We believe that technology integration is not achieved by merely providing teachers with access to technology. Research has shown that availability and access are not the sole determinants of technology integration (Hadley & Sheingold 1993). The use of technology may be associated more with teachers' beliefs about teaching, the purpose for which technology is used, and the value teachers assign to particular uses of technology. Teachers need opportunities to examine and reflect on the beliefs and practices of other teachers who are currently integrating technology. This CD-ROM provides pre- and in-service teachers with models of technology integration. The CD-ROM can transport these teachers into others' classrooms so that they can examine the instructional practices, classroom organization, and curricular emphases of exemplary users of technology. They can see for themselves the roles played by the student, the teacher, and technology in a classroom where technology is integrated.

Methodology

Application Process

Six CD-ROM case studies are currently being developed that illustrate the beliefs and practices of exemplary technology-using teachers from across the state of Indiana. The selection process began by soliciting self- and peer nominations from k-12 school colleagues located within an hour's driving distance of the university. Letters were sent to the principals of 358 public and private schools, asking them to recommend any teachers known to be exemplary users of technology. Nominated teachers completed application forms in which they briefly described their beliefs and practices regarding classroom technology use as well as their visions for technology use in the future.

Selection Process

Upon receipt, applications were reviewed using research-based criteria that placed learning at the core of the integration process. Informal conversations with "promising" teachers (via phone or e-mail) helped narrow the list. Classroom observations and interviews were conducted with the most favorable candidates to obtain additional information about teachers' classroom organization; curricular emphases; their use of technology in the classroom; the roles played by the teacher, students, and technology; and the assessment practices of the teachers.

Development Process

Videotaping
Six teachers were selected from among their peers to be featured on the CD-ROM. During the 1998-99 school year, videotape was recorded in four teachers' classrooms, with an additional two classrooms slated for taping during the 1999-2000 school year.

The video team consisted of a small camera crew (one-two people), the principal researcher, and two graduate assistants. Using a qualitative approach to research and development, we began with a general outline of what we planned to videotape, but remained open to new ideas during taping.

Before videotaping, we held planning sessions with each teacher about the lessons to be videotaped. While we did not want to stage the classroom sessions, we were intent on capturing a representative sample of the teachers' classroom practice, including specific instances of technology integration. Using the same guiding questions that were included on teachers' project application forms, we looked for shots that illustrated the guiding visions of the teachers, their approaches to classroom organization, the roles of the teacher, student, and technology, and teachers' assessment practices.

**Digitizing**

The videotapes were logged and transcribed by two graduate students involved in the project from its inception. Segments were identified that fit into the different categories identified on the application form. For example, teachers in one school gave an oral quiz in their Biology class. We marked that segment as evidence of "Assessment." In another example, the students came into the classroom and took their class notebooks from the shelf and started working. We marked that segment as possibly relating to either "Classroom Organization" or "Role of the Student."

**Storyboarding**

Our storyboard was revised and refined after we had logged the videotapes from our first video shoot. This differs from common practice, in which videotaping tends to follow a finalized script. Although we knew which components each story should include, those components took shape only after we had begun the videotaping process.

After videotaping, we examined each tape to identify appropriate segments for each part of the story we wanted to tell. After we had lined up the visual evidence for the story, we determined how to narrate the story and how to supplement it with additional visuals, such as digital pictures. Our storyboards went through several drafts, starting with handwritten outlines and progressing to detailed notes, in which we decided exactly which visuals—graphics, video clips—went with which audio clips.

**Authoring**

We then started the process of creating the interface and synchronizing the video and audio clips. We began by using Flash as our authoring tool, but ran into memory problems. We then switched to GoLive CyberStudio, an HTML authoring tool. Once the first case "prototype" was on the way, the graduate students on the team began the development process for the next two cases.

**Lessons Learned**

**A Qualitative Approach to Development**

Due to the research nature of this project, we adapted an iterative approach to development, modifying various components of the outline to reflect new themes that emerged in our classroom video shoots, and thus, in our storyboards. In this sense the development did not follow a conventional production path; we began videotaping prior to having a finalized script and storyboard. This was a learning experience for all team members—those who were used to a more systematic approach developed an appreciation for the qualitative "work in progress;" those with a qualitative approach developed an
appreciation for the up-front technical aspects of development. Yet, throughout the project, the team worked together to make the project a success.

Thus this project allowed both the research and the technical teams to share and adjust their ideas and practices related to the development of a product. On the one hand, the technical team adopted a more flexible approach to development. On the other hand, the research team came to appreciate the benefits of having a more definitive style of working, similar to that which is prevalent in professional multimedia production settings.

Organization and Use of the CD-ROM

The CD-ROM is organized around the metaphor of a journey. Users explore the paths that six teachers have taken to achieve their current levels of technology use. They can examine how teachers' pedagogical visions of classroom practice have shaped their journeys. In addition, users can examine how teachers' journeys began, the roadblocks and challenges they faced, as well as the incentives that have propelled them forward. On yet another level, users can examine the relationships among teachers' beliefs (about the role of the teacher/student/technology, classroom organization, curricular emphases, and assessment practices) and current classroom practices related to technology.

Cases currently are being constructed such that users can explore teachers' classrooms either one at a time (case by case) or collectively (i.e., comparing features or themes across cases). Each case contains a variety of elements that combine to illustrate how teachers' visions for technology use are translated into practice. Classroom video examples comprise the center of each case and are integrated with teachers' interview comments, reflections on the lesson's effectiveness, descriptions of how each lesson evolved, as well as a discussion of the supporting pedagogy. Users also have access to information about classroom layout, available hardware and software, and resulting student projects.

As an instructional tool, the CD-ROM is designed to provide opportunities for users to explore a variety of examples of how effective technology use can be achieved. Although, optimally, initial uses of the CD-ROM would be completed in a whole class setting, this is not essential to effective use. Users have the option of working individually, or in small groups, to examine and compare the six cases. Users will explore and compare case components within a "reveal-reflect-refine" framework (Lesh & Kelly, in press). That is, teachers' beliefs and practice will be revealed within multiple contexts that prompt users to reflect on critical similarities and differences across cases. Recognizing that even "exemplary" technology integration is ever-changing, users are challenged to articulate testable suggestions that refine observed practices. During concurrent and/or subsequent field experiences, students' ideas can be piloted, then further refined in a continually "evolving expert" process.

Future Uses and Plans

Still in a prototype format, formative evaluation data are currently being gathered from intended users (pre-service teachers) of the CD. Based on the evaluation feedback obtained, the CD-ROM will be revised and finalized during the current (Fall 1999) semester. During the Spring, 2000 semester, materials will be piloted in two sections of Classroom Applications of Educational Technology, a one-credit course that serves as a companion to our 2-credit Introduction to Educational Technology course. During the spring semester we will begin gathering data to assess the effectiveness of the materials in fostering the growth of students' visions for classroom technology use.

The CD-ROM materials will be used to improve our k-12 teacher preparation program. In the future, use will also be extended to support local in-service teachers' efforts to envision and achieve technology integration. By providing electronic access to the beliefs and practices of technology-using peers, this project implements a cost-effective solution to a persistent problem. Using realistic pedagogical models, these materials can help current and future teachers envision and use available technology resources to create learning environments that simultaneously support and benefit from the use of instructional technology. By including teachers and students from both the University and local public schools we establish a close connection between technology, teacher education, and k-12 education. By
helping teachers envision and achieve exemplary technology use, we promote widespread, fundamental changes in teaching methods that foster the development of both exemplary teachers and learners.

Abstract: The Database Advisor (DBA) is a tool designed to guide users to the most appropriate Web-based databases for their research. When teachers, students, or library staff begin a research project it is not always obvious which database would be the best resource to locate information on a topic. As K-12 schools rely more and more on databases via the Internet, a search tool such as Database Advisor will be essential. Presented herein, is a description of how the Database Advisor works, the equipment and resources necessary to implement, where to get the source code, and why K-12 schools should seriously consider this product. To see the Database Advisor in action, visit UCSD’s public version for the Sciences at: http://scilib.ucsd.edu/Proi/dba/dba_public.html.

What is Database Advisor
Database Advisor software was developed in 1997 by the Science Libraries at the University of California, San Diego (UCSD). Database Advisor (DBA) is a web-based front-end to bibliographic and full text databases to which UCSD has remote access via the Web, Z39.50 and telnet. Database Advisor allows the user to specify terms, then automatically performs a keyword search of all profiled databases. DBA spawns a search process for each database, quickly sorts and returns the results from each database. The user can see which database contains the most information on the topic. A hyperlink to each database is included so the user can immediately get to the results or the specific database to launch a search in that interface.

Why K-12 schools need Database Advisor
When students and staff in public schools are engaged in research projects, time and cost are very big factors. Databases are often purchased by consortia, special licensing arrangements, or through specialized grants such as EDL (Electronic Doorway Library) grants. The vast numbers of possible places to find information often confuse patrons in public schools. The Database Advisor (DBA) can assist K-12 students and staff by suggesting starting points in specific databases that match the information need of the user.

Database Advisor is a tool that will simultaneously search all profiled databases, and it can increase usage of some expensive and underutilized databases. Customization of the various databases would also advise the user if there is an extra fee or provide an alternate avenue to obtain the data. Database Advisor has the ability to reduce the amount of time spent researching a topic using databases. Use of this tool will focus the user's attention on the specific databases that are likely to provide useful information. As K-12 schools rely more and more on databases via the Internet, a search tool such as Database Advisor will be essential.

K-12 school libraries are increasing using web pages as starting points for research. If Database Advisor was an add-on feature to some of the instructional web pages, patrons would immediately know which databases they could gain access to free of charge. Although many people believe that the Internet is free, this is not true. This is especially true for valid, authentic sites, including databases. Someone has to pay for the development, data entry, programming and site maintenance. In order to gain access to high quality, valid reference sites, schools have to make difficult decisions on which databases they can offer. This decision is often fiscally driven. K-12 schools simply can not afford the same databases as large academic institutions. They often have to pool resources together to be able to purchase even a single database.

Time is always an issue. K-12 students often are locked into specific times that usually range from thirty to ninety minute class periods. Schools continue to follow an agrarian calendar and school day. When Database Advisor is added to a web site, this time barrier is broken. Students can access and do a great deal
of research from home or the public library. They can also maximize their in-school research time by e-mailing information they find to their own e-mail address for later reference work.

Database Advisor has already been created and the source code is free of charge to K-12 schools. DBA is designed to be "portable" for application in any organizational environment, including schools. Schools need to pay a person to adapt the source code to meet their specific needs. This tailors the features of Database Advisor to their unique instructional needs. As K-12 libraries increasingly use web based content subscription services they need tools to assist their patrons. Database Advisor can maximize their time and improve their results.

How Database Advisor works

DBA works somewhat like a DIALOGWEB's DIALINDEX® search – on a much smaller scale, and with results customized to your unique local database mix. Database Advisor's appearance (input boxes, point-and-click, radio boxes, etc.) will be familiar to Web users. Graphic load is kept to a minimum, with a familiar, easy-to-use Web interface. For example, in the Web environment hitting the "enter" key sends a search query; DBA observes this convention. On the Welcome Screen it is obvious where the user enters search terms (Fig. 1).

Figure 1. Welcome Screen -- enter search terms

The user is given options to change default settings. Searching current files is the default, but the user can choose to include backfiles. Most users want to quickly search ALL databases but the user can select subject categories thereby limiting the databases searched (Fig. 2). Most search results are listed within one minute, but if more time is needed the user can increase the search time -- this is a useful feature when databases timeout before returning results. The Help section provides guidance in structuring DBA searches (Fig. 3).
To limit your search by subject category, click in the box next to that category. You can select more than one.

If you select nothing from the sections below, all subject categories will be assumed.

There are 10 broad subject categories included in Database Advisor, each of which includes a number of different databases.

A list of the databases included in each subject category is available.

All Subject Categories

- Biology
- Chemistry
- Computer Science
- Engineering
- Mathematics
- Medicine
- Oceanography
- Physics
- Science Business
- Science Education

Figure 2: User selects subject category(s)

Database Advisor (DBA) will take the terms you specify and automatically perform a keyword search in over 25 different databases. Your results indicate the number of hits that would be found in each one, ranked from the most to least hits. You can then link directly to the database of your choice to perform your search. Here are some tips to help you use Database Advisor most effectively:

<table>
<thead>
<tr>
<th>Tip</th>
<th>DO</th>
<th>DON'T</th>
</tr>
</thead>
</table>
| Keep it simple
  - limit to one or two main concepts
  - don't use multiple synonyms, use only one word for each concept. | bridge corrosion | bridge corrosion rust acid rain precipitation |
| Boolean searches
  - Do not use AND, OR, or NOT.
  - AND is implied between each word | aspirin headache | (aspirin OR ASA) AND (headache OR migraine) |

The following are not available in Database Advisor, but may be available in one or more individual databases when searched directly:

- author searching
- phrase searching / word adjacency
- single letters and special characters - e.g., π, Σ, ø
- wild card characters / truncation symbols - e.g., *?#
- case sensitivity - e.g., MIT vs mit

Figure 3. Search Help

When the user hits the “enter” key, Database Advisor automatically performs a keyword search of more than 25 science databases. DBA spawns a search process for each of our nine database vendors and returns the hits on the query (Fig. 4). Results are ranked, so the user can see where each database stands relative to the others. Each database has a link that can be followed to access the database and continue the search process. The concept of “instant gratification” has been implemented; the user goes directly to the results of a search when they choose a database. This function presents some technical challenges and is not available for all UCSD databases. A legend (Fig. 5) explains the Results page.

Technical Details about DBA's search strategies are available

Figure 7. Refine your search

A Database Advisor search differs from searching in a specific database. Searches are limited to the databases profiled by the librarians and databases in the user-specified subject categories. While users supply the keywords, the librarians have already supplied the search strategies to standardize the search across the various databases. Precise technical search strategies and fields are used to search each database. "Our goal in designing search strategies was to achieve an equivalent search of title words, abstract words, and subject terms in each database. This was not always possible because of the differences in the fields available and the way in which each database searches these fields. To achieve uniformity across databases, DBA's search strategies are by necessity rather generic" (Hightower, et al., 1997). Database Advisor guides users in choosing a database, it does not perform the most precise search possible in each database. Using the unique features and search capabilities of a database, more precise searches can be performed and users can refine their search as appropriate for each database used.
DBA searches three types of bibliographic databases: web, Z39.50 and telnet. Precise technical search strategies and fields searched in each database in Database Advisor are available at: http://scilib.ucsd.edu/Proj/dba/search_strat.html. Database Advisor does not search Yahoo or the rest of the Web. DBA was designed to search bibliographic indexes and abstracts, like Inspec and Compendex, because we lacked a good tool that searched across databases supplied from so many different vendors. Several meta-search engines (like Inference Find and Metacrawler) exist that traverse the publicly accessible workspace. Perhaps in the future it will be possible to offer a link to one or more of these meta-search engines from DBA...as long as the results remained useful rather than overwhelming or confusing to the user.

Implementation...how to get source code
To implement at your site someone (a technically-savvy librarian or administrator, for example) will need to work with an on-site programmer to select databases, assign appropriate subject categories, develop profiles and determine the search strategies that will work. A single programmer currently on staff in the UCSD library now maintains the code, adding and adjusting database scripts and profiles as necessary.

A fully functional version of DBA is available to users of UCSD Internet accounts (i.e., those using a UCSD Academic Computing account, or those in an on-campus building). Obviously, non-UCSD usage of databases has licensing implications. A public version is available so you can see a “live demonstration” of how Database Advisor works. Note: Some databases are removed from the public version of DBA due to license restrictions. Anyone with Web access, regardless of UCSD affiliation, can use the demo version of Database Advisor. However, many of the databases that show up on the Results page are restricted to University of California (UC) or UCSD users, and may not allow access from outside IP addresses. To see the Database Advisor in action, visit the Public Version of DBA Sciences at: http://scilib.ucsd.edu/Proj/dba/dba_public.html

The source code for Database Advisor, Sciences version, is available under the terms of the GNU General Public License at: http://scilib.ucsd.edu/Proj/dba/code/dba-source.html. The DBA program is free software. You can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation (either version 2 of the License, or any later version). The program source code is distributed in the hope that it will be useful, but without any warranty. For more details about the GNU General Public License see: http://www.gnu.ai.mit.edu/copyleft/gpl.html. To run DBA at your site you need a UNIX computer with Internet connectivity and the equivalent of an Apache Web server (common in academic settings). You need the following software to install Database Advisor: Z 39.50 API Client software for Z39.50 connections: You obtain the code from http://lindy.stanford.edu/~harold/z3950/www_gateway.html GNU C compiler: To compile the zclient code for your machine. For more information on the GNU project and a list of FTP sites for GNU software go to http://www.delorie.com/gnu/perl (version 5.004_01 or later): You can get the latest version of perl from: http://www.perl.com

Summary
Database Advisor has the ability to reduce the amount of time spent researching a topic using databases. Use of this tool will focus the user's attention on the specific databases that are likely to provide useful information. As K-12 schools rely more and more on databases via the Internet, a search tool such as Database Advisor will be essential. Many K-12 school systems now have both the technology and programming ability to implement a tool like DBA, and, at this time, Database Advisor is the only tool we have seen that meets this information need.

References
Abstract: Today's digital cameras, electronic devices that merge computer capabilities with traditional photography, have come a long way in affordability and ease of use. Digital cameras can enhance and energize many curricular activities. They allow for instant results, user flexibility, and ownership in the development of the images. Users take pictures in the standard way, store them on a digital disk, and use these images on their computers. Although film based technologies can provide the same opportunities, the use of the digital camera provides a hassle-free way to capture, manipulate, and present images relative to instruction.

As our society relies increasingly on transferring knowledge quickly and easily through visual means, the digital camera provides a powerful tool for customizing the materials we will use to transfer this information. Many of the educational reform movements of today emphasize the importance of designing the learning experience to be relevant to the child's world. A good way to bring the world into the classroom is with visual representations of the content being discussed. For example, a Kindergarten and First Grade classroom activity is the shape walk, in which teachers take their class into the neighborhood where students find instances of simple two dimensional shapes as used in society or represented in nature. Using a digital camera, the student takes pictures of the shapes instead of merely pointing out these instances. As middle grades classes discuss the form and functions of geometric shapes, digital cameras allow the students to take pictures illustrating where form enhances function. Examples of such pictures include the rectangular solids used on container ships as an efficient way to load and unload cargo or spherical gas storage tanks as representation of shapes that provide strength to resist internal pressures. A high school Geometry experience designed to develop an appreciation for geometric theorems, might include visual images. The digital camera could be used to: 1) take pictures of a building and insert the pictures into a draw program, 2) superimpose a grid over the inserted image, and 3) use the image to calculate an equation for an architectural feature such as an archway.

Additional geometric applications might be to illustrate the Golden Rectangle, a rectangle with an approximate proportion of 2 to 3, a feature of classic Greek architecture that is considered to be the most esthetically pleasing proportion to the human eye (Jurgensen, Brown, & Jurgensen, 1988). Another activity could include taking pictures of three dimensional structures at a corner and inserting the pictures into a draw program so that lines can be drawn to show perspective and vanishing points.

Today's definition of literacy moves the focus of literacy beyond facility with the printed word and toward acquiring a knowledge base. The definition of a literate person is evolving to include the ability
to gather and impart information in a visual format. The delivery and acquisition of this information includes visual images. The instructional process should include providing today’s students with proficiency in the skills necessary for handling visual information (Crockett, p.5). The digital Camera provides a tool to develop this form of literacy in the same way that word processing does for the printed word.

Integration of the Digital Camera into the Instructional Process

Within the P-12 curriculum, use of the digital camera is only limited by one’s imagination. Some instances of integration of visual images into the instruction process of common content areas are:

- Reading and Writing - This application combines reading with the visual arts and writing skills. Descriptive language can be developed by taking a picture and asking the student to describe the content of the picture, either orally or in a written format. Conversely, the teacher could describe an object or situation either verbally or in written form and ask the students to create a picture of the description. As the students develop these skills, their communication abilities are advanced through creation of a picture book or story, a storyboard for a play, or a record of an experience that imparts information both visually and verbally.

- Science, Social Studies and Mathematics - Images can be used to prepare for, document, and follow up on, field trips in the content areas. A teacher’s visit to the field trip site prior to the trip to record images that the students will observe creates a visual record to serve as an advanced organizer. As part of the actual trip, students take pictures. Follow up activities include reports or further study of aspects of the trip. For example, a field trip to a historic town could include the architectural aspects of the town. On a pre-trip visit, the teacher takes pictures of various types of architectural designs to share with the students before the trip. While on the trip, the students record their observations, both similar to and different from the architecture features the teacher observed. Reports developed as a result of the trip might include researching the defining features of an architectural style, and analyzing whether the designer/builder of a particular building incorporated more than one architectural style. Identifying the mathematical considerations that are apparent in the design of a structure, and how the design of the structure relates to it’s function are also questions to be considered.

- Projects - As students create projects in the classroom they take pictures to record the process and results of the project. A class working on folk art could take photographs of the quilts in their families. The students could then create a database for use in discussing: 1) the differences and similarities of the quilts, 2) the materials used to create a quilt, 3) the lives of the people who created them, 4) how the designs reflect the life of a quilter, and 5) the geometric patterns and tessellations required to make a quilt.

- Scientific Experiments - Students use the digital camera to record their observations in a science experiment that involves change over time. The growth of a plant or animal, the change in a specific site over seasons or years, or the effects of a chemical reaction are all possible situations which can be recorded by a series of images.

- Desktop Publishing - Student reporters for class or school newsletters take pictures of special events, students, and faculty to illustrate articles.

- Visual Arts - The aesthetic aspects and critical analysis of an image are explored by discussing the organization of visual space to convey a feeling, action, or documentation. The display of the images, criteria for selecting images, and how an image can convey a message in place of words are all considerations. Additionally, using an image to complement text, the manipulation of images to create a new image, and the isolation of certain aspects of an image to focus on a specific idea, are important aspects of visual imaging and communication.
• **Data Analysis** - Students using the digital camera can create a visual field in the database. A class that is studying the birds observed in the schoolyard could create a database of each bird viewed. The time sited, color of plumage, whether the bird is a juvenile or adult, if the bird is migratory or residential, its feeding and nesting habits, as well as an actual picture of the bird could be included. If multiple entries for each bird occur, students can analyze the data to determine if the siting were of unique birds or if a repeat siting of a single bird occurred. A teacher could also build a database over several school years providing the opportunity to track birds over time. Another application involves creating of a database of American Sign Language (ASL) to provide learners with images of each letter and of common phrases. The ASL could also be useful for special need learners.

• **Computer Literacy** - Most state and local school districts are beginning to require a computer literacy component in their graduation requirements. The digital camera is a vital part of this process and provides images that are integrated into web pages and presentation programs.

• **Classroom atmosphere** - Many teachers use pictures and images to highlight each student’s special characteristics in order to build self-esteem and a sense of place. A picture emphasizing a child’s special characteristics and their contributions to the classroom becomes the vehicle for building classroom pride. Use of a digital camera helps facilitate this idea by showing the strengths and actions of each student and helps them see themselves as part of the classroom community. Students with special needs who are encouraged to use the camera to record projects and information are given a powerful tool to help them participate in classroom learning activities and improve their self concept.

• **Assessment** - In assessing learning, digital images can be used in construction of traditional tests and in production of alternative assessment documents. Tests created that include images of items or processes from classroom experiences give the teacher an opportunity to develop test items that relate to the student’s experiences. Authentic assessment is achieved with the inclusion of images that students have taken of their work in portfolios documenting a greater variety of work than might otherwise be included.

### Advantages and Disadvantages of using the Digital Camera in the Instructional Process

When using visual images in the classroom, making the decision to include the digital camera to produce the images over traditional methods requires analysis of the camera, the learning situation and the capabilities of the learner. Several advantages and disadvantages present themselves for consideration when selecting an imaging option using a digital camera. First, and probably most important, are the advantages.

#### Advantages

Photographing with a digital camera is almost instantaneous. Images can be viewed and/ or downloaded immediately and used at the "teachable" moment. Additionally, images can be analyzed and retaken immediately on site, if desired. The capability to delete unwanted images immediately is also a plus, allowing the user to manage storage space. Film cannot be inadvertently exposed using a digital camera thus preventing the loss of an image that is common when a traditional camera is used.

Cost, following the initial outlay of funds for a digital camera and storage device (flash card or floppy disk) is minimal. Therefore, one time funding provides equipment and materials for use over several years. Eliminating continuous cost frees teachers and student to use the camera frequently.

Several features are evident in all digital cameras. They include a Liquid Crystal Display (LCD) screen and storage format. Many cameras use the LCD as the viewfinder allowing the user to see exactly how the picture is composed prior to taking the picture. Most digital cameras also allow the user to adjust the resolution of the image before the photograph is taken.

Digital cameras save pictures in standard JPEG format that is compatible with a wide variety of computer programs. When JPEG images are used they can be easily inserted and integrated into word
processing, database, desktop publishing and presentation programs. Use of the digital camera eliminates a step in the process of including images in a computer presentation. If traditional photographs are used, they must be scanned into the computer adding an additional step in the imaging process. The extra step increases the cost of the imaging by requiring the purchase of another piece of equipment. Additionally, the learning curve is increased due to the fact that the user must master the use of the scanner and its associated software. The quality of the digital camera images is as good as or better than a scanned photograph when used in computer applications.

Finally, a number of digital cameras also have video-out ports, this feature permits the projection of the digital image on a television screen or monitor and is especially helpful if a computer is unavailable in a classroom.

Disadvantages

There are, however, some obvious disadvantages in using a digital camera in the educational environment. The initial cost of one digital camera exceeds a number of regular "throw away" traditional cameras. However, the one time cost of a digital camera is offset when the continuing cost of film and developing is considered.

A second issue is printing. Printing of images that have been taken with a digital camera on either an inkjet or laser printer may diminish the quality of the printed photograph due to the printing process and the paper that is used.

Lastly, when shooting in an outdoor environment with a digital camera, bright sunlight may prevent the user from viewing the LCD. Thus, the ability to compose, focus and review an image is greatly reduced unless the user makes some provision for shading the LCD.

Considerations when purchasing Digital Cameras for the K-12 Classroom

When considering the purchase of a digital camera several questions must be answered. Who is going to be the primary user, a student (and of what age) or a teacher? A camera designed for an adult might prove too difficult for a young child to use. Another question to ask is: How and for what purpose will the camera be used? Therefore, when purchasing a digital camera, one needs to pay attention to the various features offered. These features include:

Viewfinders. Does the camera have an optical viewfinder or a LCD screen? LCD’s let you view the pictures you’ve just taken allowing the user to decide to retake the pictures or delete them from the cameras that only have LCD’s (no optical viewfinder) tend to suffer from two problems: they use up batteries quickly and can be hard to see in bright daylight. The best bet is to look for a camera that has both a LCD and optical viewfinder.

Storage. Today’s cameras store images on a number of different types of media. The most common is the Flash Card and associated compact Flash Card. These cards come in various sizes from 8mb up to cards that hold over 256mb of information. If a computer is equipped with a PCMCIA slot, one can transfer the images on these cards directly into the computer more quickly than by cable. The Sony Mavica camera uses standard 3.5” HD floppy disks. The picture files can then be used in any computer with a standard floppy drive. This inexpensive media would allow every student to have their own storage disk and edit the pictures on any computer, at home or school.

Resolution. Cameras with higher resolutions produce sharper images. The least expensive digital cameras have the lowest resolutions, 640 x 480 is the minimum needed for a decent image. Higher resolutions are especially advantageous for print, as opposed to Web pages and/or presentation programs. The one problem with the higher resolution cameras is that they tend to cost more and the pictures take more storage space. Therefore, one should look for a camera that allows one to change the resolution of the picture before taking it.
Lenses. Most low-end digital cameras offer fixed-focus lenses, like those on the less-expensive film cameras. Fixed focus lenses are all right in many situations, and are lighter and easier to use than zoom lenses, although it may be more difficult to get the picture desired in difficult situations, for example when taking a picture of a distant object or person. Cameras with zoom lenses allow the user to eliminate distracting backgrounds when shooting, and add to the camera’s versatility. However, zoom lenses add to the cost and weight of the camera. At the high end of the price scale are cameras that allow you to use different lenses for different situations. Minolta’s digital cameras will work with most of the lenses they make for their 35mm film cameras. Look for a camera that has the type of lens needed for the intended purpose of the camera.

Software. Digital cameras come with a variety of bundled software that will allow the manipulation of the images once they are downloaded into a computer. This software ranges from minimal viewing programs to complete image editors. The two most popular software programs that are currently being bundled are *Adobe Photoshop LE* and *Adobe Photo Deluxe*.

Virtual Reality. A series of pictures can be taken of a scene that covers a panorama of the site. These images can then be “stitched” together to form a 360 degree panorama allowing the viewer to control the point of view of the scene. The panoramas are initially created by using a tripod with a digital camera to create a series of individual still images. Then the images are imported into a QTVR software package and the panorama is formed. The viewer can then actually experience and control the observation of the site. Several shareware and commercial programs are available to create panoramas. The commercial software programs include Apple’s *QuickTime VR* for both Macintosh and PC computers and *VR Worx*, or one of several powerful programs which are easy to use and that can be purchased for under $100 and allow the teacher or the students to develop panoramas.

Computer. Almost all of the digital cameras will work with both the Macintosh OS and Windows computers, but it is important to be sure that the camera comes with the cables and software for the computer which will be used.

Digital Cameras are great learning tools to simulate and motivate students and teachers alike. As teachers use and experiment with digital cameras they will find applications that are unique to their classrooms. The digital camera coupled with other computer applications provides a sound basis for teachers and students to meet the National Educational Technology Standards.

NEW DEVELOPMENTS IN AUDIO AND VIDEO TECHNOLOGIES

Jeffrey W. Bauer, Ph.D.
Associate Professor of Educational Technology
Department of Educational Technology
University of Northern Colorado, USA
Bauer@edtech.unco.edu

ABSTRACT
Pohlmann (1999) describes what he calls the “X-tronic generation” as, “Younger than Gen-Xers” and having “pure, liquid technology coursing through their veins” (p. 38). Their out of school lives are saturated with high tech tools, and they have become experts in manipulating this technology. How well equipped are our educational institutions in dealing with X-tronic kids? Change theorists claim that there are levels of concerns that educators progress through as new innovations are introduced into their professional lives (Hall & Hoard, 1987). The first level is that of Awareness: Knowing that an innovation exists and understanding its uses. This article is aimed at the awareness level. It describes several emerging audio and video technologies including DVD, digital television, high definition television, and new audio formats. It focuses on technologies that have high adoption rates and appear to have some potential in educational settings, including distance delivered instruction.

THE X-TRONIC GENERATION

A few weeks ago my ten year old son purchased a device from a local department store that attached to his Nintendo 64 player allowing him to program his game cartridges with custom options not normally available to the user. Within minutes, he had programmed his James Bond game to make his character invisible, and he had an assortment of weapons at his disposal that would make the politically correct shudder with horror. A quick surf on the Internet provided him with even more programming codes that allowed him to do things that only ten year olds would understand. Later that evening, he worked on a multimedia book report on Jack London’s White Fang using the ubiquitous Hyperstudio. This activity was interrupted with Internet hookups to several major airport control towers, including Chicago’s O’Hare and Dallas-Fort Worth, so that he could listen in on what was happening in the friendly skies. His final activity of the evening was a screening of Austin Powers on DVD displayed in all of its garish glory on a pristine large screen TV with six channel surround sound. The next day I dropped him off for school with his printed book report in hand, where he spent six hours interacting with analog technologies such as textbooks, pencils and paper, and storytelling.

Pohlmann (1999) describes such kids as the “X-tronic generation” (p. 38). He states, “Younger than Gen-Xers, they have pure, liquid technology coursing through their veins” (p. 38) Pohlmann goes on to state that critics of X-tronic kids should “try looking at tomorrow through younger eyes, eyes that see sophisticated technology as a necessity instead of a luxury. Maybe then they will understand how the X-tronics instinctively use technology to broaden their horizons and reach farther than ever before” (p. 38).

How well equipped are our educational institutions in dealing with X-tronic kids whose out of school lives are immersed in technology? Can teachers capitalize on the skills that our children are learning outside of the classroom in order to enhance the teaching of reading, writing, science, math, music, history, and art? Furthermore, what are colleges of education doing to prepare the current crop of preservice teachers and library media specialists to deal with the X-tronic generation?

Change theorists claim that there are levels of concerns that educators progress through as new innovations are introduced into their professional lives (Hall & Hoard, 1987). The first level is that of Awareness: Knowing that an innovation exists and understanding its uses. As professional educators who live in the world of instructional technology, it is our obligation to understand how the change process works so that innovations can be used to enhance learning and reach X-tronic kids who are increasingly questioning the
relevance of the K-12 educational experience. This article is aimed at the first level of concern: Awareness. It describes several emerging audio and video technologies including DVD, digital television, high definition television, and audio formats such as Dolby Digital and MP3. This article is not all-inclusive, but rather focuses on technologies that have high adoption rates and appear to have some potential in educational settings, including distance delivered instruction.

