nets. The nets facilitate communication for the users, permitting them to communicative and to exchange information. This gives then feeling of participation and responsibility for the learning that is being construed. The schools gain more life, and as more students participate actively in the construction of knowledge they gain more autonomy and independence in relation to their knowledge.

The fulfillment of diverse activities and situations of learning in a netting atmosphere establish an excellent opportunity for the individual or exchange groups. The individual can work collaborating in a collective form, investigating, exchanging information developing the creativity, playing, elaborating projects, building knowledge, learning to learn, or simple, communicating between friends. The timid students in class, find in the netting more liberty to exposed and to test their ideas. This meaning, when it’s apply in an adequate way, the use of the netting becomes a very valuable work tool, compatible with the present necessity of educational process.

The Planning and Execution of Educational Projects through Nets

In the mark of an agreement the cooperation University – School, and a result of the experience gain in the development of projects, through Internet, we identify substitute appereace considering the designs, planning and the carrying out of projects through the netting. These are:

- **Foundation:** Every educational project should respond to a determine form of understanding the process of teaching and learning. It should explain why it’s being done by presenting its stages of development, work methodology goals and limitations.
- **Objectives:** the global objectives and the objectives of each phase should be stated clearly.
- **Population:** the participants should be indentified clearly.
- **Activities:** to get the work done correctly it is fundamental to identify each of the activities that would be done in every phase of the project.
- **Resources:** They are aspects to be considered in order to guarantee the successful development of the project. The human resource participating should be indentified, and be expected to coordinate and help with the work and the computer resources such as the hardware and the software that is used for the project.

During the development of the project the following steps should be followed:

- Every project should have a responsible work group that would supervise and make sure that all of the activities will be done according to the design and work plans.
- A specialist on content should follow up on the project and revise the work done by the students. Enfases should be made on aspects such as accuracy of information that is being worked on. This will give the participants confidence and will give the participants confidence and will give credibility to the project.
- One of the teachers participating in the project should check the information generated by the students checking the Grammar, the vocabulary and forms of expression that do not attempt against the integrity and morale of the participants.
- Someone in charge of support should permanently check the proper use and updating of the work resources (hardware and software) necessary for the development of the project.
- The entire group should develop dynamics that stimulate the activities in and out of the installation where the projects is developing.
The Experience of University-School Integration

The united development of projects between the Universidad Tecnologica of Panama and the Instituto Episcopal San Cristobal, surpasses the frontier of the initial project "The Environment and Its Contamination". The experience was fortified with the arrival of the Project KIDLINK to Panama, in 1997. From then they have develop diverse project in the mark of KIDLINK with the colaboration and orientation of the Educational Informatic Department. Between KIDLINK, due the nature of work they are developing, they emphazise the activities developed as: (I) Discussion list for Adults; (II) Colaborative individuals projects; (III) Colaboratives projects between collage; (IV) Translation in multiple languages; (V) Children Art in the net; and (VI) Conversation in real time and others. The colaborative projects for individuals or inter school are among the different activities that are done.

Conclusion

From the experience acquired in the setting of the agreement of cooperation between the Universidad Tecnologica of Panama and the Instituto Episcopal San Cristobal, we concluded that:

- The work through the net constitutes new environment of learning that make it easy for free exchange of ideas and favors development of knowledge.
- Internet emerges like a powerful ally in the process of teaching – learning facilitating the access to varied and actualized information.
- The colaborative work is stimulating, it sets the bases for colaborative learning, resulting as an alternative form to the process of traditional teaching permitting the development of important and new characteristic values in youths.

Future View

With the intention to accompany the advances of technology, at the present time we work on the design of new projects that will enrichen the motivation and increase the participation within the setting of the University School integration, we are placed in the phase of planning for the Video Conference project, which refers to the use of the multimedia technology for the exchange of ideas and the development of projects through the net.

Abstract: This paper describes the in-service training programs for primary school teachers to use information technology in Australia and in Taiwan. The advantages and disadvantages of the training programs in these two countries are analyzed and compared. The Taiwanese government has done an excellent job in setting up the Internet infrastructure and different levels of technical support, and its in-service training programs have good supports for the full-scale implementation of web learning in the primary schools. However, the Australian in-service training program has merit in the setup of the full time facilitators and a good record tracking system to reduce the cost. Thus, a combined approach to take advantage of the best parts of these two in-service training programs is recommended in the future. This approach will help primary school teachers to learn and to adapt information technology in the classrooms more quickly.

Introduction

The advance of network, multimedia, communication technology has made a great impact on the way people work and learn. Today, information technology enables teachers to outreach teaching resources on the Internet, communicate with subject domain experts or other school teachers through the World Wide Web (WWW).

In Australia, the Department of Education and Training (DET) in the New South Wales (NSW) has funded public primary schools to purchase at least one modem and some Internet computers under the Computers in School Policy. Moreover, DET began a statewide Technology in Learning and Teaching (TILT) program in 1996 to promote computer and network literacy of primary school teachers (Training and Development Directorate, 1997).

Similarly, the Department of Education (DOE) in Taiwan identified the importance of information technology in education. In the past ten years, money and efforts have been allocated to set up the network infrastructure, computer laboratories and technical support centers in all levels of government schools. Moreover, from 1 October 1998 to 30 June 1999, the Taiwanese Government has spent a total amount NT$647 million (approximately US$20.2 million) dollars to update computer hardware, networking hardware and software in all levels of schools with a special focus on high schools and primary schools. Also, in-service training courses and local network support centers were provided to build up the computer literacy of the primary school teachers (Department of Education in Taiwan, 1999a).
In-Service Teacher Training Programs in Australia

Starting from 1996, DET in NSW had funded many state universities to run a 2-hours Internet workshop for primary school teachers. Each school in NSW selected one teacher as the Internet Contact Person (ICP) to attend the workshop. Moreover, later in 1996, the DET conducted a statewide TILT program. Approximately 150 teachers in NSW were selected as facilitators, and they were trained so as to be able to train other teachers. The facilitators were paid by their schools, but DET allocated extra money for schools to hire substitute teachers, so facilitators could be released from teaching and administrative tasks. Their major task was to train 70 teachers in the school districts each semester every half year. Each semester, the facilitators ran a thirty-hour workshop which contained six components entitled "Powerful tools to enhance teaching and learning", "Beyond the classroom walls", "Computers and related technologies", "Software", "How can I do this in my classroom", and "Future Directions". Each component lasts for five hours. There is a one-hour video program addressing the key issues, a two-hour hands-on activity using computers and related technology, and a two-hour follow-up activity related to the practical application of skills in the classroom (Training and Development Directorate, 1997).

Roughly one-third (15,000) of the primary school teachers in NSW have participated in the TILT program from 1996 to June 1999. The participants attended the workshops of the TILT program every two or three week after school. During the training period, DET allocated funding to each school to release the participants from the normal teaching loads for three single days or six half-days. They can use the free time to practice what they had learnt or ask the facilitator to do one-to-one tutoring. Moreover, the participating teachers are not allowed to take the same TILT program repeatedly in the future (Training and Development Directorate, 1997). The goal of the TILT program is to train 10,000 more teachers (i.e. up to 55% of the primary school teachers in NSW) to participate in the TILT program by Year 2000.

In 1999, DET in NSW also ran a small-scale survey to trace the participating teachers who attended the workshop in 1996-1998 period. The survey showed that 80% of the participants applied the computer technology in the teaching and administrative work at least once a month. Among which, about 63% of the participants used a computer at least once a week (Training and Development Directorate, 1997). However, there was no real application of network technology in classroom teaching and learning activities currently due to the limited numbers of modems to access the Internet.

In-Service Teacher Training Programs in Taiwan

Before 1995, governmental organizations, universities and colleges conducted in-service teacher training programs regarding information technologies. It was very costly for primary school teachers to participate in the training courses because schools have to pay for the substitute teachers and pay the travel and registration fees for the participants. Usually, the training courses were held for half-day or one-day. Occasionally, there were some workshops that lasted for three to five days. Yet, these short-term training courses did not have a good outcome because when the participating teachers returned to their schools, they sometimes did not have the equivalent computer hardware or software to practice what they have learnt in the workshop. As a result, they usually forgot the training content quickly and could not apply what they learned in their classrooms immediately.

As far as the training of facilitators is concerned, there were a few training programs that lasted for three-months or half-year to train some selected teachers to be facilitators. However, the facilitators' teaching loads are usually not waived. Meanwhile, they were also responsible for the maintenance of computer laboratories because primary schools in Taiwan did not have the budget to pay computer companies to maintain the computers, and there are no computer technicians in schools. As a result, the workloads of the facilitators are very heavy, and there are many complaints about it (Roy, 1999).

Before 1997, not many primary school teachers in Taiwan had been trained to use information technology. The reason for the lower outcome is due to the lack of record tracking of the trained teachers. Usually, those who were interested in learning computer technology would take the opportunity to attend different teacher-training courses over and over again.
To improve the shortcoming of the traditional teacher-training model, a new “on-site, full-scale” model had been applied to train all the primary school teachers in their schools from 1 Oct 1998 to June 30 1999. The DOE in Taiwan also selected some schools in each county to be the technical support centers as well as teaching resource distribution center. The DOE in Taiwan allocated funds to conduct the teacher-training courses with an aim to train 70% of teachers in each primary school (Department of Education in Taiwan, 1999b). There are also selected universities that are network centers of Taiwan Academic Network (TANET) which provide higher level technical supports to the county level technical centers, and they may even provide direct supports to primary schools if needed.

Starting from 1 Oct. 1998, many workshops were run for a semester to enhance the learning outcomes of primary school teachers. Every Wednesday afternoon, there were no classes for all the primary school teachers in Taiwan. The experienced facilitators or university professors came to primary schools and gave a four-hour training course to teach a wide range of preliminary computer and network knowledge and skills.

There were nine units of the basic courses including Windows 95, CAI, Internet application, MS Word, The application of WWW in teaching, Network Multimedia, CD ROM, Computer Maintenance, PowerPoint. Each unit was either four-hours or eight-hours depends on the difficulty of the content or the participants' background knowledge and skills. Some schools provided advanced training courses on Saturday every two weeks. The advanced courses included Homepage Construction (18 hours), Excel (12 hours), MS Outlook (12 hours), Word 97 (12 hours). The new “on-site, full-scale” model of teacher-training programs turned out to be more efficient than the traditional teacher-training courses. (Department of Education in Taiwan, 1999c).

Comparison of the training programs in Australia and in Taiwan

Although the TILT program in NSW, Australia has successfully trained more than 1/3 of the K-12 teachers in three years, the real application of the network technology in the classrooms has not become popular due to the limited numbers of modems, network hardware and software. On the other hand, the Taiwanese DOE has spent more than ten years in training teachers and promoted the usage of email and WWW in primary schools. In the past year, the network and hardware/software have been upgraded significantly. Many centers have been set up in each county to distribute teaching materials, software, CD ROM and other teaching resources developed in the past years. In addition, many WWW web sites have been developed to support the real application of information technology in the practical classroom teaching and learning.

There are some advantages in the Australian in-service teacher-training program. Firstly, Australian facilitators are released from teaching loads, so they can concentrate on running the workshops and provide tutoring to assist the participating teachers. On the other hand, Taiwanese facilitators were very much over-loaded by the tasks of training other teachers in their schools and maintaining the computers on top of their ordinary teaching loads. However, starting from 1998, there are remedies. For example, when primary schools purchase hardware from a computer company, it is required that the company takes the responsibility of the hardware maintenance for three years. Moreover, the teaching loads of facilitators are reduced somehow to compensate their time in training other teachers.

Secondly, the Australian in-service training system keeps records on the participants' names and only takes those who have not attended the TILT programs. In contrast, there is no record tracking in the Taiwanese in-service training system. One of the shortcomings is that limited numbers of teachers who are interested information technology may take different training courses repeatedly. However, the Taiwanese government has changed the strategies of in-service teacher training. The newly introduced "on-site, full-scale" training model works quite well to make sure that most teachers in the primary schools have attended the workshops. Yet, it is very costly for the government to do so, and the new model only last for eight months.

Conclusion

The Australian teacher in-service training program is more cost effective. The ways to release facilitators to allow them to concentrate on training, and the record tracking of the participating teachers have proven to be
effective and economical. The next step to take is the setting up of the network infrastructure in the primary schools and the organizing of the technical support centers in school districts, so teachers and students will benefit from the progress in information technology.

The Taiwanese teacher in-service training programs have better support in terms of the network infrastructure, the setup of the county's technical support centers to promote web-learning and to distribute teaching resources, and development of many web sites to enhance the teaching and learning through Internet in the Taiwanese primary schools. However, both the traditional model and the new model of teacher training programs in Taiwan are very expensive to execute.

Apparently, Taiwanese in-service training programs have better supports for the full-scale implementation of web learning in the primary schools. However, the Australian in-service training program has merit in the setup of the full time facilitators and good record tracking system to reduce the cost. It is recommend taking a combined approach to take advantage of the best parts of these two in-service training systems to help primary school teachers to learn information technology.

Teachers and Trainee Teachers Perceptions about Information and Communication Technology Tools
during a Multicultural European Activity

Ariane Pierrou – Christian Bessiere
Interactions Collaboratives, Téléformation, Télé-activités
Unité de Recherche I.C.T.T Ecole Centrale de Lyon
France
Ariane.Pierrou@ictt.ec-lyon.fr Christian.Bessiere@ictt.ec-lyon.fr

Abstract: The main objective of this paper, is to report the activity of a multicultural and
Cross Country European activity: “the communication weeks” focused on three items:
- Teacher Educators and Trainee Teachers needs
- Information and Communication Technology (I.C.T) as educational tools
- Intrinsic qualities and draw back of ICT tools
The specific interest of these communication weeks is that it took place in ordinary
situations and give an opportunity to present the point of views of European users working
together in order to point out the pedagogical problematic about the use of ICT tools and to
illustrate the actors perceptions. We choose to present this paper in actual words of these
participants so that their voices are clearly heard.
The users conclusions underline the fact that there is an awareness about their changing role
through the use of Information and Communication Technology. They argue for the
integration of ICT tools in their pedagogical practices in training course and curricular.

Introduction

Different Institutes of Teacher Education (pre-service education and in-service training) in England,
Finland, France, Portugal and Switzerland, decided to carry out “Communication weeks” from January to
June 1997, in order to develop a network between project partners and users for a limited period of time (two
weeks). These Communication weeks aimed at enabling Teacher Educators and Trainee Teachers to
communicate about Information and Communication Technology (I.C.T) tools by using synchronous and
asynchronous tools such as forums, videoconferencing, e-mail... This collaboration has been held by the
research project FETICHE (Formation des Enseignants aux Techniques de l’Information et de la
Communication : CHangements et Evolution) within the framework of the European program Socrates1.

This experiment used the local environment that took place in ordinary situation and circumstances.
Small and disparate groups were involved. The priority was to support people’s involvement in relevant cross
country communication. Observing and analyzing was our second objective in order to identify the lessons to
be learned from such an European co-operation. This paper gives a brief description of the setting of this
communication weeks (1) and the results of a small scale questionnaire pointing out the users needs (2), The
ICT as educational tools (3) and their qualities and drawbacks (4). More details can be found in the full report
(Bessiere, Blackeley, Pierrou 1997) and on the Fetiche Web site2.

1. The setting up

The preparation of such an event required a lot of energy among the Fetiche team in order to
coordinate, to organize and to build a global agreement among team members.
Some prerequisite were handled, particularly:
- Basket of technology concretely available and ready to use (specially for the multipoint videoconferencing)
- Choice of an animator “boosting” the process in each country.

1 This project already finished, would continue for year 2000 (we are waiting for the agreement).
2 http://ictt2.ec-lyon.fr/fetiche/
Choice of participants with a minimal training

1.1 Identification of the participants

As we were in a distant context, we tried to give to the participants the possibility to be immediately in contact with this technology not only as observers but as real actors. Therefore, their first task was to introduce themselves before entering the conference (forum) by filling a form. This form was public and we could read 39 presentations. It's noticeable that a half of the participants were mainly Trainee Teachers and had some previous experience of collaboration at European scale. Most of them used to travel in Europe for their professional activities, and half already used e-mails for European Collaboration.

In the Hobbies section, the following are classical entries: "reading", "swimming", "fishing", "cinema" but also: "Telecommunications", "My favorite hobbies are...going out with friends and lately netsurfing", "...Travelling and netsurfing!", "Computer", "surf the net", but their personal interests and working life indicate experience using ICTs: "...I am in charge of ICT at the IUFM", "Teacher training in English ICT projects in education (videoconferencing, WWW, E-mail...)", "...developing distant learning materials...", "I have 4 hours a week with my students in English for 2 years and one of these hours is with the computer..."

It's clear that they are probably more familiar with e-mail than the average Teacher or Trainee Teacher: this is due to the fact they belong to institutions which are active in this field (thanks to Fetiche and other projects).

If we cross this identification form with the information coming from the questionnaires (48 answers), we can add, that most participants where young (less than 30 years old), mainly woman, and it is the students (Trainee Teachers) who massively answered. This is a positive indicator corresponding to one of our main objectives for this activity "involving Trainee Teachers" with a basket of media.

1.2 Media used

We try to find a basket of technology, mixing asynchronous and synchronous media, in order to give a representative pallet on what we call ICT tools. During the Communication Weeks, we never used the expression "New Tools for Teaching or Learning" or "New Technologies and training". This terminological orientation was for the project team the opportunity to offer a large choice of New technology tools used in different fields and let the participants appreciate if those tools could be used, in a learning or teaching situation: "L'enseignement ne génère pas de nouvelles techniques – affirme Robert Quinot (1986) – de l'audiovisuel à la télématique, elles sont introduites par effractions successives...L'enseignement utilise traditionnellement des aides qu'il adapte, comme les instruments de mesure, (...) les maquettes en sciences physiques (...)" and we could add the new technologies for learning and teaching.

The following summary table shows the overall technologies used.

---

3 Translation by the authors: "Teaching doesn't generate new technologies – said Robert Quinot (1986) – from audiovisuals to telematics, they are introduced by successive break-in...Teaching traditionally use some aids which are adapted, as measure instruments, (...) scale models in physical sciences (...)"
Technolgy | Aims
--- | ---
e-mail | 90% of the organisation of the communication weeks was done by e-mail. But it was just used between the team members. The participants, has they had the forum, used it hardly ever.

Teleconferencing | The forum was dedicated to the reflexive and collaborative part of the Activity. This conference, called 'asynchronous' - where each participant writes or answers to a message when it is convenient for him was one way of meeting and discussing. In this forum you found 10 main threads in order to discuss about pedagogy, teaching and learning approaches using new technology.

Teleconferencing | The videoconferencing was used for real time and immediate feedback. Videoconferencing was intended to be one of the project’s synchronous tools enabling participants to get to know one another for instance people which whom they communicate at distance in the asynchronous mode on the forum, to discuss at distance on various topics seen in the forum and learn more of how to use the medium.

Web site | A web site, called Fetiche Web site has been held at first for the project team. For this specific event, a Communication Weeks menu was created. This medium was open to the participants in order to informed them, about different subjects concerning the communication weeks, but also on the aim of the whole project. The web was principally a tool for the circulation of up-dated information but also the “ collector” of reactions, thanks to the built-in questionnaires. The participants had to go to the web for filling the initial and final questionnaire.

| Table 1 | the basket of tools used during the communication weeks |
| | 1.3 Methodological approach and observation tools |
| | The Communication Weeks was an European experiment using the local environment and composed of small and disparate groups. For these reasons we choose to have a qualitative approach. We prepared specific observation tools which were handled and used by each field partner, in order to evaluate this event such as: Automatic files (e.g.: log files from machines), individual data given by each participant (e.g.: individual presentation form) and two questionnaires (the first starting individual questionnaire planned to be completed by all participants at the start of the Communication Weeks and the second final individual questionnaire planned to be completed at the end ) available on the web server, about the interest and the limits of the pedagogical functions of each medium used and about the Communication Weeks as a whole. As we were in a real situation distributed over 5 sites, different problems occurred for some of the participants: the starting questionnaire (41 answers) and final questionnaire (26 answers) are anonymous and do not allow personal identification of initial and final responses by a given participant. Only overall comparisons are possible. In addition, a number of participants did not complete the final questionnaire. We ensured, by cross-referencing certain criteria (age, sex, country, profession, etc.), that the 26 people completing final questionnaire, had also completed the starting questionnaire. With respect to methodology the "disappearance" of part of the "subjects" is a typical characteristic when observing an experiment under real conditions. So, we had to “temper” the drop-out rate (15 out of 41) of responses in the final questionnaire. We had also, data
provided by the coordinators of each site (e.g.: observing the videoconference and writing comments on some key issues), group interview. We built a specific grid for the observers of the videoconferencing. This grid is taken from Bales (1950) and adapted for our particular context. Our main objective, with these tools, was to hear the views of users. The following participants remarks concern the users needs. When they spoke of users they think principally of Teachers (Educators and Trainees).

2. Users needs

Participants had plenty to say about the users needs, the outburst of ideas, comments and suggestions are clearly expressed. Judging by the answers, the needs for Teachers can be divided in two basic categories of training : technology and its pedagogical use. But first of all there is a prerequisite : the technology has to be available.

2.1 Emphasising the required equipment

All participants asked for the required or adequate equipment. There is was a disparity concerning the equipment between the north of Europe and the south and it was also between depending from the countries. But, even when some equipment was available, most participants pointed out the difficult access and the complex organization as significant barriers on the way towards a flexible and every day integration in school training.

"To have access to equipment, to ensure that personal aspects are catered for, especially as regards Distant Learning. " Female Trainee Teacher – aged 24.

"To have free-access to the equipment (to develop the autonomy): but this is still very difficult to organise it in schools " Female Trainee Teacher – aged 25.

One participant sums up trainee needs very clearly:

"basic ICT training at school - enough work stations at school - modern easy-to-use software - ICT integrated in school learning " Male Trainee Teacher – aged 25.

2.2 Needs for training in order to use the ICT tools

Their needs concerning training cover different aspects. The first aspect is a technical request in order to have the minimum pre-requisites :

"basic training in the use of ICT - modern easy-to-use software - ICT integrated in the curriculum " Male Teacher – aged 30,

"to strip the machine of its mystery: "You find some teachers who think that they need to be a nuclear physicist to be able to approach a computer, while others just jump in and discover that it's an easy world to navigate in " Female Trainee Teacher – aged 26, but also
to treat as something ordinary, an additional means of personal advance: "The teachers could use some extra information about ICT, some advanced computer competencies in order to increase their knowledge, not just for teaching " Female Teacher – aged 33.

They are not ready to assume a technical competence and they ask massively for a resource person :

"...Why not let the teachers get on with the job they do best, i.e. teaching and dealing with the communications portion of the exchanges, while the technicians work in the background / sidelines to help them get their job done, by smoothing out the road for them... " Female Teacher – aged 34.

"...It's really like having two legs. Cut one off and you topple over. The technician is one leg and the teacher is the other... " Male Trainee Teacher – aged 24.

This request could be perhaps a means to overcome their fear, hesitancy and apprehension... Their attitudes might be due to what Raub (1981) called the computer anxiety: "the complex emotional reactions that are evoked in individuals who interpret computers as personally threatening" ?

The second aspect is a pedagogical training desire to find points of reference for methodology and analysis :

"To study interaction of pedagogy and ICT " "To know, and analyze different experiences developed by other people " Female Trainee Teacher – aged 23.

"To have preparation in order to use ICT and be able to use it with my students in a comfortable way and also productive " Female Trainee Teacher – aged 22.

This join the idea of the teacher posture, attitude. Some participants raised the idea to focus the training on the attitudes (rather than ICT skills) of the ICT user. The reason given for this was that the changes in software
and hardware are so rapid that no institution can expect to be able to afford to train its members in every tool and software version use. In this situation it is necessary for people to have an attitude which allows and inspires them to take the responsibility of learning to oneself. They conclude saying that influencing one's attitudes through education/training is difficult but the challenge needs to be taken ...

3. ICT as educational tools

The individual opinions offered by the participants reveal two main trends concerning this subject: the role inside the teaching and learning process and the aspects of a social mediated interaction among colleagues.

3.1 Teaching and learning issues

In the following summary lines we have grouped answers by participants concerning the merits and limits of ICT for learning and teaching. We have not separated learning and training because the answers we received clearly amalgamate them. An advantage for learning, for instance, is also an asset for teaching. As we stressed above, participants were convinced of the wisdom of integrating these tools in the educational process and they consider it as an additional educational resource. But they never forget the teacher's role and they stress that those tools are only a complement of the Teaching and Learning process because the person to person contact is always essential. They also question themselves about knowledge, concluding that the ICT tools are now another important vector towards knowledge which bring additional color to the pedagogical palette: "ICT can be a potential resource to help teaching" Female Teacher aged 28; "ICT can be used to teach but we need to be careful. Pupils can exchange information with other schools, participate in projects, etc..". Female Trainee Teacher aged 24; "It another educational resource. The teacher's role is important to decide the kind of activities developed by students by the ICT". Female Teacher aged 32. ICT are in the broader context of society: "Nowadays, more and more people use new technologies, teachers must be aware of those changes." Male Teacher aged 32., "ICT is used in almost all aspects of life in the society so teaching and learning processes cannot be isolated from the trend. ICT tools give a possibility to enrich teaching and learning." Male Trainee Teacher aged 26.

The emphasis is put also on a more individual approach to teaching: "With ICT students can construct their own knowledge in their own time. They can discover a world of information" Female Trainee Teacher aged 25. In addition, ICT: "... will give the learning/teaching process a new view, increasing the stimulus and the motivation", Male Teacher aged 34, and a vector for communicating with other colleagues.

3.2 Mediated social interaction

Interaction and communication with other colleagues seems to be one of the major role of ICT tools. It is to be noted that our participants attach considerable importance to this point and we may wonder whether mediated communication, at a distance, does not represent a richer communication vector, bringing a form of liberty that is in some way "restricted" in a person to person relationship in which less rational forces (such as sensitivity and emotion) may take over. Interest in collaborative work is also apparent: "We can learn a lot from others experiences and exchanging information through ICT makes everything quicker". Female Trainee Teacher aged 22. "As a future teacher I think ICT are a new and very important tool which I can't leave aside. Although I still think we have to be very selective when it comes to the amount of information we can get! Another point is the information exchange we can rely on, thinking that somewhere out there someone is feeling the same we do and probably will help us, it is important". Female Trainee Teacher aged 28; "I don't like to work alone. Communicating with colleagues gives the opportunity of reflection and try new strategies". Female Teacher aged 29.

4. User appreciation about the Intrinsic qualities and drawbacks of ICT tools

As far as participants are concerned, the tools selected for the Communication Weeks (WWW, Videoconferencing, Forums) seem to be tools that can be used in teaching. On the other hand, no particular medium stands out from the rest. For the participants, the advantages of ICT are mainly "An active method of Training", Male Trainee Teacher aged 26, and to "Reinstate a presence in Distant Learning" Female
Trainee Teacher – aged 25, and the main disadvantage is the “heavy cost of the equipment”, Female Trainee Teacher – aged 25, and also some drawbacks:

“... it’s not yet as easy as Desk Top Processing” Female Trainee Teacher – aged 22. “Sometimes we can feel lost with so many information” Male Trainee Teacher – aged 23. “... some time we can feel lost with so many information” Male Trainee Teacher – aged 23. “... sometimes we can feel lost with so many information” Female Teacher – aged 33. “... sometimes we can feel lost with so many information” Female Teacher – aged 36.

Despite negligible technical problems for the forum and videoconference, participants were pleasantly surprised to discover the potential for exchange and communication between individuals and groups using synchronous and asynchronous tools: “The videoconference was an important way of exchanging experiences from different teachers and trainees. Sometimes their experience where similar to our”. Female Trainee Teacher – aged 25. “The forum consisted in an interactive process of communicating between different teachers and trainees, from different cultures.” Female Trainee Teacher – aged 23.

“The two main tools (WWW and videoconference) were a good combination that complemented on one another. There was however a wish for a chatting option in the forum. To some participants the idea of the WWW forum was new and needed some time for getting accustomed to”. Male Trainee Teacher – aged 25. They also express their pleasure in seeing that someone had replied to a message: “It’s been very rewarding to see that someone answered our message (on the Forum)”. Female Trainee Teacher – aged 27. The opinion of the groups regarding the choice of technologies reveals two emerging media, which seem complementary: videoconferencing and electronic conferences. It is perhaps worth noting that none of the groups suggest other media that could have been used.

Conclusions

Before the Communication Weeks, none of the participants suggested that in the future, ICT tools would not be part of the landscape of teaching. There was already some awareness among them about the interest of ICT tools but the Communication Weeks played the role of a trigger and open the door for many comments. On the whole they are very optimistic about the future of ICT Tools. All the participants are very keen on teaching and learning through ICT. Also the fact that they have chosen the teaching profession for themselves gives them a solid motivational background for developing their teaching profession. The mention of the obstacles are weak.

This Communication Weeks permitted to produce an analysis of the intrinsic qualities of ICT tools, but also a real commentary on the problems of establishing and maintaining such technical links. The views expressed in the groups and in the open questions highlight some of the abilities and skills required to use ICT properly, offering us the opportunity to sketch out a preliminary “curriculum”, but also to point out an awareness about their changing role and a great change in the learning/teaching process being more interactive and open.

The contribution of the multicultural cross country communication, create an identity, a recognition of a European global family. This European dimension could have become a World dimension: “It would be interesting that the "European dimension" became "World dimension". What do they do in the other side of the ocean? Of course it is important knowing about the ideas and the work each country develops in Europe but everyday we are more and more citizen of the world and we shouldn't forget that”. Female Trainee Teacher – aged 26.

References

In examining this year's set of papers for the mathematics section I cannot help but be impressed by the growth which this area has seen over the past 10 years. Initially, we were lucky to have papers which showed competence in the use of technology and which tended to be written from a "Golly-Gee-Whiz! It actually worked" perspective. The mathematics in many cases was at a rudimentary level, and often came in second to the computer itself.

We have indeed progressed far since those days. As you are aware, to even get consideration in this year's section you had to be able to submit your papers in electronic form via the Internet. This marks a major transition period for SITE. To this writer it marks the end of the early exploratory era where "Golly-Gee, it works" was good enough. Today you have to be a relatively savvy user of technology to even participate in the discussion. In many ways this is unfortunate, as it means that there will be some voices left out of the dialog. I raise this as an issue because to even enter the SITE discourse from this point on you must already be a fairly high end user.

Although this will certainly raise the bar on the technological sophistication that one might expect within the papers, I will miss the diversity. Part of the excitement of SITE has always been the mix of talents and abilities that it drew. It was common to find novice classroom teachers rubbing shoulders with professional instructional designers and I feel that as an organization we were richer for it. Let's make sure we continue the long-standing SITE tradition of making the "newbies" feel welcome.

As you shall see, we have indeed progressed to the point where we are now getting an abundance of extremely strong papers. In this new wave not only is "Golly-Gee" not good enough, but the papers are written within well-developed and articulated theoretical frameworks for what is being done, a high-end use of technology in some very innovative and creative fashions, and the creation of some new and powerful mathematical tools with which to teach and think. All of these serve as strong indications that this is truly a fruitful area and one in which should see much growth and research over the next few years.

The Papers

This years mathematics papers tended to cluster around three major themes. The first of these themes might be thought of as Why do we do things we do? Papers that were classified in this area tended to feature the psychological and pedagogical implications of technology. They often were concerned with how we might take advantage of what we know concerning how best one can teach, how best students can learn, and how the technology can be used to enhance existing construction.

The second major theme concerned more content specific issues and might be thought of as What should we teach? These papers were often very specific regarding their mathematical content, occasionally to the extent of limiting their generalizability to other instructional settings. The central focus of these papers is what is it that we are going to teach. However, they serve as lovely reminders of the extent to which mathematics instruction can be enhanced via technology and a reminder of the growing maturity of the field. In reading this set it is fascinating to see the various pedagogical methods that were adopted.

The third theme was that of tool construction for instruction. This area might be thought of as What do we have to teach with? These papers describe some truly cutting edge and innovative efforts of interest to all mathematics educators. As I reflect upon the new methods and opportunities for instruction represented in this section I am convinced that a careful reading would make a technology using teacher educator out of the most die-hard critic.

Why do we do things we do?

These papers contained many important philosophical and logistical concerns. Common to nearly all of them, however, is the question of why should we teach in a technologically enhanced fashion and what does this change mean to our teacher candidates and to their eventual students. In Connell and Harnisch we read of the need for strong conceptualization within technology enhanced mathematics instruction - one could easily extend the argument to mathematics instruction in general. This paper describes why it is important that we do not abandon personalized individual understanding of concepts. Upon first exposure to educational computing many teachers
candidates comment that they no longer need to understand the concepts as the computer will bail them out. This is a dangerous perception and is addressed head-on in this paper. The model for interdisciplinary collaboration put forth by LaRose and McDonald reflects awareness of this concern. This paper describes a well-developed effort in using the World Wide Web as a method of instruction. Their rich descriptions of both the day-to-day usage and the manner in which they evaluated and assessed their project reflect a nicely developed set of ideas. In particular, there was an attempt to match the technological method to appropriate methodological approaches. As published here, this particular paper is a work in progress. I would encourage interested readers to attend their session at the conference. It will be exciting to see how their Fall and Spring semester turn out! It should be noted that this paper attempts to meet both the more rigid instructional design requirements and capture the fluidity and dynamic aspects of constructivism and social interaction.

Our next look at why we teach the way we teach is by Charnitski and Croop and offers beautifully developed discussion Vygotskian notions relative to computer enhanced mathematics instruction. Given the tendency of many technologically intensive courses to become depersonalized and machine-centered I feel that this is a very important paper. It describes in easy to understand terms some of the key issues of Vygotsky and his psychological theories. The notion of creating a collaborative learning space within a computer-enhanced environment should be must reading for all teacher educators. This important paper raises issues that we need to be looking at very carefully lest we find ourselves trapped with content delivery systems in lieu of interactive learning environments.

In Slough and Chamblee’s paper we read their approach toward implementation of technology in math and science at the secondary level. For those readers who are not familiar with CBAM, or the Concerns-Based Adoption Model, it would be well worth the time necessary for reading their theoretical framework section. The variation of CBAM used in this paper involves the five major stages and reflects the dynamic nature of the change process. A major finding from this paper is that CBAM model does address the perceived concerns of the teachers. We also find further examples of the use of technology to enhance and transdisciplinary work across content areas.

The last paper in this section comes from Pianfetti and Pianfetti and illustrates some absolutely beautiful work using the World Wide Web to teach in a new fashion. The study itself can serve as a template for other researchers and I was particularly impressed by their use of actual students in actual classrooms schools throughout the creation, design, and evaluation of their project. This paper could serve as a model for researchers wishing to field based their work.

**What should we teach?**

In the paper concerning Actions on Objects, Connell describes a methodological framework for the technological enhancement of mathematics education. In this paper we see examples showing the essential parallelism of this approach, together with the expressed notion that good thinking is good thinking regardless of what tools or developmental level might be used in its’ generation.

Bounieav deals with some of the psychological aspects of using information technologies in the second paper within this subsection. In this case to teach a very specific set of concepts from linear algebra. For past readers of the SITE mathematics section you are probably aware of Mikhail’s work - Step-by-Step Development of Mental activities (SSDMA). A major strength of this paper lies in its’ carefully delineated set of actions which derived from the mathematics itself. The instructions his examples are based upon are quite well worked out, in each case showing the operations underlying the mental activities that will later be built. This paper builds a strong case for the importance of doing some type of structural analysis concerning each new action that is to be developed. I find it to be a healthy suggestion. In some constructivist classrooms there occasionally exists the notion that every construction of meaning is of equal worth.

The next view of why we do the things we do in teaching comes to us from Coffland and Strickland. They report the results of a survey of variables related teacher technology and geometry. In reading this report a noteworthy point is that one’s attitude towards use of computers appeared to be independent of other types of characteristics such as a technology awareness, attitude, training or usage. Perhaps it is the case that one becomes an adopter of technology in the mathematics classroom because of other factors not related to formal instruction in educational technology. We also find evidence supporting a reluctance toward use. In particular, almost every respondent stated that technology required more time to learn and implement. Although the field has come a long ways, as we will later see in the tools to teach with section, there is still a need for streamlining the technology preparation process.

A further examination of how technology can be used to deliver course material is offered in Weston’s paper. The content in this case is a finite mathematics course and the technological tool was WebCT – an extensive set of tools created by faculty at the University of British Columbia. As we take a look at the types of tools contained within WebCT we see a rich set of communication tools, study tools, evaluation tools and management tools. I would encourage people planning on designing their own online course to take a careful look at this selection. The paper provides important details regarding the nature and organization of these tools well worth examining.
In Galminas and Autrey's paper we read of issues that emerge in the conversion of existing courses into a technology-based or technology enhanced course. The content in this case is that of College Algebra. Given College Algebra's place in nearly every curriculum it is clear that this paper should be read with great care. They correctly point out that technology comes in many different forms and one can be skilled in one form and not another. In planning such conversions it is likewise important to remember the differences in classroom interactions and the impact this plays on the mathematical cultures which is created.

The final paper in this section serves as a true bridge between the content and tools subsections. Knudsen’s discussion of the issues dealt with in developing online learning for middle school teachers serves as both a carefully written justification piece for reform based instruction and as a rich description of a potentially powerful resource for mathematics education. In this paper we see a notable example of interactive Web pages that serve dual roles as both manipulative and as resource textbook. It is also possible to observe a keen sensitivity between the mathematics content and the manner in which the technology is used to enhance its instruction.

Together, these papers each have a well-developed reason for teaching in the way in which they do. Technology clearly not just slapped on as an afterthought but is an integral part of the instruction. They serve as evidence to a growing maturation in terms of creating interactive learning environments for both student, teacher candidate, and practicing teacher/teacher educator.

**What tools do we have to teach with?**

The third and final group of papers deals with the tools which are now available and which technology enables for us to use in both teaching and learning. It is at this level that we often see the true power of the computer in terms of both representation and instruction most fully utilized. Connell begins with two parallel examples showing the student creation of a personally meaningful, computer-enabled, referent for their mathematics. These examples show that the objects we can create to think with significantly impact thinking. This influence is felt not only in what the content is about but also in terms of what might be done in teaching and learning. The concept that these objects can themselves have built-in intelligence is something that should not be lost upon the mathematics educator.

In Campbell and Fonthal's paper we can read how a specific tool was created for use to explore whole and rational number concepts. As examine how this was done it seems to have resulted in a good match between the need of the content and the pedagogical and teacher requirements. Indeed, what sets this paper apart is that the program that was created as a thinking tool was very carefully aligned with what is technologically possible and pedagogically important. I find the recommendations for designing future software packages to be quite informative and helpful.

In the Cannon, Heal and Wellman’s paper we see the fruition of a longtime dream which I sure many mathematics educators have shared in the creation of the library of virtual electronic manipulatives on the World Wide Web. These interactive web-based manipulatives are well worth the time it takes to visit. Needless to say www.matti.usu.edu has been bookmarked on my browser and I imagine that it soon will be on yours as well. It’s amazing to think that this is just a preliminary paper. I look forward to following this work as it grows over the next few years.

In Ostler and Grandgennett’s paper we see how Web pages can be used to teach mathematical modeling. In particular there some nice observations and suggestions in terms of instructional considerations. I find it very helpful to see that care was taken in terms of not only how we can use the computer to teach mathematical modeling, but also how do we teach the students. I heartily recommend this paper for anyone who is considering expanding their own mathematical models and representations as well as those considering the use of Web pages in the mathematics classroom.

In Bernard and Ramirez paper we see a beautifully expanded problem, *The biker and the nearby town*, as it is worked out with three different technological tools – Cabris Geometry, a spreadsheet, and a TI 83 calculator. It’s fascinating to observe how each of the tools to think with subtly and some cases quite blatantly influenced the problem solving approach which was taken. This paper offers a rare insight into the manner in which technology influences student thought and problem solving.

The final paper in this section by Katkov concerns a new tool currently under development for the graphing of functions. Although not immediate related to teacher education, per se, it appears to be a powerful tool that looks to be quite extensible. The screen shots and a list of the permitted actions serve to remind us that even at a highly abstract level in the technologically enhanced mathematics classroom it is possible to see a series of well-defined actions taken upon objects of well defined properties. This tool appears to be currently under development and not having had the opportunity of using the tool myself, I would do like to examine its’ robustness in an actual classroom setting.

**Concluding Remarks**

This year’s crop of paper serves to illustrate how far we have come in this interesting intersection of mathematics, educational technology, learning theory, psychology, and pedagogy. We are far beyond the early days of “let’s plug it in and see what is can do” and are well into integrating the
computer in the mathematics classroom. Furthermore, applications and methods are emerging which are not only pedagogically meaningful but also powerful from a mathematics perspective.

As we look to the future it is easy to envision classrooms where Internet connectivity is taken for granted, where every student has the expertise which was only held by experts in the previous year, and hardware and raw computational ability rivaling those of many research institutions of only five years ago. From this vision it is clear that we are in for some very exciting times ahead. However, despite whatever educational hardware and software we might have at our disposal we must bear in mind that in order for teachers to use these tools effectively they must understand the underlying mathematics.
A Case for Strong Conceptualization in Technology Enhanced Mathematics Instruction

Abstract. It is extremely important for students to develop strong concepts regarding the nature of the objects they are manipulating and how these objects are to be used mathematically. This is increasingly important when the objects with which one is thinking are themselves active – as is the case within a technologically enhanced mathematics classroom. This serves to further underscore the need for increased mathematical conceptual awareness on the part of our teacher candidates.

Introduction

Mathematics educators have long espoused the use of hands-on manipulative objects as being essential for children's creation of meaningful mathematical concepts. As a result of this long-standing commitment to their use many of these manipulative objects have become widespread and nearly universal in mathematics classrooms around the world. Through the years educators everywhere have come to understand many of the properties of these powerful objects to think with together with many strategies for their effective use and cautions for their abuse.

Today we are seeing the growing awareness and use of technology enhanced mathematical objects, many of which possess considerable “awareness” of their function and capable of offering suggestions to the learner concerning their own use. Little is known, however, of the emerging technology enhanced environment, where the very tools with which one thinks are active as well as interactive. This paper attempts to describe some of the potential difficulties I have observed over the years. I will further argue for the creation of a strong set of mathematically relevant understandings on the part of both teacher candidates and their eventual students in order to be effective learners within this new technologically enhanced mathematical culture.

Two types of mathematical objects

One of the first things which many teachers notice when using manipulatives is that they appeal to the children across a broad sensory array. A set of Dienes' Base10 blocks, for example, will simultaneously present to the student experiences with mass, density, smell, color, texture and so forth. And, although this is a part of the manipulatives appeal to the student, not all of these sensory experiences are beneficial to the construction of the eventual concept for which they were selected. Furthermore, traditional manipulatives - such as the Base10 blocks – will also serve to illustrate many other concepts than that for which they were originally created and in a similar fashion not all of these will be of benefit to the mathematics classroom.

[1] For a further discussion of this viewpoint see Symbolic Computers and Mathematical Objects by Michael L. Connell within these proceedings.
This is typically viewed as strength of the material and as an asset to the teacher. In this scenario, we have the potential to generate more than just the mathematical topic of the day. This is generally a very good situation to have as it provides much flexibility and great linking power in a given manipulative.

Of course this multifaceted presentation of a broad array of experience to the senses is not always a good thing. It is possible that these additional added features are actually seductive details that distract from the core mathematical concepts that we would hope are being developed. This leads to the observation that the narrowing of focus brought about via a sketch is the first step toward the later highly abstracted representations such as those utilized in the algebra. Remember Whitehead in "Process and Reality" when he states that "...every advance in human understanding is brought about via an advance in the symbol systems used to think with" (Whitehead, 1929).

The technology enabled manipulatives and sketches lack many of the multi-faceted features of the traditional manipulative and serve as an important step in such a concentration of focus. For example, I have long suggested that an excellent use of a computer based manipulative is as a Visual Representation of a previously encountered physical manipulative which had been used to teach an earlier concept (see Connell, 1988). In particular, one of the key differences between a computer manipulative and the real world manipulative upon which it is based lies in the degree of abstraction that occurs due to the use of the computer to generate the object of thought.

This is not such a strange idea for most teachers and teacher educators. In the case of mathematics quite often we are trying to teach a specific representation as opposed to a broad multiple uses of the manipulative. Thus as a domain we utilize standard representations such as Dienes blocks which are specifically constructed to carry a single meaning at the expensive other potential meanings which the material might be used for.

A Case for Strong Conceptualization

Due in part to this increased abstraction inherent in many computer enabled objects it is extremely important for children to develop strong concepts. There should be well developed understandings regarding what the objects they are manipulating are to be used for mathematically and how these objects are appropriately and inappropriately use. One analogy comes immediately to my mind is the smart wizards we see more and more of in Microsoft applications. I can envision a case where the technologically enabled objects that we provide for the children think with become more and more self aware.

To see how this might play out, let's imagine that we have identified two quantifiable sets that we wish to begin working on. Let us further imagine that we have identified various operations which it is possible to use on these two sets of objects and that they are of the same class such that the operations identified are appropriate. So the student selects a set addition object using the operating software and passes it the instruction to it to combine these two sets.

The set addition object - which has more then a bit of intelli-sense and wizardry (to use Microsoft terminology for a moment) - does the cybernetic equivalent of looking at the task ahead of it and then responds back to the student, "Are you sure that you really want to do this?" In order to be successful in this new environment the child has to know whether or not this really is an appropriate operation to perform upon these objects, whether or not he's asked the right object to do the job, and how to interpret the results that he or she will eventually receive.

This is not a fanciful example. Such scenarios are becoming all to common and indeed are more than a bit of a nuisance showing up all the time in intelli-sense technologies. For example, you can be writing a letter and before you can even finish the first paragraph the Wizard de jour will pop-up. "Hi there! It looks like you're trying to write a letter. How about I help you?" Typically I really don't want or need the help because it doesn't fit with either my writing style or the way I want to put this on paper. After all let's face it as an academician things are written differently all the time. For whatever reason, however, it's important to note that in this scenario I am the expert. I can override the suggestions of any object or Wizard when it's not inline with the tasks that I need to have done.