DIGITAL VERSATILE DISC (DVD)

Since the Digital Versatile Disc (DVD) was introduced three years ago, its adoption rate has been faster than that of VHS videotape. The CD-ROM sized disc has many features that make it attractive to users. A single disc can hold up to four hours of full motion video and high quality audio information on each side of the disc. The picture is free from artifacts such as tape noise and hiss associated with traditional videotape. Furthermore, users have instant access to any of the information on the disc without having to rewind or fast forward through the information.

Many discs include soundtracks that are in different languages, typically Spanish and French. This makes it an ideal medium for foreign language classes or for students whose first language is not English. Most discs include subtitles in several languages making the information useful for deaf and hard of hearing students. Most of the titles currently available are full length feature movies, both current releases and classic motion pictures. Useful extras are often included such as commentaries from directors and producers, background information about the film, actor biographies, featurettes, and even links to websites.

Many DVD’s feature high quality Dolby Digital audio along with more traditional stereo or mono soundtracks. The digital soundtracks can contain up to six channels of discreet sound information, enveloping the viewer in the action. The six channels are center (dialogue), front left and right effects, rear right and left surround, and low frequency (subwoofer) information. In order to reproduce the six channel soundtrack, a six channel decoder is necessary along with five speakers plus a subwoofer. Decoders are included on most hi fi receivers produced in the last two years.

Another audio option offered on many DVD’s is Dolby Pro Logic surround, which is a format that has been around for about ten years. This is not a discreet six channel arrangement, like Dolby Digital; however, with a Pro Logic receiver and five speakers, the surround effect can be very effective. Dolby Pro Logic extracts the mono surround information from the stereo soundtrack and steer it to the appropriate speaker using matrix technology. The channel separation is not as well defined as Dolby Digital.

In addition to high quality audio and video information, many DVD’s offer a choice of aspect ratios, including traditional television (4 units wide by 3 units high) and widescreen (typically 16 units wide by 9 units high) allowing the viewer to see the film in its original theatrical format.

Educational titles are beginning to appear. They offer all of the advantages mentioned previously plus user friendly operation. Only a DVD player and a TV are required for viewing. Teachers can access parts of the disc instantly with the touch of a button, much like the laserdiscs that were used in education in the early 90s.
Discs are reasonably priced—most less than $30—and are not prone to mechanical problems associated with VHS tapes. The only downside to DVD for school use is that the discs require careful handling. If discs become scratched or smudged, they will malfunction. Most teachers and media specialists are accustomed to handling CD-ROMs and audio CDs, so the durability question is less of a factor.

Implications for teachers and library media specialists are many. First, library media specialists should consider purchasing DVD players instead of VHS video players as they replace machines. Also, they should consider ordering educational materials on DVD rather than videotape. Teachers should be trained on handling and operating discs and players, and integration techniques. Many of the same integration principles that apply to CD-ROM, computer software, film, and videotape apply to the use of DVD in the classroom.

Overall, DVD is a rapidly growing technology that has excellent potential in the classroom. Teachers, media specialists, and teacher educators should be familiar with its advantages and uses in the classroom.

DIGITAL TELEVISION AND HIGH DEFINITION TELEVISION

The Federal Communications Commission has mandated that digital television (DTV) will become the new standard for TV broadcasts in the United States replacing the current NTSC standard which has been around since the 1950s (Griffin, 1999). Digital television is a high quality format, free from much of the interference (ghosting, unstable picture quality, lines and “snow”) common to NTSC.

High definition television (HDTV) is a subset of the digital TV, containing the highest quality picture included in the DTV spectrum. So far, HDTV’s introduction has been slow, and there are many competing formats (Arlen, 1999). Only a few programs in major cities are currently broadcast in HDTV, and users need several things in order to decode the information. First, a high definition television set is required, and although the prices are dropping, they are still out of reach for most consumers and schools. Second, a high definition tuner/decoder—again, fairly expensive—is also required. As mentioned previously, there are several competing formats which impacts the tuner/decoders that are available on the market today. Finally, a rooftop antenna is currently required, since HDTV broadcasts have yet to hit the cable and satellite markets.

There is no question about the quality of HDTV. It is magnificent (Griffin, 1999). But cable TV companies have yet to embrace the technology, and the nation’s largest cable companies are not planning on offering any digital broadcasts until mid 2000—and then only to a few customers (Arlen, 1999).

One of the strengths of the HDTV format is its theater-like aspect ratio of 16 units wide by 9 units high. When DTV becomes the main delivery medium, current NTSC sets will require set top boxes to translate the digital signal into an NTSC form. For HDTV broadcasts, this will mean black bars on the top and bottom of a traditional 4 by 3 television.

The implications for teachers and media specialists are many, but not urgent. Eventually, decoders will be required to convert DTV signals for NTSC TVs in schools and media centers. For the time being, digital TVs are so expensive and the introduction has been so slow, that it makes no economic sense for schools and universities to purchase digital equipment. Format changes are likely, and the current crop of DTVs could be obsolete by the time that DTV becomes mainstream. It is on the horizon, however, and teachers and media specialists should keep abreast of DTV’s development as it slowly replaces NTSC.

MP3 WEB AUDIO FORMAT

There are many developments related to the worldwide web that could be covered in this article including streaming video and audio used to enhance distance delivered instruction. I have chosen MP3 (MPEG-1, Level 3) audio because it offers high quality portable audio information in a relatively small file size. As courses are developed for web delivery, audio information in the forms of lectures, music, and poetry have traditionally suffered from compression artifacts making them difficult to understand and tedious to listen to. MP3 allows the web developer to compress files at different bit rates that significantly reduce the file size, yet still offer near CD quality sound. These files can be downloaded and played using an MP3 player (available free—www.mp3.com) either on the computer or by using a portable MP3 play, much like a Walkman that can be taken anywhere. This allows the learner freedom from the computer for some of the web delivered course material.
A thirty-minute lecture recorded at CD quality would take approximately 300 megabytes of hard disk space. This lecture could be broken up into three 100 megabyte files, and reduced to MP3 resulting in three 5 megabyte files with reasonable quality. Samples of MP3 files can be found on my website at www.edtech.unco.edu.

MP3 files are fairly easy to process. You begin by recording audio information directly to your computer using an audio capture program and the microphone included on most PCs. The file can be saved as an .aiff file which will work well with MP3 processors. You can download an MP3 “ripper” from the web, and the .aiff file to MP3 (Lake, 1999). Most rippers include several choices of compression rates. You can experiment to see which compression rate works best for your audio material. Your MP3 files can be posted to a website, and users can download and play the files using an MP3 player (see Figure 2).

FINAL THOUGHTS

As professional educators it is our responsibility to keep up with emerging technologies that show potential in enhancing the teaching and learning process for our students. More and more, students are becoming technologically savvy. They cannot imagine a world without computers and other high tech tools that allow them to express their creativity and to grow as individuals. Teachers, media specialists, and teacher educators should consider how they are going to reach the X-tronic generation, so that the classroom experience is not so far removed from their daily lives outside of school. The process begins with awareness. In this article, several video and audio technologies have been discussed in an effort to enhance awareness for professional educators.

Abstract: Video conferencing for use in education has included the development of expensive yet sophisticated technology capable of delivering quality instruction to multiple sites. Limitations arise from using a closed network and a factor such as cost to establish and operate the network with video compression or satellite technology can potentially impact programming. An alternative to expensive and site-restricted technologies is desktop video conferencing. This paper reviews the process that involved selecting desktop video conferencing as the "next generation" distance learning technology. In addition, the paper discusses the creation of a multi-site desktop video conferencing network designed to serve central Louisiana and provide an array of program possibilities including courses for credit, teacher certification, and training to participating sites.

Introduction

The evolution of video conferencing for applications in education has accelerated significantly. Moreover, desktop video conferencing systems are becoming viable options to more expensive video compression systems for delivering classes (Kies, Williges and Rosson, 1997). Prevailing distance-learning technologies such as interactive satellite, video compression, audio graphics, and web-based Internet classes have a history of providing a mechanism to facilitate classes for credit or training to specific sites. What has resulted from the use of these technologies is an awareness of and sensitivity to the cost of delivering programming at a distance. With other considerations such as student attitude toward the technologies, interaction with the teacher and students, availability of access to the technology and support resources and adaptability of the technology to specific learning styles of the participants, a new desktop distance learning system emerged as a possible contender in the arena of diverse and costly distance learning technologies.

Desktop Video Conferencing as an Emerging Distance Learning Technology

The literature suggests that technologies such as desktop video conferencing have positively impacted the quality of teaching and availability of electronic resources for students (Googin, Finkenberg and Morrow, 1997). Desktop video conferencing is a relatively new yet emerging technology that provides cost-effective instruction under the umbrella of distance learning. Specifically, the cost of delivering instruction via distance learning using computer software and teleconferencing strategies—the profile of desktop video conferencing—creates savings in terms of money, time and resources without a substantial loss of effectiveness of instruction (Castellan, 1993). Desktop video conferencing has created more practical, less network specific distance learning opportunities than systems like video compression that cost $250,000 to $300,000 (Ward and Lee, 1995). It is a technology that allows students, teachers and colleagues to interact with each other from their desks or classrooms via the Internet creating the essence of a phone conversation but with video and graphics (Googin, Finkenberg and Morrow, 1997).
Technologies such as desktop video conferencing are often evaluated by specific benefits they generate that support instruction particularly for distance learning applications. Since most distance learning technologies improve access to learning, especially for students who are time and place bound, other issues such as creating positive learning environments for users are equally important. Laney (1996) noted that desktop video conferencing may foster collaborative teaching and learning environments between universities and public school districts or between rural and urban schools. Other benefits of using desktop video conferencing include sharing courses and expertise in the field with other institutions with limited resources and providing opportunities for students to participate in "electronic fieldtrips" where they meet with experts in their respective fields (Googin, Finkenberg and Morrow, 1997). Regarding the benefits of using desktop video conferencing over other distance learning technologies such as satellite or compressed video technologies, the information by Evans (1997) summarizes a comparison between the three technologies when examined by attributes such as coverage, interactivity, quality of video, cost of technology, cost-effectiveness, production and preparation, access to the technology and infrastructure.

Table 1: Summary by Evans (1997) of comparison between three distance learning technologies, desktop video conferencing, satellite and video compression

There are some disadvantages however, to delivering courses at a distance using desktop video conferencing. Video and audio quality will not be as good as broadcast television or video compression. Video and audio use a great deal of space called bandwidth, which is typically not available with desktop video conferencing technologies (Googin, Finkenberg and Morrow, 1997). Comments such as "This would be great if...the video were better...the audio were better...it could multi-point...the screen was bigger" (Johnson, 1999, p.1) are typical comments from users of first generation desktop video conferencing technologies. Additionally, users may have difficulty adjusting to live audio and video while trying to
manipulate the technology like microphones and cameras to obtain optimal operating quality (Ward and Lee, 1995). Training of users may become the element that eventually neutralizes any disadvantages of using desktop video conferencing for distance learning applications.

**Kinds of Desktop Video Conferencing Technologies**

The first and most recognizable type of desktop video conferencing system is CU-SeeMe, developed at Cornell University (Fudell, Hardy and Terrell, 1997). CU-SeeMe allows students to send and receive video and audio on a computer to other participants (Todd, 1996). Companies like Vtel and PictureTel have developed desktop video conferencing systems using ProShare operating software (Johnson, 1999). Recent entries into operating software include Ilinc Corporation's Learnlinc Version 3.1 which is the system running the desktop video conferencing network at Northwestern State University, the subject of this paper.

**Evaluation of Desktop Video Conferencing Technologies**

A sizeable body of research exists that evaluates distance-learning systems (Goldstein, 1993). Yet the majority of research has focused on evaluating high-quality video systems operating on broad bandwidth. Limited research is available on low-bandwidth systems such as desktop video conferencing. This is due in part to how new the technology is and its limited application, thus far, in education. A study by Biner, et al (1995) examined student performance and satisfaction with low-bandwidth modalities. It revealed that technology-related factors such as quality of video and audio and the impact of conferencing tools like the electronic whiteboard are important components to the success of student performance and satisfaction with the technology. Kies, Williges and Rosson (1997) examined specific factors that affect quality of presentation such as frame rates and resolution of image. They noted that a minimum acceptable range of tolerance for users was 5-6 frames per second although a full 30 frames per second is desirable. Systems like CU-SeeMe operate with fewer frames rates to run at lower bandwidths on ISDN lines. The results of performance on slower frame rates had no effect on quiz scores. Also, transmitting video images over lower bandwidth did not affect a learner's ability to absorb educational material. The authors of the study said, "Equally important is the implication that expensive hardware and software is not needed for the transmission of video to ensure learning" (Kies, Williges and Rosson, 1997, p. 84). The study noted eight recommendations for using desktop video conferencing systems in distance learning: (1) avoid frame rates less than 6 fps; (2) avoid lines of resolution less than 320 X 240; (3) if considerable motion is required, use a faster frame rate; (4) if considerable detail is needed, use higher resolution; (5) use a whiteboard for lecture notes; (6) ensure high-quality audio; (7) be sensitive to student dissatisfaction with the technology; and (8) support interactivity by creating a comfortable setting (Kies, Williges and Rosson, 1997).

**Desktop Video Conferencing as the Next Generation Distance Learning System**

Northwestern State University of Louisiana has pioneered the use of distance learning in Louisiana. Even though the history of this endeavor is predated to the late 50's when the university produced the first ITV (Instructional Television) project in the state, the university has developed and used several distance learning delivery systems including audio graphics, interactive satellite, web-based Internet and video compression technologies. While distance learning technologies possess unique qualities that make them desirable for special applications, most have weaknesses that limit their use. Moreover, the technologies that provide elements most desired by students are usually too expensive and restrictive. Consequently, the university as a result of a U.S. Department of Agriculture Rural Utilities Service grant decided to pursue a new direction in distance learning which is flexible, accommodates for most learning styles, and is synchronous but can have asynchronous applications. It also has multiple applications that replicate traditional face-to-face instruction, can access educational resources such as the World Wide Web, presentation software, video and CD technologies yet has a "price tag" that is affordable.
The challenge for the university was to select a technology that could be used in several instructional applications yet provide participating sites an opportunity to have a technology that also doubles as a powerful PC lab for training disadvantaged citizens in 10 rural parishes of central Louisiana. In effect, the network had to make available traditional courses for college credit and teacher certification, provide training for projects like "Welfare to Work" and others where people receive training on how to use computers in the workplace, and be connected to the global Internet/World Wide Web. This was a tall order for one technology, and especially a technology that anchors a multi-purpose distance-learning network. Desktop video conferencing was selected because it met all the criteria established in the grant and of course by the users who needed a cadre of services.

This desktop video conferencing network was the answer to several problems that faced the university. First, it introduced a new technology that addresses several distance learning challenges such as the need to see faces of teachers and students. Second, it provided a network where partnerships were established not out of need but necessity. Third, it allows courses for credit to be taught from any discipline without restrictions or limitations imposed by the technology. Fourth, it provides at least one site per parish where students, teachers and citizens can come together and take classes or participate in training sessions. Fifth, it affords teachers who have skills unique to a discipline, to teach classes to other students in the parish and across the state using their expertise. Sixth, it serves as a PC lab at the site and can be used for regular computer activities; not so with dedicated video compression classrooms and satellite studios. And seventh, it provides a low-cost alternative to video compression technology particularly since video compression sites were not located at public schools.

Even though Northwestern State University has in operation four distance learning systems, interactive satellite (limited because of cost), web-based courses on the Internet, video compression and desktop video conferencing it has made a commitment to this new technology and according to the desktop video software provider is the first university in the south to proffer a network like this. Collaboration within the university has expanded opportunities with desktop video conferencing. Another grant has been secured to establish a training facility for the College of Education to allow teachers to develop courseware using this technology and originate classes in graduate and undergraduate education from this site. This new lab will virtually double the teaching capabilities not only in kinds of courses but number of sections as well. The teaching stations have increased from four to fifteen. While the bandwidth needed to operate the system will limit the number of classes taught simultaneously, there will be adequate preparation stations available for teachers to prepare their classes in advance. Therefore, scheduling of classes, workshops or training sessions should be simple without sacrificing time for faculty to prepare; a problem that plagues many distance learning providers. Educational Technology in the College of Education will use desktop video conferencing to develop "hands-on" technology training, which until now has been limited, by most distance learning technologies. In effect, the faculty believes that most of the future movement in distance learning will be toward low-cost, web-based instruction on the desktop.

Funding for Desktop Video Conferencing

The initial funding for the desktop video conferencing system at Northwestern State University was supplied from a grant written to the United States Department of Agriculture Rural Utilities Service in August 1997. A second grant was submitted a year later to broaden the scope of the project to include five additional parishes in central Louisiana. The College of Education was awarded a grant in 1998 to parallel the RUS project, which would essentially double the teaching and production capabilities by establishing a second desktop video conferencing laboratory on campus, but in the Teacher Education Center.

The RUS project established a distance learning facility in ten parishes to address economic and educational challenges for the people of this predominantly rural area. These include: (1) K-12 education—standard, remedial and advanced placement; (2) higher education—undergraduate, graduate, and teacher certification; (3) adult and continuing education—GED, workforce development, and life-long learning; and (4) job searching. College-level courses were planned for the network and made available to those who are time and place bound with specific restrictions that limit their ability to take classes or attend workforce training sessions. Job training and information will also be available for those making transition from welfare to work. Public school administrators will use the system to collaborate on other initiatives by face-to-face
conferencing. The match for the project was 60 percent from the partnering institutions and 40 percent from the Department of Agriculture Rural Utilities Service.

The impetus for the grant was to address problems that faced the available user population from demographic data that include a rural population with a high drop-out rate of 50% to the ninth grade, 91% do not have college degrees, a large percentage of the population are classified as disadvantaged, and of those who attend college over 50% need remediation.

A second grant from the Board of Regents Support Fund, State of Louisiana, specifically addressed the need to prepare teachers for the emerging technologies such as desktop video conferencing. The College of Education at Northwestern State University is a leader and advocate of distance learning. The grant provided the tools for training per-service and in-service teachers and administrators to use these new tools. Area superintendents expressed a concern about the infusion of technology without proper training for teachers on how to use and integrate technology into teaching and learning. They were worried the problem may compound an already desperate situation regarding the attitude of teachers and parents about technology in the classroom. What resulted from these grants was the establishment of a network that accommodates a multitude of educational and work related issues while helping to better prepare teachers for using technology in the classroom.

The Desktop Video Conferencing System at Northwestern State University

The desktop video conferencing system at Northwestern State University joins other distance learning technologies on campus as the "next generation" of distance learning technologies. The projects valued at almost $700,000 impact residents of ten parishes in central Louisiana and teachers and school systems from throughout the state. It currently provides several undergraduate and graduate classes to rural parishes with several of those participants enrolled in classes for certification. Plans are underway to provide training to area teachers on technology use through courses and workshops. The system is user-friendly and accommodates the diverse schedules of students located across the area. And, when not in use as a distance-learning network it serves as a state-of-the-art computer lab for word processing, web searching, making power point presentations as well as other computer-related activities. These are ancillary services, of course, that most distance learning technologies cannot provide. Moreover, distance-learning technologies use fixed networks with dedicated classrooms and are usually not available as a technology support area.

A profile of the network is as follows. First, on campus there are two teaching areas on opposite ends of campus. One serves as a teacher and preparation site with four desktops while the other is a teaching/preparation and computer laboratory with 15 desktops that can also be used as a receive site. The sites are connected via T-1 lines to a server on campus then to the ten sites in the parishes. Second, each school site has ten computers configured in the lab with desktop software, camera and audio/microphone headset. The capacity of the system is three classes simultaneously. This means that at one site up to three classes could be received in one time block. Classes are currently offered starting at 4 PM and again at 7 PM if necessary. During the evening hours it is possible to provide six different classes per night or at least 24 from Monday to Thursday.

Ilinc Corporation provides the operating software for the network. The Learnlinc Version 3.1 software has a teacher or client area with conferencing window, class list, agenda list, and text chat area. Participants have a similar student area but without features that control the system. Learnlinc includes complete administration tools to register and keep records on students. It has a question and answer application, whiteboard, synchronized web browser and can use virtually any authoring tool. The Q & A application can be prepared prior to class and is a powerful device to check to see if students are grasping concepts being discussed in class. It is good for quizzes as well but has limitations as to how many questions can be asked. The Q & A application will report the results numerically or with a graph to the professor and students as desired. The system can promote interaction through "hand-raising." For example, if the professor asks a general yes or no question and seeks a yes response. Students click their "hand" icon. The teacher sees the hand appear next to the student's name on the roster. It is also a device to use when a student has a question. Control of the conferencing window can be passed to another student where his/her image in the conferencing window is transmitted to the entire class. Students may not pass control of the conferencing window but can do most other applications. The software works very well on T-1 lines but can work at lesser bandwidths.
While it is possible for all sites (100 students) to be enrolled in the same class, distance-learning protocol suggests that a class be no larger than a normal face-to-face class, which is about 30 students.

Desktop video conferencing, the RUS system at Northwestern State University, will compete with some successful distance learning technologies and initiatives already in operation on campus. Even though the network is in its first full year of operation it has already shown signs that it can provide high-quality cost-effective instruction that is meaningful, accommodating and user-friendly. As the group of users of distance learning technologies continues to diversify desktop video conferencing will continue to meet the demand.

The author wishes to express appreciation to Northwestern State University for access to grants and matches that support desktop video conferencing, the subject of this paper.
Abstract: This paper describes a course in multimedia for teachers taught as a one-week intensive course during the summer for a variety of types of students. The background and rationale for course design is discussed along with content and style of instruction are discussed. Throughout the paper, the authors describe experiences during the past offerings of the course. The paper closes with comments on the assessment of students (the grading policy) and assessment of the course itself (feedback from students and student performance in successive courses).

The Multimedia course is part of a graduate program designed to provide a masters degree for elementary and secondary school teachers, since New York State requires such a degree for permanent teaching certification. The degree is a joint one, with responsibility split between the School of Education and the School of Computer Science.

The students in this class fall into three groups. One group is the expected recent graduate going on for the masters degree. A second is teachers who already have a masters but wish to take the 15 credit block of technology-based courses that are part of this degree and constitute a "Computers in Education" certificate. The last group includes teachers who come for only one course, and often have a free voucher because of their involvement with student teachers from the University.

Given the different groups, a need exists for courses that are given in a format suitable for teachers. While this one-week-long course on multimedia is what the teachers want, the content and structure must meet what we see as the needs of the group: a course that will give them both the technology background and the knowledge to integrate that technology into their teaching.

As we structured the course, we posed the following questions:

- What should the course cover?
- How should it be structured?
- Who should teach it?

The course syllabus distributed on the first day contains the following definition of multimedia:

Multimedia refers to the orchestration of a variety of media, including text, images, animation and sound. One component of the orchestration is the feature of interaction with a user with the most common example being navigation through the material via clicking with the mouse. Material supporting this is called hypertext or hypermedia. There has always been multimedia but its latest manifestation can be called desktop multimedia. There are tools for the individual media types, tools for putting it all together and tools that support both creation and orchestration.
Course content

This definition for multimedia leads to our choices for activities during the week. From the technical perspective, the orchestration is done using HTML, a presentation tool (PowerPoint) or a stand-alone multimedia-authoring tool (Hyperstudio). We emphasize that 'content' in the form of images, animation and sound, can be used and re-used in different types of projects. For example, an image taken with the digital camera can be incorporated into either a PowerPoint presentation or a Web page. This is a difficult concept for some students, who tend to confuse the tool and the products of the tool.

From the perspective of integrating technology in teaching, the course is structured so students will use technology in planning curriculum that enables them to guide their own classes in multimedia preparation. We've built in practice in that area. The schedule given out is the following:

<table>
<thead>
<tr>
<th>Day</th>
<th>Hardware &amp; Software</th>
<th>Assignment(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monday</td>
<td>digital camera</td>
<td>PowerPoint: A presentation introducing yourself to the class</td>
</tr>
<tr>
<td></td>
<td>PowerPoint</td>
<td>Discussion: history, examples, choice of tools</td>
</tr>
<tr>
<td>Tuesday</td>
<td>Paint Shop Pro scanner</td>
<td>Original drawing, modification of acquired drawings (scanner, digital camera, download, screen capture)</td>
</tr>
<tr>
<td></td>
<td>Netscape Communicator</td>
<td>with explanation for how students producing this content will contribute to learning</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Discussion: classroom/school logistics; grouping</td>
</tr>
<tr>
<td>Wednesday</td>
<td>Sound Recorder NotePad &amp; Netscape Composer</td>
<td>Web/HTML project incorporating images &amp; sound &amp; hyperlinks, including template for students to use</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Discussion: models for students</td>
</tr>
<tr>
<td>Thursday</td>
<td>Paint Shop Pro &amp; Animation Shop Photo Editor</td>
<td>Web project(s) with animation &amp; image map including discussion of relevance to subject matter</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Discussion: teacher workshops</td>
</tr>
<tr>
<td>Friday</td>
<td>Hyperstudio</td>
<td>Hyperstudio prototype project</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Discussion: making assessments</td>
</tr>
</tbody>
</table>

In the above schedule, notice that we ask students to draw and make sound files, although many of them are uncomfortable doing so. Since the children they teach are expected to do these things, we encourage the teachers to experience this as well. The drawing and sound tools allow opportunity for creativity and fun and need to be practiced. Students take their own photographs, make original drawings, modify acquired drawings, plan and produce animations and also make their own sound recordings. The students learn that it is possible to make relatively simple drawings that still have educational content, e.g., a sketch of active transport by a biology teacher. They also learn that the production of a drawing, animation or sound file takes planning, attention to detail, and leads to a learning of the content material they are working with. They develop a "can-do" mentality.

Course structure

As the course content indicates, we've focused on assisting the students in integrating this technology into their own classroom curriculum. Some few students anticipate a more technically oriented course because the course carries a "computer science" designation. Since the Information System Department offers such a course, and because this is part of a teaching degree, we feel that an educational approach is most appropriate for this course.

We spend time at the beginning of the course on developing an educational philosophy appropriate for teaching with technology, and carry that throughout the course. We discuss teaching materials as the students need them, rather than lecturing at the beginning of the lesson. We emphasize the need to permit students to make mistakes and learn to correct them, rather than the teacher being the fount of all
knowledge. We model and also discuss how much more satisfying it is to work collaboratively to solve in-depth problems.

We are fortunate in being able to teach the class in a computer classroom in which every student has his or her own computer. Headsets are available for sound recording and playback. The room has a feature, with the brand name "Robotel", in which the display of any computer, the teacher's station or any student's station can be shown on all computers very easily and quickly. Everyone can demonstrate his or her projects to the whole group. We can have different students teach or demonstrate special techniques to everyone from their own computers. This feature facilitates the type of teaching and learning that we want to model for our student/teachers: a focus on students collaborating and sharing.

**Style of Instruction**

The course includes several different software packages and a fast pace of delivery. It was important to us to do more than just demonstrate keystrokes. Furthermore, we wanted to make sure the participants each make actual use of each package. Since we are teaching teachers, we have the explicit challenge to demonstrate how they would teach the use of tool as opposed to just demonstrating its use.

In some cases (for example, PowerPoint and Hyperstudio), we demonstrate a small number of actions and then let the students experiment themselves. We offer individual help and, while doing so, make a list of additional operations to be demonstrated by students to the whole class. The room projection system makes it feasible to go in and out of this 'sharing' mode quickly. At the end of the day, we have each student present his or her work. Their presentation includes explanation of their plans for classroom use.

In other cases, such as teaching HTML, we prepare examples beforehand. We prepare a type of template that has some explanation of HTML features, but also includes content or subject matter examples and direction. This is a way for a classroom teacher to indicate directly what the assignment task is.

Our approach in HTML is to ask students to know, or be able to lookup or copy examples of tags, and to generate the HTML using NotePad. Our experience has been that if students use tools such as Front Page, the results tend to include less real content and more distracting clip art. In certain cases (probably not this compressed one-week class), after students become familiar with making tags, we demonstrate Netscape Composer and indicate where it is advantageous (for example, constructing tables) and where it can be problematic (for example, creating a simple link to another page). For the HTML, we also use the tactics of recruiting students to demonstrate and explain features. Similarly, we include a more or less formal presentation from everyone at the end of the allotted time period.

For drawing in Paint Shop Pro and animation in Animation Shop, we do express humility about our own skills. Our tactic is to say, "if we can do it, anyone can" while producing a goofy version of a smiley face. Similarly, we produced an animation of a cookie being eaten by successively erasing irregular parts of the initial drawing. More significantly, when we go around the room seeing who can demonstrate features of the tool, we have always been able to feature examples of relatively simple drawings that still demonstrated important aspects of subject matter.

**Typical Issues**

In this multimedia course, we strive to have students acquire images in all the ways discussed: taking their own digital photographs, scanning pictures from photos and text, downloading images from the Web, making their own drawings, and modifying and combining images. We try to be sure that every student attempts every method.

Many students confuse the product of a tool with the tool itself. In particular, they need to be shown repeatedly that an image they created in one specific way can be used in more than one package, be it a PowerPoint presentation, a Word document, or included on a Web page or in a Hyperstudio folder. They
also need to learn that an image can be modified by another tool to produce a new image. We actually require that they do re-use (re-purpose) images and sound files to reinforce this concept.

A more basic source of problems is in naming and saving files. Students frequently cannot find the files they have created or modified. The Windows operating system is a source of some of the problem since in many cases, the dialog box will not show the extension or the target folder. We suggest to our students that they define naming conventions for their own students when they get to their classrooms.

**Course faculty**

This course is the responsibility of the School of Computer Science. The first few times the course was offered, it was team-taught by two faculty members, one from Computer Science and one from the School of Education. The joint planning and teaching set the direction for the course content. It also made it evident that the course is much easier to teach when there are two instructors in the room. This past summer, the faculty member from computer science taught the course alone, while still maintaining the same focus on pedagogy. A very knowledgeable University student was recruited to assist two of the days, making it possible to continue to deliver a great deal of one-on-one instruction.

If other people are to teach the course, we will recommend that there be some assistance available for the first few days of the course. In addition, we would also recommend that, at least initially, there be some team teaching required for the faculty. The learning that took place on the part of each of the faculty members involved has been necessary to make the course a success.

**Assessment of students and course**

The grading policy of the course has been fairly benevolent, since it is a one-week course. Given the time, any reasonable effort on each project resulted in an A. However, practically all students appear to be working diligently all day, often through lunch, and we do have to kick them out at the end of the day. We do discuss grading of multimedia projects and encourage the specification of well-defined rubrics that focus on the underlying subject area.

There is a possibility that the course will be more than one week in future offerings. In a less compressed version, we would require more extensive project-based work and more formal written explanations of the theoretical rationale. The ideal format would probably be one in which the one intensive week was followed by one short session a week later. This would give the students time to refine their projects and to give more thought to how they could use the tools more effectively in their teaching.

The informal and formal feedback from the students, for the most part, has been strongly positive. The students claim that they work hard and "learned much more than they expected in the week." There is evidence that the students retain much of what they have learned as they continue in other courses. For instance, the students who are in the masters program or the certificate program eventually take a capstone course requiring extensive technology in teaching. Their projects in the capstone course show the knowledge gained in this multimedia class and the fact that there has been extensive retention of that knowledge. They continue to use multimedia, and continue to use it to promote teaching and learning.
Ten Years on: Assessing Multimedia Distance-Learning

Christine Vaillant-Sirdey
Laboratoire LAIRDIL
IUT - Université Toulouse III
France
Vaillant@cict.fr

Abstract: This paper is a presentation of a 10-year experiment in multimedia distance learning in English for specific purposes within the general frame of a 3-year management diploma in the French higher education system. It defines analyses and rationalises key elements in the technical evolution against a background of epistemological and present didactic academic standards gleaned from literature scanning. An overview of the milestones of the experiment is given pinpointing some successes to adopt and pitfalls to avoid.

Introduction

This paper is a presentation of a 10-year experiment in multimedia distance learning in English for specific purposes within the general frame of a 3-year management diploma: Diplôme Universitaire de Technologie en Gestion des Entreprises et Administrations. The Instituts Universitaires de Technologie – IUTs where it takes place, are institutions of higher education within the French university system that lead to a professional degree. Over 100 IUTs account for about 10% of the student population in France. Each IUT has several departments corresponding to different technological specialities in the secondary and tertiary sectors of the economy. This multimedia project was first launched by the French Ministry of higher education in 1989 in 4 experimental IUTs as an alternative to the traditional studies. The range of available multimedia tools was very narrow at that time which led us to focus primarily on the pedagogical shifts induced by the introduction of both distance and emerging multimedia tools. Since its launching in 1989 the tools have evolved at a tremendous speed and what was considered in the first years as a long-term objective turned into actual effective, ready-to-use instruments within a very short span of time. We had to navigate between pedagogical conceptual constructions, highly sophisticated, not really user-friendly tools and real life students. While technology was evolving we have always maintained a flexible system in which the students may avail themselves of analog or digitalised materials according to their needs and capacities. In this paper we will attempt to define, analyse and rationalise key elements in the technical evolution against a background of epistemological and present didactic academic standards gleaned from literature scanning. The general term of «multimedia» refers to tools as well as contents and practices. We will review what it represents in the context of our courses in connection with the various underlying models of learning and their associated strategies as well as the field of second-language acquisition. Our ultimate aim is to provide the teachers engaged in or envisaging off line and on line distance multimedia teaching with an overview concerning: the technological evolution of IT tools, their didactic and pedagogical added value and the problem of the assessment of students’ work.

The General Frame of The Experiment

The nation-wide project presented here was first launched in 1989 by the French Ministry. It consisted, in fact in, a mere injunction from the hierarchy to field practitioners to try and set up an innovative distance training using «multimedia» tools in Business Administration. Similar projects were also run in speciality departments in the secondary sector.
It was opened to both initial and adult students. The official national curriculum was re-shaped into a set of 9 credits corresponding to the main fields of study, each one split into 3 modules, one for each year (cf. http://www.geapx.iut-tlse3.fr/programme.htm). The studies were organised into alternate distance learning periods of 2 weeks and one in-site regroupment day every other week. In the case of our IUT, - which is presented here- Resource Centres were set up in 3 cities situated in a radius of 80km from Toulouse. 3 years ago a fourth was added and we now have another one within the university itself. These resource centres are accommodated in different types of institutions such as Chambers of Commerce, vocational centres, university distant-branches, etc. They provide the students with communication and pedagogical hardware and software material. This experimental program has dealt so far with a limited number of Students. Over 1,000 students have since graduated from the various IUT's involved in the project (approx. 100 from Toulouse) This paper deals more specifically with the teaching of English.

Who are our students?

The student population is very heterogeneous in age, social and educational background and life environment. Some are high-school leavers; others have already been in the work-market for years. Accordingly their initial training in English, can still be very vivid but frequently very "bookish" or reduced to a blurred souvenir. Worse they very regularly suffer from a common nation-wide so-called « French inability to master foreign languages ». The picture is not always as black as it may seem here but it is true to say that there is a wide discrepancy in the students’ minds between the mitigated image they have of English and the nearly inescapable obligation to master it in the global exchange and communication environment they live and work in. This psychological aspect is also present in traditional language classes but quite often buried under routine teaching strategies. Because of large numbers of students and the relatively small amount of time devoted to language learning, it is widely assumed that the class must globally adjust to a theoretical average student’s pace. It consequently tends to lose the attention of the quicker and slower ones who, put together, may amount to the majority, if not sometimes the whole class.

Since distance implies remoteness, for the same number of students as in a traditional classroom , a distance learning scheme results naturally in individualisation. The dark side of it can be isolation but it can also permit individualised counselling and hence a real learner-centred training. This was an opportunity we spotted from the very beginning of the project. The entire curriculum was designed with a view to holding together the official curriculum requests with - and not at the expense of - the genuine interests and needs of the learners. We contend with Philips (1987) that « the language to be learnt must correspond to actual pragmatic needs to the learner ».

Their role and ours in the light of theory

On a purely theoretical cognitive level we are in favour of a balance between the generative and the constructivist learning theories. We do believe that « the learning process is not so much the result of an accumulation of layers of knowledge brought in from outside as the progressive elaboration of a personal inner object of knowledge » (Fijalkow, 1996). Referring to Vygotski (1985) he claims that it is therefore a non-linear, discontinued process that we view as not merely fuelled from ready-made outside pedagogical sources but by the learner’s output feedback.

Therefore to us, the teacher’s role is to constantly adapt and re-inject materials tailored with or according to the learner’s own production. This is in tune with Von Glasersfeld (1989) who stresses that learning is basically a process of discrimination. We fully support that: « [Thus] the preferred current strategy [...] is that once learners have absorbed some chunks of language and patterns of communication, they should be given access to the underlying model via a guided discovery approach that uses both learner-controlled exploration and teacher-controlled demonstration ». (Scrimshaw 1993, p147).

The real challenge/opportunity in multimedia distance learning is to take advantage of both distance and technology: distance as a means of responsibility and introspection on the learner’s part on the one hand, Information Technology as a powerful means of communication and tutored progression, on the other hand. This implies that students are able to manage their learning progress in an autonomous way. Very early in the project, it became apparent that it was not the case for a large majority of students. A new methodological
module was set up which proved to be absolutely necessary and evolved over the years from a short ½ day quite informal meeting to a very structured one-week session.

Contents

This National curriculum covers the four language skills: oral and written comprehension and expression applied to social and professional situations. The scope is much too wide to be met within the 3 modules. We therefore selected some priority sub-objectives according to the students' needs as follows:

- Checking and up-grading grammatical competence
- Improving aural comprehension
- Training in oral expression and production
- Training in specific BA language
- Restoring or building a positive socio-linguistic approach to English

These language skill objectives are spread over the 3-year span of the studies. They are embedded so to speak in different tasks and different tools (cf. table 1). Levy (1997) reports that 2 studies by Robinson et al. (1985) and Verano (1987) conclude that « [These findings] highlight the importance of integrating individual CALL work with the total program of language instruction, including the classroom, rather than configuring it as an independent, supplementary activity ». It is all the more true in our case where the classroom is so called virtual, except for the regroupment sessions. It implies that the pedagogical contents of the tools available to the students cannot merely « illustrate » our academic knowledge delivery since there is none. They are both, in their contents, form and interactivity, « the » knowledge to be grasped and encoded by self-reliant students.

Tools

Since its launching in 1989 the available tools have evolved at a tremendous speed and what was considered in the first years as a long-term objective turned into actual effective, ready-to use instruments within a very short span of time. We had to navigate between pedagogical conceptual constructions, highly sophisticated, not really user-friendly tools and real life students. While technology was evolving we have always maintained a flexible system in which the students may avail themselves of analog or digitalised materials according to their needs and capacities.

Starting from a total lack of digital medium, we have been through the era of floppy disks to diskettes, non-recordable then recordable CD Roms, and eventually DVDs, from mere fax machines to present high speed communication tools on the Internet.

The tools we are currently using are non-modifiable commercial educational software (Web English, Mediaconcept-Citcom) other commercial applications not specifically designed for educational purposes (Finance for non-financing managers), authoring tools enabling the digitalisation of existing teaching materials such as audio and video recordings used over networks (Intra and Inter) or on standalone machines (Lavac)¹, synchronous and asynchronous communication tools via intranet and internet, university-designed Web site as well as free Internet site educational facilities such as conferencing, document posting, class schedule, class administration, etc. One can also mention the use of survey or polling software turned into exercise processors. Videoconference is also available although not very much used and MOOs are envisaged.

We basically remain teachers and we are qualified to design our own course. According to the theory we exposed earlier it is evident that we are in favour of tools which enable us to adjust the program to the needs of our learners and of ourselves. We differentiate the guided autonomous learning we are engaged in, from self-instruction, which excludes the presence of a teacher. In our case we are in constant exchange process (either synchronously or a-synchronously) with our students and it is essential that a large number of the tools we use be flexible enough to, in a way, comply with our requirements.

We have always tried to keep up with the technology evolution with one notable restriction. As a matter of fact is it absolutely essential that all the students have access to the same tools. This means that we sometimes cannot use new ones, which offer more interesting services just because they are not compatible with

¹ Lavac is a rare example of an authoring system primarily devised and designed by a language teacher. Toma (1996)
one or several resource centres’ configurations. Some students may also have lower configurations at home whether in terms of machines or telecommunication connections. In short that means that very sophisticated equipment has to be left aside for practical everyday reasons. (Tab. 1)

The assessment problem

Another difficulty is the processing of the bulk of data we receive from the various tools concerning our students’ progression. Some charts are totally useless. Others are too detailed and it requires both methodology and organisation to spot the accurate information. Not to mention the flow of questions, reactions or mere information mailed by the students themselves. Still, it is essential to keep in mind that every student expects his or her « personal » teacher to be available and caring. This is a big change from our previous experience in the traditional French education system which has always been mainly teacher-centred. Even though active pedagogical theories have been put into practice over the last decades thanks to precursors like Montessori, Piaget, La Garanderie or Trocmé-Fabre it is true to say that learners throughout the system have remained somewhat passive and the introduction of distance combined with I.T usage has definitively given them a better command of their learning process and therefore more efficiency.

We have not yet solved the problem of Examination Paper Structure. The official system of evaluation requires everybody to take the same subject and to be evaluated against the same criteria. We encourage students to take a positive look at their language training regardless of their previous experiences, and to work at their own pace. We cannot therefore expect every one of them to attain a theoretical common level of proficiency by the end of year 2. The examination is rather an opportunity to demonstrate what they have learnt during their study of the course, whatever « what » is. We can see how much a student has worked and it is fairly easy to assess the quantity and quality, but the mark given doesn’t necessarily reflect the level of language proficiency. The electronic submission of assignments still poses problems. The traditional system has not yet evolved to fit new methods of teaching and learning.

Conclusion

Possibilities appear everyday and we believe that as teachers, it is our role to keep up with technological evolution in order to ascertain that students benefit from these tremendous capabilities without losing academic content value. It is also our contention that if it is the teacher’s role to choose the appropriate tools and media according to his or her teaching goals as well as the students’ needs, this is all the more true as
regards the design of his or her own multimedia courseware. It is also absolutely essential to say that strong support services are critical to success and that new rules must be set up to organise the collaboration between professionals who have never before worked together on such terms.

Teachers are often said to be afraid of being replaced by machines. That might well happen if technology remained in the hands of commercial businesses. But our experience, among others, proves quite the contrary when they are used as support for strong pedagogical theories.

Interactive Multimedia as Research Portrayal

Marlo Steed

University of Lethbridge
Canada
marlo.steed@uleth.ca

Abstract: This paper reports on an ongoing project to implement an interactive on-line multimedia web site for communicating research and development results. The value of multimedia for activating rich knowledge structures is documented in the literature. However, using multimedia as a communication device for publishing research has been largely unexplored. A research and development project into online distributive education will be used as an exemplar of how this can be implemented.

Introduction

The Faculty of Education at the University of Lethbridge (Canada) has been doing an ongoing investigation into the effectiveness and feasibility of online distributive education. A number of online courses have been developed as well as courses that are blends of online and face to face contact. As part of the development of these courses a number of custom tools were developed or generic tools were adapted. In addition, over the past years there have been a series of Science Institutes put on for practicing teachers in the field. These have been extremely popular and teachers have been enthusiastic about going back to their own classes with pragmatic ideas gained from these professional development sessions. However, one of the challenges of doing research into the effectiveness of these kind of initiatives is the degree to which text alone can adequately retell the participants' experiences or describe the tools. These initiatives can be set to words but words seem to fall short in describing an attitude reflected in the intonation of a voice or an interactive is easier to demonstrate than describe. In an effort to address these problems, a multimedia web site is under construction with the intent of communicating the results of that research to interested stakeholders. In this case the stakeholders are corporate sponsors, university administration, government granting agencies, colleagues doing similar research, and perspective participants. All of these stakeholders have an interest in the context of the course offering, its effectiveness, what the tools look and act like, and what participants thought of their experience. The web site is designed to showcase the results of the research and development efforts through various types of media. The media includes, pdf files, images, video clips, demonstration of interactive tools (shocked files), linked resources, etc. It is hoped that a multimedia approach can provide a richer experience than what text alone can provide.

Background

The literature on multimedia and its effectiveness is still quite sketchy but there is an overall sense that multimedia can have a positive impact on learning. There has been even less investigation into how multimedia can be used to enhance the communication of research results. Understanding how multimedia influences student learning, however, may transfer to interactive multimedia as a research portrayal. To that end this next section will provide a brief review of the literature into multimedia for learning and make connections to how it applies to multimedia research portrayals.

The definition of multimedia has changed over time. It started out as the idea of multiple media
devices being used in combination. Because of technological advances, there is a blending of these mediums into one device, the computer (Kozma, 1991). It is the juxtaposition of multiple representations that is the affordances of this tool; it is the combining of sound, still image, video, animation, text, music, and virtual reality to provide the user a multisensory experience. Interactive multimedia narrows the focus. Interactive suggests that users have a degree of control over the presentation of multimedia rather than being passively presented with the linear delivery of information. There are those that suggest interactivity cause students to spend more time on the material. Kennedy (1994) reports that using interactive multimedia allowed students to progress at their own rate and to quickly search information. It seems reasonable to suggest that researchers have strategies for reading textual reports that is anything but linear. A typical approach is to read the abstract, jump to the introduction and conclusion and then to a quickly skim of the rest, if something looks more important or relevant that it is read more intently. What if the structure of the document reflected this form of perusal? Interactive multimedia is easily setup to facilitate this kind of nonlinear exploration of the information (Campbell, 1997). For instance, if the reader wants more background they can drill down through the structure of the multimedia project. The other related issue is that the developers of the multimedia project can build in a great amount of data or content in bite-size pieces but the user retains the option of looking at it or not. Interactivity can be an important component of multimedia enabled publications.

Multimedia provides an environment where the users can explore the content from multiple perspectives. "Knowledge that will be used in many different ways has to be represented in many different ways, with the potential to form various combinations" (Spiro & Jehng 1990, p. 203). Studies indicate that problem solving is enhanced with the use of multiple representations (Steed, 1994; Crosby and Stelovsky, 1995). When text and images are presented concurrently this tends to result in better learning than if either are presented separately (Mayer and Sims, 1994). It is thought that if we are stimulated with more than one sense the experience is more meaningful and memorable. Pavio's research (Dual-coding theory) (1986) suggests that some kinds of knowledge can be reconstructed easier if images are used. It was also found that concrete words have a similar effect (words that paint a picture). Other research has shown that a combination of verbal and visual information are better than either presented separately (Mayer & Anderson, 91). Books use primarily text to activate knowledge structures but it has been found that if meaningful images are included it is useful and can particularly help novices (Kozma 91, Mayer, 91). The out shot of this is that there should be a correspondence between the nature of the research results and the way in which it is portrayed. When the research involves rich and thick descriptions then the form of representation should reflect that. For instance, video is an excellent medium for viewing a complex scenario where individuals are interacting with each other or their environment. Imagine that same kind of scenario described with words. A video is much easier to process because of the way the visual and auditory system parallel processes incoming information.

On the affective side, students express that they enjoy learning from multimedia (Atkins, 1993), but liking it may not correlate with learning. However, if the material can be made more interesting or engaging then surely that speaks to its effectiveness for communicating ideas. The audience will be more likely to pursue the information further and it will be more memorable because the multimedia experience potentially creates a richer set of connections, which are available when reactivating knowledge.

It was found that for students who needed conceptual organization of the content, creating hypermedia helped (Spoeher, 92). Multimedia often can graphically represent the structure of the content so it is visually accessible. Hypermedia students seemed to have richer knowledge structure than students who didn't engage in that activity and seemed better at organizing information (Spoeher, 93). Through the use of multimedia as a research portrayal tool perhaps there would be alternative ways of representing the logical structure of information. For instance, what if there was a conceptual map of the content, and each node on the map was a hot link that goes to a different level of organization, how might that type of portrayal change the way the audience represent ideas in their minds?

The notion of virtually being there, seeing the people and experiencing the tools that were used might move stakeholders to a better understanding. Stakeholders can more closely approximate the real world
experience by entering virtual worlds which provide the advantages of situated learning (Brown, 95). That emphasizes the importance of context and multimedia may be viewed as a much more immersive environment in the sense that you can potentially get a better sense for context, by seeing or hearing it. This potential benefit comes through the depiction of real-life situations with the use of digital photos, video, and sounds (Wissick, 1996).

There is a clear sense from the literature that cognitive style has an influence on the effectiveness of multimedia (Crosby and Stelovsky, 1995). Those with visual spatial tendencies tend to do better in multimedia environments whereas those with low spatial ability are thought to require more cognitive energy to build connections between representations (Mayer and Sims, 1994). This supports Howard Gardner's concept of multiple intelligences (1983) that suggests each individual has different ways of knowing: mathematical, linguistic, musical, spatial, bodily kinesthetic, interpersonal and intrapersonal, etc. Traditional research publications for the most part are represented in linguistic forms, by enabling multimedia forms, alternative learning styles might be activated that would engage the stakeholder in the content to a greater extent.

Interactive multimedia has potential pitfalls. For instance, interactivity can back fire; allowing users freedom of control may result in information that is skipped over or never viewed at all. It is suggested by some that students have poor self-regulation behaviors for making informed decisions about their learning path through multimedia materials. Clark, R. E. (1993) challenges the value of interactive multimedia and suggests we need more research. Educators on the whole seem less likely to accept visual portrayal as opposed to verbal or written arguments. Think about the kind of tools that are provided students during an exam, technology is rarely considered a necessary tool. Despite this, multimedia has such potential for providing metaphors or leverages to create mental imagery (Reiber 1995) and to help us communicate (Dede, 91).

The use of multimedia as a form of portrayal for communicating research results is something, which needs further discussion. It potentially provides a multisensory experiences which works to reinforce and highlight dimensions of the data, the researcher can use multimedia to express ideas in new ways, and it extends the definition of what is considered data (Campbell, 1997). Campbell goes on to suggest that using multimedia as a portrayal tool facilitates triangulation of data because different media types can be cross linked and represent the same concept from different perspectives. This in turn addresses credibility in qualitative research. Multimedia also lends itself to transferability through rich and thick descriptions available through video and audio elements. Understanding that alternative forms of representation have value for negotiating meaning should help us move in this direction. Second, building structures that encourage such options should be considered because we don't all think and process information in the same way and multimedia provides us with multiple representations.

There is a growing trend to use multimedia as tool to present and document educational research. The nature of emerging tools lends itself to new ways of gathering, analyzing, and sharing those results (Goldman-Segall, 1995). The benefits to learning listed above in the literature review are justification for using multimedia but there is another reason that seems to have an equal, if not a greater influence, that is the Internet. The advent of the Internet has inadvertently injected multimedia capabilities into electronic publications. As research publications move to the World Wide Web to facilitate dissemination, they naturally set themselves up for other forms of portrayal besides static images and text. Despite the potential the technical barriers for doing this are not insignificant. For instance, this document is published in PDF format and it was noticed that the sample RTF file implicitly suggests sticking with standard text and still image type of forms. What if the publication were to have a section on how to include other types of multimedia elements like, video clips, animations, virtual reality (VR), and sound files. The Internet provides a partial solution in that a URL can be imbedded in a document and interested individuals can link to that and see other types of information but then it is not part of the published work per se. Limited bandwidth is another limitation Most people are still hamstrung with slow connection speeds but that is changing quickly with the implementation of cable modems and ADSL connections. CD and now DVD provide a viable alternative in situations where large multimedia elements are intensively utilized.
The Web Site

To illustrate the concept and value of alternative forms of communication, a web site is being created as an exemplar. This web site will portray research done into the usefulness of online distributive education over the Internet. The secondary goal of the project is to facilitate the communication of tools, ideas, and experiences through multisensory experiences. In order to accomplish this, the demonstration and description of the tools are juxtaposed with supporting textual, auditory, and visual elements. These multimedia elements provide a rich source of information while the interactive component provides the audience an individualized route through the content. There are four kinds of data that the project uses in the web page. This is data collected through video taping sessions of both instructors and students (formal interviews or otherwise), anecdotal comments made through email messages or submissions to online databases, verbal descriptions of the tools and how they were used, and animated demonstrations of online tools. The intent of this is to allow other participants of these online courses and interested educators, an opportunity to hear the voices of students who have used the online components, get a feel for the kinds of issues raised through email correspondence, and sense for the tools that were used.

Before placing the video clips in the public domain, participants sign a release form and are given the opportunity to preview them to ensure they agree with the intent and the context they will be used in. Student participation is optional, as stated in the consent form.

Below is information that appears on the web page. The textual description is there to ensure there a context to the information. However the multimedia portrayal table is the driving interface for accessing the multimedia components. A table was decided on because the structure of the information (tools versus portrayals) matched the structure of the tool. This table acts like an index and links the audience to a desired section.

Background:

This study is sponsored by the Information and Communication Technology Research and Development (ICTR&D) project in the Faculty of Education at the University of Lethbridge, Alberta, Canada. The objective of this project is to study the effectiveness of on-line distributive learning. This document will use a variety of portrayals to represent the online tools which have been used to enhance online learning. It is hoped that such descriptions and representations will facilitate decision making for other educators and to communicate the nature of the experience.

Purpose:

The term "distributive" suggests that learning is not just the delivery of information but that information becomes transformed to knowledge and understanding. This process involves more than passive involvement so part of the mandate of this project is to explore diverse instructional strategies that engage the learners with the course materials, with other participants, and the instructor. This report will not make summative judgments as to the effectiveness of the tools nor the instructional design, rather it will provide context and data to help draw your own conclusions.

The Multimedia Portrayal Table:

Below you will view a table of links that will assist in creating a representation of the online course experience. Clicking on the various cells will open a new window with more information. Once you have viewed that information and want to return to this page, close that window. The data has been
drawn from an education graduate course, Educ 5410, Program Evaluation, offered in the Spring of 1999. The course was totally online. There were two sections of the course offered but only one class was sampled for video interviews, one that was totally done online and one that had a number of components online. The student information below comes from the totally online course but the instructor perspective comes from both offerings. The students were selected based on the instructor's view of a broad perspective (students who struggled and those who excelled and some in between). The description will provide a textual account of the tools, the samplers are illustrative examples of the tools, student email comments are email correspondence from students related to that tool, student video interviews are video taped interviews with a sample of the class, and the instructor video interviews will provide the instructors' perspective.
NOTE: S1, S2, S3 represent links to video taped interviews of different students, I1 and I2 represent links to video taped interviews of different instructors, likewise comment 1, comment 2, represent different student comments from email submissions. In the web version all the items in the table will be hot links, unfortunately in this version the links don't work.

This web page is intended to provide stakeholders with a altered perspective about the effectiveness of this online course because of the multimedia elements that are present. The actual web page can be accessed through the following URL:

Conclusions

This project is a work in progress, but the long-range intent is to research the effectiveness of multimedia for communicating research. Researchers and educators alike will be able to use the principles coming out of this project and apply those to their own multimedia publications. It is also hoped that this will facilitate a move by journals, conference proceedings, and professional associations to encourage and facilitate the creation of multimedia enhanced publications.

Development of two Multimedia Corpora for Adaptive Web-based Distance Learning

Evangelos V. Kopsacheilis
Emedia EVK Ltd.
Greece
Email: info@emedia.gr

ABSTRACT: The use of web-based applications for accessing structured educational material is one of the most interesting variations of Distance Learning due to its flexibility and its reduced cost. In this paper we present two cases on the usage of a web-based system designed to support online educational procedures. The presented system, called DVT (Dynamic Virtual Trainer), consists of one or more server machines which store structured educational material in the form of autonomous units which may accessed, combined and presented to the user according to user-defined criteria or choices. In order to demonstrate the system, we developed two educational packages. The first package includes educational material on Telecommunication technologies. The second package includes educational material on Mount Athos.

Introduction

In the context of Distance Learning a critical factor for the success of a specific course is the possibility of the students for accessing interactive educational resources such as animated presentations, multimedia libraries, etc. Students tend to learn more in classes in which they receive computer-based instruction supported by interactive educational information packages (Kuperstein et al. 1999). The design, development and delivery of such educational resources usually require significant effort to be spent by the teacher or the producer of the electronic educational material. In addition, a teacher should have considerable experience in computers and web authoring in order to produce a multimedia course tailored to the specific needs of a class or the needs of a geographically dispersed group of students. The problem of time consuming development of electronic educational resources may be faced through the use of flexible tools for the composition of electronic educational material. Using these kind of tools a teacher could easily create, enrich and maintain a body of electronic educational resources without the need of extended skills on computers and web authoring. As a result, the usage of such flexible tools may promote the introduction of information technologies in the day-to-day teaching practice.

In this paper we present a flexible architecture called DVT which stands for Dynamic Virtual Trainer (Kopsacheilis et al. 1999). We also demonstrate its use in developing two educational packages (multimedia corpora) on different subjects. The proposed architecture allows the dynamic composition of online lessons based on the combination of educational units according to varying user needs. The educational units are short composite entities of a variety of types like modules in HTML (HyperText Markup Language), virtual reality representations in VRML (Virtual Reality Markup Language), text, audio and video clips, etc. (Minoli & Keinath 1994). The dynamic composition of the lessons may be guided either by user defined search criteria or by other types of parameters like the desired level of lesson details, the level of relevance to other topics, etc.

A Flexible Development Platform

DVT is based on one or more servers who store the educational entities. The users are connected to the server through a common Internet browser and they have access to the introductory web pages of the server. The most important feature of these pages is the possibility for tailoring the lesson to be presented through the selection of the focal points of the discussion, the analytical level of the lesson, the levels of accompanying information, etc. The user may select one or more predefined lessons out of a menu. A much
more dynamic possibility is the real time composition of a lesson according to criteria entered by the user. The user may also use a set of questionnaires that accompanying the lesson's elements in order to self evaluate the educational procedure. The questionnaires are highly configurable (simple true-false answers, multiple choices, etc.). In addition a questionnaire may be easily formed to support the user providing tips, summarized information, etc. DVT uses the Internet-Intranet communication technologies for the distribution of the lesson (Halsall 1995). The entire architecture is supported by a DataBase, which keeps the relations between the elements of the educational material. The educational material stored in the server has the form of simple and short packages of information describing a specific topic, which are called Information blocks (IBs). An IB may include HTML pages, VRML representations, text, audio or video clips or a combination of the above components. Each IB corresponds to a set of parameters called Connectivity Block (CB) which supports the dynamic composition of the lessons. These parameters are used by the DVT Data Base in order to combine each IB with other relevant IBs or in order to combine the IB with a questionnaire. Finally the CBs include a set of key words which are used to select the specific IB each time the user enters one of the specific key words. A group of IBs forms a Chapter. A Chapter is focused on a set of relevant topics. A group of Chapters forms a Book. A Book covers a wider group of topics. This structure is depicted in Figure 1.

![Figure 1. Information Structure in DVT](image)

The overall quality of the produced lessons is a function of two factors: a) the multimedia content of each educational unit and b) the structure of the lesson which is reflected in the relations of the educational units. Courses for distance learning usually include a mix or a combination of various media. The key factors in the choice of media are the course objectives, the intended students and their geographical locations. The flexibility of the proposed system is based on the fact that any type of educational media may be incorporated in a course and presented by the system. The supported media include audio, video, text, images, Virtual Reality representations, etc. The increased flexibility of the system allows the designer of a lesson to customize and tailor the lesson according to specific student needs and, through this customization, to increase the educational effect of the lesson. The user-friendly environment for developing new educational courses is based on tools for easy composition of educational units and questionnaires. In addition the proposed system incorporates tools to setup relations and dependencies between the educational units. Finally, the educational material produced in the framework of a lesson is reusable in the sense that a number of autonomous units may be used for other courses. This is accomplished through the definition of a new relation of the educational unit in the framework of a new lesson. Based on this feature, a Virtual Reality representation of an ancient temple may be used in a course on architecture as well as in a course on ancient history, or even in a course on geometry. The proposed architecture supports the dynamic composition of related and mutually depended educational entities. The overall effect of the produced lessons depends on two major factors:

a) The structure and quality of each educational unit, and;
b) The overall course design, which is depicted in the relations between the educational units.

The proposed system allows the distribution of the dynamic educational material through low cost Internet based infrastructures. The DVT architecture is open and allows the integration of supporting
applications like real time video or voice conferencing packages. The educational resources provided to the
students may be considered as a powerful complement of teleconferencing. DVT may be implemented on
low cost hardware, software and communications platforms.

It is important to emphasize that the proposed system is not a specific implementation of an online
course. It should be considered as a generic development platform, which allows the creation of interactive
lessons on many different topics from different areas. More precisely, the proposed system allows the
educator to create electronic educational libraries of short and autonomous entities, and to compose their
contents to complete lessons or courses.

Using DVT for the Development of Educational Corpora

The above-described DVT architecture was used for the development of two educational packages
on Telecommunications and Mount Athos respectively. We use the term Multimedia Corpora for the above
educational packages in order to emphasize that they are complete educational entities made from
multimedia educational material. Mount Athos is a peninsula in northern Greece. Twenty Monasteries are
located on Athos since the medieval age (10th century) forming a unique monastic state. This package
presents the history, the medieval artifacts, the natural environment and flora and fauna of Mount Athos.

The topic of telecommunications is presented mainly by means of text and animated graphics. The
text modules include definitions and descriptions and the animated graphics are used mainly to accompany
and support the descriptions. This package also includes a number of exercises and multiple choice
questionnaires for self-evaluation of the users. The subject of Mount Athos is presented mainly by text,
photographs, audio and video clips. Both corpora include educational information covering a variety of
subjects. In Table 1 we summarize the presented topics.

Table 1. Summary of Subjects Covered per Educational Package

The two corpora are presented to the users over Internet connections using the DVT dynamic page
composition system. The composition is performed on the basis of user-defined choices. Examples of
choices are the level of details, the focal point of the discussion (i.e. Geography vs. the History of a region),
the level of difficulty, the level of correlation with relevant subjects, etc. Figure 2 depicts a screenshot of
the educational package on Telecommunications. Figure 3 illustrates a screenshot from the package on
Mount Athos.
Figure 2. Screenshot of a dynamically composed page on Telecommunications Technologies

Figure 3. Screenshot of an introductory page on Mount Athos
Conclusions

The paper presents two educational packages developed using the DVT platform. Due to the flexibility of its architecture, DVT may support the development of electronic educational packages on a variety of subjects. The two packages cover Telecommunications and Mount Athos which represent two totally different topics. The DVT architecture has the advantages of flexibility, low cost and ease in developing new educational material and new courses. The advantage of low cost relies on the fact that only an Internet connection is required in order to access the educational material. Of course, the cost of the connection depends on the data transfer rate. In order to achieve satisfactory interactive access to multimedia educational information, a data rate in the range of 128 kilobits per second (or higher) is required. The feature of flexibility relies on the fact that the system demonstrates satisfactory and adaptive performance on different educational applications, over connections that vary in speed as well as for different computer platforms and operational systems. In addition the modules of educational information used to setup a lesson may have different styles and types. The modules are composite entities of a variety of types like HTML modules, VRML representations of virtual environments, audio and video clips, Java simulations, etc. The proposed architecture allows the designer of a course to select any component of any type. It also allows the designer to establish any relation between the components and finally to create a corpus of educational material which may fulfil a variety of pedagogical targets. The ease in developing new educational material relies on the fact that the educational information is stored in the server(s) in the form of short and autonomous modules, which are combined to setup a lesson. It is important to emphasize that the system acts as a powerful tool for the educators. The performance of the on-line lessons produced by the system, depends both on the relations between the information modules stored in the data base, as well as on the content and appearance of each information module. This implies that the system allows the tutor to incorporate his/hers experience into the educational resources to be developed.

The Internet and Video: A Teaching Collaboration

Dr. Peter A. McAllister
School of Music, Ball State University
Muncie, IN 47306
Email: pmcallis@bsu.edu

Course Website: http://web.bsu.edu/pmcallis (password controlled)

Abstract: The World Wide Web enables the linking of text, images, sound and video on Internet connected servers to be presented as enriching additives to the learning environment offered to students. Depending on instructional objectives, teachers utilize the Internet to engage their students in experiences that range from technical software-specific skill development to long-term cognitive learning. While the Internet can be viewed as supporting differing delivery models, such as technology-enhanced learning (TEL) and web-based training (WBT), among others, the Internet is extremely important for educators for its support of both synchronous and asynchronous modes of communication.

Students in an undergraduate music methods course routinely videotape themselves in various teaching roles. These experiences, as captured by videotape, are usually only viewed by the professor and the student. The creation and launching of selected teaching segments that can be part of the entire class experience, for all the others in the course to view and learn from, offers a tremendously enriched learning opportunity. The methodology used to best prepare students for this experience, capturing video-tape teaching sessions, how to digitize a selected 2-3 minute clip that illustrates a “best practice” teaching sequence, and how to upload onto a course website using available technologies and application software will be demonstrated.

Importantly, a varied and emerging set of learning experiences will be shared, from both the professor and student points-of-view. The Internet and video technology can significantly impact the teaching/learning process in teacher-training undergraduate programs.

Using Web Database Tools to Facilitate the Construction of Knowledge in Online Courses

Sara G. McNeil
Department of Curriculum and Instruction, University of Houston, USA
smcneil@uh.edu

Bernard R. Robin
Department of Curriculum and Instruction, University of Houston, USA
brobin@uh.edu

Abstract: This paper presents an overview of database tools that dynamically generate Web materials and focuses on the use of these tools used to support research activities as well as teaching and learning. Database applications have been used in classrooms to support learning activities for over a decade, but, although business and e-commerce have quickly embraced dynamic Web-based databases, their potential in educational environments is just now beginning to be explored. The paper builds a theoretical framework for using Web-based databases to support constructivist learning and describes several specific applications of dynamic databases used to facilitate the construction of knowledge and support collaborative activities in online teacher education courses.