In this New World I'm envisioning, however, of computer enhanced mathematics and mathematics instruction via active objects this may not always be the case. Let's imagine that we are doing some integration and a wizard makes a suggestion on the boundary conditions over which to integrate which nine
times out of ten would be right. If your problem happens to fit the tenth condition and you succumb to the wizards’ advice in the face of your own lack of concept you are in major troubles.

This is problem occurs on a daily basis in computer programs commonly used in the statistical analyses of data. A very real problem has occurred as more and more researchers are getting access to higher and higher levels of statistical programs. In many cases programs such as SPSS and SAS will enable processing beyond the interpretive levels of the users. It is very common to find data sets that are spherical and never checked for, and post-op comparisons that are performed correctly but selected inappropriately. All of this because the tools given for the individual to think with were, in many ways, smarter than the people thinking with them. This trend is one that shows every tendency of continuing and accelerating.

This plays out with a vengeance in the educational arena. We are already able to design and implement intelligent objects with more “number-sense” than the beginning students who will be utilizing them will have. We are very close to being able to come up with objects to think with which are more intelligent then the people who working with them. This is not intended as a callused or a mean comment. We don't expect a tremendously high level of mathematical metacognitive knowledge at the first grade level. After all, the learner is just putting all this stuff together – in many cases for the very first time. So to return to our earlier example, it would be very easy to imagine a set addition object that basically says, “I will take any two numbers you give me and combine them using the operation of addition”. In terms of sheer processing power this could easily be at a higher skill level then the child using the object.

If we are to be effective teachers in this new technology enhanced environment we need to make sure that our students truly understand the concepts. If this is not done, all of our lovely correct answers are meaningless. This was a major concern in the calculator based reform effort of 15 years ago, it is even more crucial in the computer environment. Let us see why this should be the case. Using a traditional calculator you still had to plug everything in yourself – much like the old command line DOS interfaces or line-by-line BASIC compilers. The new computer environments and many of the newer calculators are becoming increasingly object-oriented. Therefore, it is entirely possible that we may end of having the terminal smarter than the user. I have always thought we were better off having dumb terminals and smart users in computing – without extreme care we will soon be facing the reverse.

Examining the Tools to Think With

The creation of new objects of thought or tools to think with can become very powerful pedagogical tools assuming we understand the concepts underlying them. The hidden danger surfaces when we cannot understand the underlying mathematical concepts upon which the active objects are operating on and we simply take them for granted, follow their recommendations blindly, and accept their results at face value.

This would be analogous to letting your writing be totally edited by wizards in your word processor. The following poem, which has enjoyed wide popularity among information technology faculty through the years, will serve to illustrate the dangers of such an approach.

**SPELL BOUND**

I have a spelling checker,  
It came with my PC.  
It plainly marks four of my review  
Mistakes I cannot see.  
I've run this poem threw it  
I'm sure your pleased too no,  
Its letter perfect in it's weigh,  
My checker tolled me sew.

Because of our in-depth knowledge of words and word usage it is easy to see the humor in this piece of writing. The errors are obvious and mostly harmless. If, however, we are looking at a
computational object which was created with a flaw in the underlying logic the errors are not nearly so obvious, harmless, or humorous.

Consider the following:

In this example it may not even be possible to identify the purpose for which the "object" was created, the assumptions that underlay it's creation, or the use to which it's results might be applied. The calculations are done correctly, of that we have no doubt, but to what use are they to be put? I am reminded of Douglas Adams Science Fiction classic "Life, the Universe, and Everything". In this classic text we learn that the answer to all of the truly deep problems of philosophy, metaphysics, etc., is actually 42. The difficulty is we do not know precisely what these questions are and in what form this answer fits.

Conclusion

In conclusion, the mathematics classroom of today is a far cry from that of 15 years ago. The technological objects upon which we act now routinely have intelligence built into them. If you made an error in using a slide rule, as was quite common when I was in school, all that would happen is that your result would be inaccurate. Today's intelligent objects have the potential notifying you of the error, suggest new options for you consider, and quite possibly lead you astray through giving information at a level which does not match with your understanding.

Ironically, the importance for understanding the underlying mathematical concepts in this scenario is significantly stronger than during the previous introduction of technology - the calculator. The calculator, despite the vast hue and cry of the time, proved to be a relatively benign intervention. Helping, as it were, with the numeric processing of skills and procedures that the child would have to construct, apply, and evaluate. The computer with its increasingly powerful objects of thought is a much more insidious problem.

On one hand it allows us to leverage our thinking tremendously forward through interaction with tools which themselves have rudimentary problem solving abilities. Furthermore, the natures of the data organization made possible through using technology lend themselves to types of approaches with known mathematical pay-off. On the other hand, however, we are in a very real danger of having our tools become more intelligent than the people using them. It is the responsibility of mathematics educators everywhere to ensure that our teacher candidates, teachers, and students are able to use the tools and not be used by them.

Faculty/Student Collaboration in Education and Math—Using the Web to Improve Student Learning and Teaching

P. Gavin LaRose, Math/CS Department

Abstract: In this paper we describe a model for interdisciplinary collaboration between students interested in teaching and faculty teaching courses in the students' area of study—math and education. This collaboration involves the education students in the development of Web materials, video recording of classroom activities, and development of rubric for pedagogy effectiveness. It has as its objectives: the enhancement of the education students' understanding and development of effective teaching strategies, including knowledge and application of instructional technology skills; the improvement of student learning in an existing course being taught by one of the collaborating faculty; and the enhancement of the teaching expertise for the faculty member teaching the course. These goals are accomplished through the use of the Web to provide immediate feedback to students in the class on topics that they find difficult, and through the faculty and education students' reflection on classroom dynamics through the use of digital video.

Introduction

The World Wide Web (or, more simply, Web) is rapidly becoming a ubiquitous feature of all aspects of society, including higher education. However, in the collegiate setting it is all-too-frequently used only to reproduce information that is available in other formats or media. Thus while it provides a new and effective vehicle for the dissemination of course information, it is difficult to determine whether its use is improving student learning. This is of increasing concern given the continual expansion of responsibilities felt by many university faculty, for whom adding Web page development to their repertoire may be part of a zero-sum game the loser in which is sleep. We are interested in the synergy afforded by the collaboration of faculty and students, especially those students interested in education, and the manners in which this cooperation may be used to enhance teaching and learning at the interrelated levels of the faculty member's course, the students learning in the course, and the education students' development as effective teachers. The involvement of the education students allows the distribution of the workload associated with the use of the Web and results in the students applying instructional technology skills acquired from a required education course, "Instructional Technology," which introduces them to a variety of educational software applications.

The use of the Web in this model has two interrelated parts, which are carried out with differing frequencies throughout the semester. First, it is used by the faculty member(s) teaching the course as a vehicle to respond to student confusion as expressed in specific classes through the use of a classroom assessment technique similar to the "Minute Paper" and "Muddiest Point" methods of Angelo & Cross (Angelo & Cross 1993). Second, it is used in conjunction with videotaped classroom sessions, taped by the education students, to similarly address students’ misperceptions and confusion. The videotaped sessions are discussed by the faculty and education students using a rubric on pedagogy (developed by both the math education students and both faculty members) to isolate areas of confusion, and the education students then develop Web materials to address these. In either part, the Web provides a unique and valuable vehicle for the dissemination of the information to be conveyed: it allows for a dynamic information base that may change on a more-or-less daily basis, and provides a universally
accessible resource for the information. Its use in this manner also allows these confusions to be addressed simultaneously with the usual progression of the course, thus avoiding the loss of the time in the classroom which is so often already in short supply. Finally, there are multiple levels of learning occurring as a result of the second component, as the students in the class are learning through the Web materials being developed and the education students are also learning through the discussions of pedagogy and development of these materials.

In the remainder of this paper we explain how we implemented this model, describe in greater detail the different components indicated above, describe the manners in which we assessed the success of the model, and draw conclusions as based on the results of the assessment in the Fall Semester.

Implementation

All of the activities described in this paper were implemented in the environment of a small (about 1500 full-time students), somewhat selective, liberal arts based university. Upper-level courses in both mathematics and education, the two subjects studied, are small (10-15 students large), as are even lower-level courses offered out-of-sequence. This has clear advantages in teaching, as well as disadvantages when it comes to assessing the impact that the methods we discuss here actually have.

We are implementing these uses of the Web in the Fall semester 1999 in a second semester calculus course in the mathematics department. In the Spring semester 2000, we apply the same methods to the "Secondary Methods" education course.

Day-to-Day Web Use

The "day-to-day" use of the Web to respond to students' confusion regarding the material covered in class was accomplished through a classroom exercise resembling the "Minute Paper" or "Muddiest Point" techniques in "Classroom Assessment Techniques" (Angelo & Cross, 1993). At the end of each class period, approximately five minutes were reserved for student consideration of the material covered during the preceding hour. In this time, students answered the questions "what was the central theme of this course period?" and "what about this was least clear?" in a couple of sentences each. These were collected by the instructor, who then reviewed the comments and, if appropriate, articulated a response. Appropriateness in this case was defined by whether a significant number of the students in the class expressed confusion on the same topic or posed questions that were of sufficiently general application as to merit a response.

The response articulated was implemented as a Web page designed to elucidate the material and resolve questions and confusions. The materials developed were limited to a single Web page per day.

Videotaping and Web Materials

Three classroom sessions were selected in advance of the commencement of the semester as being on topics that would prove especially difficult for the students taking the course. These class periods were videotaped by the education students involved in the project using a digital video camera. The faculty and education students then watched the video later in the day and assessed the effectiveness of the class presentation, degree to which the instructor accurately adjusted to the classroom dynamics, and areas that were particularly confusing to the students in the class. As a vehicle for this assessment, a rubric was cooperatively developed by the students and faculty to evaluate the instructor's teaching method, effectiveness of questioning, assessment of students' understanding, and class organization. This rubric appears in an appendix.

Following this discussion and assessment, the faculty and education students determined what type of Web-based materials would be appropriate to resolve those issues left 'hanging' by the classroom presentation. These include demonstrations, excerpted sections of the videotape with further explanation and references, text and graphical instructional pages, and links to other on-line resources providing background information for the topic being covered. The outline of the mathematics and substance for the materials was determined in advance by the faculty and education students, collaboratively, and the actual pages were then developed independently by the
education students. Excerpts from the video were obtained through video editing Final Cut, MotoDV and included in the resulting Web pages, and the resulting materials reviewed and posted by the faculty member on a class website.

The technology skills of math education students were gained in Education 187 "Instructional Technology" and the development of this project allowed these students to apply these skills. In addition, these students were able to analyze the role and impact of interactive video and website development. This approach supports the Davis' (1999) principles for technology in teacher education including “...students should experience innovative technology-supported learning environments in their teacher education programmes” (p. 9).

Assessment

This project has three primary goals, namely, 1. the promotion of the education students' awareness of effective teaching strategies and the use of reflection and assessment in the development of the same, 2. the improvement of student learning in the courses involved with the project as a result of the use of the Web to provide "immediate" feedback on difficulties encountered with specific course topics, and 3. the enhancement of faculty teaching expertise. In order to determine the degree to which these were accomplished in the course of our work, several assessment instruments were employed. However, the assessment of any of these objectives is constrained by their inherently qualitative nature and by the small size of the classes and small numbers of education students involved, and we are therefore constrained to use generally indirect measures to determine our success in accomplishing them.

To assess the first objective, the education students each developed in the course of the semester a portfolio describing their thought processes at the beginning and end of the program, as well as their reflections on the nature and success of each of the videotaping sessions. They were provided with a number of prompts to which to respond, as described in the appendix. Samples of the students' entries are also included in the appendix. The reflections in these by the students and the assessment of the cooperating faculty members of the students' portfolios and their overall development were used to obtain a picture of the effectiveness of the project in accomplishing this goal.

The second objective is assessed through three different measures. First, we surveyed the students in the course at the beginning, middle, and end of the semester to determine their perception of the effectiveness of the course and usefulness of the Web materials produced. Second, the quality and relevance of the materials were evaluated by the faculty in the program at the end of the semester, taking advantage of knowledge of the difficulties students experienced on homework and exams. And third, we monitored the number of "hits" on the course Web throughout the semester, assuming that a continued or increased number of hits as the semester wears on is indicative of perceived value by the students. It is worth observing that while we would prefer to have more direct measures of the success of this objective it is difficult to obtain them in the face of the size and number of courses taught at a small university. We have therefore instead used these measures of effectiveness of the materials rather than try to directly assess the improvement of student learning.

The third objective suffers from the same difficulty in assessment as the second, for the "faculty teaching expertise" that we seek to enhance should be measured in improved student learning. As noted above, this is notoriously difficult to determine, and we therefore used subjective assessment measures to determine its success, having the education students and faculty member who was not teaching the course evaluate the instructor's effectiveness using the rubric developed for the examination of the videotapes and through general reflection.

While it is not within the scope of this paper, the most significant assessment of the impact the program had on the education students involved in it would be an examination of those students' teaching (ideally, as compared with the teaching of students who did not participate in the project). This is again complicated by the small numbers of students in the program, but we look forward to being able to evaluate this as the education students do begin their student teaching, at the end of their university experience.

Results

Because we are still in the process of the first semester in which this program has been implemented, final results of the assessment program described above are not available here and will be presented in the conference presentation. In particular, the portfolios and faculty teaching assessments require the comparison of results from
the beginning and end of the semester, the latter of which are not available at this time. Similarly, complete results from the surveys of the students in the class are unavailable. We are, however, able to provide the preliminary results from the midterm surveys, which are positive.

In the midterm survey given in the Fall, students in the calculus class indicated that they were using the Web materials (with a majority indicating periodic or regular use, and 100% using it when an assignment referring to the materials was given). When asked to rate the usefulness of the materials on a four point scale (0=not useful, 4=immensely useful), they gave an average score of 3.13 (with some students simply responding “yes,” it was useful; no students gave the materials less than a 2 in their rating). In addition, the number of hits on the Web pages did increase in successive months of the semester, from an approximate rate of 3 hits per student in the class in the first two months to approximately twice that in the last two. This provides some material evidence that the Web pages were perceived as useful by the students in the class. Further results will be presented at the SITE Conference on 1999 Fall Semester work as well as initial research in 2000 Spring Semester.

Conclusions

We have discussed an innovative, collaborative method of using the Web to respond directly to students’ misperceptions and confusions as they take a class. The course primarily discussed here was second-semester calculus, but the method is applicable to courses in any area, and will be implemented for a course in secondary education methods in the Spring semester. In this method, we have involved faculty from our education and mathematics departments, as well as students who are studying mathematics education, to promote interdisciplinary learning at multiple levels—in the classroom, by the education students involved in the program, and by the faculty teaching and observing the class. Results from assessment of the method provide evidence that these goals are accomplished. The use of the Web is in integral to the project, as it provides a universally accessible medium that admits frequent addition of material on a regular basis and is an instructional technology to which the education students will both have access and be expected to use as they begin their careers.

Appendix

Assessment rubrics and materials are included in this appendix. The assessment rubric used to evaluate the videotaped class sessions is shown in figure 1, below. Note that the columns 3-5 headed in the second row should follow to the right of the first row in the table.

**Figure 1:** Class assessment rubric.
The prompts given to the education students at the beginning and end of the semester, and following each of the videotape discussion sessions, are shown in figure 2.

At the beginning and end of the semester:
1. Outline a classroom lesson on a topic that you would expect to teach following your graduation or when you student teach.
2. Comment on the terms “assessment” and “feedback.” In particular, what do you think about when you hear them? And how do you think they are related to teaching and the classroom.
After each videotape session:
3. Comment on what happened in the classroom and in the development of the supporting materials.
4. What key ideas or issues relating to teaching did you encounter in the course of working on this part of the project?

Figure 2: Portfolio prompt questions.

Samples of student responses to these prompts (prompt #2) are shown in figure 3.

Student response one—“When somebody uses the terms assessment and feedback, the first thing that comes to mind is tests! However, there are many other things that are involved with assessment and feedback besides just testing. First of all, assessment is….”

Student response two—“Feedback: The information students give to their teachers that convey confusion, also not always verbal. Things as simple as seating arrangements or eye contact can be considered a type of feedback for a teacher…Assessment and feedback work together in a well-organized classroom”.

Everyone was really well engaged in the discussion and development of the rubric. It looked like everyone had fun with it, too”.

Figure 3: Sample portfolio responses.

fcroop@miseri.edu

Abstract. Many elementary teachers lack the conceptual knowledge needed to teach even basic mathematics and thus create a weak link in the chain of mathematical learning for students. The sociocultural theory of L. S. Vygotsky may offer direction for the design of a concept-building mathematics experience for elementary education majors. Computer supported collaborative workspaces have the potential to support and enhance a Vygotskian approach to mathematics learning for the preservice teacher.

Introduction

According to Rech, Hartzell and Stephens (1993), the quality of teaching at the elementary level is a critical factor in the future mathematical success of the student. High quality teaching is heavily dependent upon the teacher's conceptual knowledge of the subject matter. Yet, when questioned, many elementary teachers communicated a sense of personal inadequacy in mathematics and a lack of confidence in teaching mathematics (National Science Board, 1998; Stepans et al., 1986). Simon (1993) demonstrated that teachers who do not possess solid understanding of mathematics principles are unable to teach mathematics in a conceptual manner. Simply stated, teachers cannot teach what they do not know.

The competency of those who are teaching elementary level mathematics has long been questioned (e.g., Ball, 1990; Glennon, 1949; Zaslavsky & Peled 1996). Research conducted by Zazkis and Campbell (1994) supported the general claim that elementary teachers often possess weak content knowledge and insufficient conceptual understanding to teach mathematics. Rech, et al. (1993) found that "...the elementary education majors possessed deficits in almost all knowledge and content areas in mathematics when compared with the established norms of a general college population" (p.144)

Assuring that prospective teachers possess adequate mathematical content knowledge should be a primary concern in the preparation of elementary teachers; however, it is an area that continues to be neglected. Monroe (1984) stated that the mathematics education of elementary level teachers was less than adequate "by whatever standards are used" (p.23). Leitzel (1991) contended that the weakest link in the nation's system of mathematical education is the mathematical preparation of elementary teachers. According to Hungerford (1994) colleges and universities have done little to remedy the weak backgrounds of pre-service elementary teachers; "...the lack of attention being paid to mathematics courses for prospective elementary teachers is astounding" (p.16).

Teachers' mathematics backgrounds are particularly relevant in light of the research that suggests that a teacher's academic background (i.e., both level of courses and grades earned) may be related to student outcomes (Chaney, 1994). In 1985 Galambos et al. documented a pattern that reflected the absence of college-level mathematics requirements in teacher education. There is no indication that this pattern has changed.

Courses in pedagogy influence how preservice teachers think about teaching and learning mathematics. Yet, merely training teachers in mathematics pedagogy appears to be insufficient. Chaney (1994) demonstrated that mathematics pedagogy provided added benefit for teachers only if they possessed adequate mathematical concepts. Attending to mathematics teachers' beliefs about teaching and learning is unproductive when content knowledge is absent (Brown, Cooney, & Jones, 1990).
Advocacy for a combined content-methods mathematics course in teacher education is not new (Berg et al., 1993; Glennon, 1949; Heddens & Speer, 1997; Reisman, 1981). The combined content-methods approach recognizes that pre-service teachers may not possess the content knowledge and understanding needed to competently teach elementary mathematics. This curriculum emphasizes: (a) building a strong background understanding of mathematics concepts that are taught in elementary programs; (b) addressing and replacing misconceptions with conceptually sound knowledge; (c) reducing teacher anxiety and increasing teachers' self efficacy relative to doing mathematics; (d) demonstrating appropriate mathematics strategies and methodologies.

Conceptual learning differs from the rote memorization of facts and procedures (Bruner, 1963, 1971; Piaget, 1971; Vygotsky, 1986, 1997) that have historically characterized most mathematics classrooms (Cuban, 1984). Assuring conceptual knowledge of mathematics in preservice teachers will require change in both the learning environment and the emphasis of instruction. The socio-cultural-historical theory of learning proposed by Vygotsky (1986) may offer guidance in creating such an environment.

Vygotsky's Theory of Socio-Cultural Learning

Vygotsky's sociocultural theory of mind serves as a middle ground between formalism and constructivism (Kozulin, 1990; Minick, 1987; Moll, 1990; Vygotsky, 1986; Wertsch, 1985). According to his theory, concept formation is a dynamic interaction between the concrete and the abstract; neither requiring the learner to reinvent information, nor expecting the learner to conceptualize abstractions without first engaging in concrete activities that support the formation of mental models. Vygotsky proposed several key ideas relative to the levels and types of concept formation, the role of language and collaborative interchange in concept development, and the characteristics of an instructional environment that guide and promote mature concept development. Vygotsky viewed the ultimate goal of the learning process as the development of mature concepts which are characterized by the learner's ability to: (a) synthesize abstracted traits; (b) use the resulting abstract synthesis as his or her main instrument of thought without any reference to the related concrete situation or impression; and (c) use the concept in the formation of judgments and new concepts.

Language.

Language, and its relationship to thinking, is at the foundation of Vygotsky's theory (Vygotsky, 1986). Vygotsky regarded language as an indispensable requisite for all intellectual growth. He asserted that the merging of practical intelligence with a system of symbolic representation (i.e., speech) is the essence of complex behavior (Vygotsky, 1978). According to Vygotsky (1978), speech has a particular organizing function that when combined with tool use produces fundamentally new forms of behavior. "...the most significant moment in the course of intellectual development... occurs when speech and practical activity, two previously completely independent lines of development, converge" (p. 24).

Two critical observations Vygotsky (1986) made were that: (1) the role of speech is equally as important as the role of action in attaining a solution to a problem; and (2) as situations demand more complex and indirect actions in finding a solution to a problem, speech plays a more important role in the solution process as a whole. Speech acts to organize, unify, and integrate the many aspects of the learner's behavior including perception, memory, and problem solving (Vygotsky, 1978).

According to Vygotsky (1986), individuals negotiate meaning and form concepts through verbal interactions with more knowledgeable others and by sensory interaction with their culture. Vygotsky noted that the mere association of words with objects does not imply concept formation and suggested that concept formation begins with a problem that cannot be solved other than through the formation of new concepts. The attainment of a true concept results in a qualitatively new type of thinking, therefore, merely quantitatively increasing associations of words with physical objects would never culminate in the higher intellectual activity that is characteristic of mature concepts (Markova, 1979; Moll, 1990; Ratner, 1991, 1997; Vygotsky, 1986; Wertsch, 1985). Vygotsky considered the defining moment in concept formation to be the point at which the learner is able to use words as functional tools to facilitate communication, understanding, and problem-solving.

Spontaneous and Scientific Concepts

According to Vygotsky (1978, 1986), conceptual development does not occur in a vacuum, nor does it develop in a one dimensional, linear fashion. Vygotsky viewed concept formation as a multidimensional interaction of the child’s social, historical, and cultural development. This view of concept development
considers the concept itself as being qualitatively more than the sum of its individual parts (Davydov, 1990; Forman, Minick, & Stone, 1993; Ratner, 1991; Vygotsky, 1986; Wersch, 1985).

Vygotsky identified two different types of concepts; spontaneous concepts and scientific concepts. Spontaneous concepts are those concepts that result from an individual's everyday exposure to his or her social and cultural environment. Typically, spontaneous concepts are unsystematic and highly contextualized. Scientific concepts are grounded in mediated instruction and are characterized by hierarchical, logical organization. Vygotsky (1986) proposed that spontaneous and scientific concepts differ in their development as well as their functioning, yet these two variants of the concept formation process influence each other's evolution.

Zone of Proximal Development
Vygotsky (1978) identified a construct that he called the Zone of Proximal Development (ZPD) which he defined as: "...the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers" (p.86). An individual's movement through his or her ZPD requires a mediated environment that is rich in verbal communication and collaborative exchange (Forman, Minick, & Stone, 1993; Vygotsky, 1997; Wersch, 1985). Vygotsky (1986) stated that an individual's progression through his or her ZPD involves intelligent, conscious imitation, which requires an understanding of the field structure and the relationship between objects. Vygotsky and Luria (1993) cautioned that imitative behavior that is characteristic of movement through the ZPD should not be confused with automatic imitative behavior that shows no signs of conscious understanding.

Implications for Instruction
Vygotsky's theory clearly supports a mediated, collaborative classroom environment. He asserted that every function in cultural development appears twice "...first on a social, and later on the psychological level; first between people as an interpsychological category, and then inside [the learner] as an intrapsychological category" (Vygotsky, 1978, p. 128). According to John-Steiner and Souberman (afterward in Vygotsky, 1978) teaching represents "...the socially elaborated contents of human knowledge and the cognitive strategies necessary for their internalization" (p. 131). In the socio-cultural context, instruction should be configured not so "...that the student is educated, but that the student educates himself" (Vygotsky, 1997, p. 48) through the social negotiation of meaning.

Socio-cultural learning environments stand in contrast to traditional classrooms that historically have made little use of socially shared tasks (e.g., Cuban, 1984; Ferraro, Rogers, & Geisler, 1995; Wilson, Teslow, & Taylor, 1993). Learning environments consonant with Vygotsky's theories facilitate collaborative student engagement in: (a) the active process of sense-making through meaning negotiation; (b) the use of shared signs (i.e., speech) and symbols (i.e., objects of meaning representation) as cognitive tools for concept development; and (c) multidisciplinary approaches to learning that reflect the learners' social, cultural, and historical context.

As an instructional tool, computer-mediated-communications (CMC) have the potential to support the learning outcomes, orientation of instruction, and underlying pedagogical beliefs espoused by Vygotsky. Jonassen (1996) classified CMC as a knowledge representation tool that may engage learners in critical thinking activities. He contended that CMC has the potential to involve students in active learning that is built on cumulative (i.e., prior) knowledge, and supports integrative, reflective, goal-directed and intentional learning. Current technologies, particularly functions of computer networking, provide a mechanism for developing collaborative environments that transcend the constraints of time and place, thus increasing students' opportunity for socially supported engagement (Laffey, Tupper, Musser, & Wedman, 1998; Reeves & Reeves, 1997; Riel, 1996; Romiszowski, 1997).

Computer Supported Collaborative Learning Space Environments
Computer-mediated communications (CMC) is a general term used to define any form of organized interaction between individuals or groups of individuals that facilitates and/or mediates communication utilizing computers or computer networks as the medium of communication (Hawisher, 1995; Kahn, 1997; Jonassen, 1996). CMC includes both synchronous and asynchronous communications. Synchronous communications are those that take place when two or more individuals communicate simultaneously over a network (real time), while asynchronous communications are those that do not require concurrent communication (delayed).
CMC is a medium that can be used to more closely link collaborative classroom experiences with formal instruction to create a highly student-centered learning environment (Jonassen, 1997; Riel, 1996). Results from studies suggest that teachers in a traditional classroom contribute up to 80% of the total in-class verbal interaction, whereas the total verbal contribution of teachers using CMC conferencing techniques is between 10-15% (Reil & Harisim, 1994). Curtis and Reynolds (1997) found that CMC-based interchanges resulted in more frequent exchanges between students and Scott (1993) demonstrated that students working within groups via CMC participated more evenly, and accomplished more task objectives than students not using CMC. CMC mediated environments often decrease the students' inhibitions to participate, while increasing student opportunity for reflection and knowledge accommodation (Romiszowski, 1997). This medium also offers a high degree of learner control, a wide range of environmental flexibility, and global connective capabilities (Kahn, 1997; Relan, & Gillani, 1997) that support both formal and informal learning environments at various interactivity levels (Hiltz, 1994; McLellan, 1997).

Groupware

Groupware is any type of software designed for group work or group communication. Organizational and educational trends toward increased teamwork along with the availability of networked computing has stimulated the development of computer supported collaborative workspaces (CSCW) as a means of supporting tasks carried out by participants who are physically or temporally removed from one another (Brinck, 1998; ter Hofte, 1998). Ter Hofte (1998) used the term "working apart together" to describe the essential nature and function of groupware systems. The types of groupware that may prove beneficial to preservice mathematics learning include: (a) computer conferencing systems; (b) chat systems; (c) workflow management systems; (d) shared whiteboards; and (e) coauthoring systems.

Computer conferencing systems (also known as bulletin boards) can be regarded as a variation of electronic mail (e-mail) systems. E-mail systems support interpersonal communication by sending computer mediated messages to one or more persons, while computer conferencing systems facilitate the transference of messages to a uniquely identified address or location on the Internet (URL) that is devoted to discussion about a particular topic. Conference areas allow individuals to post and to retrieve information just like they might do on a physical bulletin board. Early conferencing systems supported only textual messages, but current systems support the posting of other types of documents, such as word processor documents, spreadsheets, graphics, etc.

Chat systems provide synchronous text-based computer-mediated discussions between and among users. Discussions take place through rapid turn-taking entries by the participants. These systems provide "live" interpersonal communication for an arbitrary number of users who are connected via personal computers.

Workflow management systems have embedded workflow cooperative tasks models that coordinate actions by users by prompting the appropriate contributions at the right time by the right users. These systems can also track the progress of the workflow, provide relevant information required for particular actions, and block information entries that contradict the model.

Shared whiteboard systems are designed to support text, drawings, and sketches that are often shared at formal and informal meetings to point out particular items, clarify relations, or illustrate complex materials. Objects drawn in the shared workspace are immediately visible for all other users. These systems allow all participants to simultaneously refer to such illustrations, propose modifications by altering the drawing, or add textual comments. Entries can be saved and distributed.

Co-authoring systems are designed to support multiple users in creating a collaborative document. Classes of co-authoring systems support diverse phases of the writing process such as brainstorming, researching, planning, writing, reviewing, editing, and revising. These systems facilitate communication between authors and assist the coordination of the authoring process.

Conclusions

There is a documented need for mathematics reform in preservice teacher education. A long history of research suggests that preservice mathematics methods courses must play a dual role of delivering content in the form of reeducating students in basic mathematical concepts, and instructing students in pedagogy that supports concept development. Vygotsky's theory appears to offer guidance for structuring a learning environment that facilitates conceptual learning and promotes sound methodological strategies.
Among the roadblocks that may hinder change in preservice mathematics reform are internal institutional issues such as curriculum reform and time limitations imposed by course instructional hours, scheduling conflicts, required field work, and the length of school terms. Applying Vygotsky's theories to the application of computer-mediated collaborative workspace may help ameliorate problems associated with these issues. Computer supported collaborative work-spaces have the potential to add dimension to an existing course by extending facilitated collaboration beyond the limited classroom hours. The combination of synchronous and asynchronous communication options opens the possibility for student engagement in collaborative enterprises that otherwise may have been impossible because of distance and scheduling conflicts.

Networked technology and various categories of groupware systems offer a new spectrum of tools that, with proper implementation, may prove useful in preservice mathematics experiences. The inherent communicative nature of these tools is compatible with the underlying tenets of both Vygotsky's theories and the goals of the content/methods curriculum. As a tool, computer supported collaborative workspace has the potential to incorporate the extended boundaries of the student's social and educational milieu, thus providing an environment conducive to the application and generalization of knowledge.

Implementing Technology in Secondary Science and Mathematics Classrooms: A Perspective on Change

Scott W. Slough, Department of Early Childhood Education and Reading, Georgia Southern University, Statesboro, GA 30458 USA, sslough@gasou.edu

Gregory E. Chamblee, Department of Middle Grades and Secondary Education, Georgia Southern University, Statesboro, GA 30458 USA, gchamblee@gsvms2.cc.gasou.edu

Abstract: The purpose of this paper is to examine and describe the change process as technology is implemented in secondary science and mathematics classrooms. This paper synthesizes the results from two studies, a qualitative study on implementation concerns of secondary science teachers resulting from the use telecommunications (Slough, 1998) and a quantitative study on technology implementation concerns of middle and secondary mathematics teachers and potential teachers of first-year algebra in North Carolina (Chamblee, 1996). The Concerns Based Adoption Model (CBAM) provided a theoretical framework for both studies.

This paper synthesizes the findings from two studies, a qualitative study on implementation concerns of secondary science teachers resulting from the use telecommunications (Slough, 1998) and a quantitative study on technology implementation concerns of middle and secondary mathematics teachers and potential teachers of first-year algebra in North Carolina (Chamblee, 1996). Both studies used a Concerns-Based Adoption Model approach to frame data collection and analysis. Commonalities and differences from separate content areas—math and science—and separate methodologies—qualitative and quantitative, were analyzed in an effort to triangulate data and findings. From this approach, commonalities that exist across content and methodologies are strengthened and differences that exist point to possible content specific idiosyncrasies or need for additional corroboration. Thus, by comparing and contrasting the findings from the two studies, a more complete picture on implementation concerns for math and science teachers with respect to technology emerges, including a more holistic picture of the technology-based change process.

Theoretical Framework

The implementation of technology will require change in the classroom. One model that has been utilized to inform the decision-making process when innovations are introduced is the Concerns-Based Adoption Model (CBAM). CBAM states that successful implementation of an innovation is a process not an event (Hall & Hord, 1987; Fullan, 1991; Friel & Gann, 1993), developmental in nature (Hall & Hord, 1987), and a highly personal experience for each teacher (Hall & Hord, 1987). Thus, for any change to be successful the concerns of each individual teacher must be considered as important and their individual needs must be met.

Hall, George & Rutherford (1986) define concerns as the feelings, thoughts, and reactions that individuals have about an innovation or a new program that touches their lives. To measure these concerns, Hall, Wallace & Dossett (1973) developed the Stages of Concern Questionnaire (SoCQ). Initial research on the instrument construction verified the existence of seven stages in the concerns process: awareness, informational, personal, management, collaboration, and refocusing, with internal reliability for individual scales ranging from r=0.64 to r=0.83 (Hall, George & Rutherford, 1986).

Bailey and Palsha (1992) proposed a modification of the CBAM model to include only five stages: awareness, personal, management, impact, and collaboration. The awareness stage is characterized by teachers having little knowledge about the innovation but interested in learning more about it. The personal stage is characterized by teachers who are primarily concerned with how the innovation will affect them, with a specific focus on required changes in roles and tasks. The management stage is characterized by teachers who are primarily concerned with time management, organization, and prioritization of responsibilities. The impact stage is characterized by
teachers who focus on the effects of the innovation on learners and how this innovation can be used to change or improve learning. The collaboration stage is characterized by teachers who focus on working with others to implement the innovation as well as sharing information about the innovation with other teachers.

Data Sources

Data for the qualitative study (Slough, 1998) of secondary science teachers' concerns was collected through open-ended ethnographic interviews of twenty-four high school science teachers who had been in an emerging telecommunications-rich environment for at least two and one-half years as of the Fall Semester, 1997. The Bailey and Palsha (1992) five stage model was utilized to frame the analysis. The emerging telecommunications-rich environment was defined as including a district-wide infrastructure that had been in place for two and one-half years that included 24 network connections in each classroom, full Internet access from the network, four computers per classroom (teachers were required to attend training before receiving), and a variety of mandated and optional professional development opportunities within and outside the district. The teachers were from a single, large, suburban school district with five high schools. Teachers in the study were well distributed across each of the five high schools, across typical high school science courses, across all levels of educational attainment, and included fairly new to veteran teachers. Research questions focused on teacher and students' use of telecommunications, barriers and supporting conditions to telecommunications implementation, and the effect of telecommunications on the teaching and learning of science.

Data for the quantitative study (Chamblee, 1996) on first-year algebra teachers' concerns was collected using the Stages of Concern Questionnaire (SoCQ) by Hall, Wallace & Dossett (1973). A total of 132 middle and secondary mathematics faculties from 72 North Carolina school districts were mailed the Stages of Concern Questionnaire (SoCQ) and a teacher demographic data questionnaire during March, 1995. The SoCQ is a 35 item Likert-scale instrument that contains seven levels of responses. The teacher demographic data questionnaire consisted of 19 questions designed to obtain information in three areas: (1) standard demographic data such as age, gender, degree, years of experience, (2) teachers' school experiences such as current teaching load, and (3) teachers' technological experiences such as computer workshop experience, graphing calculator workshop experience, and in-class technology teaching experience. A total of six hundred and sixty surveys were mailed. Two hundred and sixty-six surveys were returned, with one hundred and fifty-one surveys from current teachers of first-year algebra.

Initially, SoCQ mean stage scores and total concerns score were calculated for each respective subgroup. To determine overall concerns, two analyses were performed. First, mean stage scores were converted to percentile ranks based on the norms presented by Hall, George & Rutherford (1986). Second, a peak stage score analysis was calculated. Peak stage scores are defined as the stage at which an individual has his or her highest percentile rank score on the seven concern stages (Hall, George & Rutherford, 1986). Analysis of variance (ANOVA) was utilized to determine differences for each mean stage score and overall total concern scores. Step-wise regression analysis was utilized to determine possible predictors for each of the seven stage scores and total concerns score.

Results

Results of the qualitative study (Slough, 1998) of secondary science teachers' concerns are summarized in Table 1. The data were analyzed vertically and horizontally: more succinctly, each interview was read in its entirety and then across each individual question. The data were grouped into CBAM stages by specifically looking for particularly enlightening themes, recurring ideas or language, and tacit descriptions of the social culture of the emerging telecommunications-rich high school science classroom. These themes evolved into the unique descriptors found in the summative descriptors.

results of the quantitative study (Chamblee, 1996) of secondary mathematics teachers also generally supported the CBAM model. Teachers had their highest concerns at the lowest developmental levels (awareness and information) and their lowest concerns at the higher developmental levels (consequence and collaboration). Several reported teacher characteristics portrayed teachers of first-year algebra as very involved with integrating graphing calculator technology into first-year algebra. First, over 50% of the teachers rated themselves as better than novices at using the graphing calculator. Second, most teachers stated that they have been using graphing calculators in their classrooms for several years. Third, approximately 81% said that they had been exposed to some in-service training. But when teachers' SoCQ concerns profile was compared with the self-reported teacher characteristics, there was a contradiction between self-perceptions and actuality. Teachers considered themselves to be competent users of the graphing calculator. The overall concerns profile analysis generated a non-user profile. Only 52% had progressed beyond the awareness and information concerns stage (considered awareness stage in the Bailey and Palsha Model), which are the lowest developmental implementation stages.

ANOVA results demonstrated that female teachers of first-year algebra had lower overall concerns than male teachers of first-year algebra, which means female teachers were more likely to implement graphing calculators than male teachers. Personal concerns differed according to age. Specifically, teachers in their twenties and forties had lower concerns related to graphing calculator proficiency for the lowest stages. Gender, age, graphing calculator expertise rating and graphing calculator training had a significant relationship to teacher concerns. All significant relationships were at the lower stages, awareness, information, and personal (awareness and personal stages for the Bailey and Palsha Model). No significant characteristics for higher level concerns were found.
Stepwise multiple regression analysis found few predictions of the seven stage scores and total concerns score. At the awareness stage, graphing calculator training, graphing calculator expertise rating, gender and years of teaching experience were significant predictors. At the information stage, graphing calculator expertise rating, number of years using microcomputers in mathematics teaching and years of teaching experience, were significant predictors. For the personal stage, graphing calculator expertise rating was the only significant predictor. For the refocusing stage, graphing calculator access was the only significant predictor. Finally, for total concerns score, only graphing calculator expertise rating was a significant predictor.

Finally, the results of the study indicate that teachers of first-year algebra were beginning to focus more on the universal consequences of graphing calculators in the classroom. Many teachers reported that they are becoming proficient at using graphing calculators on their own and not through in-service. But, in actuality, all of the teachers in this study were still focused on the lowest levels of concern (awareness, information, and personal).

Conclusions

These studies show that: (a) math and science teachers can implement technology if they are given adequate resources, including copious access to the technology and a variety of formal and informal professional development; (b) even with access to the new technology and a variety of formal and informal professional development, most math and science teachers had not progressed to adoption; (c) the Concerns-Based Adoption Model (CBAM) addresses many of the perceived concerns of the teachers; (d) gender, age, and technology experience/expertise were not generally found to be adoption determinants; (e) the non-static nature of technology adds to teacher concerns; (f) teachers can and do decide not to implement technology in their classroom; and (g) a new change model that incorporates changing innovations and non-progress to adoption needs to be explored (Slough, 1999).

Science teachers were able to implement telecommunications at the two highest stages. They were able to accomplish this in a relatively short period of time when the combination of available technology, formal, and informal professional development were all in place. Of these three, the formal professional development was considered least important to teachers who had begun to successfully implement telecommunications. To a lesser degree, math teachers were able to implement graphing calculators at the highest levels (a smaller percentage of math teachers reached these stages). This is possibly due to the fact that less informal professional development opportunities were present. Regrettably, the majority of math and science teachers had not begun to implement technology after several years. According to the concerns-based approach, this is due to the fact that their individual concerns had not been met. But, both studies identified individuals who had made the decision not to adopt. This is significant because, CBAM does not factor in an individual’s decision to not adopt.

Although age, gender, and technological proficiency were found to be statistically significant for mathematics teachers when using graphing calculators, the significance was only found at lower stages and were not found to be predictors at higher stages (Chamblee, 1996). In other words, males and females, young and old, and novice and expert alike were able to implement technology in both studies. In fact, Slough (1998) reported that female teachers comprised half of the teachers at the highest stages of adoption and that all of the teachers at the highest stages had taught at least six years. Technological proficiency was over reported by mathematics teachers based upon the CBAM model (Chamblee, 1996) and at least two of the four science teachers at the impact stage were relative newcomers to technology who had found telecommunications to be worth the effort to learn.

In general, the basic assumptions of CBAM were supported by both studies (Chamblee, 1996; Slough, 1998). Teachers at different stages of the implementation of technology did have different concerns; and further, teachers at similar stages of implementations did have similar concerns. Two observed shortcomings of CBAM as a theoretical framework for each study were CBAM assumes a static innovation and all individuals progress to adoption. Technology is not a static innovation. Teachers at all levels reported that one of the difficulties with implementing technology was that it was always changing, in effect constantly creating a new innovation. Also, CBAM assumes a general linear model where teachers go through each successive stage. There are no accommodations for individuals who reject an innovation. Both studies identified individuals who had, or appeared to have, rejected technology and were not progressing to adoption. The need for a change model that addresses the challenge of implementing changing innovations and non-progression to adoption must be explored.
Significant findings found in the study of science teachers (Slough, 1998) not found in the study of math teachers include: (a) administrative support, particularly from the building principal, is perceived by teachers to be a critical factor; (b) safety concerns, particularly related to wires and cables in and around sinks in science labs presents an additional safety concern in science classrooms that may not be present in other classrooms; and (c) loss of precious laboratory space, particularly related to loss of bench top space presents an additional concern in science classrooms that may not be present in other classrooms. Teachers perceived the support by the principal to be a primary concern. Where teachers perceived the principal to be supportive of telecommunications, teachers were more likely to adopt. Where perceived support was lacking, teachers were less likely to adopt. Lack of corroboration in the math teachers and graphing calculators (Chamblee, 1996) is primarily an artifact of methodology. The interview protocol (Slough, 1998) allowed teachers to express concerns about the principal that were not available on the quantitative SoCQ Instrument. But, when fourth and fifth grade mathematics teachers were interviewed about technology implementation concerns using a interview protocol modified from Slough (1998), they did perceive the principal as the primary change agent (Slough & Chamblee, in press).

Bringing telecommunications into the science classroom creates special problems dealing with loss of laboratory space and safety concerns. The science classrooms in this study, and in many other schools, typically had a lecture area and a lab area. Computers were typically placed in the laboratory area. Teachers in this study who were implementing telecommunications had done so at the expense of laboratory space and/or laboratory efficiency. Computers were either taking up permanent bench space or, where computer carts were used, they were constantly being moved for labs to occur. Neither situation is satisfactory in the long-term. Also related are the safety concerns associated with running electric wires in and around sinks and gas jets. If telecommunications are to become integral parts of the science classroom, long-term planning needs to address the potential need for lecture space, laboratory space, and computer space in a safe environment.

Significant findings found in the study of math teachers (Chamblee, 1996) not found in the study of science teachers include: (a) technology training needs to be matched to immediate teacher concerns; (b) some teacher characteristics were effective predictors of teacher concerns level, but only at the lowest stages; and (c) teachers self-rated themselves higher than the SoCQ rated them for graphing calculator expertise. While concerns models differ in the number and description of individual stages, researchers (Hall & Hord, 1987; Bailey & Palsha, 1992; Chamblee, 1996) conclude that technology training needs to be matched to the needs and concerns of individual teachers at appropriate times. Currently, many staff development models lack this feature. Integration of this feature will require more time pre-assessing teacher needs and personalizing instruction. It will also require having more content specific technology experts available in the schools and creating more specialized staff development opportunities with follow-ups throughout the year.

At the present time, much in-service is based on introducing teachers to new classroom innovations only at the awareness level. If studies continue to support the predictive validity of these teacher characteristics and more characteristics can be found that predict awareness concerns then selective screening can be used to place teachers with higher developmental level concerns (consequence and collaboration) in more appropriate in-service programs. For example, teachers who rated their expertise as intermediate vs. those who rated themselves novices differed on three concern stages: awareness, information and personal and overall concerns intensity. This implies that teachers who rated their expertise as intermediate have already began the process of gathering, synthesizing and personalizing the uses of graphing calculators in their everyday classroom instruction. Yet, the finding that these two groups of teachers did not differ at the other levels of concerns needs to be further explored. According to the model, to reach higher developmental levels of concern these teachers should begin to go through a refocusing phase in the near future. These data do not support this premise for these teachers. However, since neither non-users nor expert teachers were included in this analysis, further conclusions regarding any substantial differences in the groups is not possible at this time. The inability of teacher characteristics to predict higher developmental levels of concern (consequence and collaboration) was both discouraging and intriguing. One explanation of this lack of prediction is that as a teacher moves from a non-user (high awareness and information concerns) to an experienced user (high collaboration and consequence concerns) the more internal the innovative adaptation process becomes. Awareness and information about an innovation are externally controlled.

Overall, these studies demonstrate that commonalities and differences do exist between mathematics and science teachers going through the process of adopting technological change in their classrooms. These commonalities
provide opportunities for non-content specific professional development. Differences provide opportunities for content specific professional development. To become an experienced user of an innovation means a teacher has made a conscious and subconscious effort to focus on integrating the innovation into their everyday classroom activities and feels very comfortable with using the innovation as a tool for learning. If this is true then more emphasis has to be placed on being able to define the process teachers go through as they progress along the developmental continuum. Until we are able to do this, professional development opportunities which attempt to focus only on helping teachers meet low level concerns (awareness, personal, and management) are less likely to be successful.