Trends in Web-Based Instruction and Online Courses

The acceptance of the World Wide Web as a legitimate teaching medium is undeniably making educators rethink how they design and deliver courses. As access to the Internet approaches a "universal" level in higher education, the number of online courses and course-related materials continues to grow. Universities are facing an increased need to produce online training and other instructional materials, to provide opportunities for lifelong learning, and to compete with a variety of virtual content providers. Consequently, dramatic changes are occurring in the way education is delivered and shared. IBM Chairman and CEO Louis V. Gerstner Jr. (1996) stated "if one billion people are going to access education, universities are going to have to change the way they teach." How they might change will be explored in this article.

Faculty Concerns about Developing Web-Based Courses

Faculty members at many universities have already begun to create and deliver online courses. These early adopters are testing and evaluating new models and methodologies, but, for the most part, no standardized paradigm for online course development has yet emerged. One of the reasons may be that faculty who create online courses are concerned about several issues related to this new way of teaching and are uncertain about how best to proceed. A major issue for many faculty is that creation of Web-based materials is time consuming and requires additional technology skills. Continuous updating of Web pages is necessary to keep content and links current as new material and resources become available.

Another issue is that faculty who want to create online resources themselves, will need access to adequate hardware and software as well as a robust, campus-wide electronic infrastructure. In other cases, faculty will need technical support services to assist them in the design and development process. Universities must find ways to provide multiple levels of support in order to maintain a dynamic university, one that can take advantage of the many technological changes that will continue to appear.

In addition to the need for technical support, faculty are also concerned about pedagogical issues that arise with online delivery. Designing a course to be delivered in a Web-based format requires a very different set of
instructional strategies and philosophical orientations. Some faculty members see the Web as an opportunity for implementing instructional innovations (Khan, 1997; Owston, 1997), but most faculty are largely uninformed about the benefits and drawbacks of online environments and are unclear whether online courses are as effective as face-to-face courses at promoting and supporting student learning (Reeves, 1997).

If we compare the qualities and characteristics of a face-to-face class and an online class, one of the critical differences is the type of interactions that occur within the context of a course. Interaction in an online course occurs primarily through asynchronous and synchronous computer-mediated communication such as e-mail, listservs, and chat. It is the use of these communication tools that can often make the difference between a good online experience and one that falls short of its goals and does not engage students. Our focus, and one that we hope other faculty will adopt, is to encourage and facilitate meaningful interactions between students, faculty and the Web-based resources they encounter.

Student Perspective

In addition to faculty needs and concerns, the needs of students also must be considered in the design and delivery of online courses. In order to build a true electronic community of learners, communication and collaboration among participants should be considered the driving force behind successful online courses. Unfortunately, many online courses (as well as many traditional courses) fail to take advantage of the potential for interactions that can add richness and depth to the construction of knowledge. In our online courses, student homework and projects are often similar to a face-to-face classroom; that is, specific assignments are given and students either post their work on a class listserv or e-mail it to the instructor to be graded. The problem, we have found, is that student work often does not become part of the course materials, and it tends to disappear at the end of the semester. Consequently, students do not always feel that they are participating in creating or adding to a body of knowledge and information for the course, nor do they experience ownership of the content.

Windschitl (1999) has stated that “constructivism is premised on the belief that learners actively create, interpret, and reorganize knowledge in individual ways.” In that vein, we try to create a constructivist environment in our online courses, where students are able to manipulate the content of the course to fit their specific learning needs or goals. To do this, they must interact with the information they are researching and writing about, and they must share their views with the other students in the course, not just with the instructor. In a typical online course in our program area, there may be several hundred postings to the class listserv during the semester. Our efforts, therefore, have been toward having students not only interact with their own small number of postings, but use the virtual environment to explore, analyze, discuss, and debate issues and topics that cover the broad spectrum of information that arises during the course.

Dynamic Databases

Most Web pages, including the course pages that we have been developing for several years, are static and do not take advantage of the interactivity offered by the Web. Most Web pages simply duplicate print-based materials in electronic form. Simply converting existing course information to online format is not enough to effectively produce meaningful Web-based courses. Online course developers must focus on creating courses that are more responsive to students and student needs, facilitating social and instructional interactions, creating a sense of a learning community, and delivering timely and useful information. Creative strategies are needed that utilize innovative tools such as Web database tools are needed.

How a Dynamic Database Works

The integration of Web pages and dynamic database technologies allows users to access a database through a Web page and to dynamically generate Web pages that present the requested data. The variable data on the Web page is generated from the database and delivered to the user through a template page. All of the usual abilities of a database, such as searching for information, doing calculations, entering new information, and editing
existing information, are available through the Web browser. This means that any application that can be created using a database can be made available on the Web.

Figure 1: Diagram of Dynamic Web Page Generation Using IDC and HTX Files

1. Using a query form in a Web browser, the user makes a request to the server for an Internet Database Connector (IDC) file.
2. The server reads the IDC file that contains a query usually written in Simple Query Language (SQL). Other information may also be stored in this file, such as passwords and access to certain data.
3. The Internet Database Component of the server opens the database using the Open Database Connectivity (ODBC) driver and the IDC file information and runs the query to access the requested data.
4. The server merges the data from the database with a template file (HTX file) to produce a dynamic HTML document.
5. The server sends then the HTML file back to the user through the Web browser.

Features of Web-Based Databases
According to Inline Internet Systems, Inc. (1998), Web-based databases have several important features:

- Data is centralized and changes may be easily made without changing individual Web pages. This has the potential to reduce duplication and improve accuracy.
- Because the database information is changed through a Web-based form, it is not necessary for users to have the database software on their computers.
- Users do not need to have technology skills to add, revise, or use material in a database since it is driven through forms and search queries. This is particularly important for new or inexperienced users.
- The content in a database may be customized for delivery according to the user's country and language, time of day, and Web browser used.
- Databases created previously and used on one computer or through an intranet may be used to provide dynamic content.
- Because the database information has the potential to be accessed from anywhere in the world with an Internet connection and a Web browser, data can be expanded, updated or deleted easily.

Potential for Dynamic Databases in Teaching and Learning
Web-based database tools provide students and faculty with innovative solutions that promote collaboration and the creation of shared knowledge. Lynch (1999) summarizes this by stating, "To educational institutions this technology offers a challenge in using the technology to drive a more innovative and acceptable learning environment than that offered by the static Web pages of previous years. What is required now, is the classroom environment to adapt this technology into every day practice."

There are several advantages for using dynamic Web database tools:
There is increased interaction between students and the resources. This interactivity implies involvement and commitment, since it empowers the user to control the environment.

There is ownership of the material since the content is collective and not instructor-driven.

The body of knowledge is not static but continues to change without requiring extra work on the part of the faculty member.

Empowering students with control of content may affect participation, motivation and feeling of community. Material may become more interesting and stimulating when learner control increases.

Examples of Dynamic Databases

Example One: Student Pictures and Biographies for HyperGroups

Students in our online classes use a variety of listservs as a primary means of course communication. To enhance the feeling of an electronic learning community, students' pictures are taken at orientation and uploaded to the server. When a student posts a message to the listserv through a form that gathers their e-mail address, the message is displayed dynamically with their picture. The student simply has to type in their e-mail address for the picture to appear (See Figure 2).

Example Two: Computer-Based Instruction Database

Students in a graduate level instructional design course use the Web database tools to contribute different types of materials. For example, with one assignment, students review an online tutorial and post an evaluation of it using a Web form. They are then able to search the tutorial evaluation database by content area and audience/grade level.

Figure 2: Participant's Pictures Automatically Generated by E-mail Address

Figure 3: Form Used To Collect Tutorial Evaluation

Figure 4: Dynamic HTML Page Generated From Database
Perhaps the most interesting and creative use of a database is the game design assignment. Students design a computer-based game and submit their description as a newsletter article through a Web form.

**Figure 5: Form Used To Collect Game Design Data**

Figure 5 illustrates the form used to collect data for the sections of the newsletter. Students use both text fields, pull-down menus, and radio buttons to submit information about the game they have designed. When the student submits the data, it is automatically sent to the database. Students may then use the query form (See Figure 6) to search the database by content area, audience, or author. The results of the query by content are shown in Figure 7. Figure 8 illustrates the merger of the content from the database with the newsletter template, the HTX file, which is then displayed in the browser as a dynamic HTML file, complete with banners and graphics (See Figure 8).

**Figure 6: Query Form to Select Game by Content, Audience or Author**

**Figure 7: Results of Game Query**

**Figure 8: Example of Game Design in Newsletter Format**

**Example Three: Faculty Feedback for Student Assignments**

In another online course, submission of student assignments also utilizes the Web database tools. Students are directed to a Web page that contains an online form in which they enter their name, a unique identification number,
number (the last 4 digits of their Social Security number), and the number of the assignment (See Figure 9). They are also asked to copy and paste the question and then scroll farther down in the form and type in or paste in their answer. If they have created a word-processed document or a Web page in completing the assignment, an attachment feature may be used. Once the submit button is pressed, the student work is sent to the database.

The question:

Copy and paste in the question to which you are responding.

(Note: You may paste the entire question, even though the area appears small here, it will receive the entire text that you paste in.)

Figure 9: Student Assignment Submission Form

After assignments have been submitted, the instructor uses the Faculty Review form to provide feedback for the assignments that have been posted (See Figure 10). Since all of the student postings are available in the database, the instructor may review all of a particular student’s assignments or all of the postings on a specific assignment, depending on what terms are used to sort and view the database entries.

Students may also view the feedback by using the Student Feedback Review form. This page includes the questions, the answers, and the feedback in the order in which the assignments were posted (See Figure 11).

Figure 10: Faculty Review Form

Figure 11: Student Feedback Review Form

Conclusion

The use of dynamic database tools has helped us as we seek to improve our online courses, and they have indeed given students greater control over the information covered in the courses. However, there are some limitations that should be mentioned. First, the technical skills needed to develop and use the dynamic database tools are greater than those needed to create traditional Web sites. Many simple HTML editing tools are available, and converting word-processed files, for example, to static Web pages is a skill that may be mastered very quickly. Conceptualizing how the database tools will function is very different from creating static pages,
and a new set of skills must be learned that include a greater understanding of information design and management. The time needed to design, develop, and evaluate online courses that include database tools requires a larger amount of both time and patience than many educators will be able to commit. Certainly, as with other Web-related tools, software improvements will make the job easier, but at this time, a steep learning curve is the rule. Finally, students who are asked to interact with these tools will need some instruction on how to use and access the interactive elements.

References

Three major themes emerge from the papers presented this year for preservice teacher education: collaboration, modeling, and the modeling of collaboration. Collaboration aimed at changing teacher education is taking place among many individuals and groups. Working under the premise that teachers teach as they are taught, teacher educators are modeling effective use of technology in preservice teacher classes. Ultimately, collaboration itself is being modeled to preservice teachers as one of the best ways to bring about major changes in education processes. These three major themes cut across all the domains of teacher education — how interesting! What does that say about the state of Information Technology in Teacher Education as we approach the new millennium?

Collaboration in Teacher Education

Collaboration to make improvements in preservice teacher technology education is taking place at many levels. McManus (Saginaw Valley State University), Charles (Eastern Michigan University), and Rubio (Albion College) describe the Consortium for Outstanding Achievement in Teaching with Technology (COATT), a collaborative effort by ten Michigan colleges and universities. Brown (Washington State University), Appleman (Indiana University), Green (California State University) and Hansen (University of Northern Iowa) compare the goals and activities of the Educational Technology classes at their four separate universities. The courses share as a goal the improvement of the learner’s ability to use computing tools in education, but the activities employed to achieve this goal vary. In this same descriptive genre, Chambers and Tromp (University of Melbourne, Australia) outline the development of Instructional Technology (IT) skills as primary (elementary) education students progress in their course work. This development includes both generic IT skills and IT skills specifically related to curriculum areas. LaMaster (San Diego State University) and Morely (Northern State University) have designed a collaborative project between their universities using an electronic bulletin board to provide an opportunity for students to interact concerning pedagogical and professional issues. Seed (Northern Kentucky University) examines a collaborative effort involving interview and e-mail exchanges employed to gather information for evaluation of a collaborative learning environment involving faculty from the Colleges of Education and Arts & Sciences in a chemistry course for elementary and middle school preservice teachers. Peterson (South Dakota State University) focuses on the Discover South Dakota Tellecollaborative Project. This project has been used as an integral part of the curriculum in the required preservice technology class, involving future teachers in an opportunity to experience technology integration in the curriculum.

Collaboratives involving field experiences include the Fifth Dimension experience reported by Zimmerman and Greene (Appalachian State University). Preservice students participated in an after-school program in the enhanced learning environment of the Fifth Dimension center, where children were offered opportunities to experiment with educational software and other technology equipment. Morgan (Minnesota State University–Bemidji) describes a project based on a collaborative model which includes the preservice teacher, faculty supervisor, classroom mentor and school based technology coordinator. In this model, the preservice teacher has the opportunity to check out equipment and software based on a written instructional plan for the integration of the resources into a field based classroom lesson.

There are collaboratives among faculty, successful inservice teachers, and preservice teachers. For example, Dempsey, Sutton, Gallagher, and Steckleberg (University of Nebraska) describe the Scholarship, Technology, and Educational Practice (STEP) program, in which K-12 master teachers team with methods faculty to develop and model ways to integrate technology effectively. Cheeks and Liu (Towson University) describe an information centered technology course for preservice teachers in which students
collaborate with faculty to design projects that would be useful while giving them needed technology skills.

Selinger (University of Warwick, Coventry, UK) describes a project that placed preservice teachers of information and communications technology (ICT) into secondary schools, each in a particular subject area, to develop ways that ICT could be integrated across the curriculum. Preservice teachers benefited, as did inservice teachers, who were often lacking in ICT skills. Other projects involving the use of preservice ICT teachers are not always this successful, but it is expected that the cross-curriculum emphasis will be continued in the UK. Nocente (University of Alberta, Canada) describes a course for both preservice and inservice teachers. The course allows interaction between the two groups as they work on course assignments. Nocente found that inservice teachers who are vocal in their opposition to constructivist teaching can affect preservice teachers.

The goal of several multi-faceted collaborative efforts is to integrate technology into K-12 education by integrating technology into preservice teacher education. Carlson, Clark, Hosticka, Kostin and Schrifer (Georgia Southern University) provide a summary of the progress made to date on collaboration involving the University and local school districts. Needs assessment results and establishment of a website and workshops for participants are presented. Future plans include further collaboration and evaluation.

Dudt, Yost, and Brzycki (Indiana University of Pennsylvania) describe a consortium of three public universities that seeks the infusion of technology into teacher education programs. Couros (University of Regina, Saskatchewan, Canada) describes the vision and struggles of a college of education. Key participants in collaborative efforts include faculty, administration, library services, the technology committee and technicians of the college of education. Plans are being made for university collaboration with industry, telecommunications providers, and government education facilities. Snider, Gershner, Foster, and Huestis (Texas Woman’s University) present a teacher education program called Learning and Integrating New Knowledge and Skills (LINKS) in which teacher educators, preservice teachers, and mentors collaborate to document the acquisition of technology competencies through each phase of teacher education. The Wyoming Capacity Building Project is a collaborative involving the University of Wyoming, the Wyoming State Department of Education, and seven community colleges. According to Westhoff (University of Wyoming), the goal of this project is to build a technology enhanced teacher education program that will model effective infusion of technology for future teachers.

Garcia (University of Wisconsin Oshkosh) describes the assessment and planning groundwork laid for a major collaborative involving teacher educators, practicing teachers, and preservice teachers. The grant-funded project will enhance teacher education by modeling integration of technology into undergraduate instruction. Morgan (Minnesota State University–Bemidji) reports on a Federal TP3 Implementation Grant project, Class Act Preparing Tomorrow’s teachers to use Technology. The Class Act program augments a four-year competency based, technology focused teacher preparation program, a collaborative among two universities, a community college, school districts and a private foundation.

**Modeling Effective Use of Technology in Teacher Education**

Teachers often teach in the manner they were taught. To ensure that preservice teachers become competent users of technology in their classrooms, universities are incorporating the use of appropriate technologies in their teacher education courses. Burkhouse and Ruthkosky (Marywood University) call for the infusion of technology in the curriculum as a tool, not a toy or a trophy. They call for the use of technology by teacher educators as a model in the academic community. Merideth and Steinbrom (Drake University) outline a constructivist approach to learning and work for preservice teachers as producers and consumers of technological resources. This approach utilizes FileMaker Pro database customized to gather test, graphics, sound, video, and references from the Internet. The information stored in the database is then used to create lesson activities for K-12 classrooms. Terwindt (Amsterdam Faculty of Education, Netherlands) describes a constructivist professional education program, “the experimental teacher education in the Netherlands” in 1997. Willis and Tucker (Northern Arizona University) describe a constructivist approach with their description of the “Multimedia Content Development Company.” Teams of students complete content-centered projects that integrate technology tools in the presentation of topic.

Teacher education programs in the Netherlands are attempting to provide a foundation in the integration of ICT. The EXPLO project is one of these innovative attempts. Westboek (Ichthus Faculty of Education, Netherlands) reports that this program is related to the Dutch government’s Prommit program, based on the learn-as-you-work concept. He further outlines this project as he describes the Producing Student’s role in learn-as-you-work and work-as-you-learn paradigms.

Teacher education programs vary in their ability to provide strong programs of instructional technology. Duran (Ohio University) surveyed three groups of preservice teachers in one college of education and found they felt ill-prepared to proceed with technology integration in their own classrooms. Albion (University of Southern Queensland, Australia) examines the influence of problem-based learning and multimedia methodology as a means of increasing preservice teachers’ feelings of self-efficacy for
teaching with computers. Hargrave and Sadera (Iowa State University) found that, prior to their teacher education program, preservice teachers hold naïve ideas concerning effective use of technology in the classroom. Student teacher views support traditional teaching methods. The authors conclude that teacher educators must find effective ways to give preservice teachers more comprehensive views of technology in their educational process. Watson (Griffith University, Australia) points to students' expression of the greatest satisfaction with the IT course when it includes adequate human and technological support accompanied by online resource material.

When preservice students experience the effects of new technologies they will be inclined to use them in the classroom. A course described by Brown and Ferry (University of Wollongong, Australia) incorporates concept mapping into preservice training for teachers of science and visual arts. Since the students found that constructing concept maps was helpful in their own learning, it is expected that they will continue to use this tool and incorporate concept mapping into instruction they design for their own future students. Reynolds (University of Wyoming) and Reynolds (Rock River School, Wyoming) have developed a program integrating moral education in the student teaching practicum, using technology as a delivery tool to facilitate student project development. Wilkerson (Baylor University) presents a triad (communication, productivity, and research/instruction) model of technology infusion in the classroom. This triad model is one approach to designing curriculum and experiences in a teacher preparation program.

Higher order thinking skills are used in the creation of electronic portfolios of preservice teacher's accomplishments used for assessment of progress. Morris and Buckland (University of Vermont) report on the use of these portfolios and the evidence that using hypertext and multimedia tools to create these presentations enhances technology skills. Ehli and Sorknes (Northern State University) also report on this method of skill enhancement. These portfolios were used to communicate a personal profile to mentor teachers, K-12 students, and future employers.

McGrew-Zoubi and Hirtle (Sam Houston State University) describe a series of courses and a summer camp that provided field experience for preservice teachers. Both the courses and the summer camp used technology in a variety of ways that required the preservice students to utilize technology in their learning. Further, constructivist methods were used in several instances, putting the students in situations that resembled the learning environment of their future students. Cooper and Hirtle (Sam Houston State University) describe the use of computer message boards during a field experience portion of preservice training and concluded that such computer-mediated communications systems offer valuable means of connection for faculty and students.

Hagen (University of Nebraska) points out that while the use of technology for learning is often a solitary process, teachers and students like to interact. Therefore, group learning appears to be appropriate for preservice teachers as they acquire technology skills. Wentworth, Monroe, Orme, and Lynes (Brigham Young University) used e-mail as a tool to encourage students to reflect on their observations and link their field experiences to theories learned in the university setting.

Jacobsen and Clark (University of Calgary, Canada) describe the steps being made to integrate mandated technology curriculum into an inquiry-based teacher education program. Through a series of technology training workshops, preservice teachers are given tools they will incorporate into their future classrooms. Pan (The College of New Jersey) stresses the importance of teaching preservice teachers to integrate technology correctly into curriculum. He describes a study in which preservice teachers observed elementary students as they explored Microsoft's Magic Bus software. Maushak, Lincecum, and Martin (Texas Tech University) are developing a web site that will assist preservice teachers and teacher educators create and evaluate inquiry-based Internet assignments for K-12 students.

Teacher education programs experience difficulties in making technology transitions. Chiero, R. Bohlin, C. Bohlin, and Harris (California State University, Fresno), and Casey (Cal State Fullerton Regional Center) describe the efforts of several teacher education programs to implement state mandated technology infusion. Norton (George Mason University) categorizes technology practices in teacher education classrooms. She identifies technology problems teacher educators face and gives examples of successful solutions.

Carter (Iowa State University) points out that teacher educators need models illustrating successful technology integration so that they can, in turn, model for their preservice students. She describes the development and evaluation of a CD-ROM titled Videos in Technology Integration, which features videos of teacher educators using technology in their preservice teacher classrooms. Andre, Schmidt, Nonis, Buck, and Hall (Iowa State University) describe the development of CD-based video clips and case histories demonstrating K-12 teachers using technology in real teaching situations. Staudt and Fuqua (University of the Incarnate Word) describe another use of the videotaping process to enhance teacher education. In this paper they describe the use of video as a self-evaluation tool for preservice teacher preparation. This videotaping program provides accurate data for prospective teachers to reflect and assess their progress toward mastery of state competencies.
Modeling Effective Collaboration

For preservice teachers, collaboration itself models effective ways to bring about major change in education processes. Often experienced teachers do not have time to acquire new technology integration skills and may be inclined to continue their traditional teaching patterns. Preservice teachers can observe classroom realities by working with practicing teachers. Hornung and Bronack describe a unique K-12/university collaborative that pairs preservice teachers with experienced inservice teachers. Preservice teachers observe and assist their mentor teachers a minimum of 20 hours. The pair decides on one area of established curriculum that would be enhanced by appropriate use of technology. The preservice teacher prepares and presents the technology-enhanced lesson. Both gain from the experience, and practicing classroom teachers gain new technology skills that otherwise may never have been used in their classroom.

In a similar program, according to Coe (Midwestern State University), preservice teachers model the integration of technology for mentor K-12 teachers. In this collaborative teacher education classes are taught in public school classrooms. Preservice teachers spend over 50 percent of their learning time in K-12 classrooms and they develop classroom technology enhancement and model its use for K-12 mentor teachers. Christie (Arizona State University West) points out that, in a K-12 school district/university collaborative, all participants learn: university faculty, K-12 teachers and students, and preservice teachers. She describes a partnership in which K-12 teachers and university faculty team-teach middle school students in university computer labs. Dobson (Bloomsburg University of Pennsylvania) reports on a collaborative project involving preservice teachers, inservice teachers, and university faculty. Future teachers were required to use their technology skills in partner schools K-12 classrooms by creating an electronic portfolio containing technology-based activities.

Anderson (Southeast Missouri State) and Anderson (Kenosha Unified School District) describe a grant funded program that provided computer equipment and software including assistive technologies for regular and special education students’ use in their field placements. Preliminary results in the form of case studies present a sample of projected outcomes as a result of this study.

Gladhart, Carroll, and Ellsworth (Wichita State University) describe Project EXCITE, which is a major collaborative effort among teacher education faculty and students, student mentors, university technology staff, and faculty and students in K-12 partner schools. The goals of this grant funded project, Expanding our Curriculum Integration through Technology Education (EXCITE), include revising curriculum, training faculty to integrate technology, while meeting the new standards of The National Council for Accreditation of Teacher Education (NCATE). As Gladhart, Carroll, and Ellsworth concluded, “Developing fearless faculty is a lofty goal, but once faculty become leaders, their students will be empowered to be leaders and advocates for change in schools.”

Barbara Moore is a Doctoral Candidate in Instructional Technology in the College of Education at the University of South Florida. She is currently immersed in preservice teacher education issues through the teaching and ongoing refinement of a preservice teacher technology course. Her interests include web-based instruction and the use of technology to bridge the Digital Divide. Email: bmoore@typhoon.coedu.usf.edu

Ruth Burkett is a Doctoral Student in Instructional Technology in the College of Education at the University of South Florida. She is currently immersed in the issues of preservice teacher education through the teaching and ongoing refinement of a preservice teacher technology course. Her interests include communications in distance education and constructivist learning theories. Email: rburkett@typhoon.coedu.usf.edu

James A. White is Associate Professor of Instructional Technology and Coordinator of Graduate Studies in Secondary Education in the College of Education at the University of South Florida. His interests are the ongoing development and implementation of the doctoral program in Instructional Technology and research on computing in teaching and learning. Email: jwhite@typhoon.coedu.usf.edu

Carine Feyten is Chair of the Department of Secondary Education and Associate Professor of Foreign Language Education in the College of Education at the University of South Florida. Her interests include developing and implementing distance learning opportunities and exploring the use of telecommunications and the Internet in the classroom. Email: feyten@typhoon.coedu.usf.edu
COATT: A statewide initiative to improve pre-service technology education in Michigan

Abstract

Like many other states, Michigan has recently instituted minimum technology standards for pre-service teachers. A diverse group of teacher preparation institutions in Michigan who believed there was a need to recognize those who reach a higher standard got together to form the Consortium for Outstanding Achievement in Teaching with Technology. The purpose of the Consortium is to set in place a formal process to recognize pre-service, and eventually in-service, teachers for going beyond the mandated standard. Here we discuss both the process of bringing the Consortium together and the progress of our students as they apply for the M-COATT certificate, the first of which will be awarded in the spring of 2000. At this writing our students are preparing their electronic portfolios to showcase their work integrating technology into their classroom teaching. By February our students will have nearly completed the first submissions to our Consortium.

The Origins of COATT

In June of 1999, representative of ten Michigan colleges and universities joined with Senator Carl Levin of Michigan to announce the formation of the Consortium for Outstanding Achievement in Teaching with Technology (COATT). The Consortium is the result of a yearlong effort begun by Levin that brought together diverse teacher preparation institutions to find a way to raise the standards for technology preparation given to pre-service teachers. Research 1 universities, regional comprehensive universities, and small liberal arts colleges are all members of this Consortium.

Each participating institution signed a letter outlining their responsibilities as members of COATT. The Consortium itself will be housed at the College of Education at Eastern Michigan University. The office at EMU will receive applications, organize evaluation teams, and generally administer the certification.
Each participating teacher training institution will assist candidates with the application process. They will name a person to act as a point of contact within the institution for potential COATT candidates. They will promote COATT to potential candidates through flyers, and other communications. Participating institutions will also provide support for candidates seeking COATT certification, such as adequate and relevant learning opportunities in the application of educational technology, and resources for COATT applicants to produce, maintain, and gain access to their COATT digital portfolios.

In addition to their responsibilities to support COATT applicants, participating institutions will retain responsibility for seeing to the health of the consortium across the years. Faculty liaisons will participate in an annual review of the COATT standards and will develop policy with other core members of the COATT organization. Faculty and other qualified personnel from participating institutions will be involved in COATT evaluation teams.

Earning the M-COATT certificate

In the 1999-2000 academic year, COATT will begin awarding a certificate, the M-COATT, to pre-service teachers who demonstrate excellence in the use of technology to enhance student learning. This certificate will exist independently of both degree programs and the state certification process. It will allow educators to demonstrate their proficiency in this area and will help school administrators who make hiring decisions identify teachers who can be technology leaders in their schools. The certificate will also allow institutions of higher education to benchmark their achievements in teacher training in technology against an independent standard of excellence. Students attending COATT member institutions who wish to receive the consortium's certificate must submit a digital portfolio for review by a panel composed of representatives of two or more of COATT's participating institutions (other than the student's own institution).

The COATT Standard

The standards used to award the M-COATT certificate are based on the Michigan Department of Education's [MDE] Seventh Standard for Entry Level Teachers. The Seventh Standard states that all entry-level teachers will have "an ability to use information technology to enhance learning as well as enhance personal and professional productivity." The Standard is divided into seven proficiencies (Michigan Department of Education, 1997):

Entry level teachers will be able to:

a) Design, develop and implement activities that integrate information technology for a variety of student grouping strategies and diverse student populations.

b) Identify and apply resources for staying current in applications of information technology in education.

c) Demonstrate knowledge of multimedia, hypermedia, telecommunications, and distance learning to support teaching/learning.

d) Demonstrate knowledge about instructional management resources that assist in such activities as writing and updating curriculum; creating lesson plans and tests; and promoting, reinforcing, and organizing data regarding student performance.

e) Use information technologies to support student problem solving, data collection, information management, communications, presentations, and decision making including word processing, database management, spreadsheets, and graphic utilities.

f) Demonstrate appreciation of equity, ethical, legal, social, physical, and psychological issues concerning use of information technology.
g) Use information technology to enhance continuing professional development as an educator.

Currently, the State of Michigan asks all entry level teachers to demonstrate achievement at the "basic" level (2 on the MDE's 4 point scale) in four of the areas and at the "proficient" level (3 on the MDE's 4 point scale) on the other three areas. We expect the M-COATT standards to set a "higher bar" toward which entry level teachers may aim. To be awarded the COATT certificate, candidates will need to demonstrate achievement at the highest level (4 on the MDE's 4-point scale) on at least three of the seven components. At least two of the three components must be from among those components most closely linked to enhanced student learning: 7a, 7c, and 7e.

The Evaluation Process

As mentioned above, all candidates for the COATT certificate will be required to submit a digital portfolio for evaluation. The Consortium found itself faced with the question of just what does a quality portfolio look like? Initially participants in the Consortium offered anecdotal ideas of what they thought would qualify as "M-COATT certified," but actual sample portfolios had not been prepared at the onset of our discussions. The challenge of getting educational technology faculty from diverse institutions to agree on such a standard with the knowledge that a third party would independently evaluate their student's work was formidable. Eventually a rubric was proposed and agreed upon.

A portfolio is a focused presentation to a prospective employer of one's professional knowledge, experiences, and abilities. A student teacher selects important artifacts, the very best and clearest evidences of their growth and learning, to include in a portfolio. Such artifacts can include: a resume and philosophy of teaching; lesson plans and implementations of classroom activities; sample works of their own students; research papers and essays which they have written; video of their classroom teaching; evaluations and letters of commendation about their aptitude with pedagogy or content knowledge; anecdotal records about students or classroom management strategies; or awards of distinction. It is focused because specific skills and dispositions related to teaching are delineated; for example, one can include specific state or national standards for teacher preparation with corresponding evidence of mastery of those standards. Besides educators, professionals in other fields such as entertainment and the fine arts use portfolios. Doolittle (1994) and Campbell, Cignetti, Melenyzer, Nettles, & Wyman (1997) describe the basic outline of a traditional, or linear portfolio. The design of the portfolio should satisfy three sets of criteria that are not equally weighted:

- **Pedagogical:** this is related to the quality of the teaching and learning that is presented and is accompanied by the students' reflections. It is very important to us that technical "style" not distract us from pedagogical substance.
- **Instructional:** having said that, we do value style quite a bit. Components of the portfolio such as navigation and aesthetics make an important statement about the student's ownership of their technological skills. The portfolio should be structured so that the reader can easily navigate and understand the portfolio.
- **Functional:** this addresses the simple question, "How user-friendly is the portfolio?"

Early in the COATT process, we set a scope for the M-COATT portfolio as something that a student could design in ten hours, given a basic mechanical understanding of how to construct a hypermedia document. We recognize that not every student-teaching classroom is on a level field insofar as the breadth or depth of available technologies is concerned. While student candidates are expected to be as creative as they wish in applying technology in the service of teaching and learning, those who are in a "technology-poor" classroom can still effectively compete if the degree to which the technology is employed is seamless and promotes learning in individual and unique ways.

It is expected that students will include standard fare such as sample units and lessons, artifacts of learning, artifacts of teaching (an electronic grade book, a classroom presentation, etc.) in their M-COATT portfolio.
We will also look for evidence of thoughtful contemplation on the part of the student - a summary justification for why the student meets a portion of the standard, a portrayal of the classroom environment, and a reflection on how "well" a particular unit or lesson was enacted and received. The COATT liaison at each member institution is responsible for sensitizing their students towards addressing these areas.

We envision submissions that follow good practices of hypermedia and instructional design. The digital portfolio should be self-guiding, and organized in a coherent, cohesive manner. Design guidelines for the students' linear portfolio are a good starting point. However, a well-designed digital portfolio will also take advantage of the non-linear presentation of information afforded by hypermedia. One may use the following pervasive questions (Rubio, Michell, Blackwell, Albery, & Kondelik, 2000) to guide their assessment of how that non-linearity was utilized: a) What do I want my reader to know now?, b) What do I want my reader to know next?, and c) How can I take advantage of the multimedia and nonlinearity at my disposal to effectively convey my presentation?

The functional assessment will be facile. Everything should "work" - links, media, etc. The portfolio should alert the reader to specific computer hardware configurations and special software needed to view the portfolio, and include links for downloading the software as appropriate. It should be web-accessible, but is not restricted to HTML. The portfolio should be largely operating system- and browser-independent.

Another question we had to answer in the first year included just when to make the M-COATT portfolios due. We wanted to issue the M-COATT certificate early enough so that recipients would have this certificate in hand for late spring job fairs. But the preparation of a digital portfolio that included actual lessons taught with students was a challenging task, as many of our applicants would only be student teaching in the spring. In addition, the timetable had to accommodate an independent review by university teacher educators. It was decided that there would be two sets of deadlines to accommodate student teachers who taught in the fall, 1999 or the spring, 2000. A web site was opened up in early November which can be used to begin the application procedure; applications can be made and changed online until January 14, 2000. Candidates from the first group will submit a nominal registration fee and a digital portfolio in web-accessible format to their COATT liaison, who is responsible for making sure that the portfolios are installed on web servers that are secured (no further modification) after March 3, 2000. The cooperating teacher will be asked to sign the application to signify that the student teacher did actually teach the unit in their classroom. At least one representative from each member institution will gather in mid-March to review the portfolios. An iterative assessment process will be performed, where each reviewer looks at several portfolios. The assessment rubric will then be finalized, and the portfolios assessed. Representatives will recuse themselves from assessing the work of students from their institution. The first awards will be announced on or around April 1, 2000. Candidates from the second group will have their portfolios secured by May 5, 2000, and will receive award notification on June 2. If selected, the students' name will be placed on the COATT web site, they will receive a certificate, and they will be invited to a public awards ceremony.

Issues

A number of issues have emerged through the process of creating the Consortium and certificate. These include the marketing of the M-COATT, certificate opportunities for in-service teachers, and financing COATT. We set a marketing goal that the M-COATT would become a credential valued by both job seekers and those who make hiring decisions in school districts. In order to bring this about institutions participating in the consortium have agreed to take a leadership role in promoting the certificate to their students. Senator Levin's office has agreed to work with the K-12 community to market the certificate to schools and school districts. We are also working for the endorsement of the M-COATT certificate by all relevant education organizations in the state. These marketing efforts will also include working with the news media to publicize this "first in the nation" approach to upgrading technology training standards for teachers. The question of developing a parallel certificate for in-service teachers is still under consideration. One of the main questions is whether inservice teachers should be offered the same certificate for the same level of work, or a more advanced certificate that would necessarily reflect a more thorough integration of technology in their teaching methods. It is also recognized that the evaluation methodology we will use in
granting the certificate may need to be modified as well. Finally there is the question of how will we pay for this "revenue neutral" project. In this era of reduced state budgets for higher education, some means needed to be found to support the ambitious goals of the COATT project. It has been agreed that the application fees for the M-COATT will be set at a level that helps screen out clearly unqualified applicants, while not discouraging qualified candidates from applying. The hope is that the revenues generated can defray some or all of the costs involved in evaluating the applicant's portfolios. Public and private grant support will be sought to cover the administrative and marketing costs of COATT and whatever portion of the evaluation costs are not met by application fees. It is expected that Consortium institutions may give some in-kind support to COATT in its start-up phase, but we also recognize that as the Consortium scales up, it will be reliant on cash resources.

Conclusion

We have only outlined the COATT standard, described the process of applying for the M-COATT certificate, and begun a discussion of some of the issues facing us as we face this task. At this writing, we are working with our first group of students who are trying to achieve the M-COATT certificate. In February while at the conference, our students will be preparing their initial digital portfolios for submission. Already we are seeing unintended benefits from the COATT process, as teacher educators responsible for preparing students in information technology at very diverse institutions have had a forum to discuss their work as they aim for a common standard. Those of us who have helped create COATT continue to believe that it will make a significant contribution to long-term efforts to improve the technology skills of Michigan educators.

Computer Technology Courses for Pre-Service Teachers: a Comparison of Four University's Approaches

Abbie Brown: Washington State University, Pullman
Bob Appelman: Indiana University, Bloomington
Timothy Green: California State University, Fullerton
Lisa Hansen: University of Northern Iowa, Cedar Falls

Abstract: This paper is a description of the Educational Technology/Instructional Technology courses developed and delivered within the teacher education programs at four diverse state universities. Each university is presented as an individual case. The goals and activities of the Educational Technology courses offered are the focal point of the comparison.

Introduction

Computer technology skills have been targeted as a critical competency for teachers by organizations that include The National Council for Accreditation of Teacher Education (NCATE) and the National Education Association (NEA). A recent NEA resolution includes the statement, "Teacher preparation in instructional technology, including the development of effective materials, and appropriate instructional strategies must begin in college and university programs and extend through continuing professional development" (1997-98).

Accepting the fact that effective teacher preparation programs must include instructional technology (IT) as part of the program of study raises the issue of deciding how best to incorporate IT into the teacher education curriculum. Teacher education programs across the United States have been approaching the problem of developing IT competency through specifically designed courses. Although virtually all of the courses offered have as their goal the improvement of the learner’s ability to use computing tools in educational settings, the activities developed and employed to achieve this goal vary widely from program to program.

Abbie Brown, Bob Appelman Timothy Green and Lisa Hansen are each responsible for teaching computer technology courses that are part of the teacher education programs at state universities (Washington State University, Indiana University, California State University and the University of Northern Iowa, respectively). Each reports on his or her respective environment in the following four cases.

Case #1. California State University, Fullerton

Teacher education programs throughout California are in the midst of analyzing and evaluating how credential students are being prepared to utilize technology in the classroom. A major impetus for this has been brought about by the California Commission on Teacher Credentialing (CCTC). The CCTC has recently developed standards on the use of computer-based technologies in the classroom that teachers must posses. Teacher Education programs in California must document how they are implementing these standards by June of 2000.

The credential program at CSUF is a one-year, post-bachelor program. Students entering the program come from a wide-range of academic backgrounds, with many coming from other colleges or universities. Students therefore come in with varying abilities with regard to
technology. There currently are no technology requirements for admissions into the credential program.

The combination of the recent CCTC standards on computer-based technologies and being in the middle of NCATE accreditation process has prompted the Division of Education at CSUF to take a serious look at how prepared our credential students are in the use of technology when they leave our program. Students can leave our teacher education program without taking a technology course. However, students must demonstrate in their student teaching experiences competencies related to technology. Students are to gain experience in utilizing technology throughout the one-year credential program.

The main technology course in the department (Elementary, Bilingual, and Reading Education) I work for is EDEL415: Microcomputers in the Elementary Classroom. The class is designed for in-service teachers working on their professional credential (the credential teachers receive after their preliminary/probationary credential). Teachers must take this class along with two other non-technology related courses to receive their professional credential. The major goal of the course is to help an elementary teacher develop knowledge and skills that will allow him or her to integrate technology into their classroom. Although this course is designed for in-service teachers, many students take this course even before they are enrolled in the fifth-year credential program. Students enrolled in EDEL415 can range from novice to experienced in regard to their teaching abilities and knowledge about pedagogy.

As part of the master's program in Curriculum and Instruction, a computer emphasis can be taken that leads to a computing certificate for elementary teachers. "The Computing Certificate for Elementary School Teachers has been designed to provide elementary school teachers with a broad understanding of the applications of microcomputers in the elementary school classroom and the instructionally related tasks in the public schools. Competencies will enable participants to become computer curriculum specialists who will guide the integration of computers into the elementary school curriculum, their uses in instruction, and their applications in instructionally related activities at the elementary school."

The certificate consists of 15 semester hours. Listed below are the courses that make up the certificate.

Core Courses (13 units)

EDEL 415 Microcomputers in the Elementary Classroom (3)
EDEL 515 Problem Solving Strategies Including Logo (3)
EDEL 519 Advanced Technologies (3)
EDEL 516 Integrating Elementary School Software into the Curriculum (1)
EDEL 517 Practicum: Elementary School Teachers and Computers (3)

Elective Courses (2 units selected from the following courses)

EDEL 512 Improving Elementary Students Writing with Microcomputers (1)
EDEL 513 Microcomputer Utilities for Elementary School Teachers (1)
EDEL 514 Strategies for Using Data Base Management with Elementary Children (1)
could be done, and what can be done, is continually addressed beginning with the first required technology course.

Professional development becomes the focus instead of the lack of technology available in the field. Assessment of an individual’s technology literacy is calibrated using the ISTE Standards for Basic Endorsement in Educational Computing and Technology Literacy. From the beginning, each student is made aware of the importance of self-assessment using these standards, and also with the realization that they should expect to be evaluated with them upon entering the teaching profession.

Every student is required to take an introductory course entitled “Using Computers in Education” with the following description:

(W200 3 cr)
Develops proficiency in computer applications and classroom software; teaches principles and specific ideas about appropriate, responsible, and ethical use to make teaching and learning more effective; promotes critical abilities, skills, and self-confidence for on-going professional development.

From this base the student will attend practicums and/or cohorts during their Sophomore and Junior years that explore teaching methods and technology integration. Each course offering in the School of Education is strongly urged, and supported with consultant resources, to integrate technology into its repertory. If a student wishes to gain a computer endorsement, then a special course sequence is available as listed below.

W210 Survey of Computer-Based Education (3 cr.)
W220 Technical Issues in Computer-Based Education (3 cr)
W310, Computer-Based Teaching Methods (3 cr):
W410 Practicum in Computer-Based Education (6 cr)

Keep in mind that the School of Education exists among strong departments of Computer Science, Radio & Television, Journalism, Music, Fine Arts, Business, Informatics, and Library and Information Science. Electives may be chosen from this sample list below.
The College of Education at UNI has a strong commitment to technology and requires certain technology skills from its preservice teachers. All students are required to take a basic educational technology course early in their academic careers; for many students, this required course is completed in their first semester in the College of Education. Subsequently, many of the students we see in this course are new to the concepts of technology in education from a teacher’s perspective; indeed, many students are hearing words such as “pedagogy” and “objective” for the first time in our course. We therefore have to organize our required course (and additional courses offered to undergraduates) around the fact that we see them before they have taken a methods course.

In addition to offering master’s degrees in educational technology and communications and training technology, UNI provides an educational technology minor. We currently have about 22 students minoring in educational technology. This 18-hour minor includes 4 required courses and 2 electives, listed below. Eight educational technology courses are available to undergraduate teacher education majors. The first two courses listed below are the basis for all the others and should be taken first, in this order.

- **Educational Media and Classroom Computing** is required of most undergraduate education majors. This course is a general introduction to educational technology and media, and combines lectures and labs into a hands-on and survey/reading class. We offer six sections of 60 students each semester.
- **Classroom Computer Applications** is a follow-up course to Educational Media, and is required of technology minors. It is offered once a year and is much smaller in size (about
10-12 students). This class takes many of the skills and principles learned in Educational Media a step farther.

- **Technology in Education** is an undergraduate/graduate level course, and is a survey of the history, issues and trends in educational technology. This course is required of educational technology minors, and should be taken after the two listed above.

- **Media Planning and Production** is an undergraduate/graduate level course, required of educational technology minors, and should be taken after first two listed above. This class often acts as the graduate level introduction to technology course (much as Ed Media does for undergraduates), and thus provides more of a theoretical and in-depth base for skills and process development for undergraduates.

- **Databases in Education** is an undergraduate/graduate level course, and a minor elective. This course covers the use and development of databases in education, to support and enhance learning.

- **Telecommunications in Education** is an undergraduate/graduate level course, and a minor elective. Telecommunications encompasses the issues of using computers, video, and other communications methods to expedite learning.

- **Media Projects** is an undergraduate level course and a minor elective. This independent project gives students the opportunity to pursue projects of interest to them, and to further the development of skills.

- **Principles of Publication Design** is an undergraduate/graduate level course, and a minor elective. This class covers the design and development of print and web-based publications.

**Case #4. Washington State University, Pullman**

The Department of Teaching and Learning within Washington State University's College of Education currently requires all students seeking certification in elementary education to take a course entitled **Technology Used in the Schools** (TL445). Approximately 225 students graduate with provisional certification (state license) each year. Beginning next year, this course will also be a requirement in the secondary education certification program (approximately 200 students graduating each year). Currently, this is the only Educational Technology course available for undergraduates in the College of Education.

The teacher certification program at Washington State University (WSU) is selective; students may apply for admission to the program in their sophomore year (a process which includes interviews, a record of eighty hours of direct contact with children in supervised educational settings, and review of the applicant’s grade-point average). As freshmen, students at WSU are exposed to orientation experiences that include the use of e-mail and web-based communication; many students have experience with web-based conferencing (many professors are adopting WSU’s proprietary Speakeasy web conferencing system as a supplemental class activity). Students are generally well acquainted with word processing, spreadsheet and communications (e-mail) software: a recent survey of the students enrolled in the College of Education’s **Teaching Elementary Mathematics** course indicated that all but one of the fifty-three respondents had access to a computer in their home. Washington State University prides itself on being the seventh “most-wired” university according to Yahoo! Internet Life (1999).
Objectives and Rationale of WSU’s TL 445: Upon successful completion of the course, students should increase their ability to implement and evaluate technologically innovative instructional activities. Because the current trend is toward making improved use of digital technologies (i.e. Personal and/or networked computer-based presentations and interactive activities), all course activities will relate directly to computer-based presentation and instruction. It should be noted, however, that many of the concepts and procedures introduced during the course are general standards of effective instructional design and can therefore be applied to any technologically innovative instructional situation. The presumption is that the technologies currently in vogue will very probably be replaced by emergent, differing technologies during the course of the student’s teaching career, while standards of effective design and instruction will remain relatively stable. The course goals and activities are based on the recommended practices put forward by the International Society for Technology in Education (ISTE).

In accordance with the ISTE Recommended Foundations in Technology for All Teachers, (currently accepted by NCATE) students will:

- Be assessed early in the course to ensure their basic competency in the operations and concepts of computers and technology (support is provided for students in need of basic skill development). Basic competence tasks are assigned (i.e. HTML generation and articulation of essential computing concepts) in which students are required to word process, invoke network protocols (e.g. TCP/IP, http) make use of multimedia tools, and manipulate digitized images.

- Develop instructional media for personal and professional use. Students design, produce and evaluate instructional multimedia (specifically, a web site and an authored, stand-alone software package). Students learn to use and employ a variety of productivity tools including image manipulation software, digital cameras, digital sound editing software, internet-based resources, and authoring software (e.g. HyperStudio, web (HTML) editors, Macromedia Director). An anticipated side-benefit of this activity is the development of a professional portfolio of innovative instructional media created by the student and applicable to the student’s intended teaching situation. Ethical use of computers and related technologies (with emphasis on copyright issues) are discussed at length during the course of the semester.

- Apply technology as an instructional tool, exploring and evaluating its potential use through problem-based, practical activities that draw on the students’ knowledge of both subject matter and pedagogy. Through the application of instructional design protocols and practices (e.g. needs analysis, user-centered design, usability testing), students will develop greater sophistication in both the use of innovative technologies and the facilitation of the learning process. The obligation on the students’ part to produce clear documentation of the intended instructional outcome and the product’s development is intended to help students better reflect upon and understand the design/production process and its implications for developing instructional materials. In generating their own instructional software, students develop a personal understanding for the need to apply legal and ethical restrictions upon software and software components (including digitized images, video, and sound); it is to be hoped that students with direct, hands-on experience with creating these components will gain a greater appreciation for the time and effort involved in their production as well as the value placed upon them by their creators. A culminating activity of developing an evaluation
protocol for an actual educationally oriented technological innovation encourages students to
develop an increased understanding of responsible, ethical and legal uses of technology,
information, and software resources as well as the application of quantitative and qualitative
measures of success in facilitating the learning process.

Abstract: This paper discusses the Information Technology (IT) skills that are developed in the Bachelor of Education (Primary) degree at the University of Melbourne, Australia. Students graduating from this degree will be K-6 (also known as primary or elementary) teachers. The study shows that IT skills are developed over the four years of the course with the students progressively developing both generic IT skills and IT skills specific to curriculum areas.

Introduction

The Bachelor of Education (Primary) [B.Ed.(P)] degree is the principal vehicle for training primary teachers at the University of Melbourne in the Australian state of Victoria. [In Australia the term 'primary' is used to refer to K-6 education, thus what is known in the USA as 'elementary school' is referred to in Australia as 'primary school'.] In the state of Victoria there is a strong emphasis on the uses of Information Technologies (IT) or learning technologies in the classroom (Victorian DoE 1999a) with a number of major IT initiatives in place that make it critical that our graduates have good IT skills. This paper will discuss how IT skills are developed in the four year B.Ed.(P) course for pre-service K-6 teachers.

In 1995 the B.Ed.(P) degree at the University of Melbourne was restructured and updated extensively with a move from an activity-based course to emphasise a scholarly, research-informed basis of teaching and learning. New first year subjects were introduced in 1996 and later year subjects were progressively implemented from 1996 to 1999. See Table 1 for the titles of subjects undertaken by students in the new course. In the 1999 academic year the first cohort of students of the revised course were in their final year. Over the period of the development and implementation of the new course structure there has been an ever-increasing impetus to prepare our students - as much as is possible in the changing world of IT - for significant uses of IT in their teaching careers, which may extend to 2040!

In addition to the restructuring of the course for the above reasons, budget constraints imposed a rethinking of the delivery of the course and of the ways in which students undertake practical experience in schools ('teaching rounds'). From 1997 a reduction of 20% was made to the number of days of supervised practical work in schools. In response, interactive multimedia has been used in some subjects to make 'experiences' with children a well-integrated part of the university course and to maximise the learning experiences of our students while on teaching rounds. Development of multimedia resources has been undertaken within the Faculty of Education and has been progressing as funds and time allow it (see Chambers & Stacey 1999, Asp, Chambers, Scott, Stacey & Steinle 1997, Chambers, Asp, Scott, Stacey & Steinle 1997 for descriptions of some of the multimedia projects for use in teacher education). Using such multimedia resources as part of their course work also models to our students some of the ways that IT can be used to facilitate learning.
The eight first year subjects are:
- Studies of Society and Environment
- Arts 1
- Health & Physical Education 1
- Language & Literacy 1
- Mathematics 1
- School Experience 1
- Science and Technology 1
- Children, Schools and Society

The eight second year subjects are:
- Indigenous Australian Studies
- Educational Theories and Practices
- Arts 2
- Health & Physical Education 2 [standard or advanced]
- Language & Literacy 2
- School Experience 2
- Maths 2 [standard or advanced]
- Computers in the Primary Classroom

The ten third year subjects are:
- Science and Technology 2 [standard or advanced]
- Arts 3 [option]
- Children’s Literature [option]
- Mathematics 3 [standard or advanced]
- School Experience 3
- Studies of the Australian Environment [option]
- Curriculum and Teaching [standard or advanced]
- Children with Special Needs [standard or advanced]
- Health & Physical Education 3 [option]
- Language & Literacy 3 [standard or advanced]

The nine fourth year subjects are:
- Issues and Contexts in Education [standard or advanced]
- Research Project / Honours Research Project
- Curriculum Integration [standard or advanced]
- Arts 4 [option]
- Health & Physical Education 4 [option]
- Language & Literacy 4 [standard or advanced]
- School Experience 4
- Science & Technology 3 [standard or advanced]
- Mathematics 4 [standard or advanced]

Table 1: Subjects undertaken by students in the Bachelor of Education (Primary) degree at the University of Melbourne, Australia.

Methodology and Rationale

A survey was undertaken at the end of the 1998 academic year regarding uses of Information Technology (IT) in all subjects of the Bachelor of Education (Primary) course. Information was gathered
in most cases through an interview with the subject coordinator and, for the small number of subjects where a suitable interview time could not be arranged, the subject coordinator completed a survey checklist without interview. Data for years 1 to 3 reflect actual usage of IT for the subjects in 1998, whereas information for year 4 was a projection of intended usage, as 1999 was the first time year 4 of the revised course was taught.

The reasons for undertaking this study were:

- to inform subject coordinators of students' exposure to IT and the skills that could reasonably be expected of students entering a subject;
- to gain an overview of IT skill development in specific subjects so that development of IT skills could progress over the four years students were in the course; and,
- to establish use of IT in the course in 1998 so that these data could be used for comparison in later years.

The IT skills documented are those that were required to complete the subject; although many students within a subject may have used other forms of IT these were not included in this study. For example, students may have emailed lecturers, developed Power Point presentations, or used the Internet for research while undertaking a subject, but these are only documented if they were a specific requirement of the subject. The reason for this was so that we could confidently say that all students had made the stated uses of IT while undertaking a subject.

Results

Basic uses of IT such as file creation and management, using word processors and spreadsheets, and using electronic resources such as the WWW and CD-ROMs for research developed over the four year course, with some subjects such as Science & Technology, Mathematics, and Arts introducing students to IT tools specifically relevant to that learning area. See Figure 1 for a summary of findings.

Uses of IT in Year 1

All first year subjects of the B.Ed(P) required students to submit word processed assignments which incorporates the basic IT skills of file creation and management, entering and formatting text, word processing, and printing. Other basic IT skills and experiences were developed in most subjects with students required to use spreadsheets in four subjects (of eight subjects), to access the Internet for lecture notes and teaching materials in five subjects and to use CD-ROMs to find information for four subjects. Using email and participating in electronic discussions was part of two subjects, with students in 'Mathematics 1' required to report to the electronic discussion forum about their analysis of interviews about children's understanding of decimal numbers they undertook while at a school. Students then had to respond to the findings of other students.

First year students were introduced to the Education Faculty's web site in both 'Mathematics 1' and 'Science & Technology 1' subjects, which included establishing and logging into university computer account, using a web browser, and using the AltaVista student discussion forum. Using databases was introduced in two first year subjects, 'Health and Physical Education 1' required students to upload data they had collected while in schools into a database via a web interface and using databases was also introduced in 'Science & Technology 1'. The uses and evaluation of IT resources in schools was included in three subjects.

As expected, some subjects introduced students to IT tools specifically relevant to their learning areas. In the subject 'Science & Technology 1' sensors and probes were used for data logging to measure and record temperatures, and in 'Mathematics 1' graphics calculators were introduced.

Uses of IT in Year 2

The second year of the course built on skills developed in first year and, as with first year, all subjects required students to use computers to prepare work submitted for assessment. In general, in second year of the course there was a greater emphasis on students developing skills in using electronic
resources available via the Internet, particularly the World Wide Web (WWW) or on CD-ROM. Most second year subjects required students to use the Internet in some way, whether it was accessing the Faculty home page, using email, or searching the WWW for course-related information.

Education library staff introduced students to the local university library system, the 'Buddy' database, which includes paths to access ERIC in the both ‘Educational Theories and Practices’ and in ‘Computers in the Primary Classroom’. The ability to access and evaluate information from the Internet is seen as both crucial to the future teaching careers of our students and an area that was new to most students. As in first year, a number of subjects required students to use evaluate software for classroom use.

**BASIC USES OF IT**
As expected, the subject ‘Computers in the Primary Classroom’ introduced a wide range of uses of IT and developed IT skills upon which other subjects could build. For example, the programming language Logo (as part of the computer software Microworlds) was introduced in ‘Computers in the Primary Classroom’ and the uses of Logo in developing children’s mathematical understanding was developed in ‘Mathematics 2’. Using HyperStudio to develop simple multimedia resources suitable for use in a K-6 environment and all that it entails – using a scanner, creating and modifying images, working with sound files, etc. – developed in students a range of both practical IT skills and the IT concepts relating to object oriented programming. Creating web pages also allowed students to consolidate their uses of a range of file types and develop another avenue for electronic communication. All lecture and weekly workshop notes for this subject were available online and a CD-ROM (Chambers & Dobbins 1997) with other multimedia resources developed for the subject available to supplement the weekly lecture and workshop. Through this regular access to resources via technology, by the end of second year access to the Internet and WWW was a routine part of all students’ academic tasks. This was not true of the students when entering second year.

Uses of IT in Year 3

By third year of the course the IT skills of students are well developed and all subjects assumed basic IT skills and most subjects expected students to use databases, the Internet and CD-ROMs as a routine part of the research process. Again, using and evaluating IT resources for use in schools was required in a number of subjects. Intensive use of web sites was made by a number of third year subjects with ‘Mathematics 3’ having all lecture notes, a bibliography, workshop feedback and a weekly on-line quiz available only via the WWW. In one subject, ‘Studies of the Australian Environment’, students consolidated a range of IT skills by developing a multimedia resource and creating a web site.

Uses of IT in Year 4

The fourth year of the revised course was not taught in the 1998 academic year (the new program was not taught until 1999) so the information supplied was of predicted uses of IT in these subjects. All fourth year subjects will have information about the subject and lecture notes available via the web and will expect students to be able to use databases such as ERIC for assignment research. Most fourth year subjects expect and develop basic IT skills and a number, particularly ‘Arts 4’, ‘Science and Technology 3’, and ‘Mathematics 4’ make extensive uses of IT in a subject-specific way. For example, in the subject ‘Arts 4’ students scan, create and manipulate digital images and in ‘Science and Technology 3’ intensive usage of IT is required to demonstrate scientific understanding through multimedia resources and to create and use simulation software.

Discussion

Needs of Victorian Teachers

Unlike in the USA or the UK, it is the usual practice for Australian university students to go to a university in their home state, with over 90 per cent of Australian students attending a university in their home state (data extracted from Table 10, p26, DETYA 1998). Thus, it is a reasonable expectation that most students undertaking a teacher education course at the University of Melbourne will be from Victoria and are likely to start and, for many, continue their teaching career in Victoria. Because of this, the initiatives of the Victorian Department of Education (DoE) and its requirement of IT skills of teachers are very likely to be of relevance to teacher education graduates of the University of Melbourne as the Department of Education is the major employer of teachers in the state. Like Education Departments across the developed world, the Victorian Department of Education has encouraged the use of IT in the classroom and Victoria is leading the way in Australia in the uses of IT in the classroom. Among the
initiatives of the Victorian DoE is a program started in 1998 to provide up to 36,700 notebook computers to all principals and teachers in Victorian Government schools over a period of five years. This is a three-year lease arrangement with teachers paying AU$450 over the three year period - approximately AU$3 (US$2) per week (Victorian DoE 1998). This is to encourage teachers to have their own laptop computer so that IT skills can be developed and so that IT tools become a standard part of all teachers’ ‘toolbox’.

The Victorian DoE has also prepared a ‘Learning Technologies Capabilities Guide’ (Victorian DoE 1999a) that suggests goals for skill development in a full range of learning technologies and includes a ‘Skills Development Matrix’ that identifies six key skill areas for Victorian teachers for using IT (Victorian DoE 1999b). These are: (i) using and managing technology; (ii) using basic computer applications; (iii) using desktop publishing and presentation software; (iv) using multimedia; (v) using communication technologies; and (vi) using learning technologies in the key learning areas (Victorian DoE, 1999b). Thus it can be seen that it is crucial that, in addition to the raft of other skills required of a teacher, our new graduates are skilled in these areas of IT use.

IT skill development of our students
In combination with increasing availability of computers - almost all students have access to a computer at home - and the increasing use of computers for recreational activities, our later year students now regard IT tools as ‘nothing special’ and use them as a routine part of any piece of work without thinking twice. This is a very different situation from when the students now in the final year of the course were in second year (1997) and for many turning on a computer was an uncommon activity. In more recent years students are entering the course with more advanced IT skills and significantly greater exposure to IT, usually through using the WWW for recreational purposes. This change in the students’ attitudes and abilities with IT is both a mirror of the changes in the local community and a reflection of the continued exposure and uses of IT required in the subjects the students are studying.

From this study it can be seen that from the first year of the B.Ed.(P) course basic IT skills are introduced and reinforced each year, with some subjects introducing IT tools of specific relevance to that learning area. That IT skills were not further developed and more use made of IT in the third year of the course, in particular in the year following a year-long subject specifically about using computers in K-6 teaching, was made evident through this study. Greater use of IT in the third year of the course is desirable to consolidate and extend the IT experiences and skills developed by students in the first two years of the course. Now that this is evident, later year subjects can respond by increasing the range of IT skills students develop. In addition, as the IT skill levels of students entering the course rise more emphasis can be placed in the area of using IT with children in classrooms to enhance teaching and learning, rather than the mechanics of using IT tools.

Conclusions
It is now demanded that new teachers will be competent in using IT both for their own professional purposes, such as research and administration, and for enhancing teaching and learning in their classrooms. This overview of how IT skills are developed in one teacher education course for prospective K-6 teachers has demonstrated that over the course of four years through requiring our students to undertake certain tasks using IT even the most technologically-reluctant student must engage with IT and must develop the skills demanded of a teacher in the new millennium. The study has exposed some areas where greater uses of IT could be made, in particular in the third year of the programme, and has highlighted the need to keep ‘raising the bar’ of IT skill development to keep up with the ever-increasing IT skills of entering students.

Abstract: Advances in technology have made access to the Internet available to more and more individuals and have extended the traditional classroom walls. Incorporating the use of the Internet into teacher education programs is an important way to develop future teachers competent in technology implementation. The purpose of the project was to determine if students could interact with students at another university concerning pedagogical and professional issues.

Introduction

Advances in technology have made access to the Internet available to more and more individuals and have extended the traditional classroom walls. Incorporating the use of the Internet into teacher education programs is an important way to develop future teachers competent in technology implementation. Furthermore, it has been suggested that the Internet is the fastest growing educational phenomenon in the history of the world (Dryli & Kinnaman, 1995). Driven by the desire to enhance preservice teachers' technology experiences we created an electronic bulletin board project. Our methods were developed through literature searches of other successful electronic communications studies (Downs & Rakestraw, 1997, Gamas & Solberg, 1997). Gamas and Solberg (1997) identified several strengths of including electronic bulletin board discussions in their courses. Some of these strengths include using time outside of class to research topics, students' have an increased comfort level with their peers, and value of the online discussions and technology use. “Providing a greater integration of technology into teacher preparation programs” was a driving reason for introducing technology into a course (Downs & Rakestraw, 1997).

The purpose of the project was to determine if students could interact with students at another university concerning pedagogical and professional issues. As teacher educators we believe that use of the bulletin board will allow for professional networking and provide students an opportunity to express their beliefs and concerns in an open forum outside of class with peers and current professional Physical Educators.

Methodology

Project participants included undergraduate teacher education majors at two universities (n=44), mentor physical educators (21) and two university professors. WebCT was the software package used to support the electronic bulletin board communication. In addition to the electronic bulletin board students utilized WebCT’s internal homepage development feature. Creation of homepages was intended to provide participants with a vehicle for learning and to establish a sense of community. All of the project participants completed the
homepages within the first two weeks of the project. Students and mentors were also encouraged to access the homepages and learn more about their online peers.

The bulletin board project was designed to provide the college students with an experience beyond the traditional classroom and with the opportunity to professionally network. Gamas and Solberg (1997) studied the use of electronic communication tools in five separate university courses. Their methods section suggested the use of professor posted messages to electronic bulletin board to begin the interactions. This same strategy was used in our study. Approximately every three weeks throughout the semester the professor at the Midwestern University site posted a case study and guided questions (collaboratively developed between professors) to the main forum. Participants were encouraged to respond to the cases and questions by posting a message in reply to the case. Topics included cases on the coaching issues, drug/steroid use, student teaching loyalty, and establishing boundaries with students. Participants were encouraged to openly discuss their opinions on the main forum.

Data Sources

Data sources for this project included participant responses to the case studies, interactions between undergraduate students and mentors, and survey results upon completion of the project. Qualitative methods (Bogdan & Biklen, 1992) will be used to document and describe the process of identifying emerging themes. To organize analysis of data sources, the theoretical perspectives and methodological approaches of structuralism will be enlisted. Structuralism views “documents” as “texts” (Manning & Cullum-Swan, 1994, p. 467). As such, once the data is accumulated in written form, it will be read through several times. With each reading a set of tentative themes will develop. The emerging themes and issues arising from the readings will create the codes or interpretive frames that guide and structure the analysis. Trends and commonalties will inform researcher understandings of participants perspectives on the case study issues. Finally, the surveys will provide information concerning the attitudes of the participants toward the value and perceived gains of connecting undergraduates with mentors in an effort to discuss teaching issues.

Results

Data from this project are still being collected, but preliminary results will be reported during the SITE session. The results of this project will add to the collective knowledge of mentoring and technology implementation at the university teacher preparation level. It is further intended to provide insight concerning teachers experiences in school settings versus the idealized perspectives of undergraduate students who have never taught a course with students in the school systems.

Abstract: This paper examines one collaborative effort developed to improve pre-service teacher attitudes toward teaching with technology. An interview and email exchanges were used to determine the history of the project, the benefits, and the problems associated with this collaborative effort. Recommendations for further collaborative efforts are also included.

Introduction

“We think that interdisciplinary collaboration holds special promise for research on teaching and teacher education because it addresses the multifaceted nature of teaching and learning to teach.” (Eisenhart & Borko, 1991)

While attending a conference on technology and teacher education, the keynote speaker began his remarks by asking the audience this question, “How many of you have been approached by faculty from the Arts or Sciences to work with them on using technology for teacher preparation?” I was the only one out of several hundred teacher educators to raise his hand.