Abstract: In a recent report commissioned by the Milken Exchange through Education Week, Zehr (1999) suggests that although schools have invested billions of dollars on computer hardware, the challenge now facing educators is in selecting appropriate software for use in their curriculum. The concern is that despite an emphasis on technology integration in the classroom, the use of computers fail to promote creativity, problem-solving and life-long learning unless the applications encourage these skills. The purpose of this paper is twofold: 1) to introduce educators to the Motion Media Grapher (MMG), a Web-based software utility designed by the authors of this paper in response to this growing need for effective classroom applications; and, 2) to share with educators the lessons learned when 9-12th grade mathematics students interacted with this utility.

Introduction

In a recent report commissioned by the Milken Exchange through Education Week, Zehr (1999) suggests that although schools have invested billions of dollars on computer hardware, the challenge now facing educators is in selecting appropriate software for use in their curriculum. The concern is that despite an emphasis on technology integration in the classroom, the use of computers fail to promote creativity, problem-solving and life-long learning unless the applications encourage these skills. The purpose of this paper is twofold: 1) to introduce educators to the Motion Media Grapher (MMG), a Web-based software utility designed by the authors of this paper in response to this growing need for effective classroom applications; and, 2) to share with educators the lessons learned when 9-12th grade mathematics students interacted with this utility. Additionally, this paper will show how the MMG can help teachers meet standards currently employed by the National Council for Teachers of Mathematics (NCTM, 1989) and the National Science Education Standards (NSES, 1996).

Based on a year-long research study (Pianfetti, 1998), this paper begins with a detailed description of the MMG and its convergence with mathematics and science standards. The next section presents a discussion of the research conducted on the efficacy of the MMG as a classroom resource. The last section examines three lessons learned emerging from the data. This paper concludes with insight from one mathematics teacher and her perspective on how this software utility could easily be adopted into her existing curriculum.

The Motion Media Grapher (MMG)

The impetus for developing the Motion Media Grapher was a result of observations made by one of the authors in a high school mathematics classroom of students using technology as an integral part of the curriculum. The students were effortlessly using such technologies as TI-82 graphing calculators to solve
algebraic expressions. In most instances, the technology was giving the students correct answers, but the students were failing to ascertain whether or not the answer was reasonable given the context of the problem they were trying to solve. The idea behind the MMG is that three networked-based interconnected components would give students multiple and situated representations of a single concept while they engage in authentic learning activities. Hence, the MMG would encourage the students to think critically about the answers that they were receiving because the answers would be presented to them through three different representations. These three interconnected components are a digital video component, a graph component and a table component. Students have the option of plotting points either by clicking on the graph or the digital video or setting points in the table. The other two perspectives are automatically updated to match the point initially plotted by the student. The digital video component allows the concept to be situated in an actual event and not just an abstract representation. Furthermore, this component contextualized the concept taught by the teacher. For example, in learning about nonlinear functions, such as acceleration, the digital video could be illustrating a car stopping and proceeding through a stop sign. The students could then plot a points directly on the video clip. This way, students see the concept in terms of real world events. The graph component permits the visual display of data and through its connection with the digital video component may help students better interpret what the points on the graph represent in more concrete terms. The numeric representation in the table component with its connection to the other two components may help the students understand what numbers mean and how they are portrayed in actual events. The MMG's emphasis on multiple perspectives reaches students with varying learning abilities and learning strengths while adhering to mathematics and science standards.

The NCTM Standards include among other things: 1) the use of problems representing applied settings to motivate and apply theory; 2) the use of computer utilities to develop conceptual understanding; and, 3) the use of computer-based methods for learning. Decreased attention will be given to word problems, simplification of radical expressions and pencil and paper graphing equations (NCTM, 1989, p. 125-9). Furthermore, the NSE Standards have stated that beyond basic skills and understanding, students in the middle schools should have heightened sense of inquiry that would help them understand the relationship between a concept and its explanation. By so doing, students become better problem solvers and are better able to communicate their reasoning. Students easily interact with the MMG. They may capture their own video, develop problem sets to accompany the video and by making two changes in the "html" source code of the MMG, they become creative and critical thinkers while engaged in authentic learning activities.

Moreover, there is growing concern that in introductory math and science classrooms, teachers have a tendency to oversimplify abstract and complex concepts (Kaput, 1994). This oversimplification may prevent mastery and create difficulty for the transfer of knowledge in advanced level courses (Feltovich, Spiro, & Coulson, 1989; Chi, Glaser, & Farr (Eds.), 1988). The challenge becomes finding a way for students to learn knowledge flexibly so that they may situate it into a variety of unique contexts and not simply those in which they were learned (DeGroot, 1978; Lave, 1988; Lave & Wenger, 1991). The MMG attempts to bridge all these issues by providing multiple and situated representations of an abstract concept and by permitting hands-on engagement with this network-based learning tool.
The Study

This year-long study consisted of three phases. Phase 1: The Developers' Phase involved four high school upperclassmen who were primarily responsible for collecting and digitizing video, creating problem sets and building Web pages. These upperclassmen eventually developed the MathNet Web site that consists of several pages that incorporate the MMG and ask students to solve mathematical problem sets regarding linear and non-linear functions. Phase 2: The Evaluators' Phase involved four teams of high school sophomores who conducted a formative evaluation of the MathNet Web site three times throughout its development. The sophomores' evaluations were subsequently reported back to the upperclassmen and systematic changes were made to the MathNet Web site in response to the evaluators' comments. Phase 3: The End-users' phase involved twelve high school freshmen in an introductory-level algebra class. The freshmen used the MathNet Web site as part of their mathematics class while they were learning about functions. A situated evaluation was employed as the main methodology (Bruce & Rubin, 1994). Additional measures used in the data collection included: 1) audio and videotaped interviews, 2) field notes, 3) an analysis of artifacts such as the Web pages created by the students, 4) an analysis of the

---

1 http://www.cyber-joe.com/education/Motion_Media_Grapher.html.
answers given by the freshmen to determine if they were using the multiple representations to answer the problem sets, and 5) pre and post surveys.

There were three core research issues that guided this research study. The questions addressed were built upon these core issues: 1) Technical: How can technology, specifically digital video and the Internet, be used to help students understand and interpret functions in applied settings?; 2) Cognitive: What impact does technology have on the way students learn to understand and to interpret functions in applied settings?; and, 3) Instructional: How can technology, specifically the MathNet Web site that incorporates the MMG, be integrated within a high school mathematics classroom?

Lesson learned from the data collected include: 1) The selection of visuals is important because misleading visuals may obscure the learning. The technology should not transcend the learning; 2) Collaboration is a key factor in the transfer of knowledge. Students can exchange their ideas and discuss concepts in terms that they know and they understand; 3) Digital video is a good tool that permits an abstract concept to appear more concrete in the learner's mind. The use of digital video because it can show a variety of contexts helps students better articulate their understanding. What was learned from this study will be briefly examined in the remainder of this paper 2.

Lessons Learned #1: Learning transcends the technology

The high school senior described in this mini-case study showed significant growth in her understanding of functions as well as in her understanding of how visuals can empower students by authenticating what they are learning. Conversely, she came to understand that the inappropriate selection of visuals could in fact misrepresent the content. She learned that technology should not transcend learning. In her own words,

I think like we almost have to pump them up with math. You know take it a little away from the focus of 'wow, look at the graph, look at the movie' and say, 'okay so why does this work' ... we [shouldn't] take away from the purpose of the page - learning math.

Katina was working on a problem set that centered on the descent of a fire escape. She wanted the students to determine if the fire escape descended in a linear or non-linear path. In shooting the video, the upperclassmen were limited in where they could position the camera. Consequently, when the video was digitized, Katina realized that in considering the Cartesian plane, the fire escape moved solely within the second quadrant. Hence the corresponding plots on the graph would have negative numbers for the 'x' and the 'y' axes, but a positive slope. Katina believed that this perspective would confuse the freshmen who had only completed one semester of algebra; therefore, she attempted to horizontally flip the video.

The freshmen students might think that the slope was negative because of the negative 'x' and 'y' values and because visually the students would see the fires escape moving downwards. [The freshmen] may associate the downward movement with negative numbers and forget that a negative divided by a negative number is positive. They might think it had a negative slope.

Katina was considering the larger impact the video might have on the students. Katina did not want to confound the understanding of math by misrepresenting the mathematical concept because of a limitation of the video. Katina knew that the video she collected was misleading. She did not want the visuals to "obscure the math" and subsequently obscure the learning.

Lesson Learned #2: Collaboration is key

2 This paper is based three in-depth case studies. For more detail on these case studies, contact esecaras@uiuc.edu.
In reviewing the three evaluation phases and tracing the trends of comments that were made, it appears that there was significant growth made over the duration of the evaluation phase. For the first evaluation, these sophomores primarily submitted individual evaluation forms with aesthetic recommendations. By the second and third evaluations, however, the sophomores were more critical in their comments as they considered the overall operation of the Web site and worked together to give comprehensive feedback. As one evaluator stated:

We were never asked to evaluate something before ... and now when we do [the upperclassmen] listen to us. It's a great feeling. It's forcing me to really think about the math and think about these pages. We're working more as a team because a lot of the uhm ideas we have we can talk about and see if we are on the right track. It's good to work with [our teammates] because I'm learning a lot from them about the math and about Web pages.

Comments such as the one above were echoed in many of the evaluators' comments. Other tangible evidence included the extensive recommendations that they made on their final evaluation forms. For example, one team of evaluators gave illustrated suggestions for how better to layout the three components so that the end users would be able to utilize more efficiently the multiple representations. They wanted the digital video clip to appear in the upper left-hand corner while the graph would cover a larger portion on the bottom of the screen. They included with this illustration a justification for why they wanted the layout changed.

If you put the video at the top, then you can look at the video and work your way over to the table and the graph. The video is what draws your attention first, but the graph and the table are important, too. And for the graph you need more space to really spread out the [plots].

Lessons learned #3: Digital video as a situating medium

From the data collected, it was apparent that the freshmen end-users had a more concrete understanding of function. They were able to articulate their ideas about functions more directly than before their interaction with the MMG.

A linear function is where you put something in and get the same thing out. Like when you talk on the phone and someone talks back. ... and like gas, the more miles you go, the more gas you need.

Or like when you are reading and fall asleep. You're taking your time, then you slow down and then you fall asleep ..

... and the line on the graph continues going, but the number of pages your read stay the same.

Although the pre and post survey results indicated that the freshmen still had difficulty understanding functions, dialog exchanges such as the one above suggest that the students are able to transfer the knowledge to familiar events when they are asked to make the association.

Conclusion:

One of the major findings of this study suggests that proper integration of the MMG is instrumental for its functionality as an effective learning tool. Its placement in the curriculum should reflect what the teacher is currently teaching. The teacher in this study considered how it could be used within a mathematics class.

Oh, now this is interesting. I could definitely see myself using this problem in my class. ... do you remember that worksheet I gave [the class] - the one the students had to draw graphs on different functions based on what they thought the graph would look like?
Well, they had trouble drawing the graphs ... so now see here with this problem, I could have the students draw the graph and then have a student make a graph using the Web page. Yes, I think that the video would really add to the instruction ... you know, it might not even be a bad idea to have video that represents all the graphs [the students] are asked to draw.

In this teacher's opinion, the strength of the MMG was that the Internet could now be used for more than just browsing or research. Her students could be 'constructors of knowledge'. In terms of engaged learning, they were learning by doing. In addition, this software utility could, with minor adaptations, be used in a variety of classrooms and in a variety of disciplines, including science. Since conducting this research, the MMG has been modified for use in middle school science classrooms.

In essence, the MMG is geared towards the shifts in learning and instruction that are stated in the NCTM and NSE standards. The use of the Internet to support multiple media as a means to present interconnected multiple representations of a single concept is a key feature. The network-based interconnected components encourage the students to see how the different representations of a single event each reflect a perspective of the same underlying concept. Ideally, these different perspectives would foster problem solving and inquiry because the students would have to learn to negotiate the different representations and the meanings of the variables. Moreover, the digital video component offers a concrete representation of a natural event and as such can encourage the use of contextual problems to motivate and apply theory.

Actions on Objects:
A theoretical framework for mathematics education

Michael L. Connell, Ph.D.
University of Houston
United States
mkahn1@aol.com

Abstract: When one thinks of reasoning, problem solving, communication and
connecting related ideas the tool of choice in nearly every discipline is the
microcomputer. Furthermore, unlike the traditional calculator, the modern classroom
computer has an unparalleled ability to implement both graphical and procedural
components of mathematics understanding in a single unified object.

Through creation and utilization of mathematically relevant computer-based objects
this dual encapsulation enables the students a unique opportunity to see both the form of
representation and their actions utilizing this representation simultaneously. For this
reason alone it would be a natural tool for both classroom use and theoretical musings.
This paper explores the potential for classroom uses that blend learning theory and
practical realities of student actions. It addresses the extent to which the object orientation
metaphor, found in the modern windowed operating systems and programs, transfers to
the "tools to think with" notions of current action upon objects models of mathematics
teaching and learning.

In particular, we will suggest that the object-oriented environments which modern
technology has created are ideally suited to parallel and facilitate the ability of students to
take a broader variety of action upon objects of a nature and kind hitherto unknown.

Technologically Enhanced Mathematics Learning.

Over the past ten years I have noticed that a major theme that has been emerging in my research
and writings has been that of action upon objects. This has in turn lead to some foundational questions
surrounding the nature of the objects and the types of actions that one might be expected to perform upon
them. I have found this framework of actions upon objects to be very powerful in both the laboratory as
well as in the predictive power they enable in the minds of the students. I feel that they also capture quite a
bit of current interest in the field as evidenced by recent thinking on object reification (Sfard, 1994).

What I am trying to add to the mix is the notion of a firmly developed and articulated way of
looking at what these objects might be and in particular how we might utilize them to develop
mathematical thinking. In particular, I have developed an approach that results in students developing
mathematical thinking regardless of the developmental level and nature of the object. When this method is
followed we repeatedly observe marked similar patterns of thought on the part of the students. This is all
the more significant when we consider that this parallelism shows itself in the same type of thinking taking
place at each developmental level.

I am taking this opportunity to share some of my notions concerning the action upon objects
models I have been using in my university classes and in my own personal thinking. As we will see, my
approach toward addressing these questions has been very heavily influenced by readings of and work with
Mikhail Bounieav and Sergei Abramovich (Abramovich, 1998; Abramovich, 1995). Together with
Mikhail Bounieav, we have been developing a way of thinking about step-by-step development of mental
activities as enhanced by technology (Bounieav & Connell, 1999; Connell & Bounieav, 1997). With
Sergei Abramovich we have been looking at the nature of the new tools to think with which technology
provides (Connell & Abramovich, 1999). The development of this theme includes developing concepts
through mental picturing, and the notions I've been developing over the last 20 years or so regarding
actions upon objects of various types.
Background examples.

At the elementary level, the objects the children are capable of thinking with (or acting upon) is influenced by both their developmental level and their prior experience. In particular, we find that young children are not able to think with formalized abstracted mathematical objects. This should not be a major surprise, as it has been part of our understandings of human growth and development for some time. This limitation, however, at first glance would appear to limit the degree of mathematics which might be made.

As Whitehead (1978) correctly noted, it is only when one reaches the abstracted levels of mathematical formalism that we can really leverage forward our thinking. It is at that point that the tremendous growth in the intellectual potential of the individual might happen. This has led many to speculate and even to promote the notion that young child is incapable of rigorous mathematical thinking, and in fact that much of what we do that young childhood level is basically preparatory for the real mathematics which they'll be developing later.

Based upon my experiences in the classroom and my own theoretical musings I have taken a very contrary position to this. As I have stated in many different venues the young child is capable of very well developed mathematical thinking if the objects with which they think and questions upon which they think are of an appropriate level and type for their developmental abilities. I will be the first to acknowledge that this is a different type of mathematics content than we often see in more formal mathematics, but the thinking strategies is in direct parallel to that exhibited in the higher levels.

Let us work through a few examples to see how this might play out. For a preschooler working with pattern blocks we can ask questions concerning these blocks that require acting upon these blocks and the use of some quite elaborated thinking. This thinking is to a large degree rooted in the physical actions the child is taking upon the physical object presented to them for their use.

Suppose, for example, the child creates a base pattern composed of a square followed by a triangle and then a parallelogram.

![Figure 1: Pattern block base.](image)

The child can easily and correctly predict what would come next from extensions to this pattern based upon this starting sequence as it is continued and repeated. Indeed, for any given starting sequence the children will quickly learn how to extend that pattern and to create their own patterns from bases of their own choice.

![Figure 2: Extended pattern derived from the earlier base.](image)

Now some might suggest that this type of thinking is more replication them prediction. However, we commonly see the same type of thinking occur when we observe algebra students using a guess and check strategy to fill in values in a function like the following:
Table 1: Function illustrating a guess and check solution strategy.

I really believe that we are not just laying a foundation for later mathematical thinking but that we are actually seeing mathematical thinking which is appropriate for the objects which the student is able to think with.

A model for use.

It is clear, however, that if this approach is to be effective that the objects to think with must be developmentally appropriate for the student. For the past 15 years I have been researching and writing about one such model which has proven to be very helpful in identifying the level of objects to think with and some of their properties (Connell, 1998; Connell & Ravlin, 1988; Connell, 1986). Figure 3 serves to illustrate these developmental levels.

Figure 3. Model illustrating the type of actions as performed upon the objects of thought.

Let me provide a quick general overview of this approach. The instructional goal is to enable gradual student construction of meaning through the use of manipulatives through abstraction via four transitional object types. Within each problem type three types of activities will typically be encountered by the student: 1) memory/recall - often of terminology; 2) teacher posed problems - related toward student
construction of concepts; and 3) student posed problems - based upon developing understanding of the problem space presented and it's relations to other problem types. These activities will be experienced by the student in the form of related problems requiring the use of the developmentally appropriate object to think with: manipulatives, sketches, mental pictures, and abstractions.

Furthermore, at each location in the model where a student will encounter a problem – either teacher or self-posed – the student will solve this problem via activities which are then organized and recorded for later reference.

An extremely elementary example of this model showing actions upon all of the object types might include initial actions upon a manipulative - such as a pile of counters used to develop elementary addition. A sketch might then be drawn recording the actual counters, which in turn would serve as an object of thought for further construction of meaning. Mental pictures, in addition to serving as a further representation of the problem space, provide natural entry points for technology - which will be utilized in technology-aligned classrooms. Abstraction would occur when it is no longer necessary for the student to use countable counters but is capable of reflecting upon the constructed representations in the construction of new knowledge, a process that Piaget referred to as "reflective abstraction". As we thus expand our earlier notions of action upon object we can see that we are working with a carefully selected set of developmentally appropriate primitive objects and experiences with these objects to build up a working vocabulary and subsequent conceptualization.

What should occur next, regardless of the students' developmental level, would be for a skilled teacher or instructor to pose follow-up problems or questions relating to the newly instantiated and defined object of thought. This would again hold true whether we're talking about a physical manipulative object, a sketch object of predictive power such as an interactive fractions object, or a mental picture object such as a comparison of mass based upon remembrances of experience, or a formal and logically abstracted object such as function or some other mathematical construct. In each case we observe a skilled teacher using newly developed objects as a venue within which questions are to be asked and problem situations explored via student actions upon these very same objects of thought.

Good Thinking is Good Thinking, At Every Level at Which it Occurs

It should also be noted that the nature and form of the thinking and reasoning strategies runs parallel across each of these developmental levels. We can easily observe the young child reasoning with the manipulative objects, communicating their findings with others using the manipulative objects, connecting their most recent experiences with previous experiences with the manipulative objects and using these same manipulative objects in making quality judgments regarding their work. We can likewise easily observe the same strategies being used at each of the other developmental levels of objects within classrooms utilizing this approach.

If the question that has been posed relies upon action upon objects that the child is capable of manipulating and has developed personally meaningful understandings for, then the child is typically successful in their problem solving efforts. This holds true whether the form of the action upon the object is via a physical manipulation, a symbolic manipulation, or a more abstracted application of logical formalisms. It is important to note that I am not suggesting that we are necessarily observing extreme mathematical sophistication. However, what I am arguing for is that it is possible to observe a parallel form of mathematical thinking as students perform their respective actions upon their understood objects at each of these developmental levels. Thus I am quite comfortable making the claim that we can observe quality mathematical thinking at the preschool level as well as at the graduate level.

Furthermore, as we extend this model the children are given the opportunity to develop problems of their own based upon the objects that they recently defined, worked with, and developed problem solving skills and schemata for. This is an important part of the instructional strategy, for without this piece of the puzzle the children will always look to someone else to serve as the source of their problems and as final judge as the answers to the problems they face. This ability, to pose one's own problems and to

---

[1] I am using the term primitive to refer to a foundational material from which later concepts will be built – not necessarily as referring to simple or unsophisticated. This is in keeping with the use of primitive in computer systems. Thus, Dienes Base10 blocks might well be considered as an experiential primitive upon which later conceptualizations would be built.
then successfully solve these problems, provides further opportunity for growth in mathematical thinking and problem solving. In this, we also see once again the direct parallelism between each of these developmental stages.

Conclusion

Since their inception in 1989 the NCTM Standards for Curriculum and Evaluation have been changing the face of what constitutes mathematics and how we think about its teaching and learning. Consider the following: Mathematics is communication; Mathematics is reasoning; Mathematics is problem solving; and Mathematics is connections. These statements are drawn directly from the process strands of the 1989 standards document and constituted a major revision as to what counts in mathematical thinking.

These process strands have become the de facto class of acceptable actions that are to be performed in mathematics education. These actions are much different in both form and substance than earlier procedural and content driven actions of the past. And it is in this very difference that we see that it is possible to perform these actions - to reason, problem solve, connect, and communicate mathematically - at every developmental age provided that an appropriate object for this action to act upon is present.

With the addition of the technology enhanced object there is tremendous evening of the playing field in terms of what counts as mathematical thinking. With this addition we can observe that the both the thinking processes and sophistication as shown by students of various ages begins to parallel each other. The technology serves an important role in this process. In particular, the computer can serve as a tool to record the information that has been generated by the students’ activities. It can then capture the essence of the activity by allowing the students to organize their work in powerful structures. For example, a table might be built using developed data in a row and column structure, or an organizing graphic might be constructed reflecting the series of activities the children have performed. The technology can then be used to create formal records of action that may be shared or used in later problem solving endeavors. These records of action can even be shared with others outside the immediate sociocultural milieu within which the student is working via the World Wide Web.

The computer, with its object oriented interfaces and tools geared specifically to enable the user to perform specific actions upon specific objects, lends itself perfectly to an action upon object model of learning and instruction. Some of these include Step-by-Step Development of Mental Activities (Galperin & Talizyna, 1979; Leontiev, 1972), Action Reification (Sfard, 1994), and Emergent Structural Theory (Connell, 1996) to name a few. This linkage between suggestions from learning theory and the object classes engendered by the technology is far too priceless to allow going to waste.

Some Psychological Aspects of Using Information Technologies in Teaching Linear Algebra

Mikhail M. Bouniaev
Math/Cs Department
Southern Utah University
United States
bouniaev@suu.edu

Abstract: Despite the indisputable advantages of using information technologies in teaching mathematics in general and linear algebra in particular certain problems related to technology-oriented education have become quite evident now. The presentation reviews and analyses efficiency and expediency of using information technologies at different stages of teaching linear algebra. Our research is based on the results of the experiment conducted during the last five years in teaching linear algebra with MATLAB and modern calculators. This paper is a follow up of an earlier article "Linear Algebra With MATLAB Package In Preservice Teacher Education" (Bouniaev, 1997).

Introduction. Basics of DMA Theory

Our analysis of using information technologies in teaching linear algebra is based on the theory of stage-by-stage development of mental actions (DMA theory) developed by the Russian school of psychology (Galperin 1960, Leontyev 1975, Talizina 1975) as applied by the author in teaching mathematics (Bouniaev 1991, Bouniaev 1996, Bouniaev & Connell 1996). Without going into a detailed description of this theory we will outline some of its basic concepts that are essential for this paper. We also assume that in a linear algebra course an instructor can use various technologies at different stages of instruction, such as modern calculators and software packages like MATLAB or Derive. So we are not going to specify what software or a calculator should be used in the course of instruction. In most cases this problem of choice may be solved by different means and depends on their availability. According to the DMA theory the major goal of instruction is developing mental actions with objects of the studied field. Finding a solution of a system of linear equations, proving that systems of vectors is linear independent (dependent), reducing matrices to the reduced row echelon form, finding eigenvalues or eigenvectors are examples of the actions to be developed in a college linear algebra course.

Instruction is viewed as organizing and controlling students' activities and hence organizing and controlling the process of development. Thus, instruction efficiency is determined to a great extent by a well developed system of control and management.

Analysis of component operations of any action shows that they perform different functions. A part of performing an action is taken up by some preliminary work, a preparation for an action in a certain sense. This preparatory part is called orientation part of an action. The performance itself is called executive part of an action. Analysis of an action and experiments carried out in this respect show that there also exists a control part which takes place after the executive part, when an individual compares the results achieved
in the executive part of an action with the goals of an action and the draft plan of the execution planned in the orientation part.

As a rule, the performed actions consist of other, more primitive actions and in their turn can be part of other actions. Actions that are part of a given whole, are called operations. That is, operations are also actions; hence the term emphasizes only a hierarchical subordination among actions. The DMA theory specifies four independent characteristics of any action used to determine the level of development of an action. The first characteristic is a form of action. An action can be in a materialized (material), speech or mental form. The materialized form of action is connected with manual activities (manipulation, hand-on activities, etc.); objects of action (or their models) are presented in a material form; results of action should be real transformations of these objects or of their models. For example, entering an equation into a graphic calculator could be considered as an action in materialized form.

There is no need to discuss the speech form of an action. It should be noted that according to the DMA, writing belongs to the same form, i.e. the speech form. If we consider an example of solving a system of linear equations then the speech form will mean articulation of the performed actions. There is no need for these objects to be present in the material form. For example, in the process of instruction a student may be asked to comment on all the operations of entering an equation into the calculator. The action can be an answer in the form of oral speech or a note in a workbook.

The mental form of action is the highest form of action development. An action in this form is imperceptible for one's associates and its results are recorded in an imperceptible form also. This form of action means that its objects are representations, notions and concepts. All operations are performed to oneself. The ability to perform a whole action in the mental form indicates that it has gone through all the stages of development and interiorization.

Structure of the actions to be developed in a linear algebra course

The primary goal of the first linear algebra course is introduction of basic concepts of the subject such as systems of linear equations and their solutions, the concept of a matrix, linear space and linear operator. Activities-oriented learning theories claim that development of concepts takes place through development of actions aimed at the objects that fall under these concepts as well as at the objects that fall under the concepts immediately connected with the developed one.

All actions can be referred to two categories: general logic actions and specific actions. The characteristic general logic action for a linear algebra course is that of recognition. For example recognize if a matrix in the reduced row echelon form is an augmented matrix of the inconsistent system of linear equations. Another example of a general logic action is an action of classification, for of matrices into subclasses of singular and nonsingular matrices. We will demonstrate that developing general actions is crucial in the course of linear algebra study.

Specific actions are basically inherent to a given subject field. For example, in linear algebra they are: reducing a matrix to the reduced row echelon form, matrix multiplication, finding determinant of a given matrix, etc. We will show that in developing basic concepts of linear algebra most specific actions can be performed with the help of technologies.
Let us consider the structural composition of some actions aimed at developing the basic concepts of a linear algebra course. Naturally, if we consider the development of the systems of linear equations concept, then the basic action to be developed is that of finding a solution of systems of linear equations. This action is not homogeneous, it consists of a sequence of certain operations.

*Example 1. Action of solving a system of linear equations*

- Operation 1. Recognizing the system as a linear system (general logic action).
- Operation 2. Recognizing variables, coefficients, constant terms (general logic action).
- Operation 3. Rewriting the system in the standard form (specific action).
- Operation 5. Creating a matrix $A$ – augmented matrix of the system (specific action).
- Operation 6. Reducing matrix $A$ to the reduced row echelon form (specific action).
- Operation 7. Making a conclusion based on the form of $rrefA$ (general logic action).
- Operation 8. Determining the method of solution that depends on the results of performing operation.
- Operation 9. Solving the system given in the reduced row echelon form.

In developing the concept of vector space an important role belongs to developing such actions as recognizing linear independent (dependent) system of vectors; determining whether this particular vector is a linear combination of vectors of the given system and recognizing the basis of a vector space. Let us consider the operational composition of these actions.

*Example 2. Action of recognition of linear independent (dependent) system of vectors.*

Assume we have a system of vectors $a_i=(a_{i1}, ..., a_{in}, ..., a_{im})$ in $m$-dimensional euclidean vector space $\mathbb{R}^m$. The problem is to determine whether this system is linear independent or dependent.

- Operation 1. Designing a master plan for solution (general logic action).
- Operation 2. Creating the system of linear equations $x_1a_{1T} + ... + x_na_{nT} = 0$ (specific action).
- Operation 3. Creating the matrix $A = [a_{1T} ... a_{nT} 0]$ (specific action).
- Operation 4. Reducing the matrix $A$ to the reduced row echelon form (specific action).
- Operation 5. Making a conclusion based on the form of $rrefA$ (general logic action).

*Example 3. Action of representing a vector as a linear combination of the system of vectors.*

Assume we have a system of vectors $a_i=(a_{i1}, ..., a_{im})$, $a_n=(a_{ni}, ..., a_{nm})$ and the vector $b=(b_1, ..., b_m)$ in $m$-dimensional euclidean vector space $\mathbb{R}^m$. The problem is to determine whether the vector $b$ is a linear combination of vectors $a_i$, $i=1...n$.

- Operation 1. Designing a master plan for solution (general logic action).
- Operation 2. Creating the system of linear equations $x_1a_{1T} + ... + x_na_{nT} = b$ (specific action).
- Operation 3. Creating the matrix $A = [a_{1T} ... a_{nT} b^T]$ (specific action).
- Operation 4. Reducing the matrix $A$ to the reduced row echelon form (specific action).
- Operation 5. Making a conclusion based on the form of $rrefA$ (general logic action).

*Example 4. Action of basis recognition.*

...
Assume we have a system of vectors $\mathbf{a}_1 = (a_{11}, \ldots, a_{1m}), \ldots, \mathbf{a}_n = (a_{n1}, \ldots, a_{nm})$ in m-dimensional euclidean vector space $\mathbb{R}^m$. The problem is to determine whether this system is a basis for $\mathbb{R}^m$ or not.

- Operation 1. Designing a master plan for solution (general logic action).
- Operation 2-5 as in example 2.

Then we have to check whether any vector in $\mathbb{R}^m$ is a linear combination of vectors $\mathbf{a}_1, \ldots, \mathbf{a}_n$. It may be done in different ways. Usually we choose the method that assumes the use of technologies, but not symbolic computation systems. So the idea is to check whether the vectors of standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_n$ are linear combinations of vectors $\mathbf{a}_1, \ldots, \mathbf{a}_n$. This problem can be substituted by the problem of determining whether $n$ systems of linear equations are consistent or not. Fortunately all these systems have the same matrices of coefficients, so it makes sense to determine their consistency simultaneously.

- Operation 6. Creating the matrix $\mathbf{A} = [a_{11}^\top \ldots a_{n1}^\top \mathbf{e}_1^\top \ldots \mathbf{e}_n^\top]$ (specific action).
- Operation 7. Reducing the matrix $\mathbf{A}$ to the reduced row echelon form (specific action).
- Operation 8. Making a conclusion based on the form of $\text{rref}\mathbf{A}$ (general logic action).

From the point of view of our analysis it is instructive to compare the operational composition of the action of the previous example with the action of finding a matrix that is inverse to the given one.

**Example 5 Action of finding matrix inverse**

Assume we have matrix $\mathbf{A} = [a_{11}^\top \ldots a_{n1}^\top]$. The problem is to find its inverse.

- Operation 1. Designing a master plan for solution (general logic action).
- Operation 2. Creating the matrix $\mathbf{A} = [a_{11}^\top \ldots a_{n1}^\top \mathbf{e}_1^\top \ldots \mathbf{e}_n^\top]$ (specific action).
- Operation 3. Reducing the matrix $\mathbf{A}$ to the reduced row echelon form (specific action).
- Operation 8. Making a conclusion based on the form of $\text{rref}\mathbf{A}$ (general logic action).

**Developing Actions In A Linear Algebra Course**

Comparison of the operational composition of actions of the above examples shows that actually the only “transformational” operation in all of these actions is that of reduction of the matrix to the reduced row echelon form. Analyzing the actions to be developed in a linear algebra course one may come to the conclusion that the majority of actions to be mastered by students in this course can be presented as a sequence of three absolutely identical operations. The first operation is construction of a certain matrix, second — reducing this matrix to the reduced row echelon form, the third is interpretation of results, i.e. comparison of the original matrix with the one in the reduced row echelon form.

It is easy to see that the above problems require practically identical treatment not due to the limited number of concepts we operate with in linear algebra but because these operations form only the executive part of action. The executive part of action in many linear algebra problems comes down to construction of a matrix and its reduction to the reduced row echelon form.
In real life situation (not in class) that require performing any of the above described actions it would be natural to perform explicitly only the executive part of the action. An engineer or a mathematician would enter the matrix into the computer or the calculator and then push the button controlling “rref” command irrespective of the fact whether one is looking for the solution of the system of linear equations or proving that system of vectors is linearly independent. The situation is completely different in class since all students actions are not aimed necessarily at getting the right answer for the given problem but more at acquiring skills to solve problems of this category.

In the course of the experiment while studying the linear independence and the concept of basis in the experimental group we allowed the students to start the solution of problems right from the executive part of the action. Thus, for example, in developing the action of recognizing the linear independent system (example2) students were not required to start with the system of linear equations but with operations 2–3 (entering the matrix in a computer or a calculator and finding its reduced row echelon form). In the control group the students were required to start with the system of linear equations and write down an explanation how this system is related to the problem in question. Thus the experimental group in the course of study was able to solve almost twice as many problems as the control group but 60% of the students experienced considerable difficulties substantiating their actions, and they also provided substantiation that could be related to a different class of problems. They could not extend the same idea to a similar class of problems.

While determining the fact that given vectors generate the entire space (example 4) the students of the experimental group were allowed to perform all operations (except 6 and 7) mentally. The students in the control group were required to write down all operations with detailed substitution. The day before we discussed these topics we found an excuse to remind the students how to find an inverse matrix, i.e. actually reviewed the operational composition of the action of example 5.

Proceeding from the assumption that the executive operations of example 4 (operations 6 and 7) and example 5 (operations 2 and 3) are absolutely identical the students from the experimental group came to the independent conclusion that actions of examples 4 and 5 are based on the same idea (which is a misconception). All the attempts to provoke students in the control group to come to the same conclusion failed. The control group students were fully aware of the fact that despite the superficial similarity of the execution parts of these actions their orientation parts are absolutely different and thus these actions cannot be similar.

According to the DMA theory, besides the form any action has another three independent characteristics:
- degree of generalization;
- degree of completeness;
- degree of assimilation.

Generalization of an action means the ability to determine and discriminate essential for performing an action properties as well as the ability to apply them to objects of different nature. For example, if the action of solving systems of equations is developed at a high enough level of generalization the student does not find it difficult to progress from solving the system of three equations with three unknowns to solving any system. It also does not matter how the unknowns are designated. The degree of completeness indicates whether all the operations that were to be performed in the process of performing an action have been actually completed. If the action is already developed, then the subject of the action (the student who performs it) practically does not discriminate operations from each other, i.e.
the action takes place in the compressed form. If we assume that the previous learning was successful, then failure to perform an action (without any time limits) often indicates that a student can not present the action in operation-by-operation form when all the operations are present and are clearly identifiable. This indicates that performance of the action is not completed. The ability of the student to perform an action in the operation-by-operation mode giving justification for their performance shows that the action was developed at the sufficient degree of completeness.

Going back to discussing different approaches to organizing the learning process in the experimental and control groups we can come to the conclusion that in the experimental group the development of actions did not reach the required level of completeness which in its turn affected negatively the degree of generalization of the developed action. On the other hand, the degree of assimilation was higher in the experimental group.

In the experimental group we had to spend additional time to develop the actions at the required level of generalization. For this purpose we created a class of exercises that we called inverse problems. The students were given only the executive part of the action of the problem to be solved. The task was to restore the full operational composition of the action.

This experiment as well as other experiments conducted in the course of teaching linear algebra with information technologies demonstrated that each part of the action should be singled out and developed separately. In the process of instruction the executive part of an action should be performed by a computer or a calculator.

The executive part usually is a specific action for the subject. The orientation part as a rule is a general logic action aimed at the objects of the studied field. The orientation part of an action includes intermediate goals, reducing a problem to the already familiar ones, selection of definitions and theorems related to the performed actions. Thus in the above examples the problem is reduced to determining the consistency of the system of linear equations. The expediency of this problem substitution is determined by the corresponding definitions and theorems.

In developing any new action in the course of linear algebra its orientation part should go through all the forms of development starting at least with written speech. For the above discussed examples 2-4 it means that at the initial stage of development a plan of action should be written down as well as all necessary theorems and definitions on which this plan is based. The system of linear equations should be presented in a written form. Only after completing all these actions a student can use a computer or a calculator to perform the corresponding operations. Thus major problems in teaching linear algebra arise not in developing specific actions of the course but in developing general logic actions aimed at the objects of the studied field.

The DMA theory presupposes five stages in organization of instruction. At the first stage the instructor presents new material. Taking into account a relatively abstract nature of the linear algebra course it is expedient in presenting a new material to illustrate it with practical problems and to create computer models of these problems. Thus in teaching the theme Least Squares Solutions it is worth starting with the discussion of linear regression and demonstration of vivid programs modeling linear regression. In teaching the projections it is hard to overestimate the value of visually enhanced programs illustrating the geometry of the performed actions. At the second stage the actions are developed in the materialized form. At this stage of instruction it is expedient to organize the work with blocks of texts and illustrations and move these blocks to different parts of the screen.

The third stage is development of actions in the external speech form. At this stage it is important for students to articulate their thoughts out loud and write down necessary comments. As experience showed at this stage traditional pencil and paper are hard to substitute. Group work is also very useful. Computers can be used for conducting different
experiments requiring discussions with other students. And only the fourth and the fifth stages are developing actions in the form of internal speech and mental form.

In developing every new action the executive part can be delegated to a computer. Thus for example in developing an action of reducing matrix to the reduced row echelon form it is expedient to use programs like MATLAB m-file “RREF”, providing executions of elementary row operations at students instructions. At further stages of instruction it is expedient to delegate this action fully to a computer or calculator. In finding eigenvectors and eigenvalues computers can solve the systems of linear equations and characteristic equations. At the same time development of the orientation part of this action should go through all the stages and forms.

Conclusion

In the course of study of linear algebra it is expedient to carry out the structural analysis of every new action to be developed. It is preferable to present the orientation part with all the necessary operations to be performed and to develop it going through all the stages starting with the material form of an action. The executive part of an operation can be given over to computers or calculators. At further stages the orientation part can become an operation of the executive part of an action and be performed by a computer. It is worth pointing out that in developing the orientation part of an action the use of computers can be highly efficient in creating visual models and a bank of basic concepts, definitions and theorems.

Factors Related to Teacher Use of Technology in Secondary Geometry Instruction

David A. Coffland
Idaho State University

Albert W. Strickland
Idaho State University

Abstract: This survey sought to identify variables related to teacher use of technology in secondary level geometry classrooms in southeastern Idaho. The primary variables examined in the study were teacher technology awareness, teacher attitude toward technology, teacher technology training, and teacher computer use for instruction. This study also tested for associations between these primary variables and principal attitude toward technology and a selected group of demographic variables: geometry teaching experience, number of sections of geometry taught, college mathematics major, and computer lab access. Four significant relationships were found. An inverse relationship was found between teacher computer use and the number of geometry sections taught. Direct relationships were found between teacher attitude and both teacher technology awareness and principal attitude. Finally, a direct relationship between type of teacher training and teacher instructional computer use was reported.

Introduction

The use of technology in education, especially mathematics instruction, has been recommended on multiple occasions by the National Council of Teachers of Mathematics (NCTM, 1996, 1998). In the state of Idaho, technology use has even been mandated (Watson, 1996). At the secondary level, many articles have recommended the use of computer technologies in geometry classes; however, few studies have been published on the factors which relate to teacher use of technology within geometry classrooms.

The purpose of this study was to discover relationships of teacher technology awareness, teacher technology training, teacher and principal attitude toward technology, and teacher computer use among secondary, geometry teachers in the southeastern region of the state of Idaho. This study was broken into three groups of research questions. The first set of research questions sought to discover associations between selected demographics variables (experience, number of sections taught, mathematics major, and hardware availability) and the primary variables of teacher technology awareness, teacher technology training, teacher attitude toward technology, and teacher technology use. The second research question examined relationships between the primary variables and principal attitude toward technology use in geometry. Finally, the last three research questions sought to determine associations between the four primary variables of the study.

Methods

Description of the Population

Idaho teachers and principals were considered in this study for several reasons. Since 1994, Idaho has invested heavily in technology for schools (Idaho Council on Technology in Learning, 1998). The State of Idaho has provided, and is still providing, monies earmarked for technology directly to school districts, requiring a plan for integrating technology into instruction from school districts as a condition of receiving that money. In addition, a private foundation has provided large dollar amounts for Idaho schools which incorporate technology into instruction. Finally, the state of Idaho has mandated the appropriate use of technology in instructional settings (Watson, 1996). Therefore, Idaho teachers were considered because Idaho schools have had both the money and the incentive to incorporate technology into the classroom for the last five years. Geometry teachers were examined in this study because dynamic geometry environment software offers.
opportunities for students to interact with the constructs of a field which has been described as a hurdle for high school mathematics students (National Research Council, 1989).

Data Collection Techniques

The data were collected via a mail survey instrument. The surveys consisted of both closed and open response items. The surveys were sent in packets to high schools and junior highs in southeast Idaho school districts during the latter part of the school year. Each packet contained a principal survey and teacher surveys for each geometry teacher in the school building.

After allowing several weeks for the return of the instruments, it was noted that some districts had not returned the superintendent permission form for using their districts data as required by the Human Subjects Committee. The superintendents of these districts were contacted again and asked to return a faxed copy of the permission form. The data from those districts were then added to the total data list.

Participants

The study participants were restricted to secondary school geometry teachers and their principals in southeastern Idaho. All junior and senior high schools which offered at least one section of geometry were invited to participate in the study. The principals of each of the selected schools made up the principal section of the sample. If more than one teacher from a given school was in charge of at least one geometry class, then all such teachers from that school were asked to participate in the study.

There were 75 secondary schools from 52 school districts in the three southeastern Idaho regions which fit the criteria for this study. The number of geometry teachers in each school was determined by calling all secondary schools in southeastern Idaho. A representative of each school was asked if geometry was taught in the building and, if so, how many teachers were assigned at least one section. From this initial phone survey, it was found that 75 secondary schools in 52 school districts located in southeastern Idaho offered at least one section of geometry. Each of the school districts was asked to participate in the study. One district refused to participate and two districts closed prior to being contacted. This meant that the potential sample consisted of 136 teachers in 72 schools from 49 districts across southeastern Idaho.

Completed surveys were received from 52 teachers and 33 principals from 26 school districts. This resulted in a return rate of 38% for teachers and 46% for principals. The demographic data obtained from the teachers and the principals are reported in the tables below.

Summary of Findings

The research questions for this study were divided into three sections. The first section, of four research questions, examined the relationships between the primary variables listed above and the selected demographic variables. The next research question sought associations between the primary variables and principal attitude toward technology. The final section, comprised of the last three research questions, tested for relationships between each of the different pairs of primary variables. For each of the research questions, the critical alpha value was set equal to .05.

Relationships Between the Primary Variables and Demographic Variables

The first set of research questions sought to discover associations between selected demographic variables (geometry teaching experience, number of geometry sections taught, mathematics major, and hardware availability as measured by computer lab access) and the primary variables of teacher technology awareness, teacher technology training, teacher attitude toward technology, and teacher technology use. Chi-square procedures were used to test for associations. The findings for each of the first four research questions are summarized below.

The first research question examined relationships between teacher technology awareness and the selected demographics variables. For each of the demographic variables, no significant relationship was found.

Research question two tested for relationships between teacher technology training and the selected demographic variables. Once again, no significant relationships were found for the demographic variables.

The third research question looked for associations between teacher attitude toward technology and the selected demographics variables. The results indicated that no significant relationships were found in these tests.

Research question four sought to discover associations between teacher computer use and the selected demographic variables. No relationships were found between computer use and geometry teaching experience, mathematics major, and computer lab access. However, teacher computer use was found to be significantly related to the number of geometry sections taught. The chi-square value for the comparison between number of geometry sections taught and teacher technology use was $\chi^2 = 9.776$, df=4, p=.044. The strength of the association, as measure by Cramer's $V$, was $V= .31$. Examination of the data revealed that the more sections of geometry which a teacher was assigned, the less likely that teacher was to make use of technology in teaching geometry.

Relationships Between the Primary Variables and Principal Attitude

The fifth research question examined relationships between the primary variables and principal attitude toward technology use in geometry. In three cases: teacher technology awareness, teacher technology training, and teacher computer use, no significant associations were found. However, principal attitude toward technology was found to be significantly related to teacher attitude toward technology. The chi-square test for the comparison between principal attitude towards technology use and teacher attitude towards technology use was statistically significant, $\chi^2 = 6.297$, df=1, p=.012. The strength of the association was measured using Cramer's $\Phi$ as $\Phi = .351$. It was found that those teachers with high attitudes toward technology use tended to work for principals with high attitudes toward technology use.

Relationships Among the Primary Variables

The last three research questions sought associations among the four primary variables of the study: teacher technology awareness, teacher technology attitude, teacher technology training, and teacher computer use. For these comparisons, correlation statistics were used.
The sixth research question tested for relationships between teacher attitude toward technology and the other three primary variables. No significant relationships were found between teacher attitude and teacher technology training or teacher computer use. However, a significant association was found between teacher attitude and teacher technology awareness. The Pearson product-moment correlation value was $r = .30$. Those teachers with higher awareness of the capabilities of computers tended to have higher attitudes toward technology.