During my first year (1995-96) at Northern Kentucky University (NKU), my chair, Ken Carter, asked me to attend a meeting with him and two members of the Chemistry faculty. At that meeting, Vinay Kumar and Julia Bedell described a new course they had developed for elementary and middle school pre-service teachers. The course utilized some of the latest technologies to deliver the content in the lecture sections and to perform experiments in the laboratory. I was excited about what they were doing because I had been exploring the use of many of these same technologies in my eighth grade science classes prior to joining the professorate. What Vinay and Julia were looking for was a faculty member from the School of Education to collaborate with on assessment and evaluation of the project. There was compensation for time and travel as a result of a grant. I volunteered. Thus began a fruitful collaboration between faculty of the Chemistry Department and the School of Education at NKU.

This paper will examine the history, benefits, problems, and future of collaborative programs to improve teacher education programs.

According to Robert Freeman (1993, p.33), collaboration is: “the condition that occurs when two or more people or organizations join forces over a long period of time to produce something neither can produce alone. In the process, each participant contributes something significant and different, derives something of personal and/or organizational benefit, and acknowledges the mutual dependence on the other required to achieve the mutually desired results.”

History of the Project

Vinay Kumar, Professor of Chemistry, provided the history of this collaborative effort. “The proposal for this project was originally submitted by Leslie Leverone. Soon after the proposal was funded, Leslie left to accept another job. Before leaving, she asked me if I would be interested in becoming the principal investigator and conduct this project. I said yes. I became interested in this project because of its
two main goals: To improve students’ attitudes toward the learning and teaching of chemistry, and to develop students’ problem-solving skills through discovery and guided-inquiry activities. Subsequently, Julia Bedell and I expanded the project to include the following additional goals: To integrate technology in both the lecture and lab courses, to enhance learning through multimedia presentations, and to provide information about chemical education, energy and educational technology resources.

Benefits of Collaboration

In an interview with all participants in this collaboration, the following benefits were mentioned. Julia Bedell provided the following comments: “Vinay and I started to work together on this new chemistry curriculum in the fall of 1994. Within the first year, we recognized that an important component of curriculum development is assessment. While developing a pre-and post-survey to assess our proposed new course, we recognized that collaborating with an expert in the area of evaluation would greatly enhance the project. We approached…Vern, who has always maintained a close relationship with the School of Education to arrange a meeting with interested Education faculty members. We were very fortunate that Ken Carter, acting chair of the School of Education, was very supportive and promptly met with us along with Steve Walker, and [you], from his department. Through [your] contributions we were able to develop, administer, and process multiple evaluation instruments that better measured the impact of this new curriculum. Our cooperative efforts which led to scholarly publications and permanent curriculum changes reaffirm the age old saying, ‘The whole is greater than the sum of its parts.”

Vern Hicks added, “There are several benefits. First of all, you look at different ways of presenting things. Secondly, I think that the people in the School of Education have more experience in communicating to school teachers and identifying with the discipline problems that we don’t have in the colleges. So it helps in really meeting the needs of teachers in terms of where they are… I found that some of the tips I picked up while working with teachers and teacher educators, I use in my own classroom. While coming up through the science program, I never had a formal course in education. So some of the questioning techniques, some of the ways of presenting things that KTIP [Kentucky Internship Program] and KERA [Kentucky Education Reform Act] emphasize are finding their way into my own teaching.”

Vinay replied to the question, “What benefits have you found through collaborating with other faculty members?”

“We have a strong and friendly working relationship with the School of Education at NKU. Prior to this project, Education and Chemistry faculty had worked jointly to establish and support science and chemistry alliances for middle and high school teachers. The curriculum for the new chemistry course (CHE 105) for pre-service elementary teachers developed under this project was modified with input from the education faculty. Two surveys that are used for assessment in this course were refined based on the input from [you] and Ken Carter, faculty in the School of Education. This type of cross-college interaction has proved to be extremely beneficial and has enabled us to successfully implement the KERA reforms.”

I find working with faculty from the Chemistry Department personally and professionally rewarding. Besides the opportunity to attend and present at conferences, I enjoyed writing an article, “Technology: Catalyst for Enhancing Chemical Education for Pre-service Teachers” (1999), with Julia and Vinay. I also feel validated in my field when asked to share and utilize my expertise in educational assessment and research. I recall one particular meeting with Vinay and Julia fondly. We were discussing performance assessment in their class. I told them about rubrics, “the criteria for judging students” (Popham, 1998, p.148). When told that students should be provided with these prior to the performance, Vinay’s response was, “You mean you tell the students beforehand how they’ll be graded?” I replied in the affirmative. Vinay thought a while and said, “Interesting. It could eliminate some of the problems I have with students arguing about their grades.” After our meeting, they developed a lab practical as part of the final exam with a rubric. The students did well.

Problems
During the interview, only two problems connected to this collaboration were mentioned. The first dealt with time. Vern summarized this concern, "It's very hard to find time to work with people from the School of Education because so many of you work in the field and spend so much time advising students. The main problems I've had are in terms of arranging times. I can't think of any friction

I do find it difficult to arrange my schedule to fit with the others. Teaching and supervising off campus makes it hard to attend meetings with faculty from other colleges.

The second concern dealt with lack of recognition for participating in these types of projects. Vinay stated, "Overall, our chair has been supportive. I did point out to him that these activities—developing multimedia lessons or computer-interfacing lab experiments, their assessment based on collaboration with faculty in other colleges, etc.—are extremely time consuming and should be treated as scholarly activities, and recognized as much as doing research with students. As far as deans are concerned, the Dean of Arts and Sciences is very enthusiastic and serves on the board of the grant provider. When he sees faculty from two different colleges collaborating, he personally thinks it's great."

There are groups within the sciences that want to collaborate and other groups that think that science [faculty] should work only within their departments and not work with other departments. No offense, but there are those who think that faculty in departments of education show people how to do something without having a substantial background in that field, and this perception is not limited to the sciences.

The School of Education tends to look quite favorably on these types of activities and has encouraged faculty to seize opportunities to collaborate with faculty from other departments.

The Future

As schools, colleges, and departments of education come under more scrutiny by state legislatures and as NKU endeavors to strengthen and enhance P-12 math and science education through its new Center for Integrative Natural Sciences and Mathematics (CINSAM), it will be necessary to build more bridges between faculty. Janice Fauske (1993) notes that lack of collaboration between arts and science faculty and teacher education faculty inhibits effective reform of teacher preparation programs and the development of programs such as CINSAM. To foster and promote collaboration at colleges and universities that improves teacher education programs and increases the likelihood of successful integrated programs, Fauske (1993) recommends five sustaining conditions. The first is administrative support that legitimizes collaboration. Second is viewing collaboration as legitimate research. Establishing arrangements for encouraging communication is third. Fourth is building consensus around shared goals. And fifth is the institutionalization of collaborative practice.

Abstract: This paper focuses on the Discover South Dakota Tellecollaborative Project and how South Dakota State University is using the project to tie together technology and teaching in the preservice required computer class. Two semesters of the computer classes have been involved in this project providing some interesting experiences and anecdotes in response to technology and collaboration. The paper will touch on the telecollaborative curriculum in the Discover South Dakota project. Students in the preservice computer classes provide clues for the Mystery City portion of Discover South Dakota, involving them in a rich opportunity to make technology come alive. Finally, the paper will examine how the project reinforces the opportunities that technology provides in the classroom for preservice teachers.

Introduction

The emphasis on technology in preservice education has been significantly heightened in our state. South Dakota was awarded a technology challenge grant in 1998, and has been using the grant to strengthen the means in which K-12 students and teachers interact with preservice students. The technology challenge grant (Learning Organizations for Technology Integration – (LOFTI) provided a connection between Technology Innovations in Education (TIE), K-12 teachers and higher education. The focus of the grant and the people involved in the grant has been to provide technology-rich curriculum to preservice students as well as providing practicing teachers the opportunity to strengthen their skills with technology.

Through this grant, individuals were introduced to a project called Discover South Dakota, which was being piloted with a few school districts around the state. The project facilitated by TIE provided a telecollaborative environment in which fourth, fifth, and sixth graders studied about South Dakota history and geography. The facilitators of the project asked if the Integrating Computers into the Classroom students would like to participate in the Discover South Dakota Project by providing clues for the Mystery City section. The request for participants occurred during the Spring 1999 semester so the project was quickly inserted into the current schedule. After participating, my students indicated verbally at the end of the Spring 1999 semester that this was a project they enjoyed and felt beneficial to understanding technology use in the classroom.

The focus of this paper is on the Discover South Dakota Project as it is being used in the South Dakota State University’s Integrating Computers into the Curriculum class. It is an opportunity for the preservice students to interact with K-12 students using technology. First, the paper will touch on the telecollaborative curriculum in the Discover South Dakota project in particular the Mystery City component. Next, the paper will discuss how preservice students become involved in the project and the requirements of the classroom assignment. Finally, the paper will examine how the project reinforces the opportunities that technology provides in the classroom for preservice teachers.

Mystery City
In the book, Virtual Architecture: Designing and Directing Curriculum-Based Telecomputing, (Harris, 1998), telecollaboration is defined as “using a computer connected to a telecommunications network, like the Internet, to collaborate with others at a distance” (p. 133). The Discover South Dakota Project involves students by connecting at a distance through the use of the Internet. The project focuses on fourth, fifth, and sixth graders during the South Dakota history curriculum. “South Dakota students can explore the rich and diverse heritage of the Land of Infinite Variety through creative projects and telecollaborative connections to classrooms statewide,” (TIE, 1999). Teachers that utilize Discover South Dakota are provided with training and curriculum materials to use during the project. There are various activities associated with Discover South Dakota: three themes, weekly features, and an area for the K-12 students to participate with one another and outside experts. Also available online is a teacher’s resource page. There is a cost for K-12 schools to participate in the project.

The three themes are used to explore South Dakota each focusing on specific questions about South Dakota’s diversity, people and events, and places. The weekly features include “ which display photos from the nooks and crannies of the Cultural Heritage Center in which students are asked to guess what the object is. Another feature is “Mystery City”, which is the feature the EDFN 365 students were involved with. In Mystery City, clues are provided for students to research and reason the answer as to what the Mystery City is for the week. Fourth, fifth, and sixth grade students with the help of their teacher check the Mystery City site during their Monday class. Some students do venture guesses on Monday based on research that they may have completed previously. Clues are posted daily so the classrooms generally check the site daily.

Preservice Participation

In early Spring 1999, preservice students in the Integrating Computers in the Curriculum course were asked to provide clues for the Mystery City portion of the project. The preservice students worked in groups and started to participate in the project as an add-on project in our syllabus. The preservice students were given an option, they could participate in the Mystery City project or choose to complete the course’s original final project. Over 85% of the students opted to participate in the Mystery City Project. As part of the project, the groups also created a PowerPoint presentation about their city. They also put together information about their expectation of the project and what they discovered about student’s abilities to research by responding to the questions of:

- What went well and what did not go so well
- What was learned about how kids think and do research
- What was unexpected
- How might this approach be adapted for other teaching/learning activities

These groups submitted their Mystery City clues to the project and three groups were chosen to participate. The clues were posted each day by the project director, and the fourth, fifth, and sixth graders sent emails to the selected preservice students, furnishing what the kids thought the correct answer was. The preservice students emailed back to the K-12 students providing feedback about the answer and giving additional suggestions and encouragement to the K-12 students. Three groups participated by facilitating Mystery City during March. These students indicated that the K-12 students were providing reasons for their answers and for the most part were using the clues to deduct the correct answers. The groups averaged about seven messages a day during their week of Mystery City. That number was affected by the high number of classrooms participating in our first week, the second week had a lower rate of participation.

Overall, the preservice students that participated expressed satisfaction with the project. One student emailed comments stating the opportunity showed to her that technology has a place in the classroom, even in the primary and middle school levels. When asked about retaining the project for the next semester, students agreed that the project should stay in the course curriculum; suggesting, however, more structure for participation in the project. Other comments focused on the competitive nature of the project – only three groups can participate so not all the EDFN students experienced contact with the K-12 students. However, the number of groups actually facilitating the project are determined by an outside entity.

The following fall semester, the Mystery City project was formally incorporated into two sections of the Integrating Computers into the Curriculum syllabus. The design plan was to devote time and energy
to research and produce not only clues for Mystery City, but also a virtual tour of the city along with some historical background. Therefore three weeks were allotted for the Mystery City “Unit”. Students were instructed in the use of PowerPoint presentations, information searching, and the use of digital cameras and scanners before starting the project. The EDFN 365 students would learn as they completed this project skills including information research using both electronic and traditional resources, PowerPoint presentation skills, integration of resources, and communication via email and discussion boards.

Mystery City was used as the EDFN 365 assessment project for the unit on Multimedia applications. The purpose of the project was to engage students in learning with technology and develop confidence in using technology-integrated curriculum. Each team was to choose a South Dakota city to develop as the Mystery City. The team researched information about the city to develop the clues as well as a multimedia presentation about the city. Students had to use sources that K-12 students would have available to them including the Internet, library and textbooks. Preservice students kept a search log which indicated the date of their search, the sources of information, and who found the information. We talked about formulating clues that wouldn’t be dead giveaways yet not so difficult that the fourth, fifth and sixth graders wouldn’t be able to guess the city.

The preservice students responded by searching information using various sources and discovered interesting facts about their respective cities. Several students were surprised that they couldn’t find information on the Internet – they had become so reliant on it! So we had the opportunity to expand our database discussion by referring to the various newspapers resources online around the state. They spent numerous hours gathering information for the project as well as crosschecking information. For example, one of the groups came up with some great clues based on their personal knowledge but they had to be reminded that K-12 students had to be able to find the answer so they spent time verifying their personal knowledge with existing sources.

Once the students submitted their clues for Mystery City, they turned to creating their presentations for class. In class, information about planning PowerPoint Presentations was shared and students were expected to storyboard their presentations. In the final assessment, not only would their PowerPoint presentation be assessed so would their presentation ability using the PowerPoint as a visual aid and the ability to collaborate with others be evaluated. The presentations were insightful as to how PowerPoint Presentations are perceived. Several groups read their PowerPoint presentations word for word, which doesn’t capture the true use of PowerPoint as a visual aid. Several groups however, grasped the importance of PowerPoint as further illustrating the oral presentation by providing a format for visual information. The other interesting event that occurred was the class’s freedom to provide additional information to other groups and to even question the sources in terms of reliability requiring students to use higher order thinking skills to pull together their information and answer the questions. And we all learned something new in terms of South Dakota history.

Three groups of EDFN 365 students had their clues chosen for Mystery City. SDSU’s EDFN 365 class was responsible for providing clues during weeks five, six and seven. In week five, right away Monday morning we were notified of the chosen city by email and the first clue was posted to the Discover South Dakota website. Group One was asked to check the web site for the students’ guesses beginning Monday morning, checking at least twice daily responding to any emails. If there were any emails, the group would read and respond to the students. The group continued checking throughout the week until the answer was revealed on Friday. Group One received several emails during the first day with various attempts from the K-12 students to reason out the correct answer. According to the group, they had some correct answers the first day but they were surprised at some of the answers they received. The group also indicated that K-12 students backed up their guesses with research by citing textbooks they had read. Tuesday’s clue helped many K-12 students answer correctly. Overall this group received email each day of the Mystery City project with some great results.

- Monday’s clue: What city in South Dakota had the first telephone exchange?
- Tuesday’s clue: What town was made famous by the “dead man’s hand”? 
- Wednesday’s clue: What town has a hotel that is supposedly haunted by the town’s first sheriff? (1999).

In week six, again we were notified Monday morning as to which clues had been chosen. Group Two, when informed was very excited about participating. This group had personal ties to the city chosen and came up with clues that would get the K-12 students hunting! For their presentation, they had gone out to take pictures with the digital camera so that their clues would be visual as well as textual. We were informed however, that at this time Mystery City would remain textual clues. The group, however, used
their pictures in their PowerPoint presentation, which added visual clarity to their presentation. Monday came and went with no guesses. The group had a few guesses on Tuesday and Wednesday but participation in Mystery City was not as high as the previous week. The group speculated as to why they did not have a high participation rate. A couple of reasons may have caused less participation. One reason may be that classes use Mystery City as it fits their schedules so if there were tests or other curriculum requirements used in the classroom, students may not have participated for that week of Mystery City. The group also inquired about the level of difficulty of their clues and thought maybe they could have used other facts they had discovered during their search.

- Monday’s clue: The development of the railroad caused the whole town to move from its original location to C.B. Kennedy’s Homestead.
- Tuesday’s clue: This town was the 1995 South Dakota Community of the Year.
- Wednesday’s clue: If you are looking for an exhibit of former Prairie life in South Dakota, this group of 40 buildings 3 miles outside of town will show you what you are looking for, (1999).

In week seven, we were notified Monday morning as to the clues for the week. Group Three began their facilitation of Mystery City. Again this group was very excited about the opportunity to participate. This group had also compiled some interesting facts and figures about the “Mystery City”. This group used again personal knowledge coupled with facts and figures available in textbooks and Internet to create their clues. This group also gathered pictures from a local historian and used the digital camera to illustrate one of their clues. They had several guesses on Monday but no correct answers. Tuesday and Wednesday brought more guesses. When the K-12 students guessed the correct answer, this group sent the students a picture of the elephant hunt. Group Three also created some excitement in their town because of their participation – the state championship trophy had been locked in the bank vault for years and my students went to take pictures of it for their presentation. As they were taking pictures, many people that had lived there for years stopped to look at the trophy and hear about their project!

- Monday’s clue: What is the name of the town that is located 207 miles from the capital of South Dakota?
- Tuesday’s clue: On May 15, 1916, a circus was in town for a couple of days. One day one of the circus elephants escaped from its cage and was loose in town. In order to capture the elephant they were forced to kill it with a gun.
- Wednesday’s clue: What is the name of the town that was the first team in South Dakota to win three consecutive State Championship Boys Basketball titles? (1915, 1919-1920, - in 1916, 1917 and 1918 there were no state games because of World War I).

Preservice Technology Opportunities

Mystery City as a project has provided preservice students an opportunity to achieve several objectives within the EDFN 365 classroom and provide a model of telecollaborative to my students. According to recent technology and preservice surveys, students know they will have to use technology in their teaching but their current educational situation focuses on acquiring the skills not the modeling of technology (Deal, 1999). Modeling of technology integration is important for the success of preservice students’ implementation of technology in their classroom teaching. This project has given EDFN 365 students interaction with K-12 students using Internet as the only means of communication which has provided additional thought in our classroom about the uses of technology in their teaching. Another outcome that was unexpected was the desire to use pictures as clues. We approached the project leaders about this explaining that my students were developing PowerPoint presentations about these cities. Currently, we are exploring the use of pictures as clues and having the EDFN 365 students publish their PowerPoint Presentations on the project website. Having the students participate in a public project also improves the quality of their work. This semester, many of the EDFN 365 students went far beyond my expectations.

It has real-life relevance, which has excited the preservice students and has inspired a couple of them to think of similar projects that they could incorporate into their own classrooms. One student wrote a lesson plan based on her experience, which she plans on delivering and sharing as she goes into her student
teaching. Several of the students in this class are social studies majors and will actually teach South Dakota History—these individuals seemed to look at this project as having possibilities in their classrooms of the future. Students also get an idea of some of the projects that the K-12 students are completing with the use of technology. Besides Mystery City, Discover South Dakota also has space for the K-12 students to publish their work. The EDFN 365 students were amazed at some of the projects these kids are doing from simple web publishing to short movies.

That is what is so exciting about using telecollaborative projects, it provided students a springboard for other ideas that excite and ignite them to use technology as a tool for learning. Several students have indicated that they may continue to participate in projects such as Discover South Dakota because they are aware of the possibilities after their experience. Students suggested activities such as using the same format but using presidents instead of cities. Another group came up with a mystery disease plan.

As several of my groups discovered, they not only have the power to touch their own lives with technology use, but they have reached out to K-12 students, and community members through the project. There are other possibilities of expanding the project to include other technology assignments as well as linking with the Education of Place curriculum that is currently being developed.

Not only does this experience provide students an opportunity to meet the ISTE standards, but also the activity in future will provide students a way to meet their technology graduation requirements. Students attending a state university will be required to demonstrate technology competency upon graduation. As EDFN 365 is a course that goes a long ways to meeting this requirement in the College of Education, the Mystery City project provides a great vehicle for information searching skills, evaluation of information, using technology tools to produce a presentation, communication abilities with email and various other aspects that will meet this requirement.

Conclusion

In conclusion, telecollaborative projects provide a link between K-12 and higher education that is beneficial for the preservice teachers and the K-12 students. It provides both with the ability to experience real-life interactions that are exciting. The Discover South Dakota project not only provides a curriculum for school districts, but also helps to structure the Integrating Computers classroom by providing the opportunity to have students create and deliver a technology enhanced lesson. This experience has had a positive influence on the possibilities of technology in teaching, which has been a goal in the class.

References

Abstract: Through a field experience in the Fifth Dimension, preservice teachers are acquiring technology competencies required for licensure in the state of North Carolina. This technology rich environment allows observations of numerous learning experiences involving computers and multi-media. Simultaneously, this program offers unique opportunities for children to experiment with educational software and other technology equipment. This paper describes an analysis of both preservice teachers and students and their learning experiences during this program.

Introduction

For years we have conducted research on a learning environment, the Fifth Dimension, that is based in the doctrine that learning and development are cultural-historical in origin (Cole, 1996; Luria, 1979; Scribner & Cole, 1981; Vygotsky, 1978). This view is based on the social constructionist idea that learning is a collaboration of both person and environment (Resnick, Levine, & Teasley, 1991). At our Fifth Dimension sites, children volunteer for a form of play on computers using a variety of multimedia and software. University students enrolled in practicums during their preservice teacher education programs aid children in achieving their goals by participating in setting goals, developing daily objectives, making decisions, and developing strategies.

To enhance the concept of the importance of collaboration of both persons and environments in the context of learning and ultimately teaching for preservice teachers, we have created an after school program using the technological rich learning environment of the Fifth Dimension. Through this program, we have attempted to provide "hands-on" experiences in which play, education, peer interaction, and affiliation are deliberately mixed while using technology as a tool. We have demonstrated that participants in this program achieve higher levels on tasks in which they engage (Nicolopoulou & Cole, 1993), acquire proficiency in using technological tools in the process of attaining personal goals (Schustack, King, Gallego, & Vasquez, 1994), and that special education students who participate in the Fifth Dimension progress in the same manner as their regular education counterparts, with similar success (Zimmerman & Blanton, 1993).

Preservice teachers participated in this after school program as part of a field experience during a class, "Teachers, Schools, and Learners." While preservice teachers are participating in this technology rich environment, they are acquiring technology competencies required for licensure in the state of North Carolina. The environment also allows for the preservice teacher to observe numerous learning experiences involving computers and multi-media and the learning that takes place during these tasks. Simultaneously, the program offers a unique opportunity for children in grades kindergarten through sixth to experiment...
with educational software that refines technology skills that are a part of the state's standard course of study.

Technology Competencies for Preservice Teachers and K-8 Students

In 1994 a Task Force was established to recommend educational technology initiatives which would eventually encompass the total North Carolina Educational system. This Task Force created a list of technology competencies for inservice teachers, teacher education faculty, and preservice teachers in the state. Each institution of higher education was given authority to devise and implement a technology program for their preservice students and teacher education faculty. Preservice teachers must now demonstrate competencies on basic technology skills and develop technology portfolios demonstrating competence on advanced skills.

The basic technology competencies defined by the task force include skills and knowledge in the areas of: Computer Operation; Setup, Maintenance, and Trouble Shooting; Word Processing and Introductory Desktop Publishing; Spreadsheets and Graphing; Databases; Networking; Telecommunications; Media Communications including Image and Audioprocessing; and Multimedia Integration. Advanced competencies include: Curriculum; Subject-Specific Knowledge; Design and Management of Learning; Child Development, Learning, and Diversity; Social, Legal, and Ethical Issues. Verification of competence in advanced areas must be demonstrated in a portfolio format. These competencies may be found on the North Carolina Department of Public Instruction web site: http://www.dpi.state.nc.us/tap/techcomp.htm.

All eighth grade students in the state of North Carolina are tested on computer skills. The computer curriculum for the state may be found on this web site: www.dpi.state.nc.us/testing/#curr. This curriculum consists of nine strands: keyboarding; word processing/desktop publishing; telecomputing; database; spreadsheet; societal issues; ethics; computer terms, operation and care; and independent curriculum software use.

Web Site Database

In order to observe the impact of this experience on preservice teachers a web site was created to hold a database of student biographies, fieldnotes from the after school Fifth Dimension sessions, and preservice teacher attitude surveys. This web site: http://www.ced.appstate.edu/intercollege/2800 is a place for preservice teachers to write fieldnotes about their experiences in the Fifth Dimension. General observations and experiences are described and are accessible to preservice teachers and their professors in the sections of “Teachers, Schools, and Learners” that correlate with the Fifth Dimension experience.

Fifth Dimension

About seventy-five percent of the activities in the Fifth Dimension use computers and telecommunications, including educational software, computer games, telecommunications activities for searching the Internet, and tools for computer-mediated and video-mediated conferencing. Subject matter covers the traditional school curriculum and includes communication skills, math, social studies, health, science, technology, and the arts, all with an emphasis on problem solving. Over 120 educational computer games such as “Carmen San Diego”, “The Amazon Trail”, “Dino Park Tycoon”, Opening Night”, “Lego Logo”, are used in this program. Other technology tasks include Internet searches, digital cameras, and video conferencing equipment.

Analysis
An examination of preservice teacher fieldnotes was completed. Common themes were found. Many comments were made as general site observations discussing the setting and apprehensions about dealing with a new educational environment. One such statement:

When I walked in today it was real quiet again and the doors in the hall were closed. In the computer lab all of the interns were in there working on the games. As we had said in class, we all were not sure about the games and felt like we did not know what we were doing. As Stephen and I walked down the hall he said that he was going to go in and work on games until it was time to get our kids. Well, everyone else was doing the same thing. I guess we all are on the same level and worried about what we are doing. Interesting!

Another common theme to fieldnotes dealt with technology. Preservice teachers may have been exposed to technology as students and they may have been told about educational uses, but until this experience, they may not have observed first hand how technology can be applied to learning. The following entry illustrates the virtues of telecommunications and the inspiration for further learning in technology.

In this course, I find the telecommunications that we set up with UCSD to be very interesting and exciting. It allows me to interact with fellow students across the country. Through these telecommunications, I am able to learn about how their Fifth Dimension operates, as well as their classroom. From this class, I am finding that it is a challenge to learn all of today's technology and how it operates.

Comments from other preservice teachers included feelings of ignorance, although very little despair, about computers.

The whole idea of the lab amazes me. I think it is a wonderful way for the children to learn and for us to learn also. Also, the technology that comes with this class is incredible. I am very "dumb" when it comes to computers so this class will definitely be a challenge for me.

Others wrote that they were excited about the technology aspect of the Fifth Dimension, especially with students who are computer literate.

I am interested in learning how children work with technology since many of the students were practically brought up in the computer era.

A large part of fieldnotes included reflections on the learning process,

I am convinced that when a child sees something more than once she will learn it well and know how to do it.

I was reinforced that children learn after seeing things more than once and that they can do things faster after they get it into their brain as to what they are doing.

the social-constructivist environment,

I enjoy working on computers and being able to go through the Fifth dimension program with the children, not teaching the children, but learning together as we go will be very rewarding.

and motivation.

I learned that they look up to us as older role models, and it is us that motivates them along with their peers.

That some get more excited than others about achieving but if the intern gets excited with them it will motivate them more.
To better understand how classes, that corresponded with field experiences in the Fifth Dimension, met technology competencies with preservice teachers, four professors of these classes were surveyed. Professors answered that they used email, required assignments to be word processed, used web sites to download articles, required students to subscribe to listservs, taught skills for multimedia presentations, and introduced the state's technology competencies. One section of the basic technology competencies is computer skills operation. In the Fifth Dimension, preservice teachers along with their student partners complete many of these such as:

1.1 Start up and shut down computer system and peripherals
1.2 Identify and use icons, windows, menus
1.3 Start an application and create a document
1.4 Name, save, retrieve, revise a document
1.5 Use printing options

Some of the professors gave more specific information that can be connected with advanced state technology competencies. One professor wrote that she encouraged students to find articles on the web relating to special education, which corresponds with an advanced competency in "essential knowledge and skills":

13.4 Use appropriate local, state, and national services or resources to meet diverse learning needs through technology.

Another professor encourages the use of technology in class presentations which meets a requirement under advanced essential knowledge and skills:

12.3 Use computers and other technologies effectively and appropriately to communicate information in a variety of formats on student learning to colleagues, parents, and others.

All four professors were practicing the integration of technology in their courses. Positive attitudes toward integrating this technology accompanied the descriptions of their use.

Conclusions

After North Carolina adopted technology competencies for licensure, colleges of teacher education throughout the state scurried to meet the needs of preservice teachers. Faculty at institutions of higher education were offered training in technology and encouraged its integration, when appropriate into their classrooms. It was felt that skills alone would not prepare new teachers for the technology challenge. Technology must be modeled in order to foster positive attitudes and encourage appropriate use in public schools.

The Fifth Dimension has provided a "hands on" technology and learning experience that corresponds with a class on "Teachers, Schools, and Learning". Initial exposure to state technology competencies may be obtained in this setting. Many of the basic and advanced competencies could also be completed in the Fifth Dimension.

Most preservice teachers in our program gained an insight into the value of technology in education. Fulfilling state requirements was seen as an added bonus during the Fifth Dimension. Achieving an understanding of children's learning processes, being involved in a social-constructivist learning environment, and gaining hands-on knowledge of student behavior early in a teacher education program were reported as valuable experiences by our preservice teachers. Overall, this program was highly successful in these areas and hopefully will continue to provide a model for teacher education programs.

Four Year Collaborative for Preparing Teachers to Use Technology

Kathryn Morgan, Professor
Instructional Technology
Minnesota State University – Bemidji
United States
Kmorgan@vax1.bemidji.msus.edu

Abstract: The Class Act Preparing Tomorrow's Teachers to Use Technology project is a four year teacher preparation program that utilizes technology as a tool for the delivery of instruction as well as an integral part of the teacher preparation program skill development for the beginning teacher candidate. The program is composed of students who apply for admission to a community college, complete a field based teacher education focused year one and two program followed by a competency based technology enhanced professional program at the University. The program reflects a learning community technology linked professional development model.

INTRODUCTION

National Teacher Preparation Needs

The role of the teacher is becoming more complex. Teachers are being asked to learn new methods of teaching, while at the same time they are facing the greater challenges of rapidly increasing technological changes and greater diversity in the classroom aggravated by societal issues outside the classroom related to poverty, crime, and family dysfunction. In a recent survey on the quality of teacher preparation, it was reported that less than half of American teachers reported feeling “very well prepared” to meet many classroom challenges:

though educators and policy analyst consider educational technology a vehicle for transforming education, relatively few teachers reported feeling very well prepared to integrate educational technology into classroom instruction (20 %)

54 percent of the teachers taught limited English proficient or culturally diverse students, and 71 percent taught students with disabilities, relatively few teachers who taught these students felt very well prepared to meet the needs of these students.

28 percent of teachers felt very well prepared to used student performance assessment techniques; 41 percent reported feeling very well prepared to implement new teaching methods, and 36 percent reported feeling very well prepared to implement state or district curriculum and performance standards. (National Commission Report on “The Demands of Current School Reforms, 1996)

According to the National Commission on Teaching and America’s Future (1996), the demand for teachers in the next two decades will increase substantially. Statistics that underscore this urgency are a combination of societal and teacher force demographics. Higher birth rates and immigration have caused the teaching force to grow from 2.5 million in 1980 to 2.8 million in 1991. It is projected that by the year 2002, we will need over 3.3 million teachers to meet the need for educators to fill positions to meet the growth in student populations. Concurrently, our present teacher work force is at a point were large numbers of experienced teachers are near or at retirement. The commission reported that nearly one fourth of the teachers in America in 1991 were over 50. Over the next decade, more than 200,000 teachers will need to be hired annually. The dramatic change in the teaching force presents an opportunity to influence educational reform via the preparation of a new teacher professional. An individual who understands learning theories, has the ability to address the needs of a divergent student population, can prepare student focused lessons that encourage knowledge creation and creativity in a technology rich community based learning environment.
National Response to Teacher Preparation

National Education Goal 4: Teacher Education and Professional Development

By the year 2000, the nation's teaching force will have access to programs for the continued improvement of their professional skills and the opportunity to acquire the knowledge and skills needed to instruct and prepare all American students for the next century.

National Education Goal number four, provides evidence of the national level recognition for the improvement of the initial and continuous preparation of teachers. Teacher's for today and tomorrow’s schools will need skills and understandings which allow them to teach all students for understanding by in depth understanding of subject matter, a sensitivity to divergent learning styles of students, and the ability to successfully design instruction that takes advantage of constructivist, student centered, technology rich learning environments.

While there are many ingredients for successful school reform, it all comes down to the classroom teacher. Indeed, the success of the entire school reform movement is dependent upon teachers acquiring the skills, perspectives and knowledge necessary to transform the learning of all students. However, because we only now fully appreciate the ways of teaching complex subject matter to diverse students, many of our current teachers remain under- or unprepared. Insufficient or inadequate preservice and inappropriate or incoherent in-service teacher education retard the effort to realize the National Education Goals. (Teacher Education and Professional Development National Education Goals Panel, July 1995)

A reform of teacher preparation is precursory to reform in public schools in America. Public attention has been focused on the reform of elementary and secondary schools without attending to the preparation of the teachers who will work in these schools. While there are many ingredients for successful school reform, it all comes down to the classroom teacher. The success of the entire school reform movement is dependent upon teachers acquiring the skills, perspectives and knowledge necessary to transform the learning of all students. With an estimated need for two million new teachers over the next decade to replace retiring teachers and to meet increased student enrollment, well-designed teacher education programs are a critical factor in reforming our schools. Reform includes the need to create a technologically literate teaching force to meet the demands of society. Because of this, the integration of technology should be accomplished in relation to other efforts to reform teacher preparation, not as a separate reform initiative.

Minnesota Teacher Preparation Needs: P-12 Graduation Standards Change the Instructional Expectations

Consistent with the national need for qualified teachers, rural Minnesota faces a challenge in recruiting, training and retaining teachers. Teachers are needed who can address the curricular expectations for Minnesota schools. Recently, the Minnesota legislature mandated comprehensive performance-based Graduation Standards for all students. These standards will require students to show competency in critical areas such as communications, inquiry based learning, problem solving citizenship and technology. Imbedded in the Graduation Standards is the requirement that all students have an in-depth working understanding of personal computers and commonly used software, and be comfortable using electronic means to conduct research and analyze results. Not only will Minnesota need to recruit qualified teachers, but these teachers will also need to be trained to guide students in the use the technology available and to demonstrate their knowledge of the graduation standards in an observable, performance based environment.

Minnesota Licensure Requirements Change to Require Competency Based / Technology Enhanced Teacher Preparation Programs

In response to the changing demands of the role of the educator in Minnesota, the Minnesota Board of Teaching, which is responsible for overseeing teacher education has revised the way it licenses teachers. This new teacher licensing structure will be a competency-based system rather than one which grants a
teaching license based solely on completing designated academic courses. The competencies which will be used in this new structure must be based on the standards delineated by the Interstate New Teacher Assessment and Support Consortium (INTASC). For the first time, teacher preparation competencies address the development of constructivist teaching strategies supported by instructional technology resources. In addition to the Minnesota Board of Teaching requirements, the February 1999 draft of the National Council for Accreditation of Teacher Education standards for accreditation of teacher education programs identifies both the INTASC standards and also lists a specific competency which addressed candidates ability to effectively integrate technology into their instruction. Minnesota Colleges and universities responsible for educating future teachers are required by both state and national accreditation boards to implement a performance based, technology enhanced, student centered teacher education programs. This new profile for licensing teachers goes into effect August 1, 2001.

Though Minnesota has a history of educational excellence, a number of challenges face Minnesota schools, most urgently: how to recruit and train enough educators to meet the increasing demand, and how to improve all students' capacity to meet high academic standards. Gerald Christenson, former chancellor of the Minnesota Community College System writes "Our increasingly complex society will require teachers who can deal successfully with change, who are prepared to use new technology and who can recognize that children learn in many different ways" (Christenson).

Class Act Preparing Tomorrow's Teachers to use Technology (Federal PT3 Implementation Grant Awardee): A Response to Reform in Teacher Preparation

PT3 Class Act Project, augments a four year competency based, technology focused teacher preparation program "Class Act" in Northern Minnesota. Class Act was created by a collaborative which included two Universities, a Community College, School Districts, and a private Foundation. The project has two cohorts of preservice teachers who will complete their first two years of preparation at a Community College with a teacher preparation flavor in their liberal studies courses as well as continuous placement in community and public school placements. Students will then transfer to the University for their final two year professional coursework. During their final two years the PT3 Class Act students will be placed in technology enhanced field based placements.

Learning to teach to the identified skill needs of the community and the diverse student population are central Class Act Program objectives. The region's demographics reflect a rural, sparsely populated, low income area. The heritage of the region includes a high Native American population. Research indicates that visual, auditory, inquiry based instruction facilitated by effective use of instructional technology instruction enhances the academic achievement and motivation for all students and in particular Native American students.

The PT3 project will prepare teachers who can deliver inquiry, application, technology rich instruction. To participate as a Class Act student, an application process was completed. The process consisted of a written application, letters of reference, and individual interviews. Those selected, while at the Community College complete typical associate of arts course work. However, the curriculum was modified with an education preparation and issue focus. In addition to the on campus coursework, Class Act students participate in teacher preparation practica that encourage applied contextual, technology-enhanced learning. Participants are placed in both education and community/business based practica from the first semester of their freshman year continuing throughout the completion of their baccalaureate degree.

The following PT3 project examples, document the activities which will be used in the Class Act program to teach effective integration of technology into instruction. The first example is the distribution of lap top computers to Class Act students for use throughout their four year preparation.

Linkage Labs / Tec to Take Kits
Another example are Linkage Labs. Linkage labs are technology enhanced learning environments located regionally to support the instructional technology skill development for preservice, mentor teachers and higher education faculty. Linkage Lab inservices directly relate to the instructional applications for "Tec to Take" kits. Tech to Take "kits" are sets of technology resources that the preservice teacher can take to the field based practica. The Tech to Take kits will insure that the resources for effective technology enhanced instruction are available at the field site. One of the outcomes of Linkage Lab inservices will be the development of technology rich lessons which take advantage of the Tech to Take kits. Preservice teachers, classroom mentors and higher education faculty work in learning teams to create and plan practica where the innovative lessons can be taught.

TEACH Web Site Internet Resource and Communication Component

Another example comprehensive technology support resource for the project is a web crossing discussion forum and resource internet site http://TEACH.bemidji.msus.edu. The TEACH web site is monitored by education experts who facilitate and expand the topics and links for the site based on the needs identified by site users. Another aspect of the TEACH site is the ability to access state and national education experts "master mentors". The "master mentor" feature provides participants direct access to leaders in the field who can answer educational questions in an anytime anywhere internet environment.

Summary

In summary, the overall objective of the Class Act PT3 project is to refine a teacher education program that reflects national teacher education exemplary practice. The curriculum is competency based, field site focus, and collaboratively supported by school, community and institutions of higher education. The PT3 resources will strengthen the technology focus of the curriculum, expand the school and higher education participation, and contribute to the support of instructional technology resources.

During the next three years, the project consortium will continue to refine and expand the implementation of the Class Act PT3 program. The overall goal of the project is to develop a collaborative model for teacher preparation that uses technology as a critical infrastructure for the delivery and modeling of quality instruction. The final outcome goal is to develop educators who have a philosophy that reflects quality student centered instruction that fosters student achievement and supports life long learning for the student and the professional educator.
Abstract: This paper describes a current project funded through the U.S. Department of Education's "Preparing Tomorrow's Teachers to use Technology" initiative. The need and issues related to integrating technology into the preservice program, as well as early models that led to the current project design, are discussed. STEP creates a model of partnership between schools of education and K-12 school districts that prepares preservice teachers to be effective users of technology. Collaborative teams of methods teachers and K-12 teachers will work together to integrate and model technology tools in the preservice curriculum. These educator-teams share responsibility for developing and modeling teacher preparation strategies that incorporate technology tools. Through this project, preservice students observe and interact directly with K-12 master teachers to learn effective teaching strategies that incorporate technology.

Need

Technology increases the availability of information and provides powerful new tools for constructing meaning and creating new knowledge. Furthermore, standards for personal and professional success will in future be predicated on the ability to use technology tools confidently and competently to foster continued intellectual growth. Students must start now to instill effective learning strategies that incorporate technology tools, and it is imperative that students have teachers who can guide them in developing these strategies. Tomorrow's teachers must also be confident and competent users of technology tools: they must be skillful in designing, implementing, and evaluating effective learning environments that utilize these tools. According to Sheingold (1991), it "is unlikely that the ambitious goals for learning and teaching can be met without widespread, creative, and well-integrated uses of technologies of many kinds" (p. 22). This need is felt particularly in Nebraska, where the majority of the state is rural, and where there exist a significant number of low-income communities. Nebraska's rural and low-income communities need teachers who can help students use technology to supplement the scant educational resources commonly available in these areas.

However, the majority of faculty members teaching in Nebraska's teacher preparation programs do not integrate instructional technology into their courses, nor do they model effective teaching strategies that incorporate technology. Preservice students, as a consequence, do not learn about the role of technology in education, and they do not practice the use of technology during field experiences.

Nebraska faculty members reflect a national trend in the use of instructional technology in preservice training programs. In 1999, the International Society for Technology in Education (ISTE) was commissioned to conduct a survey of Schools, Colleges, and Departments of Education (SCDEs). The results of this survey finds that
faculty members have access to technology and can use technology tools for communication and personal productivity. However, the survey also finds demonstrations of effective teaching strategies that incorporate technology neither are modeled in the classroom nor are required of students as part of their field experience or course requirements. Persichitte, Tharp, and Caffarella (1997) report that "actual utilization and contextualized integration of these technologies within personal and workplace settings, for both SCDE students and faculty, is far from commonplace within SCDEs." In 1998, the South Central Regional Technology in Education Consortium (SCRTEC), conducted a regional survey, including Nebraska, that concludes: "Our institutions of higher education are still internally focused on their technology needs and are not yet able to really focus outwardly on training preservice teachers in the best uses of technology . . .". Further supporting these findings, Sutton (1997) conducted a survey of all methods faculty members at Nebraska's institutions for teacher preparation:

"The data revealed that most Nebraska methods instructors were using some form of instructional technology. However, fewer, only 58%, were requiring their students to use it. In addition, the majority of Nebraska methods instructors were not familiar with the ISTE [Recommended Foundations in Technology for All Teachers], and therefore were most likely not incorporating any of the standards into their teaching."

Several recent surveys, including the ISTE sponsored "Will New Teachers Be Prepared To Teach In A Digital Age?", point to the need for systemic changes in the way preservice students learn about and use instructional technology. First, effective teaching strategies that incorporate technology must be integrated and modeled in preservice education. Second, students must demonstrate as part of their college courses that they understand and can design effective teaching strategies that incorporate instructional technology. Third, students must be given opportunities to observe and interact with master teachers who use technology tools to support teaching and learning.

Finally, faculty members at teacher preparation institutions must be responsible for creating and disseminating models for change in preservice education. This responsibility reflects the reciprocal relationship of research and practice: faculty members need to "identify, study, and disseminate examples of effective technology integration that reflect the current needs in both teacher education and K-12 schools" (ISTE, p. 3, 1999).

Addressing the Need—Past Projects

In 1998, Teachers College of the University of Nebraska-Lincoln (UN-L) was awarded funding through the Eisenhower Professional Development Program for a proposal entitled "Nebraska Educators' Summer Technology Training Institute (NESTTI)." The goal of NESTTI was to ensure that preservice students were provided meaningful opportunities to learn about and use instructional technology in their preservice coursework. However, both national and statewide surveys indicated that faculty lacked time and support to integrate technology into existing preservice courses. Further, these surveys indicated that teacher preparation faculty would benefit from examples of pedagogically sound uses of technology to help them recognize how technology can support preservice curricula. The method for achieving this goal was to immerse faculty in training and modeling activities that reflected sound educational uses of technology. The expectation was that a residential training "camp," with extensive technical support provided, would help ameliorate the issues of time and support. The objective of this training and modeling was to enable faculty members to model the use of instructional technology in their classrooms and to provide opportunities for preservice students to use technology tools as part of their course work.

Methods instructors were selected as the target audience for the project because of their direct role in guiding students to make connections between teaching practice to learning theory. Methods instructors from across the state were invited to participate in a weeklong, residential summer training session at UN-L. Training and modeling activities for the session were based on the content areas of the participants. Attendees were immersed in classroom-oriented uses of technology, and extensive technical support was provided throughout the learning process. Attendees learned how to use software titles that were representative of "genres" of technology tools (e.g., HyperStudio for multimedia applications). But more importantly, participants were introduced to these tools during modeling sessions by K12 teachers and higher education faculty. Through these modeling sessions attendees participated directly in using technology to facilitate learning. These opportunities for connecting technology tools to learning objectives helped participants make connections between technology and their own teaching practices.

Follow-up activities were scheduled throughout the academic year, 1998-1999. The participants themselves generated topics for these sessions and were well attended. During these sessions, participants received
additional training, were able to ask for specific technical support to solve problems, and had the opportunity to share their work with their colleagues.

Data collected during the first year revealed that most participants had made significant progress in integrating technology into their methods courses as a result of their involvement with the NESTTI project.

However, it was recognized that the original NESTTI proposal would have a more long-term potential if participants were given more time to develop multiple products for use in their courses. Furthermore, the first year participants commented that the one-week approach had not left enough time for reflection, a process necessary for developing meaningful projects and products. Consequently, the original NESTTI proposal was rewritten to address this need, and UN-L received a second grant award from the Eisenhower Professional Development Program in 1999. The second year of the NESTTI project followed the same format as the first year with two notable exceptions. First, the training/modeling session was held over a two-week period. Second, participants read selected research articles related to instructional technology, which provided the basis for highly engaged discussions related to the participants’ conceptions of and uses for technology. This second year of NESTTI is still ongoing, and results will be available in fall 2000.

Addressing the Need—Current Project

The NESTTI approach has proven very successful, and has served as a useful first-step in faculty professional development related to instructional technology. However, it is recognized that this approach can be improved upon. Training and support for any faculty development project should be immediate and ongoing, not periodic throughout the year. Moreover, learning activities should relate to specific course needs and individual teaching styles of participating faculty in order to be of most benefit to the participants, not generic modeling exercises. Ideally, integrating instructional technology into preservice courses would become part of an ongoing process of renewal in preservice education, and technical support would be provided as a means of facilitating what instructors are already doing in their classrooms.

In 1999, the University of Nebraska-Lincoln and the University of Nebraska-Kearney received a grant award from the U.S. Department of Education as part of the “Preparing Tomorrow’s Teachers to use Technology” initiative. This project, entitled “Scholarship, Technology, and Educational Practice (STEP),” is designed specifically to improve upon the NESTTI approach to faculty development and top the improvement of preservice education. This project creates an effective model that supports continuous renewal of teaching content and strategies in preservice education related to instructional technology. Through this project, partnerships are established between methods faculty members and K-12 teachers for integrating and modeling teacher preparation strategies that incorporate technology tools. Furthermore, this project creates meaningful opportunities for preservice students to observe and interact with K-12 teachers who use technology tools in their classrooms. Most importantly, preservice students in this project will work directly with K-12 teachers in developing teaching strategies and materials for use in the teacher’s classroom. This project will prepare tomorrow’s teachers to design, implement, and evaluate classroom environments in which children learn with technology.

Goals

This project creates a model of partnership between schools of education and K-12 school districts that prepares preservice teachers to be effective users of technology. The project has four goals. First, this project will establish a process for collaboration between teacher preparation faculty members and K-12 teachers. Through this collaboration, faculty members and teachers will share their respective expertise in research and practice for mutual professional development. These educator teams will jointly develop and model teacher preparation strategies that incorporate technology into the preservice curriculum. Second, this project will establish a process for creating authentic learning opportunities for preservice students in which they observe and interact with K-12 teachers to design, implement, and evaluate teaching strategies that will be used in the K-12 classroom. Preservice students will be challenged to examine their own behavior and the practices of their cooperative teachers, learning how scholarship and practice inform and build upon one another. Third, instructional technology training and technical support will directly support the needs and learning objectives established by the faculty members, teachers, and preservice students. Technical expertise will be shared and coordinated to support participating members and project activities, and technical staff will be given opportunities for continued professional growth. Finally, this project will ensure that teachers who fill positions in rural and low-income areas have the skills and knowledge to use technology effectively to overcome the scarcity of educational resources found in these areas.
Objectives for the Project

This project will impact a significant number of preservice faculty members and preservice students over three years. The project will include 20 methods faculty members and at least 20 K-12 teachers. This project will directly impact approximately 1020 preservice students.

1) Increase the number of preservice students using technology tools to support teaching and learning.
2) Disseminate resources, activities, and teaching strategies that integrate technology tools into preservice education programs.
3) Disseminate a collaborative model between higher education and K-12 to evaluate and improve preservice education experiences using technology tools.

Comprehensive Effort

This proposal describes a broad and inclusive vision for improving preservice education. This project is based on a scholar-practitioner model, which forms a framework for student learning in the preservice program. Through this model, faculty members and teachers are jointly responsible for guiding preservice students as they build connections between scholarship and practice activities. Students interact in field settings in which they can inquire about and reflect upon the use of instructional technology, and how instructional technology affects their own work as educators. The scholar-practitioner model ensures that the goals, objectives, and activities of this project are based on best practices and on scholarly literature.

Furthermore, this proposal couples collaborative activities with ongoing training and technical support to create a comprehensive model for integrating instructional technology into preservice education. The proposal comprises three interrelated functions:

- Practice, Scholarship, and Scholarly inquiry
- Training
- Technical Support

The diagram below helps visualize the relationship of these three components. Each component forms one corner of a triangle, with arrows indicating their reciprocal relationship:

Abstract: This paper is a summary of procedures used to design and implement an undergraduate course for all entry level students in the College of Education. The question asked: What do pre-service teachers need most in a teacher education program that will effectively prepare them to meet the demands of the 21st Century classroom? The answer is apparent: effective methods of teaching the use of information using a technology framework. The answer to this query was the genesis of a course designed for entry level students in the College of Education that met three unique features: 1) individual student flexibility in selecting research projects and technology tools; 2) collaboration among faculty and students in presenting research strategies and investigating current themes in education; and 3) empowering students with self management skills that prepare them for lifelong learning. This approach successfully presented applications of information, utilizing a technology framework. The conclusion indicates that higher education is improving the learning experience of college students.

Introduction

Teacher education institutions have the opportunity to prepare pre-service teachers to be effective users of information and its accompanying technology. The National Council for Accreditation of Teacher Education (NCATE, 1997) described the vision needed for teacher education programs in the 21st Century classroom to include full utilization of information technology. The American Library Association stressed the importance of information literacy in its new national standards and defined it as the ability to seek and effectively utilize information sources, including knowledge and how to use technologies. (ALA, 1998). Changes in society and technology have resulted in massive changes in education. Learners look to their schools for information beyond academics. This growth in information and technology has precipitated the creation of a community of lifelong learners. Information literacy is at the core of lifelong learning (ALA, 1998). OAT (1995) recognized that technology in all of its applications is still underutilized by many teachers. A band-aid approach following a training program has not been effective. Something different is warranted.

The Course

In the process of preparing 200,000 new teachers annually (President’s Committee of Advisors on Science and Technology, 1997), colleges of education have turned to a comprehensive and systematic approach to curriculum redesign that starts upon entry. Towson University has taken a direct approach to addressing the obvious problem of little or ineffective research, technology and curricular integration skills used by pre-service teachers. New students beginning the teacher education program were introduced to a curricular model that focused on best practice in teacher education literature, and included information, research, technology and collaboration.

One of the initial steps taken by the College of Education was to require all entering majors to take a course entitled Using Information Effectively. This course was introduced to all freshmen and transfer students and focused on techniques useful for research investigation, connectivity, collaboration, productivity and integration. The purpose of the course was to introduce students to techniques for gathering, evaluating and communicating information using a variety of resources and
educational technology. The course emphasized team collaboration and problem solving techniques to examine current themes and issues in education.

Faculty collaborated on the design of the course, course requirements and assessment criteria and produced a common syllabus for all classes. The main library cooperated by releasing the services of reference librarians to serve in course planning and team teaching. Technology experts from the university's Computer and Network Services joined the team as consultants. The course components included:

- Team Collaboration
- Connectivity
- Team Teaching
- Resource Experts
- Productivity
- Information Evaluation
- Technology Integration
- Portfolio Design & Assessment

The first two sections were taught in the spring of 1997. Twenty students were in each section. The instructors met weekly to discuss the problems, progress and successes noted in the course. A summary of those sessions revealed: inappropriate placement of instruction; too much content covered in specific units; additional lab time needed for students with little experience using technology; the need for more communication between team leaders and faculty; closer guidance in the selection of team projects; and careful explanation of the criteria and expectations for individual and team projects. All of these changes were made before the start of fall 1998. Sixteen sections of this course are currently being offered during the spring 2000 semester.

The Facilities and Resources

The College of Education has supported the integration of technology into the curriculum. It has been one of the dean's top three priorities for the past five years. Funds were made available to equip two PC electronic classrooms each with 31 Dell Optiplex Workstations, Windows 98, SPSS 8.0, and Inspiration 5.0, KidPix Studio Deltux, and Hyperstudio 3.2; one MAC classroom with 25 Macintosh G3 workstations with standard configuration; one computer lab with 22 Gateway P-120 workstations, Windows 95, Inspiration 5.0, KidPix Studio, and Hyperstudio 3.2; and one multimedia lab and an assistive technology lab. One additional MAC lab will be going online in fall 2000. Hawkins Hall, which houses the College of Education, is networked and supported by the university. Education faculty has access to a two-way fiber optic distance learning classroom and a compressed video lab. The building is wired for connectivity, which allows Internet access in classrooms. A network administrator and a technical support staff person hired by the College of Education, maintain these areas.

- Real Player
- Shockwave and Flash
- PowerTerm
- Telnet
- WS_FTP
- McAfee 4.0
- Toolbook II Publisher 5.0

Information technology is essential in our framework. Stephen C. Ehrmann’s (1998) perspective on technology in higher education reminds us of the importance of breaking ranks with the traditional. His view resembles a four-level tower with each level more sophisticated than the one below it. The basement level contains traditional technologies (textbooks, audiovisual materials), and the infrastructure for their use (libraries, labs, etc.). These basic elements support the four traditional pedagogues on the first floor: directed instruction (lecture halls and textbooks), learning by doing (labs, typewriters, libraries), real-time conversations (seminars, office hours), and time-delayed exchange (homework). The second floor houses enhancements to these practices that require students to use instructional technologies. Finally, the third floor represents large-scale structures supporting new educational concepts. Successful integration of technology into college appears to hinge on the willingness of faculty to move beyond the basement and first-floor technologies with which they are most familiar and move into the upper levels that incorporate information technology.

That is precisely what the faculty did. Those who needed additional expertise in course design worked with instructional designers in the university’s Center for Instructional Advancement and Technology (CIAT). Two instructional designers, a graphic artist, and a support staff provide easy access to resources for faculty. Currently the institution is supporting training for faculty from across the university to learn a web-based application for designing courses. CourseInfo by Blackboard will be used to put 50% of the course Using Information Effectively on the web in spring 2000. Five faculty from the College of Education are participating. Those faculty who needed knowledge in computing, databases, spreadsheets, presentations, publications, word processing, the Internet, and project management, registered for workshops provided by the CANS (Computer and Network Services) Technology Center.

It is an indisputable fact that faculty bear the major responsibility for student learning (Davis, 1993). The public has been very vocal in demanding improved student outcomes. One of the methods used by the College of Education to improve student learning is to improve college teaching. Several faculty development initiatives have been implemented to promote the development of expertise in teaching: CIAT, CANS, VICTORWeb (Online Public Access Catalog), and Microsoft Network.

The Model

Collaboration, research, information technology and assessment are the cornerstones of this model. This model pairs teaching faculty with librarians: each an essential member of the team. It is very challenging to examine the relationship between college faculty and librarians. The proliferation of information sources and educational technology have created a dysfunctional relationship between college faculty and librarians that is based on an outdated teaching/learning paradigm (Tompkins, 1996). Traditionally, teaching has been the purview of faculty, while librarians were viewed as merely custodians of printed information resources. In the current Information Age however, librarians have become the primary instructors to teach research methods and critical thinking skills as applied to information access. There is support for librarians to be seen as key instructional team members and as partners with faculty.
Over the past 20 years, librarians have worked hard to move from teaching isolated library skills to teaching integrated information skills. Effective integration of information skills has two requirements: 1) the skills must directly relate to the content area curriculum and to classroom assignments and 2) the skills need to be tied together in a logical and systematic information process model (Eisenberg, 1996). Successful integrated information skill programs are designed around collaborative projects jointly planned and taught by faculty and library professionals.

In this course, the team agrees upon the goals and objectives. Instruction is planned, follow-up activities identified, homework criteria discussed, team and individual projects assigned and assessment built into each component. Collaboration between faculty and librarian is essential. In addition, there is collaboration between instructors and students as well as between team members. Connectivity on and off campus involves: tele-mentoring, e-mailing assignments, using list-serves, web-based forums and electronic bulletin boards; accessing VICTORWeb, and the World Wide Web and using management strategies to maintain electronic files for portfolio development.

Research is the second part of the model. Students are taught the research process from beginning to end. Emphasis is placed on understanding research in education, locating print and electronic sources, preparing a bibliography, manual and electronic note taking, presenting and documenting research, organizing the final project, and styles of documentation. Teams work with search strategies during formal class sessions, and individual projects are assigned as out-of-class assignments.

Information is part three of the model. Students are introduced to information sources ranging from traditional to non-traditional, from book to e-book, from library resource to virtual resource. All formats of material are used including artifacts, realia, proceedings, journals, magazines, newspapers, web sites, books, multimedia, video, and audio. Teams are encouraged to generate topics of interest to them as well as selecting projects for presentation that may combine any of these materials.

Technology is the one component that is apparent throughout the model. Technology productivity tools allow students to use word processing, data base and spreadsheets, graphic design, desktop publishing, video, audio and multimedia design and the creation of educational presentations. The integration of connectivity and productivity allows students to demonstrate what they have learned using performance-based criteria.

This demonstration is evident in student-managed information or educational portfolio development. Authentic assessment allows student to demonstrate desired performance through real-life situations (Meyer, 1992). The method includes projects that require students to demonstrate their problem-solving skills as well as their skills in analyzing and synthesizing information. Improved student performance is directly attributed to authentic assessment (Herman, 1992). Paulson, Paulson & Meyer (1991), define an educational portfolio as a purposeful collection of student work that exhibits the student’s efforts, progress, and achievement. The project must include student participation in selecting contents, the criteria for selection, and judging merit and evidence of student reflection.

The types of portfolios designed by students are:
- Developmental - includes samples of student’s work used by faculty to document a student’s improvement over the entire semester, with self-evaluations of specific assignments;
- Proficiency - used to determine eligibility for students to advance in any assigned skill area when competence and performance are demonstrated;
- Showcase - used to document a student’s best work accomplished during one semester, but can be used during an entire educational career; and
- Employment skills - includes samples of student’s work over time which may be used by a prospective employer to review work readiness skills.

Requiring students to develop student portfolios provides authentic demonstration of accomplishments, and allows students to take responsibility for the work they have done. This motivates them to accomplish more in the future.

Conclusion

Teaching the use of information in a technology framework proved to be an effective strategy in the College of Education. This course Using Information Effectively has demonstrated that when faculty and students collaborate, positive results occur. Student projects met the needs and
interests of students because they were selected by students following insightful collaboration with team members and instructors. The course design was effective because of collaboration and technology support. Students felt empowered and equipped with self management skills to go on to other courses and continue to use knowledge and critical thinking skills acquired, thus promoting lifelong learning.

DEVELOPING A CROSS-CURRICULAR FOCUS TO INFORMATION AND COMMUNICATION TECHNOLOGY TEACHING

Michelle Selinger
Centre for New Technologies Research in Education
University of Warwick, Coventry, CV47AL, UK
m.s.selinger@warwick.ac.uk

Abstract: In the UK, instructional technology teachers, (more commonly known there as information and communications technology (ICT) teachers), with the support and cooperation of other curriculum specialists educate students mainly in basic ICT skills and rarely consider the application of ICT in a range of subjects. This paper describes a project to encourage ICT student teachers to work with teachers from other subject areas on a school based cross-curricular project in four local secondary schools. The outcomes of the project are discussed, including the effect on the way preservice teachers changed their perceptions of ICT across the curriculum; the teaching of ICT skills, and what changes were made the following year for the next cohort of preservice teachers.

Introduction

The role of instructional technology teachers in schools varies considerably in UK schools, and how best to prepare preservice teachers of technology in secondary schools (known as information and communication technology teachers in the UK) is a difficult issue. The way ICT is approached can be from fully integrated across the curriculum with a faculty having responsibility for the teaching of one package or application (e.g. English teaching word-processing, mathematics teaching spreadsheets, etc), to generic ICT lessons, or to ICT being team taught in personal and social education sessions. The ICT teacher in each of these scenarios alters notably, moving from a support role in the first scenario, to a full teaching role in the second and third. In addition there are numerous ICT syllabi for public examinations at age 16 and 18, which vary considerably in content from a systems approach to computing to the applications of information processing. At the Institute of Education at Warwick University we are now into the fourth year of training ICT teachers. Since last reporting (Selinger, 1998), preservice teachers' ICT teaching experience and observations are still often in lessons in which pupils are taught basic skills, often devoid of a context; and the process of using ICT as a tool to support and enhance all aspects of their studies and understanding is often lost (p1280) (although there are some different and exemplary lessons emerging more and more which were disseminated to the group and identified as good practice). Ofsted, the schools' inspectorate, has also continued to report unfavourably about the content and delivery of ICT across the curriculum.

The management of information technology is weak in a substantial number of schools. In this subject, it is the curricular provision and management of resources, rather than the quality of teaching in timetabled information technology lessons, that often limit achievement and need to be monitored carefully. The co-ordination of this work across the curriculum is often poorly managed, and too few schools report progress and attainment of all pupils in Key Stage 4.

Ofsted, 1999, para 127
In University sessions the preservice teachers are involved in discussions about the importance of devising ICT lessons which will empower pupils with the tools of tomorrow, and not just teach them the rudiments of an application. As an example I discuss two scenarios for the teaching of spreadsheets. In an ICT lesson the focus would be spreadsheets using some piece of mathematics as the context in which to teach the basic functions of spreadsheets, whereas in a mathematics lesson the focus would be on a topic in mathematics, yet the same aspects of spreadsheets are being taught. There is no consensus as to which provides the most robust learning, and there appears to be little research in this area, and if my own experience is typical of others, what the learner is attending to and learning may not always be clear. However, as a tool in the mathematics lesson, the spreadsheet is being used in a meaningful way.

We discuss ways that can enable students to understand the role of ICT in all their curriculum subjects; and that help them to make informed choices about when, where and how to make use of the technology. The argument I make is that the mathematics staff and the ICT staff in a school ought to jointly plan the teaching of spreadsheets so the purpose and value of the spreadsheet is articulated from the viewpoint of a mathematician, (later the use of spreadsheets in other subjects can be discussed, and the generic functions of spreadsheets made explicit). Learning how to set up and manipulate a spreadsheet is taught in a mathematical context in which students are familiar, and the mathematics is understood, and then, when the basics have been mastered, students develop their mathematical understanding with the spreadsheet acting as a tool, perhaps learning more functions as needed on the way. The class enters into the expert mathematician's domain to observe how spreadsheets are used for doing mathematics. Spreadsheets for example have elevated trial and improvement as a mathematical process. ICT ought to be perceived as a transferable skill and taught as such.

However, it is also pointed out that there is a considerable body of research evidence which demonstrates students' difficulties in applying their learning in one context in another; this means this transferability will not happen automatically (Brown et al, 1989; Lave, 1991). Consequently we agree that ICT teachers, with the support and co-operation of other curriculum specialists, ought to be educating pupils not only in a skills base, but also teaching them to consider the application of ICT in a range of subjects, and to be aware of opportunities for appropriate uses of ICT and how ICT can enhance both the development of their curriculum subjects and their understanding of them.

**Implementing the Project**

In order to put this to the test, four local schools were approached whose principals had indicated their willingness to involve the 1997/98 group of Postgraduate Certificate in Education (PGCE) ICT preservice teachers beyond their statutory school experience. Previous attempts within the course to encourage ICT preservice teachers to work with peers from other subject areas had met with some limited success, so the prospect of a cross curricular project within a school context might prove even more successful. Two meetings were held with the heads, professional mentors and ICT coordinators from the four schools and a programme was negotiated.

The 27 preservice teachers were then allocated to one of the 4 schools to work in pairs in specific curriculum areas to be identified by the school. They were to spend four sessions in the school, one in the autumn term and three in the spring term and were expected to:

- research the use of ICT in their selected curriculum area
- write a joint report about the use of ICT in the that curriculum subject, (preservice teachers were also expected to find out about how their block placement school used ICT in their selected curriculum area and incorporate that in their report).
prepare, teach and evaluate two lessons for a group of students who had particular demands, e.g. high
attainers, competent ICT users, students with special educational needs. (These lessons had to be
negotiated and agreed with the university tutor and the subject teacher in school to whom they had
been assigned.)