The seventh research question examined relationships between teacher technology awareness and teacher technology training or teacher computer use. The results of this study indicated that teacher technology awareness is significantly associated with neither teacher technology training nor teacher computer use.

The eighth and final research question looked for a relationship between teacher technology training and teacher computer use. The results of this study indicated that there was a significant relationship between these two variables. The Kendall tau value was $\tau = .34$. Those teachers who were trained in the integration of subject-specific software into their geometry classes were more likely to make use of technology when teaching geometry.

Conclusions

Relationships Between the Primary Variables and Demographic Variables

Three of the four demographic variables tested in this study showed no significant relationship to the primary variables. From these findings, it may be concluded that years of geometry teaching experience, college mathematics major, and access to a computer lab were not related to teacher technology awareness, technology attitude, technology training, or teacher computer use. This is in keeping with Dupagne & Krendel’s (1992) finding that attitude towards computers was independent of personal characteristics.

The fourth demographic variable, number of sections of geometry, was not significantly related to technology awareness, attitude, or training. Therefore, the results of this study lend evidence to the conclusion that no such relationships exist in the general population of secondary geometry teachers.

The only significant finding involving a demographic variable developed in this study was the relationship between the number of sections of geometry which a teacher was assigned and the use of computer technology in the classroom. It is interesting to note, however, that none of the high users taught more than three sections of geometry per day. Further, the majority of those teachers in the medium use group only teach one section of geometry. This may be a result of the large number of small schools in the sample which can only offer one geometry section per year. However, if these results are indicative of a more general population, it may represent a trend of those teachers which have a larger number of geometry classes proving to be less willing to experiment on a new teaching technique. Additionally, it may be that unequal access to computer technology may lead teachers to adopt a least common denominator strategy: if it isn’t available for all students, it won’t be used by any students. Several teachers specifically mentioned the lack of time as a factor in their decision not to use technology. As one teacher put it, “We don’t have time to teach the current curriculum; much less add time with technology.” Many of the respondents stated that technology required more time to learn and implement than they had available or were willing to give. This is in agreement with findings from previous studies on both principals (MacNeil & Delafield, 1998) and teachers (Cooper, 1998).

Relationships Between the Primary Variables and Principal Attitude

This study found no significant relationships between principal attitude toward technology and the variables of teacher technology awareness, technology training, and teacher computer use. The lack of a significant relationship between principal attitude and teacher computer use is in contrast to Stegall’s (1998) finding that enthusiastic principal leadership was related to high technology use. This discrepancy may be explained by Stegall’s definition of enthusiastic leadership. That term encompassed actions as well as attitudes. This study examined only the principals’ attitude. In order to effect classroom practice, it may be necessary for the principals to act upon their beliefs about the usefulness of technology. In other words,
principal attitude may be a necessary but not sufficient condition for changing teachers’ technology practices.

The interpretation of the significant relationship between teacher and principal attitudes towards the use of technology is straightforward. As the principals’ attitudes go up, so do the teachers’ attitudes. These findings are consistent with Drake & Roe’s (1994) assertion that the principal should be able to foster change in teacher attitudes. It should be noted, however, the results of this study could also be explained as teachers effecting a change on their principals’ attitudes.

An examination of the open response items indicated a potential problem. In both the teacher and the principal samples, approximately one third of the respondents indicated that the amount of use was their primary gauge of appropriate technology use in the classroom. Since Roberts & Stephens (1999) found that merely increasing the amount of time students spend at the computer does not increase achievement in geometry, those who advocate simply more technology access or higher usage levels in secondary geometry classrooms have no current research to support their position.

Relationships Among the Primary Variables

This study found that teacher attitude was not significantly related to technology training or teacher computer use. These findings are in contrast to Okinaka’s (1992) results. One possible reason for the difference is that Okinaka surveyed pre-service teachers’ interest in taking more computer courses and their intent to use computers after being hired. It may be that inservice teachers have enough demands on their time that their attitude toward technology does not always lead to training on technology and use of technology in the classroom.

The variable of teacher technology awareness was not significantly related to teacher technology training or teacher computer use. This is somewhat in opposition to the conclusions of Okinaka (1992) and Sheingold & Hadley (1990), that awareness is necessary for technology implementation. It may be that mere awareness of the capabilities of technology is insufficient to guarantee technology training or use.

In spite of their non-significant associations with technology training and teacher computer use, teacher attitude toward technology and teacher technology awareness were significantly related to each other. This finding does not contradict Okinaka’s (1992) conclusion that teacher attitude toward technology can be positively affected by making teachers aware of the capabilities of technology.

Several papers have recommended additional training for teachers in order to increase their level of technology use (Cooper, 1998; NCTM, 1998; Mathews et al., 1996). Yet none of these studies have shown that technology training and teacher computer use are related. Therefore, the significant association between teacher technology training and classroom technology use found in this study is a step toward justifying the recommendations for teacher technology training.

Recommendations

Recommendations for Future Research

This study found a relationship between teacher and principal attitudes. A portion of the relationship was based on the attitude that appropriate computer use could be described as an amount of time or level of access. Since merely increasing the amount of time spent in geometry class on a computer has been shown to be unrelated to achievement (Roberts & Stephens, 1999), the shared attitude has no supporting evidence. Therefore, it is recommended that one topic for future research should be an investigation of how teacher and principal attitudes towards the use of technology can be changed.

The relationship between type of technology training and teacher computer use also has more room for exploration. This study did not determine any causal relationship between these two variables. If a specific type of training is found to cause a higher level of computer use, that type of training should become standard. Therefore, it is recommended that the relationship between type of technology training and teacher computer use be a topic of future study.

Since the use of technology is both recommended (NCTM, 1998) and mandated (Watson, 1996), the inverse relationship between computer use and the number of sections of geometry taught becomes important. If it is a goal to use technology, the teachers who teach the most students should be using technology. Discovering the reasons behind this lack of technology use by these teachers should also be a topic for future research.
Recommendations for Practice

The results of this study can provide school districts with several recommendations for practice. The inverse relationship between technology use and the number of sections of geometry taught provides one such recommendation. School administrators need to be aware of this relationship and take steps to discover if it holds true in their district. If those administrators should find the inverse relationship among the geometry teachers in their district, an attempt should be made to determine the reasons behind the lack of technology use. At that point, the administration could seek to alter the factors which lead to low technology use among teachers with the most sections of geometry.

The teachers in this study were asked to report on the type of training they have received in the use of geometry specific software. Of the 52 teachers who responded, 25 (48%) indicated that they have received no training in the use of geometry specific software. Another 9 (17%) reported that they had undergone training only in how to use geometry software. Since the use of technology has been both recommended and mandated, another recommendation for school districts is to even out the levels of training received by providing integration training to all geometry teachers.

The results of this study indicate that 26 of 51 (51%) of the respondents indicated that they had low or medium levels of awareness of the capabilities of technology in geometry classrooms. It is recommended that school districts make an effort to assure that their teachers are kept up to date with the latest products available in their field. Since it is not possible to use technology that the teacher is unaware of, this will remove a potential impediment to technology use.

Finally, this study offers recommendations for current practice in teacher education. Schools of education should provide opportunities for pre-service teachers to become aware of the capabilities of technology in the teaching of geometry. Pre-service teachers should also be trained in the integration of technology into their specific subject areas. In this way, colleges of education will assist school districts in accomplishing the previous two recommendations.

Using WebCT to Deliver a Finite Mathematics Course to Preservice Teachers.

J. Harley Weston
Department of Mathematics
And Statistics
University of Regina
Canada
weston@math.uregina.ca

Abstract: In the spring of 1998 five faculty members at the University of Regina in Saskatchewan, Canada received funding to implement an online version of an introductory mathematics course. This course, Math 101, was designed to meet the needs of students in the elementary education program in the Faculty of Education and to satisfy the "critical thinking" requirement in the Faculty of Arts. This paper chronicles the development of Math 101 Online from the initial conception through the first full offering of the course in the Fall of 1999. It includes an overview of the tools that are available in WebCT. Strengths and weaknesses of WebCT are addressed from the course developer, instructor and student points of view. The paper also addresses the difficulties in online communication with students when such communication involves diagrams and mathematical notation.

Introduction

Math 101 is an introduction to finite mathematics which is delivered through a standard lecture format to 500-600 students per year on campus, and through regional and community colleges at various locations in Saskatchewan. The content contains arithmetic and numeration systems; problem solving; number theory; rationals, irrationals, ratios and percent; sets; and logic. In the spring of 1998 funding to implement an online version of Math 101 became available from the provincial government which has a desire to expand the number of university level courses that are accessible to learners in remote communities. Our motivation was to use this opportunity to tailor the course more closely to the needs of Saskatchewan learners and to improve accessibility for students who, for whatever reason, find it difficult to attend lectures. The proposal was made by five faculty members, four in the Department of Mathematics and Statistics and one from Mathematics Education.

Once the approval for funding was received a variety of possible software platforms were considered and a decision was made to use WebCT, a collection of course tools created by academics at the University of British Columbia. A number of factors influenced this decision. Software features that were required for delivery of the course were used to narrow the range of possible platforms and then versatility of the tools available and cost were the final determining factors. An added bonus was that WebCT was being used at the University of Regina to deliver a non-credit course in genealogy and thus there were people on campus with experience using the software. In the intervening eighteen months WebCT has been used to deliver and supplement other courses at the University of Regina (Maeers, SITE 2000).

Content Creation and Organization

Two undergraduate students were hired in the spring of 1998 to begin collecting, organizing and inputting the content. Both students were familiar with the content of the course and one of them, a geography major,
had experience the previous summer creating web pages. The second student, an elementary education major, had only minimal experience with HTML.

During the summer of 1998 the students took course notes and problem sets from three of the faculty members involved and began to design the course around this material. Each of the six units in the course was assigned to a faculty member who wrote the first draft which was then formatted for web delivery by the students and uploaded to the WebCT server. Each unit went through several iterations as all the participants read, edited and reread the material.

The content was prepared for WebCT delivery using a text editor and most of the HTML coded from scratch. Adobe Photoshop was used to draw the diagrams and MathType for construction of the mathematical symbols. Creating the HTML from scratch is certainly not necessary as any page creation software that produces HTML could be used. The File Manager in WebCT was used to easily move the content pages from the local computer to the server. Collections of files were zipped together, moved to the server as one file and then unzipped. The course material was organized on the server into units and sections using the Path Editor and problem sets were collected into the quiz database.

Pilot, Revisions and Delivery

In the fall of 1998 a pilot section of Math 101 Online was offered to five volunteer students. These students met with the instructor in a laboratory setting, three hours per week for the semester and worked online. The students, for the most part, communicated with the instructor through the Bulletin Board and the Private Mail Tools in WebCT. The scheduling of the class at a particular time and place was to observe the students and identify any problems they might have with the technology as well as allow for the class to be continued in a lecture format should some major problem develop. The class was completed without incident and the students performed well on the common final examination. The students had some constructive criticisms of the course layout and the number of worked examples but there were no serious criticisms of the technology or format of the class.

In the summer of 1999 revisions were made to the course material based on the comments from the students in the pilot section. The page layout was changed to improve the readability. The material was expanded in areas where the students found to be thin, more worked examples and practice questions were added and the quiz database was expanded. Work also began on translation the course into French.

Math 101 was scheduled in an online format for the first time in the fall of 1999. Twelve student registered and subsequently three dropped. Of the nine remaining students four live in Regina where the university is located, four live in other locations in Saskatchewan and one lives out of the province. At the time of writing this paper the students are completing the sixth quiz in the course and the final examination is scheduled in three weeks. The quizzes are written online but the final examination, which is common for all students in all sections, will be written with pen and paper.

WebCT Tools
The tools in WebCT can be roughly categorized into four sets, communication tools, study tools, evaluation tools and management tools. The specific tools used in Math 101 Online are outlined below.

Communication Tools

Bulletin Board
This is the main tool for communication among the students and the instructor. Messages posted to the Bulletin Board are viewable by everyone in the class. Messages are threaded and can be organized into fora by the instructor. The Bulletin Board is hypertext based which allows graphics, mathematical symbols and hypertext links to be included in posted messages.

Private Mail
The Private Mail Tool is used by the students and the instructor for private communications. Private mail between students or between students and the instructor is visible only to the individuals involved. In many instances students asked the instructor questions about the course material using Private Mail Tool. In these situations response were posted to the Bulletin Board without identifying the student. This helped to open up the discussion and show individual students that they are not alone with their difficulties.

Calendar
Important dates were posted on the Calendar, dates of quizzes, the final exam and university holidays when it might take the instructor longer to respond to questions. The instructor can post to the Calendar for everyone to see and the students can post notes to the Calendar which they alone can see.

Chat Room
The Chat Room was made available to the students in the course although the instructor had no plans to use it.

Study Tools

Compile notes for printing
Using this tool a student can collect pages into one file for printing. Since the course is organized into units and sections, with each section being an individual file, this tool make it very convenient for students to print individual sections, collections of sections or whole chapters.

Resume Reading Notes Where You Left Off
This tool, which uses the WebCT Path facility, allows students when they log on to return to the last page they were previously reading.

Glossary
A glossary of important terms used in the course.
Search Content
Students can search the course material for a particular word or phrase.

Evaluation tool

Quiz tool
Quiz problems and solutions are organized in a database. The questions can be multiple choice, matching, short answer, paragraph answer or calculated answer. All except paragraph answer can be graded automatically. In Math 101 the Quiz Tool was used for six quizzes given throughout the semester, one at the end of each unit. Students had a forty-eight hour window in which to write each quiz, but once a student began a quiz there were sixty minutes to complete it. One additional practice quiz was given in the first week to allow students to become familiar with the Quiz Tool. All questions were graded by the instructor. After each quiz was graded the student was able to see the questions, their responses, the correct solutions from the quiz database, their grade and any comments from the instructor.

Student management

The instructor is able to create and delete student accounts and manage the student password file. Students are able to change their own passwords. Grades on quizzes are automatically stored in a spreadsheet-like format which can be used to manipulate grades and compute averages. The instructor is able to view tracking information on each student which shows the distribution of hits on each page and tool in the course. The only time this facility was used in Math 101 was to ensure, in the first few days of the class, that each student was able to successfully log on.

WebCT: Strengths and Weaknesses

WebCT has strengths and weaknesses that need to be considered by anyone considering it as a delivery platform. From the designer’s perspective it has a rich array of tools which can be used in a variety of ways to present course material. The course material is created using standard HTML with no special of custom code creation software required. The ability to structure the material using Path Editor was extremely valuable in making Math 101 function as desired. This reliance on standard HTML does however have its drawbacks. A designer can use a WYSIWYG editor to produce the HTML code but in the author’s experience there are times when the HTML code has to be edited directly to get the page to perform exactly as desired. Also the fact that the WebCT File Manager is used over the web to manipulate the files means that it is slower than if you could manipulate the files on your own computer. The main means of support for a designer is the WebCT mailing lists, and this support is excellent. Replies to questions posted to the mailing list is very quick and helpful, both from the employees of WebCT and other subscribers to the list.

As the instructor in Math 101 one of the most useful features was the Bulletin Board. Since the Bulletin Board is a hypertext environment it allows the instructor to respond to students’ questions using diagrams and mathematical notation when required. This however requires that the instructor have a knowledge of HTML or create the reply using a WYSIWYG editor and upload it to the server. The Private Mail Tool has also proved to be valuable. The instructor found it very helpful that the private correspondence with students in the class stays within the WebCT environment. The course record facility which keeps the grades on quizzes in a spreadsheet-like format was found to be limited and slow since it has to be accessed over the web. It is, however, easy to download the grades from this facility to a spreadsheet on the instructor’s local computer.
Each student in the class is being asked to complete a course evaluation form but at the time this paper is being written these forms are unavailable. The students have used the Bulletin Board, the Private Mail Tool, the Quiz Tool and the ability to compile and print the notes but their reaction to these and other tools, and to the course in general is not available at this time.

Concluding Remarks

There are no easy solutions to many of the problems that arise in designing, implementing and teaching an online class. One of the first problems to face is the choice of software. The author has been satisfied with the selection of WebCT despite the weaknesses mentioned. No other course delivery software has been found which contains its versatility and array of tools. The requirement of mathematical notation and diagrams adds an additional level of complexity to a mathematics course. For Math 101 the requirements of mathematical notation are minimal and the use of MathType by the designers and instructor met these requirements. The students however have difficulty with mathematical notation when posting to the Bulletin Board or answering quiz questions. There are also times when a student asks a question that would be easier to articulate if a diagram were possible. The White Board, which is available in WebCT and in other web delivery software, may help to fill this need but its synchronous nature made it unsuitable for Math 101.

On reflection the author has misgivings about the choice of Math 101 as a first attempt in creating an online course. Many of the students who register in Math 101 have a fear of mathematics and would not be expected to enroll in a web based class. The participants, however, have learned from this experience and have produced a version of this existing course that complements the lecture format and expands the options for students wishing to enroll in Math 101.

A version of Math 101 can be seen at http://online.math.uregina.ca/public/math101sampler/. This sampler version of the course contains all the structure of Math 101 and a sample quiz but most of the content has been removed.
Online Conversion of a Technology Based “College Algebra” Course

Galminas@alpha.nsula.edu

Kathy Autrey
Northwestern State University
Natchitoches, LA 71497 USA
Autrey@alpha.nsula.edu

Abstract: The aim of this paper is to report on the authors' experience in designing and implementing an online version of a technology (graphing calculator) based “college algebra” course. College algebra is one of several courses mandated by the State of Louisiana as a component of the core curriculum requirements for undergraduate students. This is a course, which many K-12 educators will go on to teach in their classrooms. We identify some of the problems we encountered and the solutions we employed in order to resolve them. In particular, we discuss the unique challenges we faced in communicating mathematics online and utilizing the graphing calculator technology. Finally, we examine the compatibility of the standards advocated by the National Council for Teachers of Mathematics (NCTM) with the online paradigm, and we describe what we believe to be strengths and weaknesses of online learning models for college algebra.

Introduction

“College Algebra”, a course offered by every university in the State of Louisiana and by many universities around the country, contains material which should have been covered in the K-12 curriculum completed by many of our incoming students. Nonetheless, few Louisiana students (less than 2%) place out of this course. Thus, it appears that many students are not learning this material before entering college. Eight years ago, the Department of Mathematics at NSU was motivated to “reform” the course. A major component of our reform effort involved making the course technology-based. Namely, graphing calculator technology was heavily integrated into the course.

Several considerations led to the development of an online version of the course. NSU has a large proportion of nontraditional students (i.e. students who work full time and/or commute). For many of these students, the online alternative is not only more convenient, but may also be the only alternative. A second reason is the university’s current mission of making it possible for a student to complete an associate degree program completely online by the year 2005; it will be necessary to have this course in place if the university is to achieve its mission. A third consideration for the authors was the compatibility of the course goals and objectives of our reform based college algebra course with the online paradigm. At first, we were cautiously optimistic that we would be able to provide a “reasonable” alternative to the traditional on-ground class for nontraditional students who were sufficiently motivated. As the development of the course progressed, we knew that we could do much better than simply provide a “reasonable” alternative. After only a minimal amount of training, it seemed apparent to us that the principles which guide current reform efforts in undergraduate mathematics education went hand and hand with those which tend to guide the design of online learning models. We began to think that perhaps the online learning environment was more conducive to achieving some of these “reform” goals than the “on-ground” one was.

Section 1: Challenges/Problems Encountered — Some Resolutions and Advice.

In this section we discuss some of the challenges we faced and some methods we used to resolve (or at least attempt to resolve) the problems we encountered. Some informal advice and recommendations are offered.
Training & Non-technical Support

We knew that the project could not even get off the ground without certain preliminary resources, as well as general support from our institution – both departmental and administrative. We needed time to develop the course, new personal computers, and professional training. We obtained these through a grant from our state Board of Regents (with matching support from the university). The grant provided us with course release time, money to take training courses in the design and delivery of online courses from the UCLA Online Extension Program, and new computers. We strongly encourage anyone developing an online course or program to get some training. Only a very short time into our own training process, we were amazed at our initial naiveté and at some of the misconceptions we had held. The online experience is inherently different than the on-ground one, especially when the online mode is asynchronous. Bedore (1997) maintains that online experience and training, as well as content expertise, are necessary prerequisites to a successful online curriculum conversion. This is particularly important for those who are facilitating more interactive learning models. Bedore also recommends having a “champion” in your corner, someone dedicated to the success of your project who will do what it takes to keep development and support for the project on track. In our case, we had this from the dean of our college and our departmental coordinator. Finally, for the purposes of doing justice to your course and preserving your sanity, we recommend against developing an online course for the first time without release time and/or help from a graduate assistant (both would be preferable).

Technical Support.

As concerns technical support, we did run into some problems. Use of the course management system TopClass was mandated by the university; a lack of training in its use, and a lack of support when things went wrong were major stumbling blocks. We strongly recommend that, before jumping in, you find out about the existing technological infrastructure at your institution and the level of technical support you can expect it to deliver. Unreliable or difficult to use technology and poor support services could doom a program to failure and put a permanent dent in your market. Fortunately, NSU has been a Louisiana leader in distance learning. There were many people around for us to talk to during the process of developing our course. We strongly recommend actively seeking the advice and expertise of people who have experience with whatever technology you are using.

Course Management Systems

We found Top Class, the course management software, to be somewhat inflexible (especially in terms of our need for graphical representations). As it turns out, that problem may be resolved as the university is switching to a system called Blackboard (which appears to be more user friendly). For anyone in the position of being able to choose a course management system, we would recommend giving this careful consideration. Learn something about the different alternatives and make an informed choice rather than just choosing one randomly. They really do differ, and it doesn’t seem to be the case that the more expensive options are necessarily the better ones.

Accomplishing Learning Objectives & Choosing Technologies

We wanted to accommodate different learning styles, yet at the same time keep it simple. We did not want to burden students with complicated technological demands or overwhelm them with distracting state-of-the-art “bells and whistles.” We were especially concerned about the availability and quality of technical support services. We felt there was no reason to use a given technology unless it would clearly support/enhance the learning objectives for the course. We did know that something beyond plain text and “lecture” was needed to convey problem solving techniques and develop problem solving skills. One develops problem solving skills by solving lots of problems. Some mechanism needed to be in place to provide students with an opportunity to attempt problems and get immediate feedback. While we would be available to answer students’ questions via email, we did not feel this would be sufficient to provide
students with an appropriate level of guidance and feedback. Initially, we considered requiring students to purchase an interactive CD ROM device (such as Math Systems’ Mathpert Assistant, Quant Systems’ Adventures in Algebra, or Academic Systems’ Mediated Learning software). But we decided against this for two reasons. We wanted to keep student costs at a reasonable level and we discovered that there were already wonderful free resources available on the Internet. In addition to the text and TI-83 graphing calculator which we also require for our on-ground class, we required students to purchase one additional piece of software called Graph Link that allows communication between calculator and computer.

The course was structured as follows: students received weekly assignments that included readings from the text, problems to solve, and discussion question(s) requiring responses in our class “discussion” area. Each assignment was accompanied by a “lesson enhancement.” The lesson enhancements were Web pages (written by us) containing summaries of key concepts, examples, suggested interactive activities, and links to interactive tutorials and self-quizzes. Many of the tutorials offered multi-layered dynamic presentations of concepts with visual/graphic explanations, opportunity for experimentation, and self-quizzes with instant grading and feedback. Weekly quizzes were given for credit. (We provided solutions to assigned problems before posting quizzes-for-credit.) Another integral component of the course was the use of both group and individual projects. These provided students with an opportunity to apply the concepts learned in the assignment to “real world” situations (i.e., choosing the best cell phone plan from options offered or predicting market value of property for a given geographic location). Finally, we gave midterm and final examinations (administered online via the TopClass testing feature).

Graphing Calculator Technology

Research has suggested that use of graphing calculators enhances students conceptual understanding of mathematics and tends to foster a more positive attitude toward mathematics in general among both students and faculty (Hubbard, 1998). One of the major issues involves the need to effectively use the graphing calculator within the academic setting and its incorporation in the solution of real-world problems (Testone, 1998). Based upon our own experiences and that of others (Hollar, 1999), students using graphing calculators tend to have a better understanding of functions than those who do not use this technology and, therefore, have a better grasp of the implications in problem solving. The calculator allows students to easily view problems and principles from multiple perspectives, including visual or graphic, numerical, and symbolic, and it allows them to see the relationships between them. It also makes it feasible for students to attack “real world” problems without losing the forest for the trees.

As we mentioned, the graphing calculator is an essential component of our current on-ground course; also our text is intended to be used in conjunction with the graphing calculator. Knowledge of the graphing calculator is assumed in all courses for which “college algebra” is a prerequisite; it was essential that we find a way to incorporate this technology into our online course. That is where the Graph Link software came into play; this software allows the user to send images generated by the calculator to the computer for inclusion in documents. We used this technology to send graphical representations, tables, instructions, etc. to our students and the students were able to send graphs to us. The biggest problem was the way that must be done; check your course management software. Graph Link saves images as .tif files but the software would only accept .gif files; the conversion was time-consuming but not impossible (you need good technical support here to find out exactly what is required). In addition, we created a "Calculator Corner" where students could go for help in using both the Graph Link and their calculator. In some cases they were referred to various sites for assistance; in others, we wrote simple instructions and provided images from the graphing calculator using Graph Link. Other than that, the students used an ordinary keyboard for most of their work, using the same symbol conventions as they do with the graphing calculator. There are nice websites out there that explain “how to type mathematics” on an ordinary keyboard.

Students’ Computer Literacy

We did encounter some problems with computer literacy on the part of students. The university does not officially require a computer literacy prerequisite. We strongly encouraged literacy in a course
“disclaimer;” nonetheless, we did end up with some students who had very little or no computer experience. In the future, we would like to see a computer literacy requirement for incoming freshmen.

Other Considerations

We had high hopes about the discussion component of our course. Based on our experience with online learning, we imagined an active and stimulating “virtual classroom” where we as facilitators would ask leading questions, steer the conversation in the appropriate direction and bring about understanding of the key concepts. We have since reconsidered our assessment of the potential value of the class discussion. Many of the learning objectives for our algebra course involve specific “skills” which must be mastered. These are probably best demonstrated through an interactive component that can provide meaningful feedback. We still have hopes that discussion of the class projects can be fruitful. We intend to make the projects our main vehicle for assessing the achievement of learning objectives centering upon “real world” application of mathematical knowledge, critical thinking and communication skills, and building cross-disciplinary knowledge.

Section 2: Compatibility of Online Paradigm with NCTM Standards.

In 1989, the National Council of Teachers of Mathematics (NCTM) published standards for mathematics education. The document provides general guiding principles for mathematics instructional programs and specific standards about mathematical content and processes students should know and use as they progress through school. The chief premise is that the underpinnings of everyday life are increasingly mathematical and technological; students will live in a world where intelligent decisions often require quantitative understandings. Just as the level of mathematics needed for intelligent citizenship has increased dramatically, so too has the level of mathematical thinking and problem solving needed in the workplace.

The guiding principles for instructional programs include promotion of the learning of mathematics by all students and the use of technology to help students understand mathematics and to prepare them to use mathematics in an increasingly technological world. We believe that the online paradigm is particularly compatible with these basic principles. The abundance of Internet resources and emergence of new technologies are creating opportunities to accommodate a wider variety of learning styles. Concepts can easily be presented from many points of view. Mathematical software, computer algebra systems such as MAPLE, and graphing technology are being integrated ever more seamlessly online.

The Standards are divided into two categories – those which focus on content and those which focus on process. Embedded in the standards we found many of the learning objectives for our college algebra course, as well as other lower level math courses offered here at NSU. One of the content standards includes a recommendation that attention be given to patterns and models so that students acquire the ability to “use mathematical models and analyze change in both real and abstract contexts.” Another is that attention be given to data analysis and statistics so that students learn to “pose questions and collect, organize, and represent data to answer those questions,” “interpret data using methods of exploratory data analysis,” and “develop and evaluate inferences, predictions, and arguments that are based on data.” We believe that the combination of graphing calculator technology with Internet resources offers outstanding potential in these content areas. Numerous Internet resources are available for data gathering and experimentation with patterns and models. The TI-83 graphing calculator is particularly well suited for statistics and data analysis. Students can readily test predictions of models by collecting information from the Internet or by running simulations on their calculator.

The process-oriented standards focus on problem solving capabilities, reasoning abilities, communication skills, making connections, and mathematical representation. It is not only recommended that students learn to express mathematical ideas coherently and clearly to others, but also that they extend their mathematical knowledge by considering the thinking and strategies of others. It is also recommended that students develop a repertoire of mathematical representations and learn how to use them to “model and interpret physical, social, and mathematical phenomena.” We believe that the process-oriented standards can be met most effectively through interactive discovery-oriented learning models in which the student is
expected to actively assume responsibility for his/her learning process. The capability of the online learning model to accommodate asynchronous interactions allows much greater opportunity for students to learn by drawing on their own experiences and the experiences of others to apply knowledge in a real world context, and to make connections between math and other disciplines. It is worth noting that asynchrony, as well as being a convenience is what makes the high level of interaction possible. Internet resources further facilitate the goal of having students draw on a number of resources to answer questions and solve problems. Internet resources also facilitate multiple representations of phenomenon and the illustration of ideas from different points of view (e.g. graphic, numerical, and symbolic).

It struck us from the beginning that the guiding principles advocated by proponents of online learning models tend to be similar, if not identical, to those which continually pop up in the undergraduate mathematics reform literature. For example, Berge (1996) recommends avoiding lecturing, encouraging group interaction, and intentionally giving students little direction. De-emphasis on lectures, cooperative learning, and student-centered learning are all cornerstones of the current reform efforts and appear to have positive effects on student learning (Reynolds, 1995, Rogers, 1988). Other “reform” goals include emphasis on concepts and the “big picture and de-emphasis of rote memorization (particularly of isolated facts and techniques for which no context is provided.). Research supports the contention that students learning objectives are better achieved when “teachers regularly utilize the computational, graphic, or symbolic capabilities of technological tools to develop mathematical ideas. (Carpenter 1998, Heid 1988, Hiebert & Wearne 1996).

Section 3: Strengths and Weaknesses.

Strengths of an Online Program

Offering college algebra online accommodates both "distance-free" and "time-free learning." The asynchronous element of the program opens educational opportunities for students with varying backgrounds and experiences. Each brings a unique mathematical perspective to the "class" which promotes interest and may provide each with a better understanding of why mathematics is so important. Furthermore, the online environment is especially suited for fostering the development of critical thinking skills as a vehicle for students to apply course content in a "real world" context. Not only does the online discussion encourage students to draw upon their own experiences to tie theory to practice, it also provides an environment conducive to cooperative learning activities. In addition, the lack of time constraints gave students an opportunity to digest the material and relate it to their own experiences.

Conversion of traditional algebra courses to online courses will vary but utilizing grant resources, as we did, can provide some budgetary relief. Naturally, as faculty experience grows and technology changes, these costs can be expected to decline. According to Bedore (1997), curriculum conversion costs should be about $500 per course with setup and technology costs ranging from $0 to $1,000. Complete course development costs would be substantially more (about $2,000).

Weaknesses of an online program

With the need for major modifications to the existing infrastructure, the cost of implementing an online program could be prohibitive. Without the kind of support we had for this project in terms of equipment, release time, and faculty education, this project would have been doomed from the start. In addition, poor promotion of the course could lead to frustration on the part of both faculty and students. We had problems with students who were registered for the course but really had no desire to participate in an online course (their advisors put them in the section because it was the only one open at the time).

Research suggests that the dropout rate for online courses may be higher than that of traditional courses (Sherry, 1996; Starr, 1995). Students taking a college algebra course online (or any other online course) must be sufficiently motivated, self-directed and dedicated to the task. They must understand that they share a somewhat greater responsibility for their learning than might be expected in a traditional class.
of our main concerns was student interaction; the students were reluctant to "discuss" mathematical concepts with each other for a variety of reasons. The lack of face-to-face contact was a real problem for some; this may have been due, in part, to the novelty of the situation since these students had limited online experiences.

Issues in developing an on-line mathematics learning series for middle school teachers

Jennifer Knudsen, Institute for Research on Learning, USA, Jennifer_Knudsen@irl.org

Abstract: Online learning could be an important resource in meeting the need for helping teachers learn more mathematics, which is critical to the success of long-term change in mathematics instruction. We report on a pilot of an online learning series for middle-school mathematics teachers. An existing Web-based professional development center was utilized together with specially designed interactive web pages to structure and support six weekly synchronous meetings. The mathematical content of the series was proportions. The pilot yielded initial success in fostering mathematical discourse among participants and raised issues, technological and other, for the future.

As a decade of reform work in mathematics education—based on the National Council of Teachers of Mathematics’ Curriculum Standards (NCTM, 1989)—comes to a close, reformers are looking to technological solutions for the problem of delivering high-quality professional development to teachers nationwide. Subject-matter expertise is of particular importance as recent research (Ball, 1989; Schifter, 1997; Darling-Hammond, 1998; Ma, 1999; Sowder et al, 1996) highlights the mismatch between teachers’ knowledge of mathematics and what and how they are expected to teach. Neither simply exploring student activities nor taking traditional college-level mathematics courses will help teachers develop the mathematical practices they need. Reformers are designing new programs focusing on developing content knowledge in support of change. Online learning communities hold promise for providing professional development that is convenient to schedule; can be offered to urban, suburban and rural teachers; can fit in with ongoing reform programs rather than be simply “another inservice.” The question of how well subject matter learning can be supported online is an open one.

This fall, we at IRL developed and offered a pilot version of an online seminar for teachers, designed to contribute to this reform work. The pilot, Brush up on Proportions, is part of our WebMath online math learning community for middle school teachers, which will expand into a larger program next year. The intended audience includes teachers who are already engaged in implementing a Standards-based math program or are at least using some materials or processes recommended by the Standards. The seminar consisted of six hour-long sessions, offered as a series. Each session was devoted to exploring and deepening teachers’ proportional reasoning—a central topic in Standards-based middle school programs—through activities and discussion. Conceptual and procedural knowledge were both emphasized, as well as the relations between them. We also aimed to establish norms of discourse that will encourage teachers to develop mathematical practices such as making conjectures and constructing mathematical explanations.

This paper describes features of our online seminar environment and issues that arose during the pilot.

Features
A suite in TAPPED IN. Rather than build and support our own interactive web infrastructure, we contracted with TAPPED IN to house the virtual classroom in which Brush up on Proportions took place. TAPPED IN is a virtual professional development center designed to house activities for teachers throughout their career. The classroom is part of a suite where various middle-school math-related events sponsored by IRL take place. Organized as a campus, with building, suites and offices occupied by tenants who provide professional development services for teachers, TAPPED IN provides an infrastructure with a graphical interface in addition to a text window through which participants can communicate with each other and use objects in the environment. Participants’ main venue for participation in class is a text window in which their comments, “emotings” and interactions with objects are seen by others, and they can see what others say and do. Objects and occupants of the classroom appear in a graphics window too. The graphics window gives participants a sense of location through maps, floor plans, and sometimes, a 3/4
view into a room. One room in our suite is portrayed visually as a corner of a classroom with objects on the walls, through which teachers can view the course syllabus, get more information about IRL and access the web pages that form the text for our seminar.

Web pages and other tools. One of our initial questions was how to build a discussion of mathematics in the relatively thin online medium of text exchange. Current math teaching and professional mathematicians’ practices include the use of many different materials and representations. In teaching, handouts, texts, manipulatives or other curriculum materials are resources for mathematical thinking and discourse. Also, there is some medium for whole class display of ideas: a white board or overhead projector. The overhead can display pre-made representations or spontaneous ones. The practices of working mathematicians often include discussion centered around a just-in-time scribbled diagram, sketch or equation.

The current TAPPED IN tools that provide similar capabilities are text-only whiteboards, which we determined to be of limited use in displaying mathematical ideas. The whiteboard did begin to serve an agenda structuring purpose, though. In future iterations, we plan to design, with TAPPED IN staff, and use a graphics-capable whiteboard and a special mathematics notation tool. In addition we are looking at inexpensive commercial devices for bringing scribbles to the digital environment. In this first pilot, however, we worked with software and capabilities we had already to create web pages.

We created interactive web pages that play the roles of both manipulatives and textbook in our virtual classroom. These pages are textbook-like in that they structure the course content; they serve as manipulatives in that their interactivity allows users to have experiences on which to base mathematical conjectures. The facilitator, or anyone in the room, may project the pages for all to see and work with. Four of these web pages were used in Brush up on Proportions:

- Page one shows the iconic proportional man by Leonardo DaVinci, where a circle is inscribed around his armspan and height and a square is constructed around him in another way. There is no interactivity to this page. Text asks users to consider what is commonly meant by the term “in proportion”, using the picture as a springboard for discussion.

- Page two shows a floorplan of a room with some furniture in it. When users type in a scale for the room, the resulting width and length of a rectangular table appear. Text asks users to set the scale so that the floorplan rectangle represents a table that is 130 cm wide.

- Page three presents a more complicated floorplan problem: selecting a table from one scaled diagram to insert in a floorplan with another scale. The ratio between the sides of the table is the first determiner of which table is a good choice.

- Page four shows a proportion form, \( \frac{a}{b} = \frac{c}{d} \). In a set of challenges, numbers replace a, b, c and d to make a false proportion and users must change one number to make a true proportion. The proportion form is tied to a picture of two rectangles—a by b and c by d—superimposed on a grid, so users can note how the rectangles compare visually when the proportions are true or not. They are asked to use this experience to help them think about why the cross-multiplication algorithm works. They are encouraged to use other representations or arguments based on arithmetic, too. In other words, they are to explain why if \( a/b = c/d \), then \( ad=bc \), without resorting to algebra.

These experiences are designed to help teachers develop their proportional reasoning and connect it to formal representations. The problems on pages two and three are not difficult for many mathematics teachers to solve; however, we have found that their connection to proportion and the relationship among all the multiplicative relationships in the pictures are not always explicit. For example, one participant said, “we don’t need proportions” to solve the problem on page two, indicating that dividing 130 by the width of the rectangle in floorplan units would suffice. This is certainly a correct procedure for solving the problem, based on an intuitive understanding of its underlying multiplicative structure. However, this solution to the problem does not help teachers help students develop their own multiplicative sense. In discussion of the problem together in seminar, we asked ourselves to justify each stage of the answer and to connect the work to the proportion \( a:b = c:d \).
The web pages worked well as a resource for mathematical discussion. Participants actively engaged in trying out solutions in the interactive structure. The discussion was anchored in the particulars of the representation but also led to more general mathematical insights. We will improve the representations based on insights we gained through using them. For example, setting the scale may not be the most helpful interaction to offer in solving the problem presented on page three. We will also build new sequences of web pages that follow other learning trajectories through proportional reasoning: for example, supporting the connection between the proportion form and linear variation.

Objects. The TAPPED IN environment, in true “moo” fashion, includes a number of objects with which users can interact. A few of these have been used as instructional devices. As a simple example of proportionality, we created a virtual pet, Shrinky, who responds to the text command, “shrink by 50%” by shrinking from 100 to 50 centimeters. This prompted others to display two cows, drawn in the text window in ASCII symbols. The cows then became the topic of discussion: what percent of the first’s length was the second? Conjectures were made and the facilitator was able to model mathematical questioning and justifying in a non-threatening way around objects that were displayed with humor.

In the future, we hope to have objects that can accept more flexible commands than “upon text x, print text y.” For example, Shrinky Jr. might be able to know her current length and calculate her new length based on the percent she was commanded to shrink. Participants could try to get Shrinky to shrink from 160 to 25 feet in exactly three shrinks and learn about the concatenation of percents, part of multiplicative and proportional reasoning.

Using research findings. We are building on existing insights into cultivating and growing Web-based communities (Reingold, 1993; Rochelle and Pea, 1999). From this research and reflection, we know, for one thing, that attention must be paid to norm setting. Our facilitators set the tone of discussion in the community and establish mathematical norms. Essential to this tone setting are both providing and requesting mathematical explanations. We have also encouraged a sense of play with the TAPPED IN objects and with light banter in between and throughout the mathematical insights.

The literature also informed us that personalities can be an important factor, and that social events and personal talk help bind people together to do the more content oriented work. In the future, we plan to focus on these aspects of community building: We will encourage participants to create profiles and use pictorial “avatars” when they are online. We will host online social events and encourage “idle chatter” as a way of establishing commonalities. We will utilize TAPPED IN’s resources and existing culture to help “enculturate” course participants.

Issues

Mathematical discourse. We aim to help teachers connect their mathematical intuitions with standard forms through discourse. This is a two-way street: teachers can use standard forms such as proportions to construct mathematical explanations of numerical insights they have; they can also use the situation presented in the interactive web pages to help support explanations of their use of the standard forms. In Brush up, this meant that we helped teachers connect the proportion form, \( a:b=c:d \), to their own multiplicative reasoning. Figure one shows one of the interactive web pages that sets up a simple scale problem: to set the scale of the floorplan so that the rectangle represents a 130 cm long table. For adults fluent in intuitive proportional reasoning, it is not too difficult to divide the 130 cm by 5 squares of the rectangle’s length to get 26 as number to put into the scale. But our participants did not immediately construct explanations for why division was the operation to use and why those two numbers were involved. Through discussion together, we came up with two explanations: that the 130 cm of the real-world length needed to be distributed across the 5 units of length of the rectangle, and that this distribution called for division. We also saw that we could set up the proportion \( 1 \text{ unit:7 cm} = 5 \text{ units:130 cm} \). The proportion related the scale to the paper and real tables. Building these kinds of multiplicative connections is facilitated by use of the proportion form, \( a:b=c:d \). The result of all this should be more conceptual resources for teachers to draw on as they help students reason about and solve similar problems.
Pace of interaction. As compared with a face-to-face discussion in a classroom, the pace of conversation is slow in our online course. One hour was not sufficient time to do an activity, discuss it, and summarize the important mathematics in the activity and discussion. The initial course outline covered the material in three weeks; our just-prior-to launch outline was stretched to six sessions, and we ended up covering about two thirds of the outlined material. This phenomenon is, of course, not restricted to syllabi of online courses, but it is our sense that the problem was exacerbated by the slow rate of conversation online. The next seminar will have ninety-minute sessions. We will also institute two leaders: a facilitator, keeping the discussion flowing and helping everyone participate, and a recorder, keeping track of insights on the white board.

There are some benefits to the slowed pace of idea exchange in the online classroom, however. The pace of the overall discussion leaves room for side conversations to emerge. And obviously, these are not disruptive the way two people whispering to each other in class can be. Two staff members participated in Brush Up from computers that were housed side by side. They were able to carry on a face-to-face exchange about a mathematical topic related to that week’s seminar: they were trying to informally prove or disprove that “three points determines a circle.” Scratch paper and white boards were involved. They made a fair amount of progress while still participating seamlessly in the discussion of Leonardo DaVinci’s iconic proportional man.

This interaction and, additionally, phone calls to solve technical problems during the class, has led to the plan to encourage participants to pair off into “buddies”, between whom some kind of communication outside but during the seminar is encouraged. Online, phone and face-to-face communications are three means for this. The online environment allows participants to whisper to each other: in other words, to type comments that only the two in the exchange can see on their screens. Phone conversations are possible if long-distance phone bills are not a problem and if the Internet connection does not take up the phone line. Alternatively, participants from the same school could participate together from their school’s computer lab.

Abandoning linearity. Giving up conventions of linearity that apply to oral conversation seems to be key to becoming adept at online, text-based discussion. In oral conversation, we allow parenthetic remarks, but they have some labeling, and they are limited in scope and frequency (depending on the speakers, of course). Online, two or more conversational topics can become quite interleaved. Online participants develop conventions for marking this, too, if the comments in the same conversation become widely spaced.
in the text. For example, a participant might preface her comment with “re table size” if table size had been the topic several lines earlier.

Our preliminary experiences suggest that the non-linearity of online, text-based conversation can allow for greater access to participation. Though new users sometimes say that the moment for their comment was lost so they kept quiet, in fact, they probably could insert their comment way down the line, with a marker, and make a meaningful contribution to the conversation. We will track data on this hypothesis in the next pilot, and we will seed, by example, appropriate markers.

Attracting participants and supporting change. We had no idea how many participants to expect at our first series. We announced the series on our Middle-school Math through Applications Web site and related Web sites visited by teachers and curriculum decision makers. We sent email to teachers with whom we had worked in the past and also announced the series on TAPPED IN’s calendar and newsletter. Seven was our highest attendance. Additionally, no one teacher attended all six sessions. These numbers were adequate for our pilot purposes. We didn’t want to have a crowd in our initial pilot, where our intention was to try out the new environment and course materials.

Our initial pilot confirmed one of our starting premises: that this online subject-matter learning series needs to be linked to ongoing professional development programs for teachers. We believe that this is important not only for attracting participants, but also for making the experience effective in supporting long-term change. We already have in place connections for the future. Connections can be made through curriculum adoption or through state and district programs. For example, our next seminar series will be offered to 20 teachers who are piloting a unit from a new Standards-based comprehensive math curriculum. They will be teaching a unit focused on scale factors and proportions, and the Brush up seminar will directly support their teaching. We have developed interactive web pages that present problems similar to those found in current Standards-based texts. We have also connected with state and district leaders to see how Brush up can be of service to their programs.

Divergence vs. convergence. We experienced the tension true of all problem-centered, conceptual-understanding-oriented teaching: constraining the conversation to keep the participants’ discussion and insights in the range of the mathematics topics defined in the lesson plan, as opposed to encouraging divergence to capture the range of mathematical insights possible based on a given situation.

For example, one week, the entire session’s discussion focused on page one of the “web text”, displaying a man with arms stretched and figures circumscribed about it. The depth and breadth of the conversation around this image surpassed our initial planning expectations. The page was designed simply to ground proportion in a familiar image, helping us tease out the meaning in everyday usage. But the discussion went beyond that: Questions were asked and conjectures made about the relationship between the circle and the square. The connection to ratio and proportion was made. Someone raised the question, “What was he trying to tell us with this image?” We agreed upon a relation among the geometric figures and the body parts in the image and, finally, shared insights about the meaning of “proportional” in common usage.

As we plan for balancing convergence and divergence in the next iteration, we are structuring the session so that time is left at the end for the facilitator, and others, to mount a virtual soapbox in order to summarize the mathematical territory covered and make connections that might have otherwise remained implicit.

Technological capacity. We did not want to limit teachers’ access to the series with high-tech demands. Yet we wanted to provide a rich online learning experience. This led to tensions. Web pages with text and graphics, like the DaVinci activity, work for any teacher with an Internet connection and a browser. The TAPPED IN environment offered both Java-based and Web-based versions of the classroom. In order to create a more interactive experience, we decided to use JavaScript. JavaScript does not take significantly longer to download than a traditional web page, but requires a Java-enabled browser. This did not seem too limiting since Java-enabled browsers are quite common. In order to support the majority of these browsers, we limited ourselves to JavaScript 1.0, the earliest incarnation of the scripting language.
In this pilot we also required participants to get the Shockwave plug-in and provided a link to acquire it. Java applets will run without a plug-in, but would take longer to download and were more difficult for us to develop. When we combined these different technologies (particularly the Java TAPPED IN window and the Shockwave activities), we found that the browser could run into memory problems. The teachers needed to be able to allocate more memory to their browser if they had enough RAM to do so. This was too difficult for some participants to do while maintaining their role in the discussion.

**Conclusion**

Online learning environments hold promise for providing professional development opportunities for teachers. Our initial pilot showed that a focus on subject matter, as called for in recent research on teaching, can be accomplished through discourse centered on interactive web displays. Issues of problem-centered instruction are mirrored on line and new issues arise due to text-based pacing. Additionally, online learning programs can be “just another workshop” unless integrated into ongoing professional development programs. Balancing the need for rich representational tools for math learning with low-tech user limitations is a constant challenge.

Abstract: Technology is best utilized as a tool for exploring the foundational objects and exploring and varying the underlying nature of the object upon which the abstracted mathematical symbol is constructed. When this is done appropriately it can serve to elicit the formation of selected concepts. This paper will serve to illustrate how the symbolic computer can serve to create psychologically foundational mathematical objects of thought for the learning.

Introduction

The potential inherent in the modern microcomputer to serve as a bridge between and among instructional theories has not been lost upon many researchers in mathematics education and curriculum theory (Brownell & Brownell, 1998; Garofalo, Shockey & Drier, 1998). The computer easily enables a dynamic and active learning environment within which each of the process strands of the National Council of Teachers of Mathematics (NCTM) standards might find a home (NCTM, 1989). After all, when one thinks of reasoning, problem solving, communication and connecting related ideas the tool of choice in nearly every discipline is the microcomputer.

Furthermore, unlike the traditional calculator, the modern classroom computer has an unparalleled ability to implement both graphical and procedural components of mathematics understanding in a single unified object. By their creation and utilization of mathematically relevant computer-based objects this dual encapsulation enables the students a unique opportunity to see both the form of representation and their actions utilizing this representation simultaneously. For this reason alone it would be a natural tool for both classroom use and theoretical musings.

This has not been lost upon teachers and despite those who would use the computer solely for the presentation of pre-packaged instructional units, there is a growing consensus that the computer can be an ideal tool for knowledge construction at an individual or group level (Harvey & Charnitski, 1998). As we explore the potential for classroom uses of computer technologies we have a once-in-a-lifetime opportunity to blend the best of learning theory and the practical realities of student actions.

Creating a New Class of Mathematical Object

Let me address for a moment the extent to which the object orientation metaphor, found in the modern windowed operating systems and programs, transfers to the “tools to think with” notions of current action upon objects models of mathematics teaching and learning. In particular, the object-oriented environments which modern technology has created are ideally suited to parallel and facilitate the ability of students to take a broader variety of action upon objects of a nature and kind hitherto unknown. These student controlled actions upon these mathematically powerful and computer enabled objects have the potential for creating classroom environments which both surpass the pale hopes of the integrated learning system and would surprise those wedded to a conservative view of Piagetian developmental levels.

Given the long history of cognitive science of borrowing the most current metaphors from computer science it should come as no surprise to see the applicability of many of the object oriented programming strategies to reflect aspects of human cognition (DuPlessis, 1995). And, indeed this new metaphor plays out very well for the case of mathematics education. The tools supported by the modern computer enable a new class of objects with which to think.

[1] For further background on the importance of what I am calling dual encapsulation Sfard offers a highly informative account of the intertwined roles of process and objects in mathematics (Sfard, 1991).
In order for this to happen, however, we must attempt to leave behind any preconceived notions about the role of the technology as being most useful for information presentation and delivery. A much healthier perspective, at least in terms of understanding this new approach, would be to envision the technology as being used to provide a milieu within which knowledge construction can occur (Connell & Abramovich, 1999). To see what this might entail, let me begin by telling a brief story from a very early research study using the Windows based authoring program ToolBook.

I had created a ToolBook program that I called a "Cognitive Playspace" for children to explore various foundational notions of mathematics. My goal at the time was to examine the extent to which traditional physical manipulatives might be augmented by technology. One activity, in particular, involved the use of various geometric shapes. I had intended these to be analogous to the traditional pattern blocks with which the children were already familiar, but to not be identical to them. In this activity, the children were presented with a variety of the puzzles to solve.

In the puzzle set for this particular day one of the tasks was for the child to reconstruct a pattern made using the provided shapes through manipulation of the geometric forms on the computer's screen. I had developed some fairly simple tools that would enable the geometric shapes to be rotated, translated, and generally moved about the screen.

Of particular interest for the notion of object creation is an event that took place when I brought a group of Kindergarten and First-grade students to the University to work with this exploration package. By this time they had had other experiences in both using ToolBook and the relatively primitive Windows machines. By the time of this incident the children typically had very little difficulty relating to the computer itself. In looking into their level of expertise I would say there were easily the equal of a computer savvy kindergarten student of today. If this is somewhat surprising given the fairly primitive state of technology at the time I should mention that these were 386 and 486 computers running Windows for workgroups. At the time of this study they represented an extremely high end product. Furthermore, for the type of software that we were running, these were more than adequate to give reasonable performances even by today's standards.

As an aside, the notion of using the most powerful technology and authoring system then available to work with kindergarten students struck many as being amazing. I made the point then, which I still believe, that in order for the computer (of that day) to be meaningful it required the highest end product. One of the major pleasant surprises of the last nine years is how well these earlier findings hold up. Indeed, the off-the-shelf machines of today are quite comparable (in terms of the visualization and manipulability of objects they engender) with these early efforts. Not only was this work ahead of the curve, it was outside the box totally.

But what I remember most, relative to the notion of object reification, came from the experiences of one young man who in his manipulation of the graphic objects managed to drag all of them off the computer screen. This was a bit more of a problematic than it might at first appear for in the nature of "it's not a bug it's a feature" I had not created a simple button to return objects to the screen once they had been dragged off the working area.

I must confess that this was a complete oversight on my part. The program was under development and I had not yet thought as to what would happen if objects were to be dragged off the screen. In the course of developing the activities I had always just clicked to the next screen and then back to reset the screen — this had become so much a habit that I had taken it for granted at the time work with the children began. Of course, this child was blissfully unaware of that strategy. When he dragged them off the screen for all he knew they were gone forever.

I'll never forget his eyes looking up to me as they swelled with tears as he said, "Help me, Dr. Connell! I have lost all of my toys."

His painfully sincere statement serves as a powerful reminder that in the mind of this child these computer images represented real objects upon which he was carrying out real operations. Furthermore, these operations carried with them a heavy kinesthetic component that was totally unexpected at the time. Subsequent observations and interviews illustrated that the physical manipulation of his eyes and hands with the motions of the mouse as translated to the computer's screen translated to his mind as a series of actual actions upon real objects.

To put it in more poignant terms, this was no virtual reality to this child. These were his real toys and they were really lost. I'll never forget his joy as I showed him how to get his toys back.

The experiences of this child that the technology had engendered were extremely powerful for him. Furthermore, they proved to be similar to the real world pattern blocks from which the geometric shapes had been designed. The combination of kinesthetic motion required manipulating the objects with the mouse and the geometric shapes on the computer screen appeared to provide a direct analog to the kinesthetic motion.
required to move the pattern blocks on the desktop. To these children differences between moving the virtual object on the computer screen and moving the physical object of the pattern walks on the desktop were so small as to be indistinguishable.

For this child this represented a valid action upon a real object. To that mathematics does represent a series of action upon reified objects of growing complexity and abstraction, then this provides an excellent clue in terms of starting place for effective technology use.

Two Parallel Examples.

Let us see how this model plays out for the case of a young child who is just beginning the process of acquiring basic number concepts. The initial task for the young child is to perform sufficient actions upon a foundational set of manipulative objects to develop a working vocabulary for later use. This vocabulary must include the terminology used for the manipulative itself, relevant properties of the manipulative, and the canonic problems to which the manipulative is used to explore.

Consider the Dienes Base, blocks as an example. Typically a child begins by using the blocks to build with - just as with any other set of building blocks. Through carefully guided activities the young child will come to explore more of the mathematically relevant properties of the blocks and begin to assign the appropriate terminology to them.

Thus, the smallest block is soon recognized as a unit. Building from this basic foundation they learn that it is this unit that we count when using the Base, blocks. This is the set of primitive objects serving as the source for later representations within this system of modeling. From this beginning other vocabulary relating to the blocks is carefully developed, such as Hundreds Flat, Tens Rod, and Thousands Cube.

![Figure 1: Traditional manipulative - Units, tens, hundreds and thousands Dienes Base, blocks.](image)

With this vocabulary in place, experiences are designed to explore the relationships between the numbers represented in these objects to think with and problems are posed which require the child to consciously and strategically act upon these objects in order to solve. The child will then pose problems of their own, which will end up involving further actions that the child will perform upon the primitive objects that they have been working with.

To see the parallelism of approach this method incorporates, let us contrast this example from early elementary mathematics with one from introductory trigonometry. First of all, the objects these students are thinking with are quite a bit more abstract. Let us look at a technology-enhanced Sketch object designed to allow exploration of the sine and cosine function via the unit circle. Just as was done with the young child we begin by developing a working vocabulary relevant to a developmentally appropriate object – in this case derived from examining selected points along a unit circle.

This Sketch object is indeed more sophisticated and is best thought of as a dynamic sketch, due to the changing nature of it's constituent parts. Despite this increased sophistication, however, we can observe the same pattern of thinking as the student uses it in exploration of their developing notions on trigonometric functions. The student must first acquire a working vocabulary regarding the object and some of its properties prior to any meaningful questioning or problem solving to take place. Careful examination of the unit circle

---

[2] Thanks to Mr. Robert Crotteau for permission to include these figures.
shows that there are two colored lines that are formed each time a ray crosses the unit circle at any particular angle, their lengths corresponding to the sine (shown in green) and cosine (shown in red) of the angle which is used. As the student explores various angle combinations the associated sine and cosine are displayed in both numeric and graphic form providing multiple representations for the same concept.

![Figure 2: Technology Enhanced Sketch – An active unit circle object from trigonometry.](image)

Just as was done with the Base10 blocks, once this vocabulary is in place experiences are designed to explore the relationships between the functions represented in this technology-enabled object to think with and problems are posed which require the student to consciously and strategically select actions using this object in order to solve. The child will then pose problems of their own, which will end up involving further actions that the child will perform upon the objects in order to solve. This same sequence may be likewise followed for the sketch and mental picture levels of the model.

What should occur next, regardless of the students’ developmental level, would be for a skilled teacher or instructor to pose follow-up problems or questions relating to the newly instantiated and defined object of thought. This would again hold true whether we’re talking about a physical manipulative object, a sketch object of predictive power such as an interactive fractions object, or a mental picture object such as a comparison of mass based upon remembrances of experience, or a formal and logically abstracted object such as function or some other mathematical construct. In each case we observe a skilled teacher using newly developed objects as a venue within which questions are to be asked and problem situations explored via student actions upon these very same objects of thought. As these examples serve to illustrate, these objects of thought become the basis upon which later mathematical thinking occurs.

Summary

The type of technology enhancement illustrated within this paper has the potential to significantly alter the nature of the mathematics classroom. This goes far beyond simple changes in content scope and sequence. The very nature of what counts as a mathematical thought must be examined when technologically enhanced active objects are a part of the learning environment. If we are to successfully prepare teachers to be comfortable within this new environment it strikes me as essential that we go beyond typical preparation programs, which for the most part use technology to present information. We must model the creation of active objects in our own methods classrooms if we expect to see them in those of our teacher candidates.

I have found that this is nowhere near the ordeal that many would suggest. What it requires, however, is a willingness to experiment with foundational representations to identify those which best benefit from technological enhancement. Although much more research needs to be done concerning such objects of thought might play it is increasingly clear that if we are to be successful in the mathematics reform effort they must find a home in our methods courses – and in the classrooms of our teacher candidates.

Exploring Whole Number and Rational Number Division Within a Computer-generated Conceptual Domain

Stephen Campbell and Gil Fonthal
Department of Education, University of California, Irvine, U.S.A.
Email: sencael@uci.edu, fonthalg@uci.edu

Abstract: In this preliminary report of work in progress we discuss a prototype computer-generated conceptual domain designed to enable learners to explore various visual and symbolic representations of whole number, fractions, and decimals, and other fundamental differences pertaining to division with regard to whole number and rational number arithmetic. Feedback from prospective teachers were included as an integral part of the design process. Other instructional design considerations regarding developmental methods, platform limitations and constraints, and future directions for improvement are discussed.

Introduction

The difficulties learners have in understanding procedural and conceptual connections and differences between whole numbers, fractions, and rational numbers is well known (e.g., Mack, 1995; Markovits & Sowder, 1991; Resnick et al., 1989; Silver, 1988). Potential causes and solutions to these difficulties usually focus on the semantic or informal experiential, concrete, contexts in which arithmetical equations can be more meaningfully formulated as opposed to focusing on the purely formal conceptual relationships expressed in arithmetical equations with respect to the particular numerical domains involved. Previous work researching preservice teachers understanding of divisibility and multiplicative structure, however, found that many students do not have a meaningful conceptual grasp of the formal differences between either whole and rational numbers, or between whole and rational number arithmetic (Zazkis & Campbell, 1996). These difficulties where particularly evident with respect to understanding whole number division with remainder (Campbell, 1996).

In this paper, we draw on Greeno's notion of number sense as situated knowing in a conceptual domain (Greeno, 1991). The basic idea is to construct a spatially-oriented environment using computer graphics that presents the learner with a variety of inter-related visual and symbolic representations of whole numbers, fractions, and decimals, along with some interactive tools for working with those representations that collectively serve to accentuate connections and differences between them. The central thematic of the environment was to render visible the division algorithm -- a fundamental theorem of elementary number theory that provides the formal basis for whole number division (as most mathematics educators tend to think of the "division algorithm" as referring to an algorithm for long division, we will henceforth refer to this theorem as the "division theorem" in order to avoid any confusion). As will be illustrated below, the environment we are designing is intended to take advantage of the division theorem's potential for illustrating procedural and conceptual differences between whole number and rational number arithmetic (Campbell, 1997).

This is a work in progress. Here we offer a preliminary report on design criteria, with particular emphasis given to the guiding design thematic of a transition model between whole number and rational number arithmetic that is based on the division theorem defining whole number division. We will then briefly discuss constraining features of the development platform, some aspects of the development process and the role of learners in that process and some ideas on how that role can be optimized. We will conclude with a critical assessment of the prototype, and our ideas for future directions with this environment.

The prototype software, developed on a Macintosh platform using Real Basic, can be downloaded at:

Guiding Thematic: A "Transition" Model for Whole and Rational Number Arithmetic

It often comes as a surprise to learners and teachers alike to realize that whole number arithmetic is fundamentally different from rational number arithmetic. This is principally due to the fact that division is not closed over the whole numbers. That is to say, there are cases, such as $10 + 3$, where there is no whole number solution. The surprising part is that this entails completely different definitions of division for whole number and rational number arithmetic. The part that is not so surprising is that if one is not clear about these differences, many problems relating to the conflation of whole and rational numbers, between whole number and rational number arithmetic can result (Campbell, 1996, July). This prototype has been developed to help learners explore, discover, and make procedural and conceptual connections regarding these fundamental differences. To avoid ambiguity in what follows, capital letters are used to designate whole, non-negative integer, number variables and small letters will be used to designate non-negative rational number variables.

The formal basis for whole number division is a fundamental theorem of number theory is the division theorem. According to this theorem, for any whole numbers, $A$ and (non-zero) $D$, referred to as the dividend and divisor respectively, there exists unique whole number quotient, $Q$, and remainder, $R$, where $0 < R < D$, such that $A = QD + R$. Most learners are implicitly familiar with the division theorem, in so far as it is used iteratively in long division and as a means of "checking" the results thereof.

Rational number division, when thought of solely in fractional terms, may be more intuitive than whole number division, but conceptually it is much more involved. Formally, rational number division depends on the fact that for any (non-zero) rational number, $d$, there exists a unique multiplicative inverse, or reciprocal, $d^{-1}$. In dividing a dividend, $a$, by a divisor, $d$, the quotient, $q$, is defined as the product, $ad^{-1}$. The quotient can be expressed in a number of equivalent ways: $ad^{-1} = a/d = a + d = q$; or implicitly, in an equation more closely related to the division theorem and divisibility, $a = qd$. There is no such thing as a remainder in rational number division. Instead, as is characteristic of rational numbers, the quotient has a decimal, or fractional component (possibly zero) in addition to a whole number, or integral component. The relationship between remainders and fractional components is not always evident to learners (Campbell, 1997).

The division theorem offers an effective starting point from which to illustrate the transition from whole numbers to fractions to decimals. Consider the following derivation:

\[
\begin{align*}
A & = QD + R & \text{whole number division: where } 0 < R < D \\
& = QD + R(D/D) & \text{where } D/D = 1 \\
& = D(Q + R/D) & \text{distributivity} \\
& = Dq & \text{where } Q + R/D = q \\
A(1/D) & = Dq(1/D) & \text{where } X = Y \Leftrightarrow X(1/D) = Y(1/D) \\
A/D & = q & \text{rational number division where } D^{-1} = 1/D
\end{align*}
\]

This derivation highlights the central role of arithmetic division in making some of the fundamental procedural and conceptual shifts involved in numerical transitions from whole numbers to fractions to rational numbers. More specifically, step (1) is essentially the division theorem defining whole number division. By definition it serves to exemplify the fact that whole number units cannot be divided. Step (2) remains implicit in the prototype as it currently stands, and yet it is both subtle and important to consider in understanding the transition from whole numbers to decimals. Here is an example of where learners' familiarity with whole numbers may be brought to bear on understanding fractions and rational numbers more generally. Conceptually, it seems to be much easier to go from whole numbers to fractions than it is to go from whole numbers to decimals. This is because the representational differences between the former are more intuitive than the representational differences between the latter. Consider, for instance, the difference between "1/8" and ".125". Moreover, the transition from fractions to decimals is much easier to make than it would be to jump straight from whole numbers to decimals. Consider, for instance, that ".125" is readily interpretable as "125/1000". Placing initial pedagogical emphasis on $D/D$, say in contrast so something like $1/D$, helps to place emphasis on...
the division of a whole number unit, rather than on a previously divided part of that unit. That is to say, there is an important way in which D/D is both logically and intuitively prior to 1/D. Step (2) is also important in that it is a necessary precondition to the distributive step (3). It has been shown that distributivity can be problematic in a wide variety of ways for prospective teachers (Campbell & Zazkis, 1994, November). Nevertheless, the importance of this step in the transition model is crucial, in that it results in a form from which the integral and fractional components of the rational quotient of step (4) is readily identifiable. The transition from step (3) to step (4) marks a clear transition from the concept of fractions to rational numbers. Of course, one could resist, or postpone, this step and consider the rational quotient as the improper fraction (QD+R)/D. One way of so doing would be to apply steps (2) and (3) once again, only this time applying the identity (D/D) to the whole number quotient Q and then distribute out (1/D). Either way, the next step would be to isolate the rational quotient, and this would require multiplying both sides of the equation by the proper fraction, 1/D, in step (5). Finally, the crucial property of every whole number except zero having a multiplicative inverse in the domain of rational numbers, and the product of a whole number and its multiplicative inverse being unity, is exemplified in step (6). For the sake of expedience, other important relations such as commutativity and the more general concept of a multiplicative inverses of arbitrary non-zero rational numbers have either been left implicit in this analysis or simply fall outside the scope of the transition model. Also note that one can move logically either forwards from whole number division to rational number division or backwards from rational number division to whole number division. Pedagogically however, moving forwards through the transition model, as illustrated here, may be the preferable approach. Be this as it may, the transition model offers a rich venue for unpacking a wide variety of procedural and conceptual differences between whole numbers, fractions, decimals, and between whole number and rational number division. It is this characteristic that makes it such a rich thematic guide for designing a computer-generated conceptual domain for learners to explore.

Guiding Thematic: Visual and Symbolic Aspects and Related Factors

Using the transition model as a guiding thematic for the development of a computer-generated conceptual environment provided part of the original motivation of this project. Another guiding thematic of this project has been to provide an environment whereby learners are provided with a number of tools for exploring relations between the visual and symbolic representations. What exactly is involved in this and how to do it effectively is a deeply problematic. A number of factors pertaining to the relationship between visual and symbolic aspects of mathematics and mathematical cognition have been implicated from a wide variety of disciplines ranging from philosophy (e.g., particular and general), mathematics (e.g., geometry and arithmetic), logic (e.g., sense and reference), computational theory (e.g., procedural and declarative), psychology (e.g., concrete and abstract), and linguistics (e.g., object and attribute) (Campbell, forthcoming). These factors pertain directly to the learners' understandings of the relations between visual and symbolic aspects of mathematics and mathematical cognition. There are, however, many other design factors involved regarding the environment in and of itself. Particularly regarding the very idea of a computer-generated conceptual environment. To what extent should one attempt to anticipate the kinds of things that learners might or might not do when they are actually engaged within such an environment? To what extent is it even possible? Such design issues are intimately bound up with assessment issues which will discuss in more detail below. We will now say a words regarding design with respect to the development platform and the developmental process.

Development and Delivery Platforms: Design Constraints

Instructional design is always going to be expedited or limited by what is possible with the hardware and software constituting the development and delivery platforms. Fortunately, as computer technology is rapidly evolving, these factors are placing fewer and fewer constraints on instructional design while opening up more and more possibilities. It is unlikely that one can ever be completely free of such constraints. We will discuss some factors that have limited our design. Predominantly due to the existing Apple cultural environment that we are in, the development and testing of the prototype software developed on and geared toward that delivery platform. Unfortunately, however, we have yet to find a robust programming language for Rapid Application Development (RAD) with the possibility to develop a Graphic User Interface (GUI) in the Macintosh environment. The only high level object-oriented programming language with the characteristics mentioned
above that we have found is Real Basic (RB). This is a relatively new implementation still in development with many similarities to Visual Basic from Microsoft in the Widows environment — which constitutes [the latest] a more robust programming language. However, the alternative to use an object-oriented language was very attractive because we included in our design objectives the possibility to construct a virtual scenario in the computer where the students have an interactive and visual environment to represent whole numbers. Numbers can be manipulated using scroll bars and can be represented in spatio-geometric form as unitary squares (area) and as non-unitary rectangular products. Using the visual characteristics of the environment the learners can make changes in the dividend or the divisor and then see instantly their graphical representation (of these two values) and also the values of quotient and remainder not only as numerical representation but also graphically.

There are, however, ways in which RB is limited with respect to VB. These limitations are particularly evident with the inflexibility of RB in the handling of the screen. We will discuss one particularly bothersome example: refreshing of the screen after it has been hidden by other windows and in the handling of the z-order of graphics — i.e., the order in which several graphics appear one on top of the other. In other words, if the screen is in the x-y plane, several graphics can be represented as occupying layers in the z-axis.

We developed a "trace" function that requires overlapping windows, so that the effect of different divisors with respect to a given dividend can be explored. The dividends and divisors are constrained, by design, as whole numbers, and the divisor is constrained to be less than or equal to the dividend. When a given divisor divides the dividend exactly we have used an areal graph — one that displays the product of the divisor and the resulting (whole number) quotient — that is colored blue. When the divisor does not divide the dividend exactly, then the areal graph that displays the product of the divisor and the resulting (rational number) quotient is colored red.

When using the Trace function over several such configurations, the areal graphs, to some extent, overlap upon one another. We can easily trace either by increasing the value of the divisor or by decreasing it. The order (z-order) in which they appear, unfortunately in this particular case, affects the way the resulting information is displayed on the screen to the learner. For the case in point, if one uses the trace function when decreasing the divisors, then the overlapping areal graphs indicate which values of the divisors that divide evenly into the dividend very well. Unfortunately, they are not so clearly indicated when tracing proceeds using an increasing divisor. If we could manipulate this order (which in RB is not possible) we could provide much more consistent picture of the configurations, irrespective of the particular order in which they are explored by the learner.

Development Process: Learner Interaction, Assessment, and Feedback

All these design factors, whether they are originate in the minds of the designer, the learner, or the computer system, will always be, to one extent or another, bound up with what learners do within the environment. Prima facie, there are a number of different ways of assessing this. For instance, designers can rely on occasional verbal or written feedback from learners regarding their experiences or from teachers reporting on their observations regarding their students experiences. Other approaches involve various ways of having the computer keep track of how students use the environment, or to use audio-video equipment to record learners' interactions, possibly in tandem with various kinds of "talking aloud" protocols. We are currently developing more rigorous approaches along these lines (see Campbell, forthcoming). If all goes well, we will be able to report in more detail on our data and methods when we present this paper. Here, we will just say a few words about how we have developed the prototype as it currently stands.

The authors have brought complementary backgrounds, interests, and skills into this project which has proved beneficial to this collaborative effort. The first author conceptualized the guiding thematics of the transition model with an eye toward developing an environment suitable for both teaching and learning arithmetic and for further research into the relation between visual and symbolic aspects of mathematics and mathematical cognition. The second author has a strong background in educational software design and development. These complementary orientations regarding design and development gave rise to a important synergy that led to rapid implementation of an initial prototype suitable for classroom use.

This prototype was then introduced in undergraduate mathematics education course called "Thinking Mathematically: Learning and Teaching Mathematics" — an undergraduate course designed by the first author for prospective teachers in mathematics. The guiding thematic of the course was essentially the same as for the
prototype: to explore ways of visualizing elementary arithmetic in ways that were conceptually meaningful. Around the middle of the quarter, the students worked with the software for about an hour and half, while remaining focused on how the environment was contributing to their conceptual understanding of whole number and rational number division. The students reported on their insights and difficulties in using the environment, and the software was adapted and refined wherever possible in accord with those reports for the next class. The students were then able to use the environment again and explore first-hand the impact of their feedback. In this way, they were able to contribute to the evaluation and design process. In what follows we will discuss a few of those contributions.

In the original prototype, there were two symbolic equation schemas that allowed for numerical instantiations immediately beneath them depending on the values selected for the dividend and the divisor:

\[
A = Q \cdot D + R \\
A/D = Q + R/D
\]

Many students experienced significant difficulties in relating these values to the visual graphic representations. Particularly the one based on the product of the quotient and divisor. The revised prototype included the following equation schemas, again with numerical instantiations included immediately beneath each one:

\[
A = Q \cdot D + R \quad \text{(with the explicitly noted constraint that: } 0 R < D) \\
A = D(Q + R/D) \\
A/D = Q + R/D
\]

With the revised prototype students were more successful in linking visual with symbolic representations. Other factors likely implicated with this success may have related to greater familiarity and overall involvement with the environment. In the upper right of the revised (and as of this writing, the current) prototype is a bar graph of each of the values of the division theorem from left to right. In the original prototype the bar graph was "top-down" in scale rather than the more usual "bottom-up" bar graph representation. Some students found the "top-down" graph distracting or disconcerting. They felt much more comfortable with the standard "bottom-up" representation.

In the original prototype, only changes in the divisor were possible for a given dividend. Some students felt unduly constrained by this, so the prototype was revised so that the dividend could be changed for a given fixed divisor, thus adding greater user-flexibility to the system.

In the revised version the remainder was also represented as small blue dots in the Quotient-Divisor graph. These dots provided a good focus task for the students. Many of them worked individually or in pairs, trying to see some connection. Gradually, the connections were made. Two students finally conceded that they could not figure it out and asked their neighbors. Once they were informed that they related to the remainders, they instantly made the connection. It seems that they had not expected yet another representation of that value, and thus were blocking themselves, a priori, from considering it as a possibility.

Overall, the students' first exposure to the original prototype allowed them to feel as though they were actively participating in beta-testing and de-bugging. Surprisingly, the students seemed to enjoy this role, rather than be dismayed by it, especially when they were able to see that many of the problems that they pointed out had been fixed in the revised version. Some of these bugs and suggestions for improvement included things like:

a) No windows refresh after hidden by another window.
b) No Restart function after closing the main window of the program
c) Suggestion to include up to 100 numbers in the dividend
d) Introduce cross hairs or some form of indicator as to the current operation in the graph
Critique and Future Directions

We think that the prototype it is still unclear the transition from whole numbers to real numbers (with decimals). There is much more that can be done to help bring out visual meanings that remain implicit within the symbolic representations, as evidenced by the analysis above. Perhaps a graphical representation of those decimals could be more appropriate adding a new window (floating) to illustrate that. In this window a magnified unitary square could be depicted to show fractions of it.

Other improvements can be made regarding more familiar representations of division with remainder. In particular, whole number division is often expressed as $A/QD=QremR$. Some caution must be exercised here. Note that this "equation" is imprecisely formulated and does not conform with standard arithmetic meaning and use. Some learners may be prone to operating on this common expression of whole number division as if it were a well formed arithmetic formula.

The software could be refined (despite current limitations of Real Basic) in the following ways:

a) Including the floating window mentioned above to enhance the "vision" of decimals
b) Shows in a notorious way the presence of prime numbers
c) Increase numbers up to 100
d) Redesign of the color bar graph for more meaningful information
e) Define three independent levels of difficulty for the division theorem: (1) including only whole numbers; (2) including real numbers; (3) including prime numbers.
f) Include a "help" service in the main menu for some directions
g) Include a "print" service for hard copies
h) Possibility to include a "freeze" function to insolate desired configurations
i) Work on the suggestions and difficulties (above) manifested by the students.

We will be running additional tests with the current prototype with preservice teachers and making further refinements prior to presenting this paper at the conference and hope to have a fuller report available then. One of the areas that we hope to gain much greater insight into between now and then is in how preservice teachers navigate their attention within the environment. Toward this end, we will be videotaping the screen during some of their sessions using talk-aloud and cursor-pointing protocols and analyzing the results using video-processing software. We will be presenting some of the preliminary results of these experiments at the meeting.

Abstract: The authors are co-principal investigators for a National Science Foundation project to create a web-based National Library of Virtual Manipulatives for learning mathematics in the elementary grades (K-8 emphasis). Many of our virtual manipulatives are based on physical manipulatives commonly in use in the schools (i.e. geoboards, tangrams, pattern blocks, fraction bars, etc.); others are concept manipulatives especially designed to teach or reinforce basic mathematical concepts. Our emphasis is on interactivity for the user, so the learner controls the variable aspects of the manipulative and is not only free, but encouraged, to explore and discover important mathematical principles and relationships. Teachers or parents can provide direction, but control of the activity remains with the user. This paper is preliminary and descriptive only, but it describes aspects of our experience in the design of manipulatives and some of the delightfully unexpected advantages of interactive technology for discovery learning.

Introduction and History

This paper must partake of some aspects of self-contradiction, intended as it is to describe in words some of the advantages of not using words. Our goal is to convey some of the unexpected, or at least unanticipated, consequences of interactive software in the educational experiences of both elementary school children and their teachers, both pre- and in-service. Since we have no choice but to rely on words in proceedings such as these, we will do what we can using verbal descriptions, supplemented by static figures. At the same time, however, we invite readers to visit our web site (www.matti.usu.edu), where it is our hope that they may experience for themselves some of the things we describe.

The authors of this paper have a history of working with interactive computer-aided mathematics instruction that predates their current National Science Foundation funded National Library project. The first two authors earlier received funding from the state of Utah to develop an interactive pre-calculus project for use in the state system. We learned early on, however, that despite rather extravagant claims to the contrary, there were no commercially available tools adequate to support the kind of interactive mathematical experience of the sort we envisioned. It was our extreme good fortune to add to our design team a colleague (Dr. Wellman, also in mathematics), whose interest in computer programming led him into the creation of a mathematics editor and related tools sufficient for our purposes.

With the completion of our pre-calculus project, we recognized the potential of our approach for both elementary students and for pre-service and in-service elementary teachers. That potential was magnified by the growing possibilities of a new programming language, Java. It was the Java language that has really made web-based instruction possible.

Java has many advantages over other object-oriented programming languages, especially C++. One of the most obvious—and critical—advantages is multi-platform and web accessibility. But while Java improves on a number of features of C++, it does not have the maturity of some of the older programming languages or the extensive libraries of built-in functions readily at hand. It has been necessary to build many of our own fundamental classes and our own mathematics editor to accomplish some of the things we considered essential to our long-term goals.
Our Utah State University team, in collaboration with a colleague from Fayetteville State University (North Carolina), proposed to the National Science Foundation that we build a National Library of Virtual Manipulatives, interactive applets for learning and reinforcing concepts in elementary mathematics. We intended our applets for the use of elementary (primarily K-8) students, but recognized that the same instructional tools could also serve to strengthen the mathematical preparation of pre-service and in-service teachers.

In the process of our negotiations with the National Science Foundation, it was suggested that we communicate with people working on the new Principles and Standards for School Mathematics ("Standards 2000") for the National Council of Teachers of Mathematics (NCTM). The NCTM had released their original Standards document in 1989 and recognized the need to update their national guidelines for the teaching of K-12 mathematics. As part of the planned publication of the new standards (which also address changes in technology) an Electronic Format Group was established to create a web-version of Standards 2000, including a new approach, "E-examples," to suggest and illustrate ways to incorporate technological resources into the mathematics classroom.

At the 1998 International Conference on Technology in Collegiate Mathematics, we demonstrated to some members of the NCTM Electronic Format Group some prototypes of the kind of virtual manipulatives we had developed for our proposal to the National Science Foundation. The upshot of that meeting has been a very productive collaboration. We are now working very closely with the Electronic Format Group and the writers of the new Principles and Standards to provide appropriate E-examples for all four grade bands. The majority of E-examples that will appear with the web version of the Standards, to be released at the annual national meeting of NCTM in April of 2000, will be our interactive applets.

In addition to productive exchanges with writers and teachers associated with NCTM, we have had the opportunity to work with several groups of in-service elementary teachers. In both web-based distance instruction (in Utah and in North Carolina) and in on-site classes (in North Carolina and Ohio), we have used our virtual manipulatives as part of our technology-supported mathematics courses. Participating elementary teachers in our current North Carolina project are designing ways to incorporate our materials into their curriculum and will conduct in-service efforts in their home school districts to make these resources available to elementary students throughout their districts.

Design Philosophy

Initially, as we contemplated constructing electronic manipulatives that could be used by children, we were guided by existing physical manipulatives. We were confident that we could make electronic versions that, because of their residence on the Internet, could be made available to students, teachers, and parents, at any time and in any location having a web-connection.

One of our first creations was a virtual geoboard, mimicking the common "nails in a board" version using rubber bands. As we shared an early version with teachers and asked for suggestions, several teachers said how nice it would be to be able to color the regions inside the rubber bands. So we did it. Later reviewers wondered if it would be possible to translate an elaborate construction around the board without having to shift the band from every vertex. We are now working on incorporating both translations and rotations, illustrating the mathematical concepts of "slides" and "turns."

Building such features into a virtual manipulative allows users to do things that aren't conveniently possible with corresponding physical manipulatives. We constructed a circular geoboard and another one using "nails" spaced to form an equilateral triangular grid instead of squares. The circular board has immediate applications as diverse as creating pie-chart fractions and illustrating trigonometric functions. But in the design of all of our virtual manipulatives, we try strenuously to avoid doing too much. We would rather have five manipulatives, each doing a well-defined task, than a single applet that requires more complicated operations to accomplish the same five tasks. Each applet has a tightly designed focus and the simplest interface we can create. The mathematics underlying the functionality is often very sophisticated; what the user sees and does is very simple.

Another principle that guides all of our design is that the student must interact with the applet to accomplish something. There is never simply a "watch this clever animation" or "see what happens when we do this" attitude. Mathematics, perhaps more than any other discipline, cannot be learned by watching someone else do it, no matter how elegantly. Any student, to be successful, must be involved, engaged in
the activity. And thoughtful engagement requires participation. Interactivity is thus essential to the design of every one of our applets, the one feature that we absolutely require.

The kind of interactivity we have in mind requires the user to think about a specific task, to formulate strategy to achieve a specific goal (almost always informally, and seldom articulated), to engage in some physical action (clicking to select something, dragging an object, or moving a slider), and to observe (and perhaps, describe) consequences of the action. The goal is to allow students to control events and to discover relationships. Differences between coincidence and causal relationships become clearer when we allow the user to repeat an activity as many times as desired. We can ask questions to direct explorations and, we hope, guide meaningful discovery, but control remains in the hands of the user. Nothing happens until the user takes action, and an activity can be repeated until there is satisfaction; the computer never tires of repetition.

Unexpected Consequences

With NSF support for our three-year project to build a National Library of Virtual Manipulatives, we could begin to focus our effort to accomplish some of our objectives. But even with early prototypical examples, before we had any formal structure to our project, we were learning something of both the limitations and advantages of working in an electronic environment and more specifically within the virtual machine of Java programming.

It is impossible to convey in words an accurate picture of what can be done on-screen with our interactive applets, so we compromise by giving a few pictures of some of our applets, simple snapshots of the kinds of screens produced by students actually working with these manipulatives. We will accompany each figure by a description of some of the functionality of the applet and some of the dynamic features available to the user. We hope thereby to communicate at least a little of what we have discovered in both the design and implementation of some of the virtual manipulatives.

Again, we invite interested readers to visit our web site (www.matti.usu.edu) and to explore freely. Everything is, of course, in a state of continual flux as we get feedback and suggestions from teachers, students, and evaluators. Applets already on the site are also changed as we build tools to support one particular concept applet and learn that such a tool would add value to another.

The serendipity to which we refer in the title of this paper is of two varieties. One is unexpected responses or capabilities that an electronic manipulative possesses in contrast to the physical model that inspired the computer implementation; the second occurs when we are led to unanticipated design changes that enhance the educational value of a virtual manipulative. We will try to illustrate both.

Figures 1 and 2 show two screen shots of a virtual manipulative on the Platonic solids. To help develop spatial visualization, we wanted students to be able to see all sides of a solid object. What neither figure can show is that by moving the mouse the student can rotate the given object freely in space. In future variations of this applet, we will paste different images onto the sides of a cube and ask questions about, say opposite faces. But as we worked with this applet, we realized that there was an opportunity to let students discover Euler's relationship among vertices, faces, edges (V - F + E = 2). As the user rotates the solid in space, a Shift-Click changes the color of a face, an edge, or a vertex. In Figure 1, we have changed the color of five faces with their surrounding edges and corners. The color changes make it easy to determine when you have counted everything. In the implementation shown, there is a running tally of the numbers, which the teacher can either choose to show or not.

One of our most exciting experiences with this applet took place during a visit to several inner-city schools in Cleveland. The settings and circumstances were less than ideal, but we took CDs containing some of our materials to leave with the teachers, some of whom we had worked with in an earlier NASA project. We took a projector and a lap top computer into the classroom and let the children (first, second, fourth and fifth graders) take turns with the mouse, rotating objects, selecting and changing colors while the entire class kept a (collective verbal) running count. The sense of ownership—and excitement—felt by the children as they controlled the magic of rotating the image and changing colors was palpable.

Figure 2 illustrates both kinds of serendipity we mention above. In the original discussions we had not thought of illustrating the idea of a dual of a solid (taking as vertices the mid-points of each face), but after seeing the solids in space, we serendipitously realized that we had another teaching opportunity. And, as may be seen from Figure 2, the electronic setting (using some fairly sophisticated mathematics) allowed us to show something that would probably never be constructed physically.
Figure 1. An icosahedron, showing the selection of some faces, vertices, and edges.

Figure 2. A transparent (wire-frame) icosahedron with its dual, a dodecahedron.
Figures 3 and 4 together also demonstrate both kinds of serendipity. The virtual geoboard in Figure 3 is "standard" in the sense that the nails or pegs form a square grid, as do most physical geoboards, although few boards have as many nails as ours. With the added size, the electronic version makes it much easier to explore such concepts as similarity, transformations, or symmetry. The smaller physical geoboards have that built-in limitation. As mentioned above, it was teachers with whom we were working who suggested the addition of color to geoboard regions. We thought it a nice idea, but we did not anticipate some of the advantages we have since observed. With color, the comparison of sizes of regions or geometric figures is much more natural. When we ask students to use their rubber bands to divide a square region into halves, challenging them to find ways that are different from the obvious one in the upper left of Figure 3, the color stimulates choices. In particular, it seems less likely that the solution in the lower right of Figure 3 would be as apparent without the use of color to put together the two outside bands to form a region matching the central band.

Having the standard spacing of nails with our first implementation of geoboard, we realized that a very minor change would allow us to keep all the functionality while illustrating a number of different mathematical concepts. Thus we constructed a geoboard with a triangular grid, leading to a natural tiling of the plane with equilateral triangles or regular hexagons, and we have two different geoboards making use of circular symmetry. Now, taken together, our set of geoboards permit a completely unanticipated flexibility and versatility. Figure 4 shows how one student constructed a pie chart to answer the question, "What is 1/3 of 1/4?" Again, the ability to add color greatly aids the visualization of the answer.
Conclusions

As is obvious at this point, we are submitting here only a preliminary report. This paper is intended to be neither technical nor definitive. In the future there will be a number of evaluation studies of the virtual manipulatives in our National Library. The summative evaluation for our project will be handled by Douglas Clements and Julie Sarama of the University of Buffalo. Given the direction of their previous educational research, Professors Clements and Sarama are uniquely qualified to assess the effectiveness of computer technology in early childhood education. Other teacher educators, including another of our co-principal investigators, James Dorward, will be examining the use of our materials in public school settings and plan comparative studies.

What we describe in this paper is purely descriptive, based on our own observations and information passed along to us from in-service teachers who are learning with and using our materials. However limited our observations, we have been delighted by the response of students actually using our manipulatives. The measurement of learning of specific mathematical content at different grade levels over an extended period of time is an important task that will extend into the future. But in our own development work, as we try to better understand, and address, the needs of various groups of students, the reactions have been wonderfully heartening. As typified by our visit to the Cleveland inner-city schools, the level of engagement, the enthusiasm, excitement, and participation of children will not soon be forgotten.
Using Web Pages to Teach Mathematical Modeling: Some Ideas and Suggestions

Abstract: Mathematical modeling can perhaps be best defined as "the process of scientific inquiry" for mathematics. This is obviously a comfortable mode for teachers of science, but is rarely seen in the mathematics classrooms of today. This paper explores the possibilities of using interactive web pages to help facilitate an understanding of practical applications based mathematics. Because the scientific process is emphasized as the general operating framework, situations where students can hypothesize and experiment, and create data tables are most valuable. Special emphasis is placed on the fact that students and teachers both need to re-conceptualize effective mathematics instruction in order to really embrace a modeling approach.

Introduction

An important aspect of the continually changing reform movement in secondary level mathematics is that teachers are able to absorb and integrate what they have learned from both the classroom dynamics and from new research. It is perhaps most important that teachers of mathematics continue to grow with respect to the pedagogical techniques that have the greatest classroom potential. Although finding these techniques requires a great deal of effort, good teachers would certainly agree that the resources they bring to bear on behalf of their students set a foundation of success or failure for those students from both a competence standpoint and from a motivational standpoint as well.

The reform efforts of the past decade have resulted in a mass of professional documents, curriculum standards, and reports, all of which are intended to strengthen a teacher's profile of techniques. Yet with all of the various forms of assistance, the mathematics classrooms of the 21st century will probably look very similar to those that have been so common for the past 50 years. The fact that we know so much more now than we did 50 years ago, at least from a scientific standpoint, has appeared to have very little impact on what is taught or how things are taught in the secondary math classroom. Agreed, technology has brought flavor to the mathematics classroom, but the textbooks along with their very familiar format still seem to be the preferred method of instruction. Although there are instructional perks to this classroom format, the fact that students aren't internalizing the information would suggest that other formats merit exploration.

Instructional activities using a mathematical modeling approach have proven to be both effective and engaging for students. Additionally, some of the most valuable curriculum-application considerations in today's mathematics classrooms can be revisited in the context of an interactive web based format that preempts the "what do we need this for" question. The mathematical modeling approach to instruction is indeed a "front heavy" technique for teachers, but allows for the kind of valuable exploration in mathematics that has been absent to date.

Classroom Considerations for Mathematical Modeling
Mathematical modeling can perhaps be best defined as "the process of scientific inquiry" for mathematics. This is obviously a comfortable mode for teachers of science, but is rarely seen in mathematics classrooms. Students engaging in mathematical modeling activities would spend the majority of their time experimenting in applied physical situations in an attempt to find patterns and consistencies in sets of data. Data sets could already exist in a number of different forms, or they could be collected as part of a classroom activity. Part of the impetus for mathematical modeling activities in the classroom is to help students understand that mathematics is not a discipline where complex solutions to problems are innately obvious or solvable in a matter of just a few minutes. In fact, any good mathematical modeling activity should be appropriately vague so that the students don’t get the impression that the activity is just another textbook assignment. The teacher designing the activity has the difficult task of articulating the problem in such a way as to provide clarity without being too prescriptive. This is done to emphasize that mathematical modeling is a process of continual refinement and modification. In most cases, this process of refinement serves two distinct tasks. First, the refinements are intended to create a working model that is more efficient, faster, or more accurate in some way than any previous model. Secondly, refinement and modification are natural processes of building any axiomatic system of notation. Students in essence build their own mathematical system of notation and in turn, greater mathematical understanding. Some instructional considerations related to the use of mathematical modeling activities in the classroom are as follows:

1. Students have some control over how they approach a problem. This is not typically the case with most textbook problems.
2. Good modeling activities are adaptable to many different ability levels.
3. Good modeling activities are easily scalable to different grade levels.
4. Problem solving and mathematical modeling are different processes. Problem solving typically acts as a process oriented approach whereby students find a specific solution to a specific problem. Mathematical modeling is an experimental approach where a problem is solved and continually refined over time in order to be more efficient, faster, or more accurate. Problem solving in many cases has a solution that is either correct or incorrect. Mathematical modeling is a process where few answers are incorrect, they just require continual revision.
5. Mathematical modeling focuses primarily on the "general case." Students must at least generally understand the concept of a variable, which is why modeling activities below the fifth grade are difficult for teachers to construct.
6. Mathematical modeling activities are difficult to assess. An elegant solution may be an approach that works in a way that appears to be coincidental, but a student can justify why. Another solution to the same problem may utilize some specific procedure from the textbook, yet the student has no understanding of why they chose that method nor why it works.

The premise of the mathematical modeling concept is not that the traditional courses in the curriculum need to be replaced, but rather accented in the appropriate spots to better emphasize the practical use of the concepts we do teach. Because mathematical models can take on many forms, the processes by which problems are approached are numerous and varied. Some of the more basic modeling structures lend themselves very well to established secondary level curriculum (i.e. numerical tables and patterns, graphs, systems of equations, etc.). Others may be more algorithm-based problems that require a computer or graphing calculator as an extension. Although no one set of rules is inherent to all mathematical modeling activities, the following set of steps can act as general guidelines for students engaged in mathematical modeling activities:

1. Identify what the problem and resulting model should look like
2. Establish the factors that affect the outcome
3. Define which of the factors are parameters and which are outcome variables
4. Establish a relationship between the parameters and the variables to derive a formula or alternately defined model or algorithm
5. Test the model with known values from previously collected data
6. Refine the model for accuracy and efficiency
Using Web Pages for Modeling Activities

Although modeling activities in the mathematics classroom don’t have to be technology driven, the interactive nature of Java applications on many web pages can provide a physical context which students can use to test conjectures and build generalizations. Because the scientific process is emphasized as the general operating framework, situations where students can hypothesize, experiment, and create data tables are most valuable. Well designed web pages using Java allow for the kind of interactive experiments needed for success without the hassle of setting up a physical lab situation. The following example illustrates a possible modeling problem that could be practically used on the web:

Problem

Suppose we wanted to find the time of day without using a clock. In ancient times, sundials were used for this purpose, and were fairly accurate. The first step in finding the time without using a clock is to use the relative movement of the sun and earth to predict how shadows might fall at different times of the day. Assuming that the meridian line (or noontime mark) has been established and the gnomon has been angled, we must find a way to mark the hour lines on the dial plate. Create a mathematical model that uses the angle of the sun on the style (top of the gnomon that creates the shadow) to mark hour lines on the dial plate of the sundial. Using angle A as the base angle of the gnomon, and angle t as the angle of the arc the sun passes through in a given time frame, we should be able to calculate angle h by using the length of the resulting shadow. This is illustrated in figure 1.

Figure 1: Shadow used to mark the dial plate

![Diagram](image)

One Possible Solution

Angle t is perhaps the first angle that needs to be defined. Because the earth rotates through a central angle of 360° in 24 hours, we can assume that each hour is defined by a 15° arc of the sun’s apparent movement over the surface of the earth. This is true at any longitude. Angle t then measures 15° for each hour away from the noon hour.

1. If the length of the style on the gnomon is known, the vertical side of the gnomon can be calculated as follows: Height = sin A (S); where S is the length of the style.
2. At 11:00, angle t = 15°. So, if we want to mark the 11:00 hour on the dial plate, angle h can be calculated by measuring the length of the shadow from the noon mark and subsequently estimating the length of the adjacent side as equal to the length of the style, so that the tangent ratio can be used. The side of the shadow opposite angle h = (tan t)(sin A)S.
3. Also, \( \tan h = \frac{(\tan t)(\sin A)S}{S} \) since the tangent ratio isopp/adj and S is being substituted for the adjacent side in this ratio.

4. Therefore, our model could be as follows: \( \tan h = (\tan t)(\sin A) \).

Because we know the longitude of our specific location, we also know the measure of angle A. Let us assume for the sake of easy calculations that we are at a 30° longitude, and that our style length is 8 inches. Because we are marking the 11:00 hour line, angle \( t = 15° \). We need to find angle \( h \) for several different hours in order to mark the dial plate appropriately. The following is a test calculation:

1. \( \tan h = \tan 15°(\sin 30°) \)
2. \( \tan h = (.268)(.5) \)
3. \( \tan h = (.268)(.5) \)
4. \( h = \tan^{-1}(1.134) = 7.63° \)

Therefore the 11:00 hour line would lie at an angle of 7.63° to the left of the meridian mark. Also, since the hour marks are symmetrical with respect to the noon mark, it is an angle of 7.63° to the right of noon for 1:00. We could continue in this fashion to mark the rest of the dial plate for each hour of daylight.

Other modeling activities would be used as primers to get the students to the point where they could successfully manipulate the web experiment in such a way as to define an answer. Because students and teachers both like self contained educational packages, much of what is provided on the web page can really help smooth out problems that might arise during the course of the activities. Other hints that create successful web experiments are as follows:

1. Help students define and modeling heuristic similar to that found on page 2 of this paper, and have this listed on the page as they progress through the activity.
2. Create an on-line hint button that directs students when they are off track. This may even be a step by step derivation of a sample approach to the problem.
3. Use data tables on the web page where students can enter the data from their experiments.
4. Provide a virtual notepad where their models can be entered.
5. Have specific objectives that the activity will highlight, but don’t be afraid to deviate.

Modeling activities sometimes lead us in directions we may not think of, but turn out to be valid solutions.

As in any educational activity, good planning and lesson design are key to successful implementation. It is important to remember that for every minute of planning on the front end, we save ourselves headaches during the activities themselves.

**Conclusion**

Of course the models being presented here take some time to develop and even more time for the students to research. Workload is perhaps the biggest obstacle when it comes to developing on-line math modeling activities. In addition, students and teachers both need to reconceptualize effective mathematics instruction in order to really embrace a modeling approach. Those students who are comfortable in an environment where a math problem can be done in a matter of a few seconds will need to embrace a more realistic view of “scientific” mathematics. In some cases, the students may not come up with the models that we have intended even after hours of work; however, through careful investigation, and with some guidance, students can learn many things that we haven’t even thought about. Yet, it is important to remember that many of the greatest inventions of our times have been accidents. Mathematical modeling though provoking problems appears to be a great way to pave the road to accidental learning, and history has taught us that accidents can sometimes be good!
Technological Tools to Develop Mathematical Problem Solving

John E. Bernard, Ph.D. and Olga M. Ramirez, Ph.D.
Department of Mathematics
The University of Texas-Pan American
Edinburg, Texas (USA)
bernardiet@panam.edu, oram@panam.edu

Abstract: Problem-solving processes should extend beyond mere working problems by type where students are provided algorithmic approaches to fit situations (e.g., rate, mixture, coin, investment, work) since reducing these typical problem situations to "algorithmic processing" is counter-productive relative to higher-level problem-solving goals (NCTM, 1989, 1991, 1996). By incorporating technological tools (CABRI Geometry II, spreadsheets, and graphing calculators) coupled with the problem solving principles espoused by George Polya (famous mathematician and teacher of mathematics and mathematics teachers), secondary school algebra problems can be taught as recommended by the NCTM curriculum standards to appropriately meet recommended problem-solving goals. Even typical problems can therefore be used to expose students to multiple problem-solving approaches that extend understanding and meta-cognitive abilities.

In the quest to teach Atype® problems as genuine problems versus exercises as defined by Baroody (1993), technological tools, when appropriately used, bolster opportunities for students to think mathematically. For example, using computer and graphing calculator simulations and spreadsheets, even with typical problems one can expose students to multiple approaches that extend cognitive abilities to learn mathematics concepts, discover patterns, detect relationships between variables, and to apply processes and strategies to explore systems and structures of mathematics. By specifically utilizing George Polya=s (1957) four-step problem solving model and appropriate technological tools, typical Arate® problems can be explored and solved so that students further their intuitions and knowledge about the interrelationships between mathematical ideas, thereby fostering the learning of problem-solving skills in a responsible and enriching manner.

Paraphrased, in the problem to be solved, entitled AThe Biker and the Nearby Town Problem® shown on the next page the goal is to find how many kilometers it is to the town from where Bill started. By utilizing three technological settings: (1) a simulation model programmed in Cabri Geometry II; (2) a trial and error simulation model programmed in Microsoft ExCEL; and (3) an algebraic and related geometry representation shown in a TI-83 Graphing Calculator setting, the traditional Arate® word problem selected which normally provides a context for using particular formulas or algorithms will be re-visited in such a way that critical thinking will be encouraged In each setting, the aim besides solving the problem, as per Polya=s Problem Solving Model, is to promote better understanding of what problem solving is while concurrently enhancing the learner=s problem solving ability. In the AUnderstanding the ProblemA phase of Polya=s model, the problem solver is encouraged to spend time and effort developing an understanding of the problem. Prominent in this, is to identify which is the goal, what it is that is to be found, proved, accomplished, or whatever. Also among the essentials is to obtain a clear understanding of the given(s) and requirements or conditions of the problem. In the ADevising the Plan® phase, it is common that a plan or at least a part of a plan evolves from an understanding of the problem. This may involve knowing relevant definitions (concepts), non-definitional generalizations (axioms, postulates, formulas), principles (generalizations, theorems), skills (operations, processes, algorithms, prescriptions), logical reasoning, and problem solving strategies (heuristic or otherwise) that might be applied, and in what order. Often plans change as steps are carried out (see the next phase) and/or new understanding arises. Thus, one should not restrict this phase to a lock-step position that keeps one from moving on if a complete plan is not known, nor should one erroneously keep from returning to a search for understanding after embarking on this phase. In the ACarrying Out the Plan® phase, a systematic, step-by-step guided "straight-line" sequence of operations, deductions, and processes is ideal, but often unrealistic when one is working on a REAL problem. Expect some blockage, some dead-ends, some back-tracking, and so on. Persistence (related to motivation) may be one of the most essential qualities of a problem solver.

There is a need to be tolerant of confusion, uncertainty, frustration, errors, and the like. Expect also that some backtracking may lead to changes in plans. Assuredly, REAL problem solving is often a dynamic situation. In the last phase, the ALooking Back® phase, is the idea of CHECKING a possible solution to see if it really satisfies the requirements of the problem, has the problem really been solved? But, there is more beyond mere checking. Here, one should be encouraged to check if there are other solutions, other strategies for solving the problem, or if applicable, whether there is an extension to the problem. Looking back should not be a mere review of what has occurred to arrive at a solution,
but rather, looking back should allow for additional thought-provoking stimulation about the problem-solving process undertaken. Polya, in his model, views the looking back phase as an opportunity to have the student rise to a higher level of metacognition relative to the problem-solving process in general, as well as to the local subject-specific matter.

The Problem

Bill bikes to a nearby town at 12 kilometers per hour and returns at 10 kilometers per hour. How far away is the town if the entire trip took 3 and 2/3 hours?

A. The Cabri Geometry II Setting

Figure 1

Rate going: 12 Km/Hr

Rate returning: 10 Km/Hr

Starting Place

Nearby Town

"Back at Starting Place"

Distance Traveled: 6.82 Km

Experimental Travel Time: 0.57 or non-existent Hrs

Allowed Target Total Time: 3 plus 2 / 3 Hours

Experiment HERE:
Adjust for Distance to the town: 25 Km
Check against the Allowed Total Time Target

By Dr. Bernard April 1999

Figure 1, programmed using Cabri Geometry II (see Keyton, 1996, Laborder et al., 1994-1997, Vonder Embse et al. 1994-1997, Vonder Embse et al., 1996) suggests the use of a simulation to depict how Bill, in the problem, might be traveling to the nearby town. The figure makes a major adjustment from reality in laying the trip out linearly and consecutively without overlap. It explicitly shows the two parts, first the part going to the town, then the part returning from the town to the starting point. Other things "fall into place" once viewers have made this adjustment. The model provides for experimenting (guessing) with the distance to the town. Following a given guess, one can then act the trip out using the Grab point, a built-in feature in Cabri Geometry II. Readouts of the distance traveled and the lapsed travel time (Experimental Travel Time) enable one to evaluate what is happening as the bicycle moves from the starting point to the town and from the town back to the starting point; i.e., over the course of the entire trip. If the distance guess is correct, the dependent total trip time (when the Grab point is at the right "starting Point") will match the target total time. Experimenters can distinguish when the dependent time does not match the target total time and separate such into two cases; those when the dependent time is too large, and those when it is too small. One compensates for the former by reducing the distance setting and for the latter by increasing the experimental distance setting (guess).

B. The Spreadsheet Setting

In the first spreadsheet setting (see Spreadsheet #1), AA = the distance to town traveled at 12 km/hr and B = the distance to town traveled at 10 km/hr. Once students understand that the distance to and from town Amust be equal they can be encouraged to Aguess and check which time to town and from town, at the rates given, yield the
closest distance between A and B. This can occur by having students guess, as shown below, in the column denoted by the variable x for the "Time in hours it takes Bill to bicycle into Town" and the other information calculated on the basis of this guess. Students and teacher can develop the spreadsheet together, in parts, until a discovery of the need to approximate the difference between A and B to zero is developed.

Spreadsheet #1

<table>

<td>20.0000000</td>
</tr>
</tbody>
</table>

In the second spreadsheet (see Spreadsheet #2) that follows, a different approach to a guessing and checking occurs. The guess is for distance to the town being varied until the total time given, 3 and 2/3, is reached after multiple guesses at the rates provided. This approach coincides with the Cabri Geometry II simulation shown previously.

C. The TI-83 Graphing Calculator Setting

Using a TI-83 Graphing Calculator (see Texas Instruments Guidebook, 1996), techniques that are similar to the spreadsheet methods shown above can be used. In this case, a method referred to as the Intersection Method for solving a system of equations has been utilized. The equations \( Y_1 = 3 + \frac{2}{3} \) and \( Y_2 = \frac{x}{12} + \frac{x}{10} \) (where X is the varying guesses for distance) shown in Figure 2 represent the target total time to and from the town and the partial times necessary to travel to town and back, respectively. After graphing the equations (see Figure 3), the intersection point \( (20, 3.6666667) \) indicates that when the distance is 20 miles to and from the town, the exact total time traveling to and from town is 3.6667 hours (an approximation to 3 and 2/3). Using the TRACE feature of the TI-83 Graphing Calculator to Atravel along the linear graph of \( Y_2 \) toward the horizontal line \( Y_1 \) helps to visualize the relationship between the total time and the partial times, as X or distance varies, to and from town. Figure 4 obtained using the TABLE feature of the TI-83 Graphing Calculator captures this same relationship by denoting the incremental changes between total time and partial times as distance varies. This is a powerful way to bridge algebra and geometry to solve problems!
Regarding The Problem-Solving Phase

In either setting, or cumulatively, understanding began as a result of a diagram, table of data, graph, and or probes, and continues throughout. What can we say about the nature of the answer? We can say that it is a number. Moreover, it cannot be negative and is unlikely to be zero; so it must be some non-negative real number (imaginary numbers would not make sense in this situation). Distance is a kind of measure and non-negative real numbers are the kind of numbers used for measures. More understanding: but first a devising a plan idea - That algebra can be used to solve this problem; specifically, this is a place where a letter may be used to represent the unknown. The letter, in this case, serves as a "pronounal," that is, a symbol representing a number. Here the interpretation may be that of a fixed unknown number rather than a variable, per se. Let $d$ correspond to the number of kilometers measured from Bill’s starting point to the town. Thus, $d \in \{x \in Y | x > 0 \}$, where $Y$ represents the set of real numbers. More understanding (real-world knowledge): The problem mentions the entire trip, this includes Bill’s traveling to the town and the return trip from the town to where Bill started. From the fact is that the distance for the return trip is the same as that for initial trip, we can conclude that the return trip was $d$ kilometers as well, and that the distance measure for the entire trip was $d + d$ or $2d$ kilometers. More understanding (more real-world knowledge): We should not only think about kilometers of distance since the problems, in addition, also mentions time/hours of travel - "the entire trip took $3 \frac{1}{2}$ hours." Our real-world knowledge tells us that this is made up of the time it took to travel from the starting place to the town, plus the time for the return trip; the $3 \frac{1}{2}$ is the sum of two other numbers/times. More understanding: Reflecting on the information generated thus far, we seem to have two disconnected pieces/ideas. The first part talks about three related distances. The second part talks about three related times. What we seem to need is some connection between these two things (some way to "bridge the gap"). This is a problem-solving meta-level notion or heuristic. The solver "sees" that this problem has a "missing link" or "gap to be filled" quality to it, and brings into play problem-solving organizational and planning strategies to make the connection/fill the gap. More Understanding (prior knowledge): Prompting recall, we need to "hit" on a relationship that involves distance and time. This relationship need not be to the exclusion of other entities/concepts; we just need one or more relationships whose ingredients include distance and time. This need (sub-goal) identified may be enough to activate the solver’s memory, bring to mind some such relationship as "distance is equal to rate times time." Should this not naturally occur, perhaps that potential solver never learned the principle or temporarily experiences recall difficulties at a particular point in time, more consciously controlled or directed mental processing activities may be generated. This is a carrying out the plan item for the particular sub-goal, within the activities for solving the problem as a whole. However memory is activated or even if the solver gets help or looks up/finds the relationship in a book (on the internet, or whatever) is not of concern for this discussion, only that it (the relationship "rate times time equals distance") does surface. Variations are acceptable, from "rt = d" to $\text{Time} = \frac{\text{Distance}}{\text{Rate}}$; whatever equivalent forms one might generate (restricted to avoid division by zero and negative numbers for measures). The formula/relationship $\text{Time} = \frac{\text{Distance}}{\text{Rate}}$ provides a mental frame or "template" that can and should be applied in at least two ways in this problem, for the time traveling from the starting place to the town and for the time of the return trip; measured in hours. Thus, we have the following execution (carrying out the plan) activity.
More understanding coupled with carrying out part of a plan:

\[
\text{The time going} = \frac{\text{The distance to the town}}{\text{The rate traveled going}} = \frac{d}{12} \quad \text{and} \quad \text{The time returning} = \frac{\text{The distance from the town}}{\text{The rate traveled returning}} = \frac{d}{10}.
\]

More understanding, "seeing" mental connections and acting to integrate the "pieces of the puzzle" that fit together (carrying out the plan):

The latter two specific instances of the time and distance relationship connect to the real-world knowledge mentioned earlier citing that the total time is equal to the time going plus the time returning (which itself is semantically equivalent to the equation: The time going + the time returning = the total time). Instantiating more concretely, we have

\[
\frac{d}{12} + \frac{d}{10} = 3 \frac{2}{3}.
\]

At this point in time, a major problem sub-goal has been attained. Whether stated explicitly or left implicit, producing a model equation involving the unknown and givens in a valid solvable relationship is part of the algebraic problems solving method/strategy. In essence, this "translates" the problem from one expressed in words (in this case) to one expressed in the "realm" of algebra. Solving the problem is thereby reduced to solving an equation (here, a linear equation in one unknown) which is a skill that is an object of learning in the algebra curriculum.

Carrying out the plan has been going on already. At this point in time, however, an appropriately educated/trained solver might exhibit relatively routine activity in a relative short time. Say:

\[
\frac{d}{12} + \frac{d}{10} = 3 \frac{2}{3} \quad \rightarrow \quad [\text{Multiplying through by the LCM } 60] \quad 5d + 6d = 220 \quad \rightarrow \quad [\text{Adding like terms}] \quad 11d = 220 \quad \text{and} \quad 11d = 220 \quad \rightarrow \quad [\text{dividing by } 11] \quad d = 20. \]

Here again, a sub-goal has been reached within this problem-solving episode. Interpretation mental activity takes over, noting that unknown value d stood (stands for) 20 has been revealed. Thus, 20 is the number of kilometers distance from the starting place to the town.

Looking Back: Looking back includes, but is not limited to checking. Checking will be followed by additional Looking Back ideas.

Checking: Here, checking might take the form of critically re-reading the problem in "light" of now knowing that the town is 20 kilometers from the starting point. In the critical re-reading process, one might do associated computations that reveal the specific values of other conceptually defined and formerly not known values. To illustrate: Bill bikes to a nearby town \(\rightarrow \text{[now becomes]} \rightarrow \text{Bill biked } 20 \text{ kilometers. He did this at } 12 \text{ km/hr.}

Hence, it took him \(\frac{20}{12} = \frac{5}{3} = 1 \frac{2}{3}\) hours to bike to the town.

Bill returns by bike from the nearby town \(\rightarrow \text{[now becomes]} \rightarrow \text{Bill biked } 20 \text{ kilometers, this time at } 10 \text{ km/hr.}

Hence, it took him \(\frac{20}{10} = 2\) hours to return from the town.

Our real-world knowledge directs us to add these two amounts, giving us \(2 + 1 \frac{2}{3} = 3 \frac{2}{3}\) hours; which is consistent with the given total time. Observe that revealing 20 as the value of d is consistent with the understanding the d be an positive real number. Checking may take or include other forms such as checking the steps in the algebraic solution of the equation, but consider checking for this presentation to now be completed. Looking Back includes seeing the solving of this problem in the bigger context of solving problems. One can sub-categorize this problem as one which can make efficacious use of elementary algebraic structures (a model equation) and processes. It demonstrates the value of the "try using algebra" problem-solving heuristic. Looking Back includes transfer, both near and far. The following item might seem routine (near transfer) for someone who was able to develop the above solution.

An airline flight to a certain airport travels 500 kilometers per hour and returns at 550 kilometers per hour. How far is the airport if the entire trip took 11 hours?

To add some transfer distance, consider the item and comments that follow.

Bill bikes to a nearby town at 12 kilometers per hour and returns at 10 kilometers per hour. If the town is 20
kilometers away, how long did the entire trip take? [Like the variation before this, roles are switched. Here, the formerly unknown distance is now given, and the formerly known time is now unknown.

Overall, what's important in promoting NCTM's problem-solving goal is not that technology has been used, but that it has been used appropriately. As in the activities suggested by this paper, sufficient and appropriate utilization of technology ought to be the norm rather than the exception if one is to meet the goal proposed.

The *Graph* System for Function Graph Construction

Vladislav Katkov  
National Academy of Sciences  
Institute of Engineering Cybernetics  
Belarus.  
katkov@newman.bas-net.by

Abstract: The system *Graph* intended for drawing of the function graphs is described. The general algorithm of the graph drawing is described. The function can be set in an explicit, implicit, parametric form and as a sequence of the more simple formulas. With drawing the asymptotes of graph and the limits of function in points specified by the user are calculated. For the analysis of the graph (allocation of maximums, minimums and inflections) derivatives of function can be calculated in an analytical form. The allowable elementary transformations above the constructed graph are listed. The resulting figure can be made out as the appropriate file for the most popular textual and graphic editors. The function and its derivative can automatically be presented as the descriptions in languages C++, Fortran and Pascal. In system there will be a library of frequently used functions, set of the helps and recommendations, and also mode of examples demonstration. The system *Graph* is realized in language C++ under Windows 95/97/98.

Introduction

The function graph is powerful and convenient tool for research of functional dependencies in mathematics and applications. The graph drawing is widely used in various activities at schools, colleges, universities, R&D institutes, in business, in a science, industry etc. This activity is realized in many applied programs, for example, in (Baiakovski et al., 1985), and also in a number of universal systems of numerical and analytical manipulations (Mathematica, 1989, MATLAB, 1979). The universality and the multipurpose of such systems results that the user is compelled in the beginning honesty them to study, and only after that he/she be able to modest solve the simple task - to draw the graph of interesting his/her function. (For example, the *Mathematica* user's guide occupies 1400 pages).

The purpose of our work - to create the simple and effective system for graph drawing not requiring any appreciable efforts to its mastering by the novice. At the same time for the experienced user a lot of additional possibilities allowing to build and to analyze the complex graphs of functions and to represent result in a convenient form is offered. It is permitted to make some transformations over graph for reception of the required image or analysis of function. The system will be realized in two variants: *school*, destined for the beginners, and *basic*, in which all opportunities of system will be accessible. The *Graph* system will work in a semi-automatic mode and addresses to the user in inconvenient situations at the help. Basically it occurs with updating of the singular points and work to infinity.

The system will have the built-in library of the most widespread functions, in which for each function will be given its formula, graph with some typical values of parameters and brief explanation. The library will consist of two parts: libraries of school functions (algebraic functions, trigonometrical functions and inverse to them, exponent, logarithm, power, hyperbolic and other functions) and basic library (special functions).

The *Graph* system will have the interconnected set of the helps and demonstration examples. There will be rich means of polygraph representation of the graphs for the most popular textual and graphic editors.

Construction of Function Graph

The process of graph drawing consists from the following steps:

1) To determine domain of function definition.
2) To calculate the singular points, points of maximum and minimum, points of inflection and points of function discontinuity.

3) To calculate asymptotes vertical, horizontal and sloping. To find limits of function in the chosen points, including indefinitesses of a kind $0/0$, $\infty/\infty$, $0-\infty$, $\infty-\infty$, $1^\infty$, $0^0$, $\infty^0$.

4) To set the sizes of the graphs, to draw axes to put inscriptions.

5) To draw the graph of function.

6) To edit a figure before printing or insert in the document.

**The domain of definition.** The Graph system calculates the domain of definition for what writes out restrictions on argument of function: the denominator is not equal to zero, the argument of the "log" function is positive, the subradical expression for a root of an even degree is non-negative etc. For example, for function $y = \frac{(2x - x^2)^{1/2}}{\log(1-x^{-3})}$ the Graph system will give out inequalities $2x - x^2 \geq 0$, $\log(1-x^{-3}) \neq 0$, $1 - x^{-3} > 0$ and also will ask the user to refine domain of function definition. By solving inequalities, the user can receive restrictions on allowable values of argument, i.e. the segment $[a, b]$, on which the function is given, can appear broken on smaller segments $[a_1, b_1]$, $[a_2, b_2]$, ..., $[a_n, b_n]$, on which the function is meaningful and can be calculated.

The singular points and function breaks points, points of maximum and minimum, points of inflection and points of function discontinuity are defined. The points of a maximum and minimum, and also point of inflection are calculated with use of the first and second derivatives.

**The calculation of asymptotes vertical, horizontal and sloping.** The parameters $k$ and $b$ of sloping asymptote $y = kx + b$ calculated on formulas $k = \lim_{x \to \infty} f(x)/x$, $b = \lim_{x \to \infty} [f(x) - kx]$. The uncovering of indefinitesses $0/0$, $\infty/\infty$ and others with use of l'Hospital's rule is made up in a semi-automatic mode, when the user can see intermediate result and to operate the analytical calculations.

**The setting of the graph sizes, drawing of coordinate axes and inscriptions.** Before drawing of the graph it is necessary to specify its sizes, to draw axes of coordinates, to choose types of scales for axes of coordinates (usual, logarithmic, half-logarithmic), to superscribe numbers on them, to set drawing a coordinate grid, if it is necessary. The graph can be supplied with inscriptions and explanatory text.

**Drawing of the graphs.** The Graph system works in a dialogue mode and can simultaneously build the graphs of two functions $f(x)$ and $g(x)$ in two different windows or in one window by superposition. The graphs are drawn in Cartesian coordinates.

The function can contain no more than one parameter. The Graph system can build family of the graphs with various values of parameters. Each graph is represented by a curve, at which the color, thickness and type of a line (from an offered set) are easy selected.

The system updates simultaneously two functions, which graphs can be imposed one on other. It is convenient for the various purposes, for example, for the approached definition of roots of the equation $f(x) = g(x)$.

The function is set analytically in one of the following forms:

1) Explicitly, as $y = f(x)$, $a \leq x \leq b$.
2) Parametric, as $x = X(t)$, $y = Y(t)$, $a \leq t \leq b$.
3) Implicitly, as $f(x, y) = 0$, $a \leq x \leq b$ or $c \leq y \leq d$.
4) It is possible to set function as consecutive of formulas. For example, the function $f(x)$ can be set as $u(x) = (x-1)/(x+1)$, $v(x) = \exp(2u-x^*\delta)$, $f(x) = u^2-3^*\sin(v)+\delta$, where $p$ is a parameter.

**Edition of a figure for printing or insert in the document.** The user can transform a figure to a textual or graphic file of the appropriate textual or graphic editor. It is supposed to use such formats, as .doc, .rtf, .pdf, .bmp, .html, .pox, .gif, .jpg. It is possible also to convert symbolic expression for function and its derivatives into a textual file of WinWord, Word Perfect, Latex, Adobe Acrobat etc. The Graph system can translate the function definition and its derivatives in languages C, Fortran, Pascal.

We will demonstrate an example of work of Graph system. Let user needs to select parameters $a$ and $b$ by such, that the equation $a(1+x^2) = b \cdot \sin(x)$ had two positive roots on $[-3, 3]$. With the help of an input field "f = " in the bottom part of a window (see Fig. 1) user sets the first function "f = a/(1+x^2)" and in a field "[f] = " specifies its limits of change " 0, 4". The trial value of parameter $a$, equal "4", is set in an input field "prm = ". The second function "g(x) = b^*\sin(x)" and corresponding parameters is similarly given. In a field "[x] = " the segment, interesting for the user, [-3, 3] is set, in which the limits of functions $f(x)$ and $g(x)$ are analyzed. Then
the graphs of these functions are drawn: \( f(x) \) in left window, \( g(x) \) in the right one. Finally after pressing a key "g→f" the graph of function \( g(x) \) is lain on the graph \( f(x) \). Resulting picture is shown on Fig. 1. It is obviously, that with values of parameters \( a = 4 \) and \( b = 2 \) there are two positive roots of the analyzed equation on a segment \([-3, 3]\). (Note: In an input field "df/dx = " the symbolic record of derivative \( f(x) \), received by the user on one of stages of processing \( f(x) \), was stored).

Fig. 1: The example of work of Graph system

Transformations of Functions and Graphs

It is possible to execute simple transformations above function and its graph with help of the fintrol menu (see Table 1). Such transformations are necessary in themselves, and also for the purposes of training of pupils and students at schools, colleges and universities. All transformations are carried out above function \( f(x) \). However, by changing \( f(x) \) and \( g(x) \) by button "Swap", it is possible to execute necessary transformations above function \( g(x) \).
Table 1: The list of transformations over functions and its graphs

The Graph system stores in inner list (with name f_list) the restricted set of functions and their graphs, with which the user worked earlier and has stored for future use. The set of actions above this list is given in table 2.

Table 2: The set of actions over f_list

Debugging of the Graph system nowadays is completed. The system is designed on language Visual C++ and will work on IBM PCs under Windows 95/97/98.

San Antonio Technology in Education Coalition:  
A Mathematics and Technology Curriculum Integration And Staff Development Project

Paul Tisdel  
SATEC Project Coordinator  
San Antonio Urban Systemic Initiative  
United States  
pptisdel@saisd.net

Lorraine Bratcher  
SATEC Staff Development Coordinator  
North East Independent School District  
United States  
lbratcher@saisd.net

Abstract: SATEC seeks to connect student learning to concrete experiences through the seamless and appropriate integration of technology into instruction. A training and application model is being piloted in the coalition's critical need area of mathematics through a hands-on, data-driven approach to the learning of mathematical concepts using such tools as computer-interfaced probes, image analysis software, and spreadsheet based simulation activities. While radically changing the environment of the teaching/learning process for mathematics, these tools are allowing teachers to introduce students to concepts by permitting them to discover patterns in their own collected data. The previous focus on skills has shifted to a focus on concepts and connections to the real world.

Introduction

Many adults who took high school algebra remember calculating the slope of a line from a memorized equation: \( m = \frac{y}{x} \). Unfortunately, few learned the applications of \( m \) or understood the concept of slope. Though this abstract approach was deemed adequate for some children, most of today's students are not responding to this approach, and they are not learning. For example, only 17% of students taking Algebra I in the San Antonio Technology in Education Coalition (SATEC) target schools passed the state mandated End-of-Course Algebra I Exam in 1996. We believe that sound teaching begins with questions about real events that are interesting and familiar, not with abstractions out of context. Students cannot learn to think critically, analyze information, make logical arguments, explain natural phenomena, or work as part of a team unless they are often permitted and encouraged to do so. When students connect their learning to concrete experiences, they develop a foundation for understanding more complex ideas. Because computers help to rapidly collect, organize, and analyze data, technology enables students to quickly and easily replicate time consuming and laborious experiments. Inductive reasoning is used more frequently when students collect their own data and make generalizations about properties and events in the natural world. This approach allows students to grow in their ability to make observations and generalizations, reason logically, manipulate symbols, and derive formulas. The ability to communicate abstractions and to connect that kind of reasoning with the world around them makes students more likely to succeed in a society that demands problem solving rather than repetitious tasks.

Over the past twenty years educational institutions have embraced technology as a means to improve school and student performance with a major emphasis on hardware acquisition and on building a sophisticated network infrastructure. Only recently has there been a realization that staff development and quality curriculum modules are important components of successful technology curriculum projects. We cannot expect technology alone to impact student performance. Knowledgeable, well-trained teachers must participate in the development of rich curriculum that incorporates technology where it is appropriate to do so. Putting computers in the classroom of an unmotivated and untrained teacher may do more harm than good. It is certainly not cost effective. While our project is in the preliminary stages of data collection, we are able to suggest several outcomes from our study.
Suggested Outcomes

First, technology training for the teachers out of the context of curriculum content does not transfer into appropriate integration of technology tools into teaching. Many teachers do not see the relevance of the tools to their instruction unless they are given sample lessons to work through as the venue in which the technology tool is taught. Second, since most teachers have been trained in presenting pencil and paper algorithms, the transition into conceptual learning is very difficult for them. We are also seeing that when faced with a concept to explore and no exploration lesson readily available, the teacher will abandon conceptual learning aided by technology and return to the comfort zone of teaching a pencil and paper process. Third, many teachers are deficient in mathematical content. Asking teachers to let students explore the bigger picture of how all the concepts fit together is not part of their comfort level. Usually this is due to the fact that mathematics teachers have traditionally asked students to imitate and memorize procedures to accomplish disconnected tasks. Our staff development always includes the “bigger picture.” Fourth, teachers are limited in their understanding of mathematical application to the real world. We feel this is primarily due to the fact that teachers have been trained to use procedures to produce solutions to abstract mathematical problems. Consequently, all of our training is done with respect to a real world application. Fifth, professional development must model the methods the teacher is expected to reproduce in the classroom. Teachers must experience the training in the same way with the same materials that we expect them to use with the students. Finally, teachers must be held accountable to implement what they have learned in the classroom. We are attempting to accomplish this with action plans and with commitments to use the things learned in professional development in an actual lesson within the month of attending training.

Sample Activities

The following activities are two of the units we use to work with teachers. They are expected to then use these materials with the students in their classroom. The teacher is actively engaged in using the tools the student will be using to complete the lesson. The activity called “Letter of the Law” provides teachers with training and experience in the use of a motion detector. During the training, the trainer uses questioning techniques that mirror those the teacher will be expected to use in the classroom. The central concept covered in the lesson is mathematical functions. The second activity, “Life Expectancy,” incorporates the use of a software piece called Graphical Analysis. With this software the teacher is expected to create a scatter plot with a given set of data. Next the teacher will work with creating an equation that best models the data. Central to the lesson is the concept of correlation.

As you examine the activities, you will notice that our training models the points we have mentioned above. We mention them again for reinforcement:

➤ Teachers learn to use the technology tools in the context of a lesson they will use.
➤ Mathematical concepts are stressed throughout the lessons.
➤ The rich discussion by the trainer during the training session improves teacher content knowledge.
➤ The lessons are drawn from real world experiences.
➤ The training experienced by the teacher models the way the lesson should be presented to children.
➤ The teacher will be expected to present the lesson in a class.

Conclusion

We believe that training accomplished in this way will improve teacher self-confidence and content knowledge. Teacher growth in these areas will improve their ability to provide instruction in the classroom that engages the students. Improved instruction in which the students are working instead of watching will result in improved student achievement.
Letter of the Law

Objective

In this activity, you will

- Use the motion detector to create graphs that resemble letters of the alphabet.
- Predict which letters of the alphabet you can make using the motion detector.
- Analyze why you can do some but not other letters.

Setting up your experiment

- Logger Pro Program
- ULI with Motion Detector connected.

Instructions:

1. Launch Logger Pro on the computer (Make sure the ULI is properly connected)
2. Open the Motion Detector file.
3. From the Window menu, select New Graph.
4. Stand about five feet from the motion detector.
5. Start collecting data.
6. Move in the appropriate directions to make the letter V on the data collection screen (This may take several attempts).
7. What direction(s) did you move in order to create the letter V?

8. Repeat Steps 1-3 to create an M.
9. What direction(s) did you move in order to create the letter M?

10. Predict what direction(s) you should move in order to create the letter W?

11. Try out your suggestion to see if the letter W is drawn.

12. Make a sketch in the empty space at the right of what graph appeared when you followed your instructions.

13. Predict what actions would you have to take to make a P.

14. Try out these actions to determine if you were correct. Were you?

15. What are some other letters you could make?

16. What are some other letters you could not make?

17. Describe why you could not make the P but you could make the V, M and W.
Correlation Study: Life Expectancy

Data from
Parade Magazine, "Must We Age?" Hugh Downs, 1994
Used by Permission

1. Double click on the icon for Graphical Analysis on your desktop.

2. Label the axes appropriately. To do this, click once on the blue X in the Data Table window. A Column Options window will appear. Type the word YEAR and hit the Return key on your keyboard. Repeat the procedure for the Y-axis Label but use the words LIFE EXPECTANCY.

Which is the independent variable? Explain.______________________________________________

Which is the dependent variable? Explain.______________________________________________

3. Input data for either gender on the x-y table. To do this, click once in the first cell of the left-hand column of data. This is cell X1. Type in the number for the first year reported in your data set, 1900. You may use left and right arrow keys to move from cell to cell or you may use the Return or Enter keys to move from cell to cell. Experiment with these keys to find a method that works well for you. Enter the rest of the data - year in the X column and life expectancy (either male or female) in the Y column. The points will automatically be plotted on the graph.

Looking at the data table, what do you notice about the life expectancy as the years increase from 1900 to 1990?______________________________________________

4. When examining how variables relate to each other in a scatter plot, you are studying CORRELATIONS. There are three types of CORRELATIONS (relationships between variables): positive correlation, negative correlation, or no correlation.

Positive Correlation As the values of one variable increase, the values of the other variable also increase.

Negative Correlation As the values of one variable increase, the values of the other variable decrease.

No Correlation As the values of one variable increase, you cannot tell if the values of the other variable are increasing or decreasing.

Identify the type of correlation illustrated in your scatter plot._________________________________________
5. Give two other examples from your experiences of this type of correlation.

6. Identify the domain and range for the data displayed in the scatter plot.

   **DOMAIN**
   
   **RANGE**

   - Change the scale for your "x-values" by clicking on the last value at the right. Replace this value with 2050. Repeat this procedure for the "y-values" and replace the value with 110.
   - Title the graph: To do this, select Double click on the title. After the current title, type the gender you selected (male or female) and then type a dash followed by your initials.
   - From the File menu, Click on Print and choose Selected Display.

Using a straight edge, draw a Line of Best Fit on your graph and use it to answer the following questions:

7. According to this information, what is the best prediction of the Life Expectancy for your gender in the year 2000?

8. According to this information, what is the best prediction of the Life Expectancy for your gender in the year 1958?

9. What is the best prediction of the Life Expectancy for your gender in the year 4 B.C.?

Double click on your Data table window. Click Edit and choose Select All. Now, hit the icon containing at the top of the screen. Notice how the computer creates a Line of Best fit. Now select Analyze and click Interpolate. Using your cursor, scroll up and down the line of best fit. With the aide of this feature, answer the following questions:

10. What is the best prediction of the Life Expectancy for your gender in the year 2000? How does this compare to your previous answer?

11. What is the best prediction of the Life Expectancy for your gender in the year 1958? How does this compare to your previous answer?

Click File menu. Select Exit. **DO NOT SAVE ANY PREVIOUS DATA.**
This is my sixth year introducing this section of the SITE Annual, and every year I am renewed both academically and creatively by the papers in this section. This year is no exception. In this section you will see that the authors have approached the subject of multimedia in many diverse ways. In the preface to the book, Integrating Educational Technology into Teaching, Roblyer and Edwards and (2000), state: “As we stand at the edge of this new millennium, gazing out into its uncharted expanse, some of us feel as if we are stepping out onto a launching pad; others feel at the brink of an abyss. Some see the challenges and marvels to come and are exhilarated; some see only the certainty of change and its uncertain outcomes and are apprehensive. How amazing it is that the influence of technology is a primary force shaping both perspectives.” (p. v). These authors are certainly standing on the launching pad. I’ve organized the papers in this section around four themes involving multimedia: assessment, design and development, tools, and distance learning.

Assessing Learning with Multimedia

This year, the New Media section contains five papers that describe and document different methods of assessing student learning with multimedia tools. Three papers specifically describe and discuss the rationale for and creation of electronic portfolios. For many of us, who are just beginning to use electronic portfolios, these articles provide an excellent description of both the process and current literature about creating and effectively using electronic portfolios. For each stage, Barrett has identified the tasks and appropriate technology tools. This article provides an excellent step-by-step guide for others who are interested in using electronic portfolios as a means of assessment.

Melissa Pierson and Siva Kumari, University of Houston, summarize initial plans to implement Web-based portfolio assessment for graduate students in the Instructional Technology program. They outline the goals for implementation that include a plan for informational seminars, criteria for item selection, portfolio components, anticipated barriers, and the role portfolios will play in the graduation process for students. One of the most important reasons for using portfolios, they state, is that it reflects a jointly negotiated process, reached by the teacher and the student, that entails detailed discussions and customized evaluation of learning. This paper also provides an excellent review of the electronic portfolio literature.

Dennis Holt, University of North Florida, reports on the development of multimedia portfolios by pre-service teachers who have completed their undergraduate internship. The portfolios were created in PowerPoint and depict the accomplishment of select Florida Sunshine State Standards. Holt also describes the participants and important outcomes of the Technology 2000 project, a collaboration between the University of North Florida and the Duval County Public School District in Jacksonville, Florida.

Lynda Abbott, Holly Siskovic, Val Nogues, and Joanne Williams, University of Texas at Austin, discuss learner assessment in multimedia instruction and the related considerations for the instructional designer. They state that the most critical issues for instructional designer are those regarding how best to plan, present, and evaluate objectives and outcomes for both computer-based and Web-based instructional materials. This article provides an overview of several factors to consider in the assessment process including portfolio and project assessment ideas. The authors emphasize the role of the instructional designer in...
establishing educational objectives and selecting appropriate assessment instruments and procedures.

Finally, Fern Tavalin and David Gibson, the WEB Project, describe the construction of simple assessment tools to foster improvement by focusing on discussions that lead to high quality work and sustained professional growth. Tavalin and Gibson describe the development of successful advanced technology strategies in three broad areas of work: developing and using online assessment systems, achieving high quality work, and sustaining professional growth. Their description is illustrated with examples of student work that provides a clear link between theory and practice.

Multimedia Design and Development

Five papers in the New Media section report specifically on the design and development of innovative multimedia projects. These examples are certainly imaginative and provide exciting examples of multimedia product development. Even though each project is very different both in content and purpose, all projects have several things in common. First, collaborative teams complete the design and development of each project. In addition, each project developed strategies for understanding the needs of the target audience. Finally, formative evaluation is a critical element of each project throughout the design and development process.

Stephen Victor and Sherry Vafa, University of Houston, describe the design and development of an interactive multimedia project for library research. A collaborative team of instructional designers, content experts, and media consultants used Authorware to develop the program for a faculty member who served as a client. The authors describe the program that uses multimedia elements, interactivity, Web-based media, and games to enhance the learner’s experience of the instruction. Illustrations of the interface are included to provide a complete description of the program. The paper also briefly discusses the use of interactive multimedia for instruction.

Tomohiro Miyamoto, Tsuneo Yamada, and Yuko Hiraga, the National Institute of Multimedia Education in Japan, and Delwyn Harnisch, University of Illinois at Urbana-Champaign, describe the development of a prototype of counseling materials on DVD-video to assist in the training of both college students and in-service teachers learning counseling skills. Like the previous paper, this project is also a collaborative effort of multimedia developers working with professional teaching/counseling experts. The prototype provides a multilateral learning environment for students to observe and analyze the counseling process and includes multi-angle scenes depicting client, counselor, and complete classroom views for three counseling cases. A flowchart of the project is provided as well as screen shots. The authors note that it is important for users to be presented with several examples of how to use the educational materials rather than to be provided a single model.

Mario Steed, University of Lethbridge, Canada, describes an ongoing research project that uses a set of formative evaluation activities involving peer and target population evaluation. These activities are designed to help students involved in multimedia production to develop a greater sense of audience. Peers as well as individuals from the target population will review multimedia projects, and changes and non-changes to the design will be documented. Steed describes the manner in which data will be gathered and categorized and speculates that feedback from an audience is a powerful influence on implementing changes to multimedia.

Peggy A. Ertmer, Sangeetha Gopalakrishnan, and Eva M. Ross, Purdue University, describe VisionQuest, a project to help current and future educators envision and achieve technology integration by providing access to electronic models of technology-using teachers. The authors discuss both the development and organization of the VisionQuest CD-ROM, which includes six case studies that illustrate the beliefs and practices of exemplary technology-using teachers from across the state of Indiana. The application and selection process is described, as well as brief descriptions of the development process. The authors also describe future plans and potential uses.

Susan Berteaux, University of California San Diego, and Sandra Strong, Norwich City Schools, NY, describe the Database Advisor, a search tool designed to guide users to the most appropriate Web-based databases for their research. The authors describe how the Database Advisor works, the equipment and resources necessary to implement, where to get the source code, and why K-12 schools should seriously consider this product. Berteaux and Strong include many screen shots of the Database Advisor in their description.

Multimedia Tools

Three papers discuss the use of specific multimedia tools for capturing images, sound and video. Kenneth Clark, Alice Hosticka, and Jacqueline Bedell, Georgia Southern University, discuss the use of digital cameras in the K-12 classroom. The authors describe the digital camera as a powerful tool for customizing and transferring information. They include many examples of the integration of visual images into the instruction process of common content areas. The authors also include a brief discussion of both the advantages and disadvantages of using digital cameras and an overview of the basic features found on many cameras. Web sites for obtaining more information are also given.

Jeffrey Bauer, University of Northern Colorado, describes several emerging audio and video technologies including DVD, digital television, high definition television, and new audio formats such as MP3. He focuses on
technologies that have high adoption rates and appear to have some potential in educational settings, including distance delivered instruction. Bauer shares some interesting insights about the younger, X-tronic generation, and states that the classroom experiences for these students should not be so far removed from their daily lives outside of school.

In the third paper dealing with multimedia tools, Ronald McBride and Robert Gillan, Northwestern State University, review the process that involved selecting desktop video conferencing as the "next generation" distance learning technology. In addition, the authors discuss the creation of a multi-site desktop video conferencing network designed to serve central Louisiana and provide an array of program possibilities including courses for credit, teacher certification, and training to participating sites. A useful table that compares three distance learning technologies, desktop video conferencing, satellite and video compression is included.

Multimedia Courses and Distance Learning

Sandra Flank and Jeanine Meyer, Pace University, describe a graduate course in multimedia for teachers taught as a one-week intensive summer course. The background and rationale for course design is discussed along with content, course schedule and style of instruction. The authors describe their experiences during the past offerings of the course as well as issues that have arisen. The paper closes with comments on the assessment of students and assessment of the course itself.

Christine Vaillant-Sirdey, Université Toulouse, France, discusses a 10-year experiment in multimedia distance learning in English for specific purposes within the general frame of a 3-year management diploma in the French higher education system. Vaillant-Sirdey defines, analyzes and rationalizes key elements and briefly describes the content, tools, and assessment techniques. She also gives an overview of the milestones of the experiment and discusses some successes to adopt and pitfalls to avoid.

Marlo Steed and Richard Mrazek, University of Lethbridge, Canada, reports on an ongoing project to implement an interactive online multimedia web site for communicating research and development results. A research and development project into online distributive education is used as an example of how this can be implemented. The web site is designed to showcase the results of the research and development efforts through various types of media. The media includes pdf files, images, video clips, demonstration of interactive tools (shocked files), and linked resources.

Evangelos Kopsacheilis, Emedia EVK Ltd., Greece, describes two educational packages developed using a Web-based system called Dynamic Virtual Trainer that is designed to support online educational procedures. The two packages cover telecommunications and Mount Athos. This Web-based system allows the dynamic composition of online lessons based on the combination of educational units according to varying user needs. The educational units are short composite entities of a variety of types like modules in HTML, virtual reality representations, text, audio and video clips.

Peter McAllister, Ball State University, provides a short description of the creation process and the uploading procedure of selected teaching segments for an undergraduate music methods course.

Finally, Sara McNeil and Bernard Robin, University of Houston, presents an overview of database tools that dynamically generate web materials. Their article focuses on the use of these tools used for educational purposes to support research activities as well as teaching and learning. The paper builds a theoretical framework for using web-based databases to support constructivist learning and describes several specific applications of dynamic databases used to facilitate the construction of knowledge and support collaborative activities in online teacher education courses.
Electronic Teaching Portfolios: Multimedia Skills + Portfolio Development = Powerful Professional Development

Dr. Helen Barrett, School of Education
University of Alaska Anchorage, 3211 Providence Drive, Anchorage, Alaska 99508
Tel: 907-786-4423 Fax: 907-786-4444 E-mail: afhcb@uaa.alaska.edu

Abstract: Two bodies of literature define the process for developing electronic teaching portfolios to support long-term professional growth: the multimedia development process (Decide/Assess, Design/Plan, Develop, Implement, Evaluate) and the portfolio development process (Collection, Selection, Reflection, Projection/Direction, Presentation). As further defined, the Electronic Portfolio Development Process covers the following stages: Defining the Portfolio Context and Goals, the Working Portfolio, the Reflective Portfolio, the Connected Portfolio, and the Presentation Portfolio. In addition, there are at least five levels of technology for developing electronic portfolios, based on ease of use, including technologies that are appropriate at each level and stage. This combined process creates a foundation for powerful professional development.

The process of developing electronic teaching portfolios can document evidence of teacher competencies and guide long-term professional development. The competencies may be locally defined, or linked to national teaching standards. Two primary assumptions in this process are: 1.) a portfolio is not a haphazard collection of artifacts (i.e., a scrapbook) but rather a reflective tool which demonstrates growth over time; and 2.) as we move to more standards-based teacher performance assessment, we need new tools to record and organize evidence of successful teaching, for both practicing professionals and student teachers.

Electronic portfolio development draws on two bodies of literature: multimedia development (decide, design, develop, evaluate) (Ivers & Barron, 1998) and portfolio development (collection, selection, reflection, projection) (Danielson & Abrutyn, 1997). Both processes are complimentary and essential for effective electronic portfolio development. Understanding how these two processes fit together, along with understanding the role of standards in electronic portfolio development, will provide teachers and students with a powerful tool for demonstrating growth over time which is the primary value of a portfolio.

For the last decade, students at the University of Alaska Anchorage (UAA) School of Education have developed exit portfolios, initially in the Adult Education Masters Program and most recently to earn an institutional recommendation for a teaching certificate under UAA's MAT in Secondary Education. An electronic portfolio based on the ISTE/NCATE Standards is now required to earn the new competency-based Educational Technology Endorsement for the state of Alaska. In addition, teachers have been developing electronic portfolios to demonstrate their achievement of the Alaska Teaching Standards, and their reflections show the power of the teaching portfolio to guide long-term professional development.

Benefits of Electronic Portfolio Development

Based on research into the implementation of electronic portfolios since 1991, the following benefits appear to result from developing electronic portfolios with teachers and students:

1. Creating an electronic portfolio can develop teachers' as well as students' multimedia technology skills. The multimedia development process usually covers the following stages (Ivers & Barron, 1998):
   - Decide/Assess - determining needs, goals, audience for the presentation
   - Design/Plan - determining content, sequence of the presentation
   - Develop - Gather and organize multimedia materials to include in the presentation
   - Implement - Give the presentation
   - Evaluate - Evaluate the presentation's effectiveness
2. Modeling: If teachers develop electronic teaching portfolios, their students will be more likely to have their own electronic portfolios.

3. Each stage of the portfolio development process contributes to teachers' professional development and students' lifelong learning:
   - Collection - teachers and students learn to save artifacts that represent the successes (and "growth opportunities") in their day-to-day teaching and learning
   - Selection - teachers and students review and evaluate the artifacts they have saved, and identify those that demonstrate achievement of specific standards (this is where many electronic portfolios stop)
   - Reflection - teachers and students become reflective practitioners, evaluating their own growth over time and their achievement of the standards, as well as the gaps in their development
   - Projection (or Direction) - teachers and students compare their reflections to the standards and performance indicators, and set learning goals for the future. This is the stage that turns portfolio development into professional development and supports lifelong learning.
   - Presentation - teachers and students share their portfolios with their peers. This is the stage where appropriate "public" commitments can be made to encourage collaboration and commitment to professional development and lifelong learning.

Robin Fogarty, Kay Burke, and Susan Belgrad (1994, 1996) have identified ten options for portfolio development, further defining the stages and increasing the quality of the portfolio process:

1. PROJECT purposes and uses
2. COLLECT and organize
3. SELECT valued artifacts
4. INTERJECT personality
5. REFLECT metacognitively
6. INSPECT and self-assess goals
7. PERFECT, evaluate, and grade (if you must)
8. CONNECT and conference
9. INJECT AND EJECT to update
10. RESPECT accomplishments and show pride

Figure 1: Portfolio Development Options

The Electronic Portfolio Development Process – Five Stages and Five Levels

From the discussion of both the Multimedia Development Process and the Portfolio Development Process, along with a discussion of the appropriate technology tools, five stages of Electronic Portfolio Development emerge. Here are the issues to address at each stage of this process.

Table 1: Stages of Electronic Portfolio Development
Differentiating the Levels of Electronic Portfolio Implementation

In addition to the stages of portfolio development, there appear to be at least five levels of electronic portfolio development. In reviewing the electronic portfolios that are produced, it is important to establish different expectation levels for development. Just as there are developmental levels in student learning, there are developmental levels in digital portfolio development. Below are different levels for digital multimedia development and electronic portfolio development, which are closely aligned with the technology skills of the student or teacher portfolio developer.

Table 2: Levels of Digital Portfolio Software Strategies based on Ease of Use

STAGE 1: DEFINING THE PORTFOLIO CONTEXT & GOALS

Multimedia Development: Decide/Assess

Tasks:

- Identify the assessment context, including the purpose of the portfolio.
- Identify the learner outcome goals (which should follow from national, state, or local standards and their associated evaluation rubrics or observable behaviors). This is a very important step, setting the assessment context, which should help frame the rest of the portfolio development process.
- Identify the resources available for electronic portfolio development.
- Identify the hardware and software available and how often students have access.
- Assess the technology skills of the students and teachers.
- Identify the audience for the portfolio—student, parent, college, employer (often based on the age of the student). The primary audience for the portfolio will contribute to the decisions made about the format and storage of the formal or presentation portfolio. Choose a format that the audience will most likely have access to; i.e., parents may not have a home computer, but may have a VCR.

Appropriate Technology Tools at this Stage:

- Use whatever software tools are currently being used to collect artifacts, storing them on a hard drive, a server, or videotape.
- Set up electronic folders for each standard to organize the collection of artifacts (any type of electronic document). [Level 1] AND
- Use a word processor, database, hypermedia software or slide show to articulate the standards to be demonstrated in the portfolio and to organize the artifacts. [Level 2] OR
- Use an HTML editor to articulate the standards to be demonstrated in the portfolio and to organize the artifacts. [Level 4] OR
- Use a multimedia authoring program to organize by the standards to be demonstrated in the portfolio. [Level 5]
STAGE 2: THE WORKING PORTFOLIO
Multimedia Development: Design/Plan                      Portfolio Development: Collect, Interject

Tasks:

- Identify the content of portfolio items (determined by the assessment context) and the type of evidence to be collected. This is where the standards become a very important part of the planning process. Knowing which standards are being demonstrated should help determine the types of portfolio artifacts are to be collected and then selected.
- Select the software development tools most appropriate for the portfolio context and the resources available. Just as McLuhan said, "The medium is the message", the software used to create the electronic portfolio will control, restrict, or enhance the portfolio development process. Form should follow function as well, and the electronic portfolio software should match the vision and style of the portfolio developer.
- Identify the storage and presentation medium most appropriate for the situation (i.e., computer hard disk, videotape, local-area network, a WWW server, CD-ROM, etc.). The audience for the portfolio will have a major impact on this component. There are also multiple options, depending on the software chosen.
- Gather the multimedia materials that represent a learner's achievement. Once the questions on portfolio context and content have been answered, as well as the limitations on the type of equipment available and the skills of the users (teachers and students), the portfolio developer will be able to determine the type of materials to digitize, such as: student written work, images of student projects, sounds of students speaking or reading, and video clips of student performances. Of course, if will be appropriate to collect artifacts from different points of time to demonstrate growth and learning that has taken place.
- Interject personality into the portfolio design. Use some of the graphics capabilities of current computer systems to add style and flair to the portfolio.

Appropriate Technology Tools at this Stage:
Select software tools to organize selected artifacts:
- Use Word Processing, Slide Shows, Hypermedia, or Database programs to list and organize the artifacts that will be placed in the Working Portfolio. [Level 2] OR
- Use an HTML editor (or any tool that is normally used) to develop and organize the artifacts for the Working Portfolio. [Level 4] OR
- Use a multimedia authoring program to organize the selected artifacts. [Level 5]

Convert portfolio artifacts into digital format
- Use appropriate multimedia to add style and individuality to portfolio.
- Use a scanner (or camera) to digitize images [Level 2]
- Use a microphone and sound digitizing program to digitize audio artifacts [Level 4]
- Use a video camera, digitizing hardware and software to digitize video artifacts [Level 5]

Table 3: Levels of Digital Multimedia Development

STAGE 3: THE REFLECTIVE PORTFOLIO
Multimedia Development: Develop                      Portfolio Development: Select, Reflect, Direct

Tasks:

- Record self-reflection on work and achievement of goals. The quality of the learning that results from the portfolio development process will be in direct proportion to the quality of the self-reflection on the work. One challenge in this process will be the need for confidentiality of these reflections. This is the place where the personal, private reflections of the learner need to be guarded, and not published in a public medium.
• Record feedback on work and achievement of goals. Even more critical is the confidential nature of the assessment process. Feedback should also be kept confidential so that only the student, parents and other appropriate audiences have access, and not published in a public medium.
• Write general reflective statements on achieving each standard.
• Select the artifacts that represent achievement of the standards or goals.
• Write reflective statements for each artifact, elaborating on why it was selected and its meaning and value in the portfolio.
• From the reflections and feedback, set learning goals for the future.

Appropriate Technology Tools at this Stage:
• Use Word Processing, Slide Shows, Hypermedia, or Database programs to record the reflections and future goals that will become the Reflective Portfolio. [Level 2] OR
• Use an HTML editor (or any tool that is normally used) to record the reflections and future goals that will become the Reflective Portfolio. [Level 4] OR
• Use a multimedia authoring program to record the reflections and future goals that will become the Reflective Portfolio. [Level 5]

STAGE 4: THE CONNECTED PORTFOLIO
Multimedia Development: Implement, Evaluate  Portfolio Development: Inspect, Perfect, Connect

Tasks:
• Organize the digital artifacts. Use software that allows the creation of hypertext links between goals, student work samples, rubrics, and assessment. The choice of software can either restrict or enhance the development process and the quality of the final product. Different software packages each have unique characteristics which can limit or expand the electronic portfolio options.
• Identify patterns through the "linking" process.
• Final review of the portfolio and goals.
• Share the portfolios with an appropriate audience. This will be a very individual strategy, depending on the context. An emerging strategy is the use of student-led conferences, which enable learners to share their portfolios with an appropriate audience, whether parents, peers, or potential employers. This is also an opportunity for professionals to share their teaching portfolios with colleagues for meaningful feedback and collaboration in self-assessment. This “public commitment” provides motivation to carry out the plan.
• Evaluate the portfolio’s effectiveness in light of its purpose and the assessment context. In an environment of continuous improvement, a portfolio should be viewed as an ongoing learning tool, and its effectiveness should be reviewed on a regular basis to be sure that it is meeting the goals set.
• Depending on portfolio context, use the portfolio evidence to make instruction/learning or professional development decisions. Whether the portfolio is developed with a young child or a practicing professional, the artifacts collected along with the self-reflection should help guide learning decisions. This process brings together instruction and assessment, portfolio development and professional development, in a most effective way.

Appropriate Technology Tools at this Stage:
• Convert word processing, database or slide show documents into either PDF [Level 3] or HTML [Level 4] AND
• Create hypertext links between goals, student work samples, rubrics, and assessment.
• Insert multimedia artifacts [Level 3 & 4] OR
• Create a hypermedia presentation using a multimedia authoring program, creating links between goals, multimedia work samples, rubrics, and assessment. [Level 5]
STAGE 5: THE PRESENTATION PORTFOLIO
Multimedia Development: Present, Publish

Tasks:
- **Record** the portfolio to an appropriate presentation and storage medium. This will be different for a working portfolio and a formal or presentation portfolio. The best medium for a working portfolio is video tape, computer hard disk, Zip disk, or network server. The best medium for a formal portfolio is CD-Recordable disc, WWW server, or video tape.
- **Present** the portfolio before an audience (real or virtual) and celebrate the accomplishments represented.

Appropriate Technology Tools at this Stage:
- Post the portfolio to WWW server OR
- Write the portfolio to CD-ROM OR
- Record the portfolio to videotape

Table 4: Levels of Digital Storage

Conclusions

The process of creating an electronic teaching portfolio should incorporate not only multimedia technology skills, but also the portfolio development process. Otherwise, we will continue to produce web pages or multimedia presentations masquerading as electronic portfolios; a portfolio without goals (or standards) and reflections is just a multimedia presentation, or a fancy electronic resume, or a digital scrapbook. By following the portfolio development process as defined above, including reflection, direction (goal-setting) and connection (dialogue with others about the portfolio), a teacher creates a foundation for powerful professional development.

Abstract: This paper summarizes our initial plans to implement portfolio assessment for graduate students in our Instructional Technology (IT) program. Specific advantages of portfolios, and electronic and Web formats in particular, hold promise for the development and assessment of our student population. We outline the goals we have for implementation that include a plan for informational seminars, criteria for item selection, portfolio components, anticipated barriers, and the role we intend portfolios to play in the graduation process of our students.

Introduction

Performance-based portfolios are gaining acceptance as a viable alternative form of assessment in educational settings. Teacher education programs, in particular, have found portfolios to be an elastic assessment format capable of addressing criteria not a part of traditional assessments, such as continuous student reflection, individual assessment of growth and change, iterative evaluation of learning goals, and the contextual examination of created products in relation to complex teaching processes (Barton & Collins, 1993; Guillaume & Yopp, 1995; Levin, 1996; Richards, 1998; Snyder, Lippincott, & Bower, 1998; Wade & Yarbrough, 1996). Portfolio assessment allows for the development of pedagogy and discipline-oriented philosophy (Carroll, Potthoff, & Huber, 1996), as well as the evolution and expression of a professional voice (McKinney, 1998). The distinct advantage of portfolios that appeals most to us, as faculty in an Instructional Technology program, is that the ownership of learning and product production shifts away from the teacher (Wiggins, 1989). Instead it reflects a jointly negotiated process, reached by the teacher and the student, that entails detailed discussions and customized evaluation of learning. In compiling a portfolio, the student selects multiple samples of work for the purpose of demonstrating personal competence in various facets of learning required by the program.

In an Instructional Technology (IT) program, essentially all artifacts of learning, whether products that demonstrate skill or reflection, are by definition digital products. Thus, we assert that as a storage and display medium, electronic portfolios in particular would provide a natural solution to representing student learning in Instructional Technology. Philosophically, we adhere to the notions of constructivism, and with regards to the assessment of digital products, we subscribe specifically to "constructivism" as expressed by Resnick (1998) as the idea that people construct new knowledge with particular effectiveness when they are engaged in constructing personally-meaningful products. We argue that the processes of learning, implementation, and production common in IT programs can be best represented through the use of digital portfolios. Further, the emergence of the Web as a predominant learning environment in education and business led us to consider this particular medium as the portal to student portfolios. The Web format encourages individuality by allowing students to demonstrate creativity in presentation and organization, to create multiple design formats for multiple audiences (Watkins, 1996), and to easily establish connections.
among related portfolio components (McKinney, 1998). The Web, as both a technology and an interface, enables the student ultimate control in assembling and ease of re-organizing, as well as the ability to integrate narrative captions among the learning evidence to emphasize the interrelated nature of the learning (Watkins, 1996). The Web environment permits students the flexibility to maintain their portfolios in a Web-space that can be remotely accessed from anywhere at any time, by the student, faculty, peers, and potential employers. Finally, Web-based portfolios promote seamless access to student work by eliminating software and platform incompatibilities encountered when viewing electronic portfolios created with multiple authoring tools (Mills, 1997).

Our Context

The Instructional Technology program in the College of Education at the University of Houston offers both Masters and Doctoral degrees to primarily part-time, commuting students who hold full-time jobs in both education and industry. Assessment strategies currently vary among our courses depending on the course content, structure, and individual instructor preference. Digital design and multimedia projects are typically submitted on disk or uploaded to a specific course server location, while traditional reports and papers are turned in either electronically or on paper. As students progress through our program, we currently have no consistent standard for collecting and comparing the work they produce in separate courses, therefore there is no easy way to draw any type of comparisons of program-wide effectiveness.

While much of the literature on the use of portfolios describes implementation within preservice teacher education, our faculty sees the promise of a portfolio assessment strategy for our graduate program, for many of the same reasons. First and foremost, we value and encourage student ownership of learning, and we see the compilation of portfolios as the ideal instrument to coach students to observe and manage their own learning progress. We believe we can use portfolios to accomplish this goal not only because their creation helps make explicit the connections among seemingly discrete but realistically related courses, but also because portfolios will assist our students in valuing the course projects in relation to our larger program goals. We want to eliminate the prevalent idea that course products are produced in isolation merely to get a grade, destined only to collect dust on faculty shelves. Portfolios would allow our faculty the opportunity for more meaningful and interactive feedback to guide our students toward learning goals, dialogue which would ultimately allow students to originate and hone their individual professional voices within the diverse IT field.

We see Web-based portfolios, in particular, as the most versatile format for incorporating the multiple projects that our students produce using a variety of software. A key advantage for our commuting, and frequently telecommuting, population of students and faculty, is that Web-based portfolios could be revised and assessed from any computer at any time. We envision portfolio assessment as initially supplementing, and potentially replacing, our written comprehensive exams as a graduation requirement. Such a change would better reflect our constructivist teaching and learning philosophy, as well as the project-based nature of our program. Finally, we look forward to the ongoing feedback on the effectiveness of our program that portfolios would provide our faculty (McKinney, 1998; Snyder, Lippincott, & Bower, 1998). Such feedback, we believe, could directly feed the continuous improvement and development of our program.

Digital portfolios for our IT program seem to be the natural format whose time has come, both for our students and for us. Other plans we are considering for portfolios include capturing the work examples to provide our students with examples of exemplary models produced by their peers and archiving these products in an organization scheme that benefits the larger education community. The driving force behind our interest in portfolios, however, is the progressive and comprehensive review of the projects, process, and learning across courses and throughout the entire experience of the student in the program.

Initial Plans for Incorporating Portfolio Assessment

In planning for a portfolio strategy in the IT program, we began by asking questions relating to the nature of the knowledge, application, and synthesis level skills that students will encounter in the program. What information do we want students graduating from the IT program to know, and what skills should they be able to demonstrate? What kinds of evidence will verify that the information and skills have been
learned? How effective is our program at preparing future instructional technologists, and what could we do differently to give our students an even more meaningful preparation in instructional technology? These questions are aligned with portfolio development criteria discussed by others (Barton & Collins, 1993; Georgi & Crowe, 1998; Snyder, Lippincott, & Bower, 1998).

With those over-arching questions in mind, our portfolio process will begin with a, required seminar at the beginning of the semester for entering Masters-seeking students, allowing ample time to assimilate the concept of using portfolios before courses have begun (Stone, 1998). In this seminar, we will orient students to the ideas of "digital portfolios," articulate flexible criteria that will provide guidelines for the individual portfolio requirements, and enable them to think of the program and the learning process as one that is evaluated by more than the individual instructor. By presenting these criteria in the form of organized rubrics, students will be made aware of expectations we have for the demonstration of proficiency and skill, thus de-mystifying the evaluation process and allowing students to take an early and active role in the planning for and management of their own learning during the course of the program.

Instruction on technical considerations and style guidelines for the Web-based portfolio will be presented in an effort to ensure ease of accessibility of student work throughout the graduate experience. Upon entering our program, each student will be given permanent disk-space on the department server to be used for the duration of their studies. To assist with the details of file-management, we will establish a consistent hierarchy of file organization within each student’s Web index that is based on our course numbering system. Sufficient hands-on time for practicing such procedures as file transfer and organization will be given at the seminar so that students walk away with a clear understanding of portfolio maintenance basics.

The seminar will conclude by addressing the actual work of compiling portfolio components. Substantial time will be spent demonstrating strategies for selecting portfolio items to represent a range of work quality and type, with a focus on ethnographic methods of collecting and analyzing data. By addressing portfolios with specific research and analysis methods, we will empower each student with the skills necessary to use the data to develop an individual theory of instructional technology as it relates to his or her own learning artifacts (Snyder, Lippincott, & Bower, 1998). Specific examples will be given to students to illustrate the process of authoring reflections on their work, or “sustained hard personal looks at oneself and one’s practice” (p. 54). Final thoughts in this first seminar will involve establishing the focus of each student’s portfolio through the writing of an individual goal statement.

Once established, the portfolio procedures will be regularly reinforced throughout the individual courses in the IT program, allowing us to design and adhere to standard policy and a consistent technical format for all of the various courses. We anticipate that this advanced and sustained attention to the portfolio construction, maintenance, and presentation will contribute to the overall success of the evaluation procedure.

The Balance among Utility, Reflection, and Creativity

Our IT portfolios will be useful only if they transcend a merely pleasing display of completed work to instead make compelling arguments of each student’s knowledge and skill. At the same time, we hope that the portfolios will highlight interrelations among instructional theory, research, and practice, both intended and serendipitous, as evidenced in the products of learning and the ability of each student to articulate these ideas.

Despite our intention to provide a consistent overriding portfolio framework, we do not believe that the requirements of included work should be entirely prescribed. Such demands for conformity would counter our goals of reflection, individuality, and customized feedback, and might, in fact, preclude student creativity and individuality, thus resulting in artificially similar products from all students (Mills, 1997). Like others (Scanlan & Heiden, 1996; Snyder, Lippincott, & Bower, 1998), we recognize the need for a convergence of perspectives in the design of our portfolio process so that our portfolios can be useful for both summative purposes and individual student reflection. Therefore, we will strive for a balance between student-selected items chosen to illustrate personal learning and items suggested by the faculty to demonstrate learning in accordance with program goals. Consideration of item selection will be encouraged regularly at the conclusion of each semester, and items previously selected may be re-evaluated in comparison with newer projects. Students will compose narrative captions to rationalize the inclusion of each item in the portfolio, thus constructing a unique comparative thread linking skills and projects.
Student-written captions will enable faculty to evaluate learning products with the students' voices articulating the reasoning behind projects (Barton & Collins, 1993). In addition to formal narratives, students will have the opportunity to include personal reflections about the progress toward attaining their learning goals.

Considered along with the selected work examples and various written commentaries, the Web interface and navigational sequence will serve as the ultimate demonstration of creative design and systematic development expected of IT graduates. The final portfolio component will be a summative "epilogue" written by each student to bring closure to his or her graduate experience. This culminating document will address questions specifically posed by the faculty that are intended to guide the student to synthesize his or her understanding of theory and practice.

Successful completion of the portfolio process in our program will be marked by a "portfolio consultation" to occur during the last semester of the student’s program and involve the participation of peers and faculty advisors. Consultations will take the tone of a collaborative forum, a collective “think tank” of instructional technology issues led by the portfolio author, as opposed to the generally one-sided, directed nature of an academic inquisition, a hurdle commonly seen as part of a graduation defense. This collegial approach will allow us to further capitalize on the portfolio as a tool for the continued growth of both students and faculty. Such examination of learning evidence and subsequent reflection, we argue, is not possible in our existing traditional written comprehensive exam format (Bali, Wright, & Foster, 1997; Barton & Collins, 1993).

Challenges and Future Directions for Portfolios

As our portfolio evaluation process matures, we foresee related research investigations, such as examining the impact of portfolio development on student learning and reflection, the benefits of increased student and faculty collaboration, the extent to which portfolios allow us to assess the validity of course objectives, and the role of the information gained through the process on ongoing improvement of course-to-program goal alignment. For now, portfolio assessment is scheduled to commence in our Instruction Technology program with the incoming Master’s students in the Spring semester of 2000. We understand, however, that the best-laid plans will not ensure flawless implementation. The literature reviewed thus far has been clear about the potential challenges we may face by incorporating portfolios into our program. For example, we anticipate that ensuring grading consistency with this alternative assessment strategy can prove problematic, as can establishing the expectation that students honestly reflect on their learning rather than report back only what they think we want to hear (Scanlan & Heiden, 1996). We concur with the recommendation of Scanlan & Heiden that developing an evaluation rubric will address this issue by explicitly communicating our evaluation criteria to students early in the program. Genuine faculty participation with and commitment to the benefits of portfolio assessment, consistently communicated to students, should also invite more honest student participation. Another barrier we expect is the additional time commitment required from both students and faculty advisors to assemble the portfolios concurrently with fulfilling project requirements for individual courses (McKinney, 1998). Our goal of consistently addressing portfolio format and content as a component of each of our courses will, we believe, make the necessary time commitment more manageable and ultimately worthwhile. Our exploration of possible solutions to these and other perceived and anticipated obstacles will continue. We are convinced, however, that the authentic assessment and related benefits possible through the use of Web-based portfolios are much too advantageous to ignore.

Harness the Power of Multimedia
Portfolios for Teaching and Learning

Dennis M. Holt, Ph.D.
College of Education and Human Services
University of North Florida
United States
dholt@unf.edu

Abstract: This paper is a report on the development of multimedia portfolios by pre-service teachers who completed their undergraduate internship at the University of North Florida in Jacksonville, Florida. Included are samples from portfolios, which display Florida's pre-professional accomplished practices. Created in PowerPoint, the portfolios contain samples of electronic portfolios developed by PreK-12 students featuring the accomplishment of select Florida Sunshine State Standards.

Introduction

During the past six years the author has completed collaborative university–school district projects for improving teaching and learning using state-of-the-art educational technology. This work has involved the simultaneous improvement of PreK-12 education and teacher education. By appropriately using educational technology, the pre-service teachers and their directing teachers were engaged in the collaborative alignment of curriculum, instruction and assessment to facilitate student achievement. This article describes and illustrates important outcomes of the Technology 2000 project, a collaboration between the University of North Florida and the Duval County Public School District in Jacksonville, Florida. The participants believe that the outcomes of the project have important implications for the improvement of teaching and learning in other Pre-K education and teacher education settings.

Project Overview

The Technology 2000 project was a collaboration between the University of North Florida and the Chets Creek and Lone Star elementary schools of the Duval County Public School District, and Logical Business Systems, a collaborating IBM K-12 Division business partner. The project was designed to improve teaching and learning through the use of educational technologies.

Participants

Participants in the project included:

- Five directing teachers from Chets Creek and Lone Star elementary schools;
- The two school principals;
- A Media Specialist;
- Five University of North Florida pre-service teachers completing their internship semester;
- A University of North Florida professor who served as project director;
- A business partner technology trainer; and,
- Students in three first grades, a third grade, and a fifth grade classroom.
Project Focus

The project provided the five participating pre-service teachers with the educational technology skills necessary to excel in the schools of the twenty-first century. This included the ability to not only use computers and related technology for word processing and record keeping tasks, but as tools to significantly enhance classroom instruction, documenting student achievement and extending it through the creative uses of multimedia tools for teaching and learning.

Participants in the project:

- Learned to use multimedia computers, including laptops, scanners, digital still cameras, digital video cameras, and microphones for creating presentations and for instructional activities;
- Learned to use software, courseware, and related technology-based materials available at the schools for classroom teaching and learning activities, with an emphasis on IBM’s Teaching and Learning with Computers (TLC) approach to instruction;
- Became knowledgeable about the available technologies for use with a single computer to present whole-class instruction while successfully conducting technology-infused lessons.
- Used the multimedia presentation tool, PowerPoint, to create instructional materials which incorporated text, video, sound, and graphics; and,
- Used instructional and assessment strategies to assist PK-12 students with the creation of multimedia portfolios using PowerPoint.

Technology Training

The Session One training topics included:

- Effective use of multimedia desktop and laptop computers, large screen projection devices, scanners and digital still and video cameras.
- Teaching and Learning with Computers (TLC), IBM’s approach to classroom instruction utilizing technology.
- Training in the use of the School Vista Instructional Network Management program and instructional courseware available on the network for assessing, instructing and evaluating the effectiveness of computer-based instruction.
- Training in the use of PowerPoint for displaying student and pre-service teacher work in electronic formats.

Session Two topics included:

This session involved assistance to pre-service teachers in finalizing their multimedia portfolios and those of their students.

Outcomes

Each intern involved in the project:

1. Presented lessons to their respective students utilizing educational technology resources within the framework of Teaching and Learning with Computers using appropriate IBM courseware;
2. Created a personal multimedia portfolio with PowerPoint, providing information on their intern experiences, displaying examples of technology-based products which their students produced;
3. Facilitated the creation of student multimedia folders that displayed a knowledge of language arts, mathematics and science subject matter and evidence of newly acquired educational technology skills;

4. Developed diagnostic and prescriptive lessons which included educational technologies as instructional and assessment tools; and,

5. Created digitized photographs and video clips of their teaching and learning activities using a wide variety of educational technology.

Learner Assessment in Multimedia Instruction:
Considerations for the Instructional Designer

Become Aware of Current Practice in Learner Assessment

The designer of instructional multimedia needs to be aware of currently accepted practices to stay appraised of the array of methods and applications from which he or she will want to choose and also to be aware of practices that appear to be expected, appropriate, and functional. Most experts agree that several measures and methods should be used to determine course effectiveness.

Current computer-based instruction (CBI) and Web-based instruction (WBI) assessment practices include a variety of methods such as instructors evaluations of students, students' self assessments, peer to peer assessments, exams, project based assessment, and assessments that are tied into log-in and usage data. Bergman and Moore (1990) suggest three questions that designers should answer about the evaluation process: Is the evaluation voluntary or required? How much user activity is being assessed? What type of feedback is provided? Bergman and Moore believe that voluntary self-assessment "is a sound strategy for adults" (p. 63). However, they also list three more traditional categories, common in assessment, that they feel are appropriately used for specific circumstances: single items -- to test knowledge of single concepts; grouped items -- for assessing knowledge of "logical units" (i.e., on chunked material); and multiple groups of items -- for a final test. Nicholas Iuppa (1998) makes a useful distinction between test styles, specifically concept tests and simulation tests.

Concept tests are used to assess learners' understanding, while simulations test learners' performance. In discussing how to assess concept and performance via digital media, Iuppa cautions that digital assessment has its limits. He says, for instance, that tactile skills are "among the very few" types of skills that digital media cannot assess and points out digital media cannot, for example, test how smoothly the student manages to screw in a spark plug, which is an important part of the process.

Current evaluation procedures range from "one shot grading," such as taking a final or semester test, to mastery or "perfection-based" grading, which allows students to redo assignments, within an acceptable time frame, until they are perfected (Cox, 1999). Counter to traditional design theory is the growing need to specify instructional goals and learning outcomes to accept what is termed as a "diversity of outcomes." Duchastel explains that this can best be achieved by, "aligning evaluation not with knowledge, but with task accomplishment that utilizes knowledge" (1997, p. 225).

Planning and Presenting Instructional Objectives

The most critical issues for instructional designer are those regarding how best to plan, present, and evaluate objectives and outcomes for CBI/WBI instructional materials. Bannan and Milheim (1997) describe the issue in this manner:

The World Wide Web is becoming a major source for educational material delivered to learners who prefer (or are required) to learn apart from a traditional classroom. While the educational
potential of this medium is just beginning to be realized, its utilization will certainly increase over
time as larger numbers of educators and learners see the significant value in this type of
instruction. However, while there is tremendous potential for this type of learning, there is also a
significant need to describe these Web-based courses in terms of their overall instructional design
characteristics, rather than defining each course only by the specific content it provides. Without
this organizational process, courses will be perceived and categorized based primarily on their
subject material, rather than the instructional strategies and tactics used for the delivery of the
educational material (p. 381).

These issues are also concerns of the designer of instructional programs delivered by means of
CD-ROMs or other computerized stand-alone tutorial materials. In traditional instructional design,
doctrines are the critical, conceptual foundation on which the instructional designer constructs the
framework of the instruction to be. The instructional objectives are usually the starting point, and serve as
the basis for all other instructional design decisions made during the instructional design and development
process (Dick and Carey, p. 5). As explained by Dick and Carey, the objectives establish the purpose of
instruction in terms of desired learner outcome behavior or performance, conditions under which the
behavior is to be evaluated, and standards for evaluation and assessment.

In terms of learner assessment, then, objectives tell the learner, at the outset, what he or she is
expected to learn in the course of the lesson. For the instructional designer, identifying the objectives of
the instruction to be delivered is a critical step in choosing the best cognitive and presentational strategies
for the instructional material and involves awareness of the learner's needs as well as issues such as
cognitive styles, need for learner interaction, and other related concerns (p. 126).

For the instructional designer who is developing CBI or WBI, instructional objectives appear to be
as critical as they are to the designer of "traditional" instruction. That is, for the designer, objectives are a
critical step in (1) the designer's choice of the best cognitive and presentational strategies for the
instructional material to be developed as well as (2) in the choice of best media for instructional delivery
and other, similarly critical decisions in instructional development (Pernici and Casati, pp. 246-247).

Basically, the designer of computer- or Web-based instruction has to know the outcome intended —
learning desired or task to be achieved — and the assessment method that will be used to evaluate that
outcome before the designer chooses the best way to inform the learner about those objectives.

Objectives' Role in Learner Orientation

The instructional designer has to plan so that the initial objectives provide, for the learner, clear
and reasonable expectations about the assessment phase of instruction. In general, because multimedia
instruction is usually at least one step removed from face-to-face teacher-to-student interaction, the
statement of objectives at the beginning of a lesson plays a critical role in learner orientation. For distance
learners, the stated initial objectives of an on-line course of study or a CD-delivered tutorial may be the
chief means of allowing the learner to self-advise in selection of one course of instruction over another
(Benson, 1994).

In addition, for "remote" or CBI instruction delivered as "automated" computer-tutorials, initial
stated objectives have proved to be important as "advance organizers" for learners' outcome performance.
For example, in an experiment by Beasley and Waugh (1996), groups of college students studying
computerized units of instruction showed remarkably different test scores and significant differences in
content retention that were affected by only one experimental factor. The experimental group of students
was told that, after viewing the instructional materials, they would be asked to draw a concept map of how
the topics of the lesson related to one another. Knowing the objective -- and the means of assessing what
they were to study -- acted as a powerfully effective "advance organizer" in allowing the students to view
the instructional materials in the context of the performance goal and to perform the target task far better
than the control group, who were not told anything other than that they were to "cover" the unit of study.
Not only did the experimental group -- the ones told the objective -- perform better than the control group,
these differences in assessed performance were still present a week later when the two groups were given a
"pop quiz" to check their retention of the information. Again, the group that was informed of the
assessment objective performed significantly better than the "unknowing" control group.
Objectives and "Just-in-Time" Learning

The role of learning objectives as indicating performance outcomes and being critical in deciding on a course of study is also related to the issue of "just-in-time" learning, which is an important source for Web-based learning and instructional design. Just-in-time learning is information delivered "so that each individual may learn just what he or she needs at the time when he or she needs it" (Romiszowski, 1997).

The "just in time" learning concept is related to the idea of both goal-oriented learning and to performance-based assessment. It is therefore similarly related to the requirements that objectives and assessment outcomes be clearly established from the beginning of the instructional development process so that the instructional designer can choose which cognitive strategies and which presentation and assessment methods are most probably going to result in the desired learning.

Feedback to the Learner During Instruction

In addition to a final assessment, in the sense of an overall "grade" for the learner who completes the unit of multimedia instruction, Bergman and Moore discuss three types of more sophisticated feedback categories for learner interaction that they believe should be considered by the instructional designer: Informative feedback, that simply identifies a correct or incorrect response; Reinforcing feedback, that praises or critiques (both of which should be limited); Diagnostic feedback, that involves comments or suggestions about the learner's response.

Dick and Carey (1996) agree, believing that learners need a variety of types of feedback during the course of the lesson in order to improve their performance on the final examination for the instructional unit (p. 192), which applies whether the instruction is delivered in the electronic or the traditional classroom. Even more important, then, is feedback to the learner using multimedia instructional materials in lieu of an instructor's providing this type of interaction.

Learner Assessment via Computer-Scored Testing

Online or computer-based multimedia instruction can utilize instructor-based evaluation in a multitude of forms, just as the face-to-face classroom setting affords multiple methods of evaluation. One method of evaluation that is unique to CBI and WBI is the option of having the computer score the student's work and record a grade "automatically."

As more and more emphasis has been placed on behavioral objectives and "statements of explicit behaviors that learners must demonstrate, it has been increasingly obvious that a fair and equitable evaluation system is one that measures those specific behaviors. Although it is possible to create computer-based testing and scoring, there are many concerns related to this type of evaluation. Grades are grades, and students are sometimes ingeniously determined to improve their grade point averages or acquire credit where credit is definitely not due. One solution to the academic honesty issues appears to be administering "final" exams in proctored computer labs. Other possible approaches to the issues of academic honesty and reliability raised in relation to assessment of student learning in CBI/WBI instructional modules may involve use of the technology that has introduced the problem in the first place. For example, some virtual colleges and online universities are discussing use of security and identity-verification methods, such as voice recognition or fingerprint-recognition systems.

Online Course Assessment Methods

Two basic types of assessment for online college-level courses prevail: (1) those with CBI and "automated" or computer-administered types of instruction, the most typical final assessment method is the proctored exam, and (2) those with instructor-monitored distance learning types of instruction, with the most typical assessment method being criteria-based evaluation, with a final grade assigned by the instructor (Rasmussen et al, 1997).

Instructor-monitored distance learning courses tend to follow one of two models: (1) the "portfolio" or "contract" model, with students turning in frequent, small reports or completing a scheduled, sequence or series of assignments, and (2) the project model, in which the student turns in, at the end of the course, one big project or term paper (Hudspeth, 1997).

An example of typical statements about proctored tests and exams is this one from Indiana University's online Chemistry 101 course:
Quizzes and Exams preferably can be taken on the Internet. This will require that you have a proctor with a computer system that meets the system requirements to administer the exam or quiz. Your proctor should be associated with a reliable office or agency in your community (employment supervisor, library, high school, bank, office, business personnel, etc., (no relatives or personal friends). If this is not possible, a second option is to find a proctor with faxing capabilities....We suggest you make arrangements with your proctor and have him/her complete and return a Proctor Agreement as soon as possible (by or before the orientation meeting). This signed agreement is a necessary prerequisite.

Clearly, age-old concerns about ethical practices in assessment (i.e., cheating) take on new twists in the distance-learning environment. The issue of authorship of student work has always been one that is difficult to resolve, even when the course is taught with traditional methods. A statement about expectations for online students, again from Indiana University, illustrates a common philosophical approach to the problem of authorship:

Much of American life operates on the honor system — and so do a number of areas of this course. Thus the laboratory work and write-up, the homework assignments are done away from University supervision and are expected to be performed by you and you alone. Violation of this expectation ultimately hurts you more than anyone else.

Portfolio and Project Instructor-Based Learning Assessment

During the Web Based Training Online Learning '99 conference, Brad Cox, author of the award winning, Taming the Electronic Frontier, was asked how he evaluated instruction in his online course. He replied:

Briefly, I rely primarily on experiential learning (action learning). Each task presents instruction, invites the student to put it in practice and report the results in the context of the material that preceded this task. Some tasks have students read web-based or paper-based materials, summarize what it says, and demonstrate that they have applied each lesson to the web-based portfolio. Other tasks, such as the desert crash simulation, portfolio peer assessment, and web-based sociometric tasks, take a more quantitative approach. Each student produces a web-based portfolio and participates in a semester project. These provide considerable insight into how well the student is doing, both by me and the student's peers.

Cox's approach recommends using a series of small, sequential, individualized tasks and student-centered personal responses to provide multiple checkpoints during the online course and ensure that students, in order to complete the assignments, have to keep up with the class readings and respond to class assignments themselves. Multiple, individualized tasks are harder to counterfeit because of the necessary coordination and planning involved for the student to arrange for someone else to do the work in a timely and appropriately specific manner.

Cox suggests a sequential, portfolio-style approach to the student's progress through a course and assessment of that progress. Another, somewhat similar, approach is recommended by DeLayne Hudspeth (1997) in discussion of "just in time" learning programs. Hudspeth (p. 356) recommends a "contract" approach, which he describes as:

A written agreement, a learning contract, which defines what the instructor is proposing and what the student agrees to do. The initial syllabus might describe 20 possible assignments of which the learner must provide the first six or eight (the "must know" content), but could select another six or eight "nice to know" outcomes from an extended list. The final list could reflect individual interests or different career backgrounds. Perhaps two or three unique outcomes could be negotiated with the instructor. If a grade system is used, then a predetermined number of points could be required for a specific grade.
Hudspeth points out that the benefit of using a contract-type approach is that the course assignments and the criteria for their completion can be explicitly described for the student, but the student can use considerable flexibility in exploring issues and resources that have personal interest. This approach should encourage the student to see the benefit of actually doing the learning rather than trying to find a stand-in (p. 356).

Another method of online course assessment, particularly for adult learners, is the completion of one large end-of-course project (Mood, 1995). For example, in a business course, students may submit, at the end of instruction, a fully developed business plan, or, as the final project in an online course, the student may be required to submit a substantially researched term paper.

With project-based assessment, the dangers of having the student simply purchasing a pre-packaged term paper are diminished the more individually the project is tailored to the resources used in the course, the student's individual interests, and the use of intermittent "checkpoints" -- such as weekly, brief, e-mailed "progress reports" that are individual and specific enough to reduce the likelihood of students' thinking they can submit someone else's work and avoid being found out (Hudspeth, p. 354).

Others suggest using Internet-based videoconferencing or online synchronous class discussions or similar performance-on-demand type class activities as part of authentic or performance assessment of student achievement. In addition to encouraging participatory learning, enhancing student communication and/or technology skills, and interaction between isolated learners or between learners and the distant instructor, these "real-time" performance activities also tend to ensure, incidentally, that the actual student be present and accountable for course content.

**Durability of Final Assessments**

"Final" evaluation for certification or course credit is unlikely to be eliminated anytime in the near future. However, the advent of the technology that has provided the means to offer computer-based or online courses of study has also caused the re-evaluation of assessment issues, such as what should be assessed in a virtual, for-credit course. Many issues are currently being debated, including how to best create learning environments and evaluation procedures that encourage the application of knowledge rather than rote memorization; how to design instruction to help learners to think for themselves; and how does computer based learning works in conjunction with other resources in the planning, implementing, evaluating and improving loop? (Harvey, 1998)

In discussing learner assessment, the role of the instructional designer is growing. Because the instructional designer is intimately involved in establishing the instructional objectives for instruction as well as the assessment instruments by which the student's learning will be judged, the instructional designer's role is critical to insuring that CBI/WBI instruction works as expected. Since the instructional delivery is often remote, and results are sometimes difficult to evaluate in terms of instructional effectiveness, the unique position of the instructional designer is more critical to the development and evaluation of technology-based instruction than ever.

Abstract: Students thrive on deep engagement with people who care about their learning, especially when they are trying their hands in new territory. Through experimentation and dialog, mentors, teachers, and students support one another online as they flesh out ideas, sharpen skills, and display new work. Supported by funds and technical assistance from the WEB Project (http://www.webproject.org), a US Dept. of Education Innovation Challenge, this Vermont network has built some simple assessment tools to foster improvement by focusing on discussions that lead to high quality work and sustained professional growth.

Overview

Students thrive on deep engagement with people who care about their learning, especially when they are trying their hands in new territory. Through experimentation and dialog as part of the WEB Project, mentors, teachers, and students support one another online as they flesh out ideas, sharpen skills, and display new work. As a result, everyone learns more about the big ideas and essential questions that fuel inquiry and progress in the disciplines. Technology plays a subsidiary role to stimulate new ways of working, new media avenues for expression, and to foster communication at a distance.

Supported by funds and technical assistance a US Dept. of Education Innovation Challenge, the WEB Project (http://www.webproject.org) has built several dynamic online networks that foster professional growth and measure improvement in student learning. The classrooms and networks of teachers and community professionals involved include work in Music, Visual Arts, History and Literature.

By design, The WEB Project serves “all students.” Each classroom or network incorporates vital learning results like communication, problem solving, critical thinking, civic responsibility, and personal development into its use of technology. Community and statewide organizations aid in the educational process and help to set standards for quality.

The project has thus developed successful advanced technology strategies in three broad areas of work: 1. Developing and Using Online Assessment Systems, 2. Achieving High Quality Work, and 3. Sustaining Professional Growth.
1. Developing and Using Online Assessment Systems

Assumed in the notion of “excellence for all” is an agreement about what constitutes excellence. The WEB Project develops agreement by bringing teachers and content experts together to identify what it means to meet a standard. This is a thoughtful process that takes about 3 years to accomplish if a school is at a beginning level of aligning standards with curriculum and assessment practices. The development of assessment systems goes through an iterative process. This means that designs begin with a “best guess” that is checked and revised. Multimedia technology, interactive television, and the Internet are critical to the professional development system that allows for this network, separated by distance, to reach agreement. With the aid of these advanced technologies the WEB Project followed the performance assessment steps listed below. Teachers in the WEB Project involved their students in this process as well as professionals in the field.

1. Select standards from the Framework.
2. Base assessment systems on evidence from the standards.
3. Double check assessment systems against real student work through reference to a wide variety of media evidence of student performance.
4. Revise the assessment systems through continued use in classrooms and professional dialog using web-based communications with experts in the field.
5. Exchange a variety of media products via telecommunications and in person.
6. Assess and report student work online, in-person, and with the use of interactive television.

2. Achieving High Quality Work

Standards and benchmarks of student work samples set by WEB Project members represent both the product and process aspects of learning. Student interviews in 1995 revealed that they wanted two different types of input about their work. According to the interviews, students want to know where they stand (yardstick measures) and they want to know how to make what they are doing be better (reflection and critique of work-in-progress).

Based on the student remarks, a network formed to develop evidence of student performance with a web-based system of support for reflection and critique. Simple, yet enabling standards from the Vermont Framework such as “Students use a process of reflection and critique to improve their products” and “Students can generate and select from multiple solutions to a problem” allow students to receive feedback and select what makes sense. As a result, students report that they feel that their online mentors (experts, other teachers, and others students) take their work seriously. This is a key to increased motivation, time spent in creating and elaborating ideas through work products, developing new skills, and using feedback to improve work.

Focusing on production and elaboration of ideas

In order to assess learning and reach goals of excellence, we find it key to focus on the production of new elaborated work. The original focus of The WEB Project was exclusively geared toward building assessment systems as described above. Teachers benchmarked rubrics for visual arts, historical research, and reflection and critique. This alone did not improve performance or engage students. However, when we shifted the focus to production (multimedia, music composition, etc.) it increased student motivation and provided activities that built dynamic environments, incorporating assessment as a natural part of the learning process instead of standing out as a single event.

Using a variety of evidence
Using multiple forms of evidence of learning allows students to show what they know in many ways. To quote one parent from Brattleboro whose son worked on a multimedia team that investigated community memories of World War II:

“I was thinking that if you knew Matt by whether he wrote his essays or not, you wouldn’t know Matt. And you would think of him as a totally different kind of student than you get from watching him do a technology project. I also think that what he takes, in terms of raising a young man who is going to go out in the world and be accountable to others and responsible to himself, the separate facts of history are not as important as gaining an overview. For me it was a chance to see that this young man is really engaging in positive ways in the world which I don’t see in terms of responses to homework and things like that. He came home and talked about this a lot. He related it to contemporary events. It wasn’t just that he learned about World War II. He talked about the issues of race and gender that were going on at the time. He was saying that the socio-cultural climate was really different in the 30s and 40s than it is now.”

Outside audit confirms our internal sense of progress from school-based measures and individual anecdotes. The latest RMC (1999) evaluation shows that student motivation has increased and student learning is improving.

3. Sustaining Professional Growth

As important as the signs of improving student achievement, teachers also show evidence of change. Teachers in the project begin to routinely use the core ideas and questions of their disciplines to evoke elaborated student communication and performances. The WEB Project is a model of a technology-based professional development system that uses the collaborative efforts of students, teachers, and scholars to establish exemplars of student performance stemming from dynamic learning environments. As a result of efforts on the assessment systems, the core knowledge of teachers and the creation of an environment of high quality work, the WEB Project can show four categories of the implementation of standards in teaching and learning assisted by advanced technologies. The following examples illustrate each category.

Adaptation of existing models to align with standards, using electronic examples of performance

Example: National History Day is a program for sixth through twelfth graders. Each year a common theme is presented for students to explore. They select a topic, relevant to the theme, from any time period or place in history. Using primary resources and extensive research, students then demonstrate what they have learned through a research paper, a project, a media presentation, or a theater performance. The WEB Project sponsored teachers and historians to developed an interface to the national scoring guide, which shows the relationship between History Day criteria and the Vermont Standards in the categories of project and media. The student work samples from the Vermont History Day competition have been included on this site to serve as references for students and teachers in future competitions.

Articulation of standards to include evidence of performance and student work samples

Example: Multimedia Communication Rubric and annotated exemplars
Schools across the United States agree that multimedia communication is important. In Vermont, Standard 5.15 represents this value, “Students design and create multimedia products that successfully communicate (what they intend).” A group of teachers gathered in the fall of 1998 to attach evidence to this standard so teachers across the WEB Project could look at multimedia communication through a similar lens. After trial and revision, this evidence became:
Evidence
K-4 Students explore media elements that may include sound, images, movement, text and interactivity to communicate. Students contribute in the creation of multimedia products.
5-8 Students communicate through the creation of multimedia products that effectively combine media elements that may include sound, images, movement, text and interactivity with emphasis on clarity and focus, use of media, and attention to detail.
9-12 Students integrate multimedia elements to communicate understanding, synthesize content material, and present new insight.

A 6-point rubric (0-5) was then constructed to show development. The rubric contains benchmarks for Levels 1-3 only because attainment at higher levels requires significant adjustments to school schedule and an interdisciplinary team of teachers (or outside expertise) from technology, the arts, and the content areas under investigation.

Multimedia Level 3 Exemplar (http://www.webproject.org/multimedia/iguana.html)

Level 3 users successfully communicate by combining multimedia elements in an engaging, organized, easy to navigate format. Clarity and focus are clear and attention is given to detail.

Complex slide show that retells the story "Why Mosquitos Buzzz." Colorful artwork is used along with clever transitions and instrumental/voice audio to keep the viewer engaged in the story. The presentation exemplifies the use of ingenuity rather than reliance on special effects to solve artistic problems. Many solutions combine artistic principles such as perspective with the subtle use of transitions.

Demonstration of student achievement via web based portfolios

Example: Cabot Student Art Portfolio excerpt exemplifying: 1B: Students can create works of art that show how their ideas relate to medium, techniques, and processes. 2B: Students can evaluate the effectiveness of artwork in terms of design elements and principles.
(http://www.webproject.org/cabot/melissaart.html)
"This piece has the visual elements focus, contraction, expansion, complexity, and chaos. The focal points are the large negative spaces. The shapes contract and expand as the spaces in between get larger or smaller. I think that this piece is pleasant to look at but it is also chaotic. I believe that this piece is well balanced with all the negative space. It is spread out evenly through the piece. I think that this was one of my favorite pieces of artwork that I did this year." Student quote

General Guidance for improvement while work is in-progress

Example: Rubric for Reflection and Critique
Reflection and critique of work in progress form the basis of the WEB Project's strategy for improving student performance. Students, teachers, and mentors collaborate online to discuss student work as it progresses. A three point scale is used to assess the level of response given to students by adults and by other students.

Reflection and Critique Level 3 Exemplar (http: //www.webproject.org/exchange [select Projects to view public example])

From: Lee
Organization: VT Elementary School
My name is Lee; I am a sixth grade student. I need help on my pencil drawing; I have no clue what I should do next. Do you think you could give me some help? I like this drawing a lot.
Requested feedback: What can I do to the background? What should I do with the bird's chest? How can I make the values show more than they do?

Comment Excerpt from: Joan Curtis, Artist
The strength of your picture so far, I believe, is the interesting composition. The way you have arranged the close-up eagle within the picture's edges is quite powerful.... I would like to see a little more description of the feathers you are seeing.... Is it possible to be more specific with your pencil?....

Comment Excerpt from: Ken Leslie, Johnson State College Visual Arts Center
.... You asked about "background." This is the place where you can add information that will tell a bit of a story. Imagine how different this same drawing would be if there were tree branches and leaves in the background, or hunters
with guns, or zoo cage bars. Not one line of the eagle has changed, yet the meaning of the drawing is completely different for each of those backgrounds...

From: Lee
Thank you so much for all of your remarks. What I ended up doing is I put bars in the back so it looks like it is in a cage in the zoo.

Acknowledgements

Special thanks to the students and teachers who participated in the process described in this paper. Particular acknowledgement goes to the work of Regina Quinn, Barbara Flack, and Bill Holiday in developing and refining the multimedia rubrics; to John McSweeney and Ruth Kaldor for the guidance they provide to their students that makes online portfolios possible; and to Beth Hughes, Eric Achenbach, Gary Blomgren, Michelle Smyth, Ann DeMarle Pollack, Scott Chesnut, Verandah Porche, Jim Robinson, Lia Roozendaal, and Penny Nolte for the professional guidance they have lent to our work.

Design and Development of Interactive Multimedia for Library Research Instruction

Stephen P. Victor

Abstract: This paper describes the design and development of a multimedia program that provides instruction in locating, evaluating and citing information in a university library. The paper also discusses the use of interactive multimedia for instruction. The program was developed by a collaborative team of instructional designers, content experts, and media consultants using Authorware. The program uses multimedia elements, interactivity, Web-based media, and games to enhance the learner’s experience of the instruction. Preliminary evaluations indicate the program is an effective means of providing undergraduate library research instruction.

Introduction

Instructors of university freshmen and sophomores often find that their students lack basic library skills. Because the ability to acquire and evaluate information is vital to success in our information society, it is crucial that students learn the tools and skills required to effectively access and use information resources. Colleges and university libraries have adopted many strategies for teaching library research skills, including instructional handouts, library tours, classes, and online instruction. Hallis (1996) notes that electronic library resources provide access to library expertise at the user’s convenience and that elementary and secondary students are gaining facility with electronic resources and an increasing expectation that such resources will be available at the university. This paper describes the design and development of a multimedia project that provides instruction in locating information in a university library, evaluating the information for relevance and value, and citing the information using accepted citation formats.

Interactive Multimedia and Instruction

The term multimedia has a number of connotations. Essentially, multimedia is the integration of some or all of the following components: text, audio sound, static graphic images, animations, and full-motion video (Perry, 1994). Interactive multimedia empowers the user to control the software environment (Phillips, 1997).

The team chose to create a multimedia tutorial for this project because of the advantages that integration of multimedia would bring to the instruction. While some researchers believe that media is merely a vehicle to deliver instruction, and that media itself does not affect student achievement (Clark, 1994; Soloway, 1994), recent research does indicate advantages to the integration of multimedia in education. Yaverbaum and Nadarajan (1995) gathered several studies pertaining to multimedia and learning. One of the studies they review describes the following benefits of multimedia (Shim, 1992, as cited in Yaverbaum & Nadarajan, 1995):

- Increased learning and a reduction of learning transfer time
- The presentation of nonlinear access to information
- The ability to link information
- The promotion of a collaborative work environment
- The ability to present information in multiple media
Another important advantage is the control that learners have in multimedia instruction. Barker (1990) notes that in multimedia instruction learners select what they learn, and they control the pace, direction, and style of the learning experience. In addition, visualization of instructional materials through the incorporation of graphics, audio, and video help students better comprehend the instruction (Kozma, 1991). Kozma also states that multimedia instruction allows learners to quickly retrieve previously learned information, facilitating review of instruction.

Numerous studies have compared multimedia instruction to more conventional methods of instruction. Most of these studies indicate that multimedia instruction is more effective. For example, Oz and White (1993) conducted a meta-analysis of 47 studies comparing multimedia instruction with conventional instruction in the military, industry, and higher education. Analysis of “knowledge,” “performance,” and “retention of trainees” variables revealed that multimedia was more effective and less costly than conventional instruction.

In a study of middle school students, Small and Ferreira (1994) found that when given an information-gathering task, students using a multimedia resource spent more time exploring the information and performed better research than students using printed resources. Interestingly, the authors suggest that middle school students perceive information delivered through video and sound as more credible than information delivered in printed form, and so they have a greater trust of multimedia information and are more engaged when conducting research with multimedia.

Developing Multimedia Using Authorware

The team used Authorware Professional by Macromedia as its development tool. Authorware provides a feature-rich environment for the development of interactive multimedia instruction. Authorware presentations can be distributed via a network, on CD-ROM, or a combination of the two. It supports a wide variety of file formats and media elements, including graphics, sound, and digital video files. Our project makes full use of the interactive capabilities of Authorware and includes sound and animation, quizzes with popup feedback, the ability to access library resources on the World Wide Web, and games intended to provide practice and feedback on comprehension. Indeed, Authorware is particularly noted for its ability to provide multiple choice quizzes and similar learning interactions (Phillips, 1997). User control is enhanced by Authorware’s ability to accept many kinds of input, including keypresses, mouse clicks, text responses, conditional responses, and limits on response times (Jenkins & Cartledge, 1995). Authorware can also be used to test for correct or incorrect user responses and to provide learner feedback (Niemeyer, 1997). Authorware uses a flow line interface in which various interaction icons can be dragged and dropped, reordered, copied, and deleted as required (Jenkins & Cartledge, 1995). Authorware has been used to develop multimedia instruction for a number of diverse content areas, including biotechnology (Jenkins & Cartledge, 1995), forestry (Seiler, Peterson, Taylor, & Feret, 1997), library skills (Niemeyer, 1997), and airline flight staff training (Snydar, 1998).

About the Project

The project, “Library Research: Learning the Basics,” was designed by a team of graduate students in an instructional technology course. The two-semester sequence, entitled “Collaborative Design of Multimedia” and “Collaborative Development of Multimedia,” was intended to teach the skills needed for developing educational multimedia using collaborative teams (McNeil & Varagoo, 1999). Using the Seels and Glasgow (1997) model of instructional design, the team worked with a professor of history to identify instructional needs, formulate objectives, write content, and create storyboards for the project. The initial target population for the project was freshman and sophomore students in an American history survey course taught at the University of Houston.

During the second semester, three of the original team members used Authorware to develop the project. The team worked with artists to design the interface and graphical elements of the piece, and with technical experts to record spoken word portions of the instruction.

The design team identified four primary objectives for the instruction:
- identify and refine a research topic
- find information related to the research topic
- evaluate the information using the evaluation criteria presented in the piece
Each of these primary objectives was further divided into smaller objectives. Several lessons and interactions were created to address each objective. The program's opening menu provides access to each topic area and to further information about the project (Figure 1).

**Program Interface**

Our goal in designing the program's interface was an uncluttered appearance and ease of use. Because the program was intended for use by undergraduate students of United States history students, our graphic design consultants used embossed buttons and historical images to create a "feel" of American history in the program.

The **Menu** button provides instant access to the main menu at any time. The **Find** button displays a popup window that allows the learner to enter a desired search term; the window then displays a listing of screens in which the term appears from which the learner can select. The **Map** button displays a listing of all of the program's learning objectives and sub-objectives. The **Exit** button allows the learner to close the program (this option is also available from the **File** menu in the upper left corner of the window). The left and right arrow buttons allow linear navigation backward and forward through the instruction. The **Help** menu in the upper left corner of the window displays descriptions of navigational elements and other icons in the program.

**Using Multimedia to Enhance Learning**

Small and Ferreira (1994) write that the goal of the library media specialist is to develop information problem solving skills that apply both to printed resources and to newer information technologies. Our goal in developing a multimedia project for library instruction was to teach library research skills in a stimulating way. We did not want learners to passively receive instruction but rather to become engaged by it. To accomplish this, we took advantage of multimedia elements such as sound, motion, and feedback to capture the learner's interest and enhance learning (Lee & Boling, 1999). For example, upon opening the program, the learner is asked to type his or her name. This entry is stored as a variable so that the program can displayed the learner's name in selected interactions throughout the instruction, thus personalizing the experience for the learner.

**Sound and Visual Elements**

Dual coding theory suggests that a combination of multimedia elements, such as sound and visual cues, can enhance learning (Mayer & Sims, 1994). Several screens in the project present the learner with the opportunity to hear spoken commentary and to read a transcript of the commentary if desired. By clicking on the bell icon, the learner can be notified of new content or events.
A learner can hear recorded narration on information literacy. Clicking on the scroll icon causes a transcript of the narration to appear (Figure 2).

**Interactivity**

Various icons in the program provide access to tips and examples of topics covered in the instruction. As shown in the following figure, by clicking on the key icon, the learner can learn expanded information on the instructional text. In many screens, interested learners can find more information on a topic by clicking on star-shaped icons for examples and directions to sources of further information. In other interactions, the learner can position the mouse pointer over an item to display explanatory text (Figure 3).

![Figure 2: Sound and transcript.](image1)

![Figure 3: Using the key icon to get a tip.](image2)

**Feedback**

Meaningful feedback on student performance is an important component of all instruction, including interactive multimedia (Laurillard, 1993). While it is difficult to simulate the personal interaction between teacher and learner in a software program, our program provides quizzes and other practice activities containing feedback tailored for each question and response. Incorrect feedback provides assistance with identifying correct response, while correct feedback provides positive reinforcement, as shown in Figure 4.

![Figure 4: Feedback for correct response.](image3)
Games and Simulations

Games and simulations of real-world activities can provide learner motivation and reinforce concepts learned in instructional multimedia (Rieber, 1996). We incorporated three such interactions into our program: a drag and drop exercise to reinforce information evaluation criteria, a book shelving game to practice the Library of Congress classification system, and an adaptation of Rieber's (1997) board game design to provide practice of all the concepts learned in the instruction.

Library Book Shelving Game

Welcome to the Library Book Shelving Game! The purpose of this game is to let you try your skill at reading Library of Congress call numbers and then placing books in correct call order number on the shelf.

Just click on a book on the top shelf and then drag and drop it on the bottom shelf. Click the DONE button in the lower right-hand part of the screen when you are finished.

Good luck!

Figure 5: Library book shelving game.

Web-Based Media

The Windows version of Authorware allows the inclusion of URLs (unfortunately, this feature uses an ActiveX control, which is not available on Macintosh platforms). We used this feature to allow learners to access and use the university's online catalog within the program. Exercises ask learners to answer questions about the library's holdings and to evaluate Web-based sources of information.

Discussion

This paper has described the collaborative design and development of an interactive multimedia project to teach library research skills. Instructional designers, content experts, graphic artists, and technical specialists worked together to create an engaging instructional product. Initial formative evaluations, including evaluations by the dean of libraries and other librarians at the university, suggest that the piece is an effective tool for providing self-paced instruction in basic library research skills. While instructional examples focus on using the library for historical research, we believe the program could readily be used to provide library instruction for undergraduate students at any level and in any course.

**Acknowledgements**

We particularly thank our colleague Ann Jenkins for her tireless work on the project throughout the entire design and development process. We thank Donna Smith and Cathy Matuszak for their work on the interface and other graphical elements. Gary Kidney recorded the audio components. Lloyd Schuh contributed some graphics. Joe Lynch and Vanessa Burford contributed to the initial design of the project.
ABSTRACT: To cope with dramatically increasing problematic behaviors among primary and secondary school students in Japan, training for counseling skills is considered one of the most important areas in current teacher education. We have developed on a DVD a prototype of counseling materials to both assist in the training of college students and in-service teachers learning counseling skills. Multi-angle scenes depicting client, counselor, and complete classroom views were made of three counseling cases. The teachers, by using these DVD materials in training, can observe and analyze counseling sessions from a multilateral perspective by using the multi-video function to select and observe three-angle sequence, the multi-audio function to select and hear comments by expert supervisors, and the subtitle function to show aims and technique of each counselor during each counseling session. Evaluation results showed that this was an effective approach for learning counseling skills with the use of DVD-video.

Current Issues in School Counseling and Teacher Education of Japan

During the past ten years in Japan there has been a dramatic increase in the number of cases of problematic behaviors among primary and secondary students. These include school refusal, bullying, violence inside and outside of school, committing suicide, drug usage, sexual activity, and so on. Of them, school refusal, bullying, and violence (e.g., attacking teachers, peers and residents in general and damaging equipment) are most serious at lower secondary school. The Ministry of Education, Science, Sports and Culture (MONBUSHO; 1999b) reported that the number of lower secondary schools with bullying (n = 4,684 - 44.6% of the total) and with violence inside of school (n = 3,551 - 33.8%) and outside of school (n = 2,000 - 19.1%) were at all time highs. Additionally, the number of reported cases of school refusal (more than 30 days absent) were 101,680, which showed an increase of 20% over the previous year and the highest count since MONBUSHO started keeping records.
To cope with such problems, MONBUSHO has implemented some new policies for the improvement of counseling systems in schools. They have developed a parallel approach to accomplish it. One approach is to introduce counseling specialists and clinical psychologists as school counselors into schools. This project started in 1995 with 154 schools. It is the first time in the history of Education in Japan to systematically introduce professional counselors into schools all over the country. Until then, in many cases, teachers have taken roles of counselor (Oono, 1997). Otherwise, students with problems have visited some educational institutions outside of schools and taken counseling by so-called professional counselors, who have different counselor certificates since there is no established counseling certification process in Japan. As a result, there are more than 15 kinds of certification of psychology in Japan (Sato, 1999). However, most counselors participating in this project are certified as clinical psychologists from a major nonprofit corporation supported by Association of Japanese Clinical Psychology. This certification process is being authorized widely in spite of heated arguments among professional associations of psychologists. Early results from program evaluation research on the impact of school counselors show positive effects on behavior (MONBUSHO, 1999a). As a result of these findings this project has been extended from year to year with 1,661 schools involved in 1998.

The second approach to enhancing counseling skills of teachers focuses on improving the professional skills of the teachers. Though some teachers have traditionally taken roles of counselor in schools due to lack of professional counselors, all teachers are now required to gain more counseling skills so that they can apply them to educational guidance, as well as management of the classroom, learning method, and cooperation and collaboration with parents and counselors. In Japan, training in counseling skills has not been considered as improving interpersonal and teaching skills, despite the recent research evidence (e.g., Peck, 1977; Hargie, 1984) which suggests the importance of training in these skills for teacher preparation. Now it is expected that teachers understand students deeply by utilizing counseling skills in daily communication with their classes. This view reflects the importance of teachers developing knowledge of preventive and developmental counseling skills in their professional training program.

Thus training for counseling skills is considered one of the most important areas in current teacher education. This has brought some changes to teacher education programs. There is an increasing number of training programs offering counseling for in-service teachers, while practicing teachers (license law was revised in 1998) and those in teacher training courses at universities and colleges, all need to get more credits for professional counseling. Given the high demand for counseling classes both by the pre- and in-service teachers it is important to identify the resources to meet these needs. But many faculties at the teachers colleges were not specifically trained to provide graduate courses in counseling and clinical psychology. Furthermore, there were few learning resources for teachers of college students on this topic. Given these conditions it is clear that the need for instructional materials on counseling training was very high. Kawashima and Miyamoto (1996) conducted needs assessment for instructional video materials at all national teachers colleges in Japan and the results showed the need for video materials on counseling was ranked third after technology & home economics and science.

**Purposes of Development of DVD-material on Counseling**

The primary purpose for the design and development of the instructional materials was to prepare a prototype of counseling materials to help professional students in the learning of counseling skills. We focused our materials on observation learning of counseling, which is a traditional and useful method in training for counselors. The three design objectives are as follows:

1. To provide concrete procedures and strategies of counseling through video since there are few chances for teacher training students to practice and observe counseling sessions.
2. To provide several points of view for observation and analysis of counseling since there are differences in counseling strategies among schools of counseling and clinical psychology. It is important for teachers to learn counseling skills in terms of eclecticism so that they could treat a great variety of students in school.
3. To provide flexible and interactive observation settings by using DVD-Video. It has a storage capacity of 4.7GB, more than 7 times that of CD, which is possible to record about 133 minutes Laser Disk quality or a broadcast-quality video (MPEG2), and various functions such as interactive menu (enabling random selection of contents from the menu screen), multi-video (enabling selection and switching of up to 9 types of video), multi-audio (enabling selection and switching of up to 8 types of audio), and multi-subtitles (enabling selection and switching/presentation of up to 32 types of subtitles).
We have developed materials for teacher training using DVD-Video (Yamada, 1997; Yamada et al. 1998). In our earlier efforts, we applied multi-video functions to four kinds of video recorded from a class taken at four angles simultaneously. Results from the field shows that it provided more positive effects in observational learning compared with the conventional tape-based video. Recently multimedia technology is being introduced into counselor training. For example, Engen et al. (1994) developed their materials using videodisc technology to provide realistic situations to which students can react as they deal with the microcounseling skills in the hierarchy of skills for helping professionals. However, this study is the first trial to develop DVD-materials on counseling.

Figure 1: Structure of the DVD material
Features of Developed DVD-materials

First of all, we designed three types of counseling cases in terms of counselor; counseling by the classroom teacher who takes the role of counselor in the school (topic: bullying), by the school counselor to be introduced by MONBUSHO (topic: career counseling), and by the professional counselor in the school counseling center (topic: school refusal). Each counseling session was constructed using role-playing, which was based on a situation that each counselor had dealt with before. The clients were junior high school students with professional young actor/actress playing the role of the client. We constructed DVD-materials using these three counseling cases as major components (Figure 1). Each case consisted of situation settings of the case (presented in text), counseling session, and general short comments by experts (see below). We also used dual layer / single sided disk, which has a storage capacity of 8.5GB. This material contains total 256 minutes MPEG2-video. The developed materials have three key features to illustrate the following contents and functions.

![Figure 2: Example of Sub Menu (Counseling Session)](image1)

![Figure 3: Example of Sub Menu (Short Comments)](image2)

The first key feature is the multi-angle recording of three types of counseling cases. Each counseling session was also recorded from three angles simultaneously; with camera focused on counselor only, client

1147

BEST COPY AVAILABLE
only, and complete view. By applying multi-video function to them, it is possible to select and switch one of three sequences randomly when a video session is being played (Figure 2).

The second key feature allows comments by expert supervisors on the counseling cases. Three supervisors with different opinions on counseling were recorded to go with each counseling session sequence. Applying multi-audio function to them, it is possible to select and switch each supervisor's comments randomly during playing of each session (Figure 2). In addition to supervisors' comments, general short comments on each counseling sessions by another expert were recorded which is possible to select from the interactive menu (Figure 3).

The third key feature allows for the printing of the subtitles for the aims and technique of each counselor. Some aims and technique of each counselor during counseling were made in forms of subtitles. Applying subtitle function to them, it is possible to select randomly whether to show the subtitles or not during playing of each session. Utilizing the functionality of the system we were able to create 24 patterns of observation for each counseling session. We established Web-site (in Japanese) (http://www.nimei.ac.ip/mim/cs/index.html) to provide literal protocols of counseling sessions, supervisors' comments, and general short comments.

Evaluation of Developed DVD-materials

In the process of developing the DVD materials, we organized a focus group that consisted of six clinical psychologists, six educational psychologists, six expert teacher-counselors, and three professional counselors to conduct formative evaluation. They reviewed the quality of counseling sessions, supervisors' comments, general short comments, and subtitles of three counselors' aims and technique and usefulness of multi-functions used in these materials through several focus group sessions.

In addition, 14 teachers participated in a training program using pilot version of DVD-materials which included only teacher's case (see Figure 1) without subtitles. The instructors presented the counseling process and its analysis using all video components (three angles of video, three supervisors' comments, three general short comments) and functions (multi-video and multi-audio). After their lecture, they rated usefulness of each content and function using a 4-point scale (very useful, useful, more or less useless, and completely useless). The results showed that more than 10 teachers answered 'useful' to every content and function probe, with the multi-video function and supervisors' comments rated as 'very useful' by more than 10 of the 14 teachers.

Based on these formative evaluations the materials were revised and completed in March, 1999. We distributed these materials and questionnaires to all national teachers colleges and teacher training centers of all prefectures and asked them to evaluate it after using it for one academic year (April, 1999 to March, 2000). As the first step of evaluation, we especially focused on practical usefulness in terms of instructors who taught classes on counseling at teachers college or training program for in-service teachers. In the second step, we are planning to objectively evaluate by measuring learning effects an addition to the results from this subjective evaluation. Considering the costs of time for developing multimedia products like this material, however, a formative evaluation by experts using the focus group approach seemed to be the most practical method.

Conclusion

The collaborative effort of multimedia developers working with professional teaching/counseling experts is reflected in this project. The result is that the authors along with the professional researchers from the counseling community created a multilateral learning environment for students to observe and analyze the counseling process. Such learning resources have the potential to provide a rich context for considering multiple strategies as well as providing a chance to hear from experts their opinions regarding the counseling process based on a field based context.

The potential of DVD materials for instructional skill development is illustrated with the multilateral and multi-functionality that reflects the diversity of classrooms and the multiplicity of views for the training in the counseling process. A review of the competencies needed for the counseling certificate are needed to be matched with the counseling training skills in the design of future DVDs to maximize the support from the teacher training centers for the use of these materials. In addition, computer-based DVD technology, such as
DVD-ROM and DVD-RAM, more established and popularized would be great potential as a medium combined with Internet (Yamada, 1998).

These materials and questionnaire have been distributed to all national teachers colleges and teacher training centers of all prefectures in Japan. The questionnaire was designed for subjects not only to rate some scales, but also to write how they used this material in practice. This material was designed to allow users multiple ways to serve their educational clients. This flexibility of use is one of the natural attributes of multimedia products. Therefore, it is important for users to be presented several examples of how to use the educational materials, though examples might converge on particular patterns of use finally, rather than to be provided a single model.

Abstract: Multimedia projects are opportunities to negotiate meaning through a variety of portrayals. However, too often multimedia projects are created with inadequate thought for how it will be perceived by others. Multimedia products at times are not user-friendly or meaningful because the creator has designed it from an egocentric perspective. This paper will describe an ongoing research project that uses a set of formative evaluation activities involving peer and target population evaluation. These activities are designed to help students involved in multimedia production to develop a greater sense of audience.

Introduction

The Faculty of Education at the University of Lethbridge (Canada) has been offering a course called Multimedia and Learning as a senior undergraduate offering for the past three years. This course is a study into the tools and educational value of multimedia. The course surveys multimedia applications, discusses the value of multimedia for learning, presents principles of design and layout, and engages the user in a team approach to development. The intent of this course is to provide educators with skills and knowledge to effectively integrate and discuss the role of multimedia in learning. It also prepares education students with experiences producing multimedia materials so that they are in a better position to use it with their own students. An important element of this course is group work. Students in this course are grouped into research and production teams. Members of the team are delegated topics to research and application tools to become familiar with, a form of reciprocal learning (Brown, Campione, Webber, and McGilly, 1992). This project culminates in the creation of a major multimedia product.

Students need to be critical developers as they select tools and representations that externalize their thoughts. This takes an understanding of the media but more importantly it requires a sense of audience. Without a sense of audience, multimedia may fail negotiating meaning. Students will create a more communicative product if they consider how others interact and view their material. To foster this sense of audience, the student teams first shares their project with another group through peer evaluations and adjustments are made to the product accordingly. The product is then field tested on a small number of individuals from the target population. The target populations are individuals who the project was designed for outside the multimedia class. Based on that experience further refinements are made. Students are then asked to list and are accountable for the suggested changes or
criticisms of their projects. One of the difficult aspects of teaching a multimedia production course is timely and effective feedback at the formative stages of multimedia construction. The techniques of peer evaluation and target population testing are powerful incentives to make formative changes and refinements.

**Background:**

Peer evaluation is the process of students sharing their work with other students who have been assigned to assess it. In this particular situation it is for the purposes of formative evaluation, to improve the multimedia project that students have created. The idea is that others look and interact with a student's work and provide a commentary on the things that were good as well as things that could be improved. In reviewing the literature on peer evaluation there are two main categories. One area is the use of peer review for the purpose of teacher evaluation; the other is peer evaluation in the writing process. Teacher evaluation will not be considered here because this project is more interested in how peer evaluation influences learning. There are a fair number of references to peer evaluation into the writing process because it is a part of proof reading, having someone else to read written work. The value of this activity is rather obvious since the writers of the text knows what they want to say they often assume the reader will be able to follow their writing logic. Having someone else review writing often will reveal shortcoming in writing process and provide suggestions to improve the final product (Benesch, 1985; Bishop, 1986). The same is principle is true for multimedia. Students tend to be too close to the work and an external perspective gives the developers a sense of audience. Reviewed texts on educational assessment had few explicit references to peer evaluation and cases in which there were references to peer evaluation, they were imbedded in other approaches or glossed over. This may not be the case for all textbooks but clearly this is not a strategy that is a common component of educational assessment. It was surprising the difficulty in finding research or publications on peer assessment per se. Stiggins (1997) suggests using student as evaluators of skills and products. That author further points out that if students are to be used they need to be trained. This is also suggested as an important aspect of peer assessment in the writing process (Stern, 1992). In fact it is suggested that students come up with the evaluation criteria they will use in performance assessment. This is a strategy that is used in a variety of domains. At the University of Massachusetts for instance there has been fair amount of investigation into paired-problem solving which is a form of peer assessment (Whimbley and Lochhead, 1986). It is used in the context of Math as a way of sharing and justifying an individual’s problems solving strategies with another. The partner acts as a sounding board and will use probing of challenging questions to stimulate further thought or nudge thinking in a different direction. This approach seemed to have value in the development of effective problem solving.

To understand the value of peer and target population evaluations this paper draws not only on the educational perspective but the multimedia industry as well. Although the course is not intended to train people for the multimedia industry, there are some processes used by the industry that can be adopted by educators. In the real world when companies create quality multimedia products, much planning and testing goes into the process.
Effective planning is definitely a necessity, but there is a need for testing as well and this is understood by the industry. Most companies have alpha and beta versions of their software that is distributed to potential clients to test. In contrast, education instructors on the whole have done little with external evaluation in multimedia projects. The reason for this is multifaceted. First, multimedia projects are relatively new to education, most instructors, haven't considered multimedia forms of communication to have the same status as linguistic forms. Instructors will often address the issue of verbal and textual forms of communication in their classes and have a set of criteria for evaluating these forms of representation in assignments but don't do the same for multimedia. In addition, instructors may not think that multimedia deserves the same degree of attention because it is seen as fun rather than a serious form of communication. Another reason may be that the instructors have had few opportunities to communicate through multimedia themselves so are not sure what makes a good project and what does not. This will probably change as we have seen with the sophistication of web pages on the Internet. For instance, as people have become more discerning they have been drawn by those web pages that are more engaging and logically organized. This in turn becomes an expectation for web pages. For instance, there are numerous web sites that deal with what a good web site should be like or help designers identify common short coming in their design. Another reason is that if the multimedia industry fails to produce a quality product the consequences can be rather harsh; the audience will ignore their product and use something else, which results in a financial down turn for the company. Essentially for multimedia companies, audience is everything and companies that ignore that don't last long in the competitive market place. In education those harsh realities are removed so there is less pressure to consider the quality of a multimedia project. Case in point, provincial or state examinations for most part do not provide options for multimedia forms of communication. All these are real barriers to using multimedia and in particular using peer evaluation as a formative evaluation technique.

The Study

The research question is, if students are encouraged to make an accounting of the suggestions of others, will that be an impetus for changing their multimedia products? To address this question a number of different sources of data will be collected and tabulated. During the course on multimedia and learning, students report on their peer evaluations and the results of their target population field tests through the use of email messages. These email messages will be analyzed and categorized. This information will be put into a table, which should facilitate drawing inferences and making conclusions. Students' multimedia projects will be collected at the various stages of development. Using their projects as references one can tell a story of how their projects changed over time. The researcher plans to use students' multimedia projects as exemplars of change. Each group submits a copy of their projects before peer and target population evaluations and then again after each form of evaluation.

This study presents the notion of peer evaluation and target population feedback as tools for scaffolding students' reconstruction of multimedia projects. This is a work in progress. It is hoped that researchers and instructors will be able to use the principles coming out of this research and apply those to their own multimedia productions or related courses.
The results of this research address the value of audience in changing student multimedia constructions and suggest implications for other courses.

Data and analysis:

Ongoing data collection will begin in January 2000. This will continue for two or three years or until sufficient data has been collected to draw valid conclusions. There are two kinds of data that the study will use, data collected through email assignments from offerings of the course and projects collected. Students’ email messages will be categorized and tabulated (as seen Figure 1). The contents of student email submissions will be classified into one of the following categories to determine the kind of suggestions made:

- **Graphic Design issues**: This category will cover issues like style, color, placement of images, text, font size, and the overall look and feel of the project.

- **Usability/navigation**: This category covers issues of interactivity, the degree to which it is user friendly. This will be reflected in comments relating to how the user navigates through the project or how the project is structured. For instance, is it clear how to get from one part to the next, can users get to parts of the project they want to, is there a need for further links, etc.

- **Functionality**: Functionality will deal with more fundamental questions. Does it accomplish its purpose? Is it worthwhile?

It should be noted that the evaluators are not given any explicit criteria or categories to evaluate products, although these categories are covered in class in regards to developing good multimedia. Evaluators are asked to identify those aspects of the project that were good and those things that might be improved upon.

Once a comment has been categorized it will be determined if it is a positive comment or a suggestion for change. As part of an assignment for the course, students will be held accountable for each of the suggested changes made by peers or the target population. They will either be expected to reflect that change in their work or justify why they did not. A further category will be the justifiable nonchanges. These would be changes that are identified by the project group as being worthy to pursue but for one reason or another (time, resources, expertise) are not able to implement. This does not suggest students will be compelled to make changes. Students do not need to make changes to get credit for assignments. However, they are expected to address the suggestions either by indicating the suggestions are not necessary, the change is a justifiable nonchange, or they see the value of the change and make the change accordingly. Tabulating this information will provide data on the usefulness of peer evaluation for changing the multimedia projects. As an afterthought there may be an alternative to email, that is online databases. This too might facilitate summarizing the data.
In addition this study will track changes to students multimedia projects so copies of students’ projects at various stages of development will be retained. These juxtaposed will the tabulated data will help tell the story of how change takes place. The study will use these projects as exemplars in presentations or as screen displays in reports. Table 1 illustrates a tentative form that will be used to collect and tabulate the data that will be collected and categorized.
Role of audience in changes to usability

Table 1: This is a sample data collection form which will be used to tabulate results from student peer and target population evaluations on the category of usability. Each category would have a similar table associated with it.

There are two ways students may develop a greater sense of audience. One is that they see the value of having others review their work. This might be measured to the degree they think valuable information will come from peer and target population involvement in the production process. Another measure of a sense of audience is, the extent student creators are able to take the perspective of others in the production process. This is a difficult factor to collect information on. One way to address this issue is to determine to what extent peer and target population comments are useful in future project development? Does the experience actually raise an awareness of a sense of audience for participating students? This will be difficult to document or track over the long term. The nature of these suggestions may be endemic to a particular project, so to have students demonstrate what they have learned through the development of a different project may not be valid. However, perhaps one can infer this kind of transfer if students are able to identify the principles that they have learned from their peer evaluations. So an additional question will be posed to students for them to identify the principles they have learned from the peer and target population evaluations. It is hoped that through the course content student will have the language to articulate these principles. Another question will be asked at the end of the session to see to what extent they feel target and peer evaluation is a part of the evaluation process.

Findings

The information from Table 1 will be used to identify patterns in the data. For instance, the measure of student sense for audience comes from either a low number of changes being suggested or a high percentage of the suggested changes being acted on. The number of changes over suggestions should be high, if students have a good sense of audience with justified nonchanges taken into account. In other words, groups that have been told there are problems with their projects should make changes to accommodate those suggestions. However, there will be expected disagreements from time to time in terms of suggestions made and the degree to which the creators of the project sense it is an issue. There are two possible explanations, either the creator group ignores the perspective of the audience or the evaluator group are making unreasonable suggestions. Other patterns may
emerge from this table as well. For instance the number of positive comments might be viewed as an overall evaluation of the project. Looking at the differences in the number and type of suggestions between the peer evaluation and the target population would also be interesting information to collect. Identifying further changes through self-evaluation might further provide evidence of a heightening sense of audience. There is no need for a control group because each project is a control in the sense that before the target population and peer evaluation, the project is meant to be in a finished state. So the control is the state of the project before peer and target evaluation have been accomplished. The numbers that will be collected are not sufficient to do any kind of inferential statistics so this becomes a qualitative study.

There are no definitive results since this a study in progress. However, data from previous years were put into the table to test the categorization scheme. The pilot study data was obtained from a manually maintained email archive. Although the data was sketchy and was not categorized as finely as this proposal suggests, patterns began to emerge. One pattern was that through peer evaluation and target evaluation, numerous suggestions for change were made in all categories but functionality. Another result was that the production group acted on most suggestions. One might argue that these changes were stimulated not by peer evaluation but by the nature of the assignment. Controlling for that would be difficult but the course assignments could be setup so that they don't get any credit for addressing the suggested changes. However this in turn might skew the degree to which the students look seriously at suggested changes. Giving students credit for making changes is thought to stimulate them to be more sensitive to the issue of audience. Suggestions not acted on may have fallen into different categories. First the development group may not have shared the value of these suggestions. Alternatively, the suggestions may have fallen into the justified nonchange which would suggest that the development group realized the value of the comment but did not have resources or time to act on it. It was interesting to note that were only one or two suggestions in terms of functionality. However, through understanding the context this result becomes explainable. Suggestions regarding functionality address the very intent of the project. Functionality addresses the project's purpose, was it successful achieving its purpose or was the purpose useful? The peer or target evaluators, knowing that by this time the production team had gone to great lengths to create the product to date may have suppressed these issues. Instructional interventions are now being considered to accommodate for this. For instance, if students went through a peer review early in the process before production commenced as a sort of proof of concept, it would be interesting to see the number of comments that emerge regarding the functionality of the project. Another explanation is that the audience viewed the projects as being functional. A more systematic data collection process should provide a better indication of how student projects change and why. At this point it may be premature but the pilot study suggests that through greater audience appreciation (peer and target evaluation) many useful changing can be made to multimedia projects.

**Conclusions**

Designing and developing multimedia projects may involve different skills and engage different learning styles than that used in the writing process. However, because both processes involve creating a
product that will negotiate meaning and facilitate communication with others, both approaches can benefit from a sense of audience. In this case the role of audience comes through student assignments that involve having multimedia projects reviewed by peers as well as individuals from the target population. This study reported an ongoing project that documents the role of audience on changes to students' multimedia projects. It is speculated that feedback from an audience is a powerful influence on implementing changes to multimedia projects. On a broader note it is thought that the audience's perspective differs from the creators perspective and this information can help make multimedia projects more useful. With the current emphasis in the curriculum on students creating alternative ways of presenting and portraying ideas, students need a better sense that meaning is a negotiated issue. Using techniques like peer and target evaluations to improve multimedia projects will highlight the importance of this.

Abstract: The purpose of the VisionQuest° project is to help current and future educators envision and achieve technology integration by providing access to electronic models of technology-using teachers. By helping teachers envision and achieve exemplary technology use, we promote widespread, fundamental changes in teaching and learning methods that foster the development of both exemplary teachers and learners. We describe both the development and organization of the VisionQuest° CD-ROM. Potential future uses are also examined.

Introduction and Background

The Office of Technology Assessment (OTA 1995) recently stated that "the challenge of integrating technology into schools is much more human than technological. It is about helping people, primarily teachers, integrate these technologies into their teaching as tools of a profession that is being redefined through the process" (p. 28). Although most of our students who are preparing to teach recognize the importance of using technology in their classrooms, they tend to enter our education courses with limited visions of how technology can be used to achieve new instructional goals or implement new teaching practices. Despite the fact that the prevailing wisdom about how teachers should use technologies in schools has evolved—from teaching programming, to encouraging individualized drill and practice, to participating in electronic communities (OTA 1995), most of our students have never witnessed or experienced integrated technology use. We concur with the President's Panel on Educational Technology (PPET 1997) that integrated technology use will be achieved when technology is used to "facilitate fundamental, qualitative changes in the nature of teaching and learning" (p. 33). As such, technology will be used to support new interaction patterns and activities (e.g., changes in teacher/student roles, classroom organization, curricular emphases, assessment practices) that "simultaneously alter both the means and ends of classroom thought and action" (Fisher, Wilmore, & Howell 1994, p. 122).

Examples of integrated technology use are not readily available in our local schools. Even if they were, arranging for a large group of students to visit, and interact with, teachers in these classrooms would be logistically impossible. In previous semesters we have relied on instructional videos to illustrate exemplary technology use, yet most of these examples are situated in technology-rich schools and provide little information regarding the beliefs that support effective use or the steps that teachers have taken to achieve current levels of integration. Students often respond to these examples with varying degrees of frustration. How will they achieve this level of use if their schools cannot support this amount, or this type,
of equipment? Students need more than video examples of how to use technology in the classroom. They need opportunities to examine and reflect on the beliefs that support and shape integrated classroom practice.

Rationale (Why this CD-ROM?)

The purpose of the VisionQuest° project, and the primary purpose of this CD-ROM, is to help current and future educators envision and achieve technology integration by providing access to electronic models of technology-using teachers. Based on PPET's recommendation (1997) that "education students should be given the opportunity to observe uses of educational technology" (p. 55) yet, recognizing that many classroom teachers have not yet effectively integrated technology into their curricula, we are developing CD-ROM cases of technology-rich classroom practice. By examining both the pedagogical beliefs and classroom practices of exemplary technology-using peers, pre- and in-service teachers may gain a better understanding of how technology can be used (the practical considerations), as well as why it should be used (the supporting pedagogy) to enhance and transform current classroom practice.