Within their pairing the preservice teachers were each to teach one of the lessons and be observed by the
other, who would write a critical evaluation of the lesson. The report, the lesson plans, resources
developed and the evaluations were assessed formally by the University tutor as the second of three subject
based assignments the preservice teachers had to complete as part of the course. In addition, a copy of the
report together with lesson plans and resources were to be given to the school. The preservice teachers
were expected and encouraged to use the medium of ICT innovatively in their preparation of lessons. A
structure of the allocated time slots was suggested, as outlined below, but in fact many preservice teachers
put in more than twice this time.

Session 1
Preservice teachers will be introduced to the ICT facilities in the school, and be given a copy of the
schools' ICT policy to read. They will meet the head of department or a representative on the
curriculum area in which they are to work who will show them any specific ICT facilities in the
department, inform them of ICT policy and activities, show them schemes of work and discuss the
integration of ICT. Other resources (books and worksheets, software, etc) will be made available
for preservice teachers to explore. Possible ideas for projects will be discussed.

Session 2
Preservice teachers will observe a lesson being taught in the subject area by the teacher with whom
they are going to work. A group of pupils will be identified and the preservice teachers will spend
some time talking to them. A topic for the lessons will be negotiated with their teacher.

Sessions 3 and 4
Each preservice teacher will teach a lesson in either session 3 or 4 and be observed by the other.
The subject teacher is invited to support the observation and present a report too if this is desirable
and feasible, and to discuss the lesson outcomes with them.

Between sessions 2 and 3
Lesson plans and resources will be shown to and discussed with the university tutor, and then the
subject teacher through electronic communications, where possible.

Selinger, 1997

The schools were asked to comment on the proposal and once agreed, they would then liaise with relevant
staff and inform the University tutor of the number of preservice teachers they were willing to take; the
subject areas in which preservice teachers would work; and make suggestions for the best time for
preservice teachers to come into school. In the event four 2-hour University sessions were allocated to the
project, but as stated earlier, many preservice teachers gave far more time to the project than this. They
worked in pairs.

A few preservice teachers worked in special needs departments, while the remainder worked in one of
several curriculum areas across the secondary age range including science, art, English, food technology,
history, mathematics, leisure and tourism GNVQ (a vocational qualification). Two groups designed a web
site for the English and history departments, and one group developed a strategy for the use of a talking
word processor with special educational needs students. There were several spreadsheet projects
(including one that involved baking a very large cake), but the most exciting was by a student who had
came onto the PGCE course with an arts background. He found himself working alone in a science
department as the 28th member of the course had withdrawn. He was set the task of developing a resource
for GCSE (the public examinations for 16 years olds) high attainers in a chemistry topic. He looked
through the syllabus and considered ways in which ICT could be used: he settled on radioactive half-life, a
topic he knew nothing about. He consulted a PhD student he knew to brief him on the fundamental
concepts, and then designed a spreadsheet activity to model radioactive decay. The science teacher he worked with was ICT literate but not to the same extent as the ICT student, but they worked together on developing an interactive spreadsheet that would challenge the pupils and develop their understanding of the topic. The teacher was delighted with the final product and the pupils’ enthusiasm, and it is now built into the scheme of work for the course.

Outcomes

The preservice teachers in the main found the experience extremely worthwhile and productive, and only two groups experienced any real difficulties. In a feedback session at the end of the project a number of issues emerged about working with non-ICT specialists in their own subject areas which their statutory, and more traditional school experience had not revealed to the same extent. It also raised their awareness as to what might potentially lie behind the rhetoric of schools’ ICT policies in a way that would not have been so meaningful if they had been alerted to these issues in a taught University session. Below are some of the main findings:

- Only word processing was consistently used across different curriculum areas
- Pupils had poor ICT skills
- There was a lack of opportunity to use ICT rooms
- Learning both the subject and ICT often caused difficulties with students as they were unable to attend to learning new skills in both
- Teacher confidence was generally very low
- The beliefs about the value of ICT for teaching and learning varied considerably and many staff did not share the head’s or ICT coordinator’s vision
- There was a general lack of awareness of ICT resources for the subject
- Technical difficulties such as logging on to the network, knowledge of applications and the use of PCs at home and Acorns in schools say, often became barriers for teachers using ICT
- Access issues to suitable software, CD-ROMs and the Internet proved to be a barrier to use
- Working collaboratively with a subject specialist was a learning and rewarding experience for both the subject teacher and the ICT preservice teachers
- Subject specialists lacked new ICT skills
- Students’ use of ICT applications out of the context of ICT lessons was poorer than the preservice teachers had anticipated.

The preservice teachers said this school-based experience together with the feedback session had made them much more aware of the issues of ICT use across a school. They felt that working within an ICT department alone could be misleading. The experience had highlighted the varying levels of ICT skills amongst teachers and the lack of use in other subjects. They were more prepared for their first teaching post, and agreed that it would be advantageous to make every effort to audit the use of ICT and other curriculum specialists’ competence at the earliest possible stage, if their new department had not already done so.
The Following Year

Following on from this success, the schools involved were very keen to repeat the project. They saw the involvement of preservice ICT specialists as a way of encouraging staff in schools to make more use of ICT. However the schools' other development plans for ICT got in the way. Three of the schools were linking together over a high-speed network and had ambitions for the development of an innovative Intranet. Six local primary schools were also to be involved whose pupils usually progressed to one of the three secondary schools at the age of 11. The secondary principals got together and agreed that the university ICT preservice teachers could be instrumental in developing the Intranet, and provide links with the primary schools. In the event the Internet link was not working; the primary schools had not been briefed let alone involved in the secondary schools' plan for the preservice teachers; and the students became very frustrated by the lack of technical know-how of Intranet development. They spent considerable periods of time trying to establish what was required and produced some reasonable attempts at interactive web pages, which given the technical situation could not be published on the Intranet by the time they has completed their work and the PGCE course. The successes of the previous year in encouraging students to consider the issues involved in ICT development across the curriculum were not repeated. The students did learn, however, that cooperation between primary and secondary schools is a difficult process and that technical issues can prohibit curriculum development.

Lessons Learnt and What Next?

In the later project, we had focused too much on the schools' needs and not enough on the preservice teachers' needs. In the first scenario, the project has arisen out of a recognition for preservice teachers to gain a deeper understanding of how and why ICT can support learning in the curriculum, while in the second the need arose out of the schools' wishes to develop an Intranet. The first was curriculum driven, the second was technology led. Another lesson learnt was that preservice teachers need to be involved in developing projects from an existing situation rather than being led into the unknown. They are inexperienced and eager to please, and can be in danger of being exploited in novel situations. Preservice teachers' needs have to be recognised, and schools need to offer support rather than expect the inexperienced preservice teachers to provide training.

Negotiations with the schools had been excellent at top level, but finding willing teachers in the secondary schools to become involved is not always easy given the constraints on teachers' time and the pressure of the curriculum. However, such was the success and mutual benefits, it was agreed to run the project again and this time the 1999/2000 preservice teachers are working on cross phase projects within three secondary schools. Success is likely as the UK Government has made ICT a priority with a budget of over £600 million being made available to schools to update computers; introduce or improve existing networks, connect schools to the Internet, and train teachers in the use of ICT, (DfEE, 1997), and schools are keen to be seen to be in the forefront of development.

Pairing Up Inservice and Preservice Teachers to Develop an Understanding of Technology Integration

Norma Nocente
Department of Secondary Education
University of Alberta, Canada
norma.nocente@ualberta.ca

Abstract: This paper will describe a course taught at the University of Alberta that focuses on technology integration across the curriculum. In this course preservice and inservice teachers are combined into the same class. The experience has been mutually beneficial for the two groups and resulted in interesting classroom dynamics. The goal of the course is to help students develop a better understanding of critical thinking and the role of technology in the classroom. The strategies and assignments used in class are also described in the paper.

Introduction

The purpose of this paper is to describe a course taught at the University of Alberta that focuses on technology integration across the curriculum. The goal of the course is to help students develop a better understanding of critical thinking and the role of technology in the classroom. Naturally then the major assignment for the course requires students to develop a project to promote critical thinking while taking advantage of computer technology's unique attributes. The learning strategies used in the course are based on Brown, Collins, and Duguid's (1989) notion of situated cognition and Collins, Brown, and Newman's (1989) notion of learning through cognitive apprenticeship. These authors suggest that concepts need to be contextualized and developed progressively through activities. Cognitive apprenticeship requires making the concept of technology integration explicit through readings and class discussions. This is complimented with lab assignments that focus on developing examples of technology integration with specific applications. These steps prepare the student for the final project by scaffolding onto prior activities. The final project should be built with actual integration in mind. That is students should be in a position to implement their project. It is my belief that these students will then be able to independently create further projects for their classroom.

Before describing the course any further it is important to define technology integration as presented in this course. Taylor (1980) described three roles for computer technology in the school. One, is the object of instruction, that is students would be learning about computer hardware, software, programming etc. Computer technology's second role is to deliver instruction. In this role Taylor was referring to computer assisted instruction, which today has evolved into web-based instruction and the notion that learning can take place “anywhere, anytime.” The third role described by Taylor looks at using computer technology as a tool for information processing and communication tasks. In the course described here technology integration is based on the perspective of this third role. This role has evolved throughout the years and now computer technology is not just seen as a productivity tool but rather as a tool for thinking or as Jonassen (1996) refers to it as a “mindtool”. Although the two other roles for computer technology have merit it is this mindtool role that appears to have the most potential for cognitive development (Jonassen, 1996, Logan, 1995, President's Committee of Advisors on Science and Technology, 1997, Reginald Gregoire inc., Bracewell & Laferriere, 1996). This view of technology integration is also supported by the Alberta Government through its prescription of a new curriculum that requires technology outcomes be integrated into core subjects such as Mathematics, Social Studies, Language Arts, and Science (see http://ednet.edu.gov.ab.ca/techoutcomes/). This curriculum looks at using computer tools for problem solving, inquiring, decision making, and communicating.

Looking at technology integration in this way requires that constructivist approaches to teaching and learning be adopted. In many ways the course is more about constructivist pedagogy than it is about technology.
The potential for computer technology to act as a tool for thinking can only be realized within a constructivist activity. The constructivist approach is difficult for some students to grasp because of firmly entrenched traditional beliefs about teaching and learning. Keith Yocam was involved in staff development in the Apple Classrooms of Tomorrow (ACOT) project and observed that “It seems far easier to help a teacher who is already practicing constructivist methods learn to use technology to enhance student learning than it is to help a teacher who has a lot of knowledge about technology but limited knowledge of constructivist pedagogy” (Yocam, 1996, p.268). I try to model constructivist approaches in as many ways as possible in the hopes that class participants will recognize the impact such strategies have had on their own learning and thus consider similar strategies in their teaching. Below is a description of some the activities and assignments used in class.

**Course Description**

EDSE 478/578 is an undergraduate/graduate course designed to help educators understand the role technology can play in the classroom and to develop some of the skills needed to integrate technology into classroom activities for their students. Initially combining undergraduates and graduate students was done to meet minimum enrollment criteria but it soon became evident that this was an advantageous situation. The graduate students are for the most part teachers enrolled in a part-time M.Ed. program. The undergraduates are students who have completed student teaching and are in the final stages of their program. The graduate students have additional readings and expectations, in terms of scholarly work, are higher. Combining preservice and inservice teachers in the same class has been mutually beneficial for the two groups and resulted in interesting classroom dynamics. It is in fact rare to have preservice and inservice teachers engage in lengthy discussions about teaching and learning. Each group is enriched by the other. The inservice teachers bring wisdom gained through experience and the preservice teachers bring contagious enthusiasm. Revisiting critical thinking, identifying purposeful learning activities, and working with beginning teachers has been a rejuvenating experience for the graduate students.

Students are given a number of articles to read and these are mostly discussed online but the final debriefing on the articles is held in face-to-face discussion. The online discussion of articles gives students more time to reflect on the responses and more time to formulate their own contribution to the discussion. The asynchronous communication component of the course is intended to promote reflective practice. For example, the students are given a number of readings that describe critical thinking and these are discussed online. Various points of view emerge and these are further discussed in small face-to-face groups. The various views are discussed in small groups. Students then develop a working definition of critical thinking and are asked to identify its key attributes. That is, what elements make a learning activity one that will foster critical thinking? Critical thinking is a concept that is widely used in education and yet poorly understood. In this part of the class it is important that students develop an understanding of critical thinking. They need to determine what it is and what it isn’t by examining examples of lesson activities and identifying the thought processes and skills a student would need to undergo to achieve the task defined in the activity.

Using a similar technique students are asked to identify the unique attributes of computer technology. That is, what features allow us to do things we could not do before or wouldn’t do because the task was too labor-intensive? Students are asked to brainstorm these attributes. It should be mentioned at this point that the prerequisites for this course require students know how to use the Internet, spreadsheets, and databases. Even though students have the prerequisite skills some cannot be considered confident computer users. When asked about the unique attributes of the computer they usually refer to automation of labor-intensive tasks. In many ways they continue to use the technology to perform old tasks faster. For example, they continue to use a word processor as a typewriter and a spreadsheet as a calculator. After much discussion students realize that computer technology lets us communicate with experts or individuals who can offer an entirely different perspective on an issue. The use of the Internet now exposes students to authentic problems and research. Computer technology helps us to manipulate data and reorganize it in a way that makes patterns or relationships evident. It also allows us to visualize data in a way that could not be done before.

Once students have looked at critical thinking and the attributes of technology they are asked to create short lesson activities that require the use of spreadsheets and databases. These activities have to be designed to promote critical thinking and take advantage of the unique attributes of technology. For example, one activity might have students extract authentic data from the STATSCAN site (http://www.statcan.ca/english/Estat/estat.htm) to examine smoking
habits of 15 year olds across the world. Students would have to generate their questions about smoking habits and then query the database for an answer. Ideally one question would lead to another.

Guided discussion of critical thinking and technology integration is used to provoke undergraduate and graduate students into examining their own beliefs about teaching and learning. This examination of beliefs is often difficult for undergraduate students as they make the transition from student to teacher. Many undergraduate students are in the initial stages of forming a teacher identity and coming to grips with their role in the classroom. As a result it is difficult for them to develop meaningful activities instead of “busy” activities. Often these students do not have a clear sense of purpose for the activities they develop. They also lack knowledge of the curriculum. Undergraduate students have small pieces of the picture but at this stage of their career they lack the vision an experienced teacher would have of curriculum. In our face-to-face and online discussions the undergraduate students have many opportunities to ask questions and to develop a better understanding of teaching and learning. In addition, these students listen to the discussion (sometimes heated discussion) amongst the experienced teachers. Not all the teachers in the course are open to trying constructivist strategies in their own classes. This usually generates quite a bit of controversy as other teachers challenge the nonconstructivist teachers’ beliefs about teaching and learning.

Regardless of teaching experience both groups struggle with the concept of technology integration. To assist in this concept attainment the students are presented with videotape segments of learning activities that incorporate technology. The videotapes used were purchased from the North Central Regional Technology in Education Consortium (NCRTEC) which is a subgroup of the North Central Regional Educational Laboratory (NCREL) (see NCRTEC’s website http://www.ncrtec.org/). The examples are discussed and evaluated in terms of their ability to promote critical thinking and to take advantage of computer technology’s unique attributes. This examination of example/nonexample technology activities prepares students for their major assignment.

Keeping with a constructivist perspective the major assignment for this course is meaningful and relevant for the student. The graduate students (inservice teachers) develop a project that can and should be implemented in their own class. For the undergraduate student this task lacks relevance and is difficult because of their lack of familiarity with the curriculum. Therefore these undergraduate students are paired up with teachers in the field who have been interested in technology integration but have not had the time to develop curriculum in this area. The cooperating teachers are carefully selected with the assistance of personnel in the surrounding school districts. It is imperative that these undergraduate students are placed with teachers that support constructivist pedagogy. The undergraduate student meets with the teacher to get background information needed for the project. In this discussion the undergraduate student can describe some of the activities presented in the course. Together the teacher and undergraduate student generate an idea for a technology integration activity that focuses on a specific curricular area. The undergraduate student is responsible for developing the project so that it will work with the technology and resources available in the school. This assignment presents undergraduates with an authentic task and they become accountable to someone else other than their instructor for the course. The teacher and undergraduate student meet face-to-face and online to discuss the project. Draft versions of the project are submitted to the teacher for feedback. The cooperating teachers view the relationship as mutually beneficial and in the end they have a product that can be used in the classroom. Some projects are better than others but nonetheless the result is a valuable learning experience for all those involved.

Conclusion

The course has varying amounts of success. Much of this seems to hinge upon the participant’s beliefs about teaching and learning. Students that believe in constructivist approaches tend to enjoy the course and believe the class assignments are practical. Students that do not believe in constructivist approaches feel the course is far too theoretical and the assignments could never be implemented in their own class situation. There seems to be much more resistance from the high school teachers. Some of the hesitation stems from the infrastructure in place at a high school. Teachers are given 60-80 minute blocks of time to cover their subject making it difficult to pursue project-based activities. In addition, teachers of a particular subject area tend to have their own staff rooms thus little dialog is promoted between the teachers of different subject areas. This kind of dialog is necessary for the creation of interdisciplinary projects focusing on authentic tasks. But even without these obstacles there still are teachers who do not believe constructivist strategies could be used effectively to cover all the content that needs to be covered in a high school curriculum. If participants of the course strongly hold such beliefs there can be quite a
bit of tension in the class atmosphere. Sometimes that tension intimidates the undergraduates and can defeat the purpose of combining graduate and undergraduate students into one course. At the same time though this tension stimulates deeper introspection, students are challenged and they need to explain their beliefs not just assert them.

Abstract: This paper reports on a project designed to change the way pre-service teachers use technology. A consortium of university and public school faculty are collaborating to improve pre-service technology integration skills by modeling those skills in their classrooms and in the field and requiring technology components for student field activities. A thorough needs assessment of the population was followed up with a plan to increase instructional effectiveness of faculty and Demonstration Teachers modeling for pre-service teachers.

Introduction – The Need for Change

Pre-service teachers will be the teachers of the 21st century. As such, they must develop the necessary technology knowledge and skills to prepare the next generation of students. If they do not, they will perpetuate the lack of technology expertise that is the national norm of the current generation of teachers (Moursund & Bielefeldt, 1999). Not acquiring these skills during their pre-service program will cost school districts greater hardships because they will ultimately have to bear the financial responsibility for expensive staff development. Pre-service and in-service education systems have struggled to keep up with the rapidly changing pace of technology development (Moursund & Bielefeldt, 1999). Since the publication of A Nation at Risk, student to computer ratios have improved from 125:1 in 1983 to 13:1 in 1998. Becker, et al. (1998), however, estimate that the total number of computers in private and public schools is slightly more than one per five students 15-fold increase in 15 years. Internet access has now been provided to eighty-five percent of schools and forty-four percent of classrooms (Jerald, 1998). These tools are influencing the way we think about, access, and use information. In an effort to prepare students for the information age, public schools are increasing access to these tools by putting more hardware and software in schools; connecting schools to the internet; and providing cable and satellite capabilities (Zehr, 1997; Zehr, 1998).

Having access to technology tools is only part of the answer. Teachers must become more knowledgeable about technology and be able to integrate these tools into their teaching and student learning projects. School districts throughout the country are making efforts to increase the use of technology through staff development activities and providing on-going technology support. However, this training must begin with pre-service teacher education (Wetzel, Zambo, Buss, & Arbaugh, 1996).
In a 1998 national survey, the International Society for Technology in Education (ISTE) surveyed schools, colleges, and departments of education (SCDEs) in the United States about how they were preparing new teachers to use information technology (IT) in their work. Among other findings, the institutions reported that most of their faculty do not model use of those IT skills in teaching, so therefore, most student teachers do not routinely use that technology during their field experiences and do not work under master teachers / supervisors who can advise them on IT use.

In 1998, a South East and Islands Regional Technology Consortium (SEIR*TEC) survey concluded that students do not know how to integrate various technologies into their teaching. The Georgia Department of Education (1998) published a technology needs assessment, which found that there is a large gap between the plans for needs and the actual uses of technology and the capacity of the present technology resources and infrastructure to meet those goals.

Carlson and Gooden (1999) surveyed 92% of the Georgia Southern College of Education students who had completed their student teaching experience over a one-year period to investigate how student teachers assimilated and applied technology. This study found that students felt comfortable using word processing and, to a lesser extent, email and the WWW - the only technologies they saw modeled by their professors.

All of these studies, national, state, and local, come to the same conclusions concerning the use of technology in teacher education. Overall these studies recommend that:
1. Technology should be integrated into all courses that pre-service teachers take.
2. Institutions of higher learning should identify examples of technology integration for all courses that pre-service teacher take.
3. College faculty, that teach pre-service teachers, should model effective uses of technology in their classroom.
4. Pre-service teachers need more opportunities to apply Instructional Technology during their field experiences under qualified classroom supervision.

Additionally, the Board of Regents for the University System of Georgia recently mandated curriculum changes in all pre-service education programs. Key elements of these changes include: 1) strengthen the content background of the pre-service teacher to meet rigorous academic standards; and, 2) assure that future teachers are technology-proficient and understand how to infuse technology into the curriculum to improve learning and achievement.

The Project

In order to address these mandated changes and to build an active learning community that bridges the gap between post-secondary institutions and K-12 schools in Southeast Georgia, a consortium was created. The consortium members include an institution of higher education, Georgia Southern University (GSU), GSU's College of Education (COE) and five local public school districts (LEAs). The public school districts include 27 elementary schools, 10 middle schools and 10 high schools.

This consortium was carefully crafted based on the memberships' history of cross-disciplinary collaboration and their potential contribution to innovative teacher preparation program reform that will enable future teachers to infuse technology into the classroom. Each member has unique resources available to support a shared vision of an innovative teacher preparation program and willingness to contribute to the comprehensive effort of improving teaching and learning with new technologies.

This consortium forms a new community of learners that provides sustained support for both the experienced and novice teacher. Further, it helps bridge the gap between college teachers, pre-service teachers, and K-12 classroom teachers by providing continuous professional development. This also paves the way for future teachers who might enter the profession through alternative certification by supporting them as they build the experience they need to become technology-proficient teachers.
This project was designed to document and identify specific gaps and weaknesses in the delivery of instruction to pre-service teachers and to support comprehensive teacher preparation program improvements that infuse technology throughout the teaching and learning experience of all future teachers. The goal of the project is to develop technology-proficient future educators by providing professional development for college faculty and public school demonstration teachers through the integration of technology into the curriculum. This goal is a part of a comprehensive restructuring of GSU’s teacher preparation program designed to improve teaching and learning with rigorous academic standards for all students. This goal will be met through an extensive needs assessment; the identification and development of “Best Practices”; extensive training of college faculty, student teacher supervisors and demonstration teachers; and, revision pre-service education curriculum and field experiences. Specifically, this project addresses the following objectives:

1. Assess needs and opportunities for technology program improvements in the pre-service teacher curriculum and course content.
2. Identify and develop a core of strategies and techniques (“best practices”) for dissemination to faculty, demonstration teachers and pre-service teachers.
3. Train College of Education methods and practicum faculty to integrate technology into their lessons and to model the effective use of technology.

Project Activities

The project is being implemented in three phases: I) assess needs and identify opportunities for infusing technology into the teacher preparation program, II) develop innovative strategies and techniques to respond to these needs, and III) provide faculty with professional development to integrate new technologies into their courses and model technology-proficient instruction. Within these three phases, the project will be divided into specific tasks.

Task 1.

An extensive needs assessment began in Task 1. Previous to this project, Carlson and Goodell (1999) had assessed the state of technology integration in the College of Education among the pre-service teachers and the faculty. Major findings were that the only technology that was available and used across the board was word processing. Internet technologies had some medium measure of use. The opportunities for this group clearly rests in extending the types of technology used in instruction and application.

To address the other groups working closely with pre-service teachers, both consortium and non-consortium Demonstration Teachers, highly qualified, specially designated public school faculty, were surveyed to establish their technology strengths and areas for possible improvement. One hundred seventeen (117) out of 262 surveys were returned for a 45% return rate. Ninety percent (90%) of the surveys were from females. Consortium teachers comprised 77% of the returned surveys, both consistent with their proportions among all Demonstration Teachers. Forty-five percent (45%) taught elementary children, 24% middle school, and 31% high school. Experience at each level was between 11 and 12 years teaching. Seventy percent (70%) held a Masters degree or higher. We were interested in the technology training and support for these teachers. Approximately half (46.2%) had completed Georgia’s InTech, advanced state sponsored technology training. InTech was also the most recent technology training for the Demonstration teachers (41%), with school-based training (24%) and the Georgia state sponsored Regional Education Services Agency (RESA) training (21%) well behind. Only 3% listed college/university courses as their most recent technology training. In-school technology support was most often provided by the media specialist (37%), with county specialists (19%), in-school technologists (15%), and RESA specialists at 14%.

Table 2: Availability of Technology for Demonstration Teachers.

Table 2 shows that technology, with the exception of highly specialized technology, is available to most teachers somewhere. The lottery money spent on technology has filtered down to the schools in rural southeast Georgia. However, more can be done to improve access to technology, especially in the classroom. Notable was teachers’ access to office productivity tools and to the internet at home.

Table 3: Demonstration Teachers' Self-reported Technology Proficiency

Demonstration teachers' technology proficiencies (Table 3) were similar to the proficiencies previously reported in other studies and similar to those reported by pre-service teachers. The only technology that the teachers showed confidence with was word processing, followed by internet-based technologies.

From these needs assessments, we determined that access to technology was adequate and improving, but can be further improved with additional allocation of resources. This observation is offered because access is a prerequisite to infusion, however this project did not propose to address problems of this nature. Teachers still do not have the proficiency in technology use required to integrate the technology into their lessons. Therefore the need is to train the teachers both in use and integration skills simultaneously.

Task 2

The Project Team has set up a Web site to provide information to all project participants. Currently the Web site provides
1. an overview of the COE Technology Infusion Project,
2. local resources (hardware and software) that are available to faculty and students, and
3. links to Web sites that provided resources for integrating technology into the instructional process.

Web sites of additional instructional resources will be added to the list when suggested by participants.

The Project Team has consulted with educators in the consortium (e.g. public school curriculum directors, principals, media specialists, COE faculty, and Demonstration Teachers) in order to start to identifying teachers who are currently infusing technology into their daily lessons. During the Spring semester, appropriate Project Team members will visit the technology-proficient teachers to discuss and observe their practices in their area of expertise.

The Project Team set up a series of faculty workshops that were delivered during the Fall Semester. The topic for each of the workshops was developed by input from faculty. The workshops delivered so far are:

1. Available Resources. This workshop provided the faculty with the resources (both hardware and software) that are available to them, their students, and the College’s Demonstration teachers. Several Web-based Resources were also discussed.
2. Search Techniques. This workshop provided faculty with information on how they could effectively search the Web. A comparison of Search Engines was discussed with an emphasis on those that are the most effective in an Educational setting. Boolean logic and how it applies to searching was also discussed.
3. GA InTech Program. The Director of the Teacher Training Center, located in SE Georgia, provided an overview of the GA InTech Program. InTech, GA Framework for Integrating Technology, is designed to support the existing P-16 curriculum using technology as a catalyst for changes in the teaching and learning process. All Georgia teachers are expected to have received InTech training by June 2001.
4. Integrating the Web into the Instructional Process. This workshop provided the faculty with information on how the WWW could be integrated into the instructional process. Included in the discussion was information on how Web Sites could be downloaded for use in classroom without direct internet connections.

This series of workshops will continue during the Spring semester and will include topics as identified by the faculty and the evaluation process. Public School teachers who are currently infusing technology into their classes and have been identified, by their county school district, as exemplary teachers will also be brought to campus to share their experiences with both faculty and pre-service teachers.

Task 3
As a follow-up to each workshop, Project Team members will identify technologies that will enhance individual courses. This will include specific classroom activities and techniques for modeling the use of various technologies. We are currently developing a database of instructional lessons, that make use of technology, that are being delivered in the school districts that are part of the consortium. This database will allow COE faculty who are in charge of practicum students, to make observation assignments for their students. Future plans include having this database available on the project web site so that it can be searched by all project participants.

Evaluation is an integral component of the overall program. It is both formative and summative by design. Information from the evaluation will provide performance feedback that will help guide the development of strategies for full-scale implementation of teacher preparation program improvements and assure that the program goals and objectives are met. Both qualitative and quantitative data will be collected on a periodic basis to inform all stakeholders of progress toward achieving the intended outcomes as well as establish clear benchmarks for documenting future improvements.

Abstract: This paper presents the concept and beginning work of one of the Preparing Tomorrow's Teachers to use Technology research grants. The Department of Education initiative is to infuse technology into the teacher education programs to prepare more technologically proficient teachers for future classrooms. The model created by a consortium of 3 public universities in rural Western Pennsylvania looks to infuse technology into the pre-service teachers core curriculum and several teacher education programs. Some 1,500 future teachers per year placed throughout the U.S. and seven foreign countries will be affected by this change. Four goals will be accomplished: 1) Instructional Technology will be moved from the periphery to the core of our curriculum. 2) Future teachers will apply and integrate Instructional Technology into the teaching/learning process. 3) Additional Faculty, instructional designers, and technical support staff will assist with the transition. 4) The consortium will provide the infrastructure support needed for teacher preparation in the digital age. Evaluation strategies will include baseline and follow-up surveys, student portfolios, interviews, and focus groups.

Introduction and Problem

The Commonwealth of Pennsylvania certifies approximately 13,000 teachers yearly and each one must be prepared to teach in the 21st century. These students must master the skills required by a digital age (problem solving, inquiry, and reflection) and have the ability to function in a workforce dependent upon access, utilization and application of information technologies. Today, at the turn of the century, there are already teaching position announcements posted only on the Internet—it is clear that computer illiterates need not apply.

Teachers teach the way they were taught, but unfortunately, they have not been taught in a manner that demonstrates technology infusion. Instead, they have traditionally been taught Instructional Technology in a separate, “isolated” course in the education curriculum. These students will face an uphill battle to integrate instructional technology effectively in content areas because they never see it modeled in their core and content courses in college.

There are many reasons why some college faculties have been slow to integrate technology into their teaching. Certainly, one significant reason is that technology in the classroom changes social relationships.
Some faculty that are exhilarated by the change brought about from integrating technology in their teaching, while others are concerned about how technology impacts their authority, control of students, and knowledge of the teacher’s role (Cuban, 1999). Other reasons include: an academic tradition that values deliberation and incrementalism, lack of suitable training, lack of technical and administrative support, lack of systemic incentives (tenure and promotion), traditional pedagogical beliefs, and the lack of hard evidence that technology can serve their needs and make their work move effective and interesting (Albaugh, 1997, Freberg, 1995, Olcott, 1999, Oppenheimer, 1997, OTA, 1995, Spotts, 1999). It is clear that getting faculty to use technology remains a challenge (Olsen, 1999).

To promote the effective use of technology in teaching and learning, we need a new approach. Hence, President Clinton’s Educational Technology Initiative appropriately made training and support for teachers to help students learn through computers and the information highway one of the four pillars of his program. The teacher workforce will experience a rapid turnover in the next decade. The need to fill a demand for 2.2 million new teachers is fast approaching, and the question needs to be asked: “Will they be ready for the digital age?”

Project Design

Clarion, Edinboro and Indiana Universities of Pennsylvania are committed to training teachers for the new millennium. These universities have worked together since 1998 as partners in the ADEPTT Consortium (Advancing the Development of Educators in Pennsylvania Through Technology Training). The ADEPTT consortium was funded by the Bell Atlantic and Microsoft corporations to provide foundation training in instructional technology for faculty and K-12 teachers. The consortium is now attempting to go one step further by infusing technology into the pre-service training of all their teacher education students. All three universities agreed on the following goals to be accomplished over a three-year period:

1. Goal 1: To infuse instructional technology more deeply into the teacher curriculum in both education core courses and selected majors.

The foundation of this goal is eleven key competencies that reflect the recommendations of NCATE and the Pennsylvania Department of Education. The competencies include the following:

- operating systems management
- word processing
- spreadsheets
- web browsers
- email
- presentation software
- databases
- multimedia packages
- video conferencing
- moderating chat rooms
- Internet in teaching

To achieve this goal, we will pursue four objectives, each one building on the preceding as it moves us to a teacher preparation program that has technology infused throughout the curriculum.

First, the grant will train faculty to effectively and appropriately use and teach the eleven key competency skills. This is the starting point of our effort and builds upon the foundation training for faculty provided by the existing consortium of the three universities known as ADEPTT.

Second, we will work to have university faculties model how to teach effectively with technology in education core courses and subject area courses. This objective is critical to change the teaching paradigm so future teachers will learn in a technology-enhanced manner and will be better prepared to teach in this way.

Third, the faculty will be encouraged and supported to create assignments within education core and subject area courses based upon the appropriate use of the eleven competencies. Through its active learning approach, this objective reinforces the acquisition of needed skills by the pre-service teachers. It also provides clear examples for pre-service teachers to use in their teaching careers.

Finally, the end result will be revisions of course syllabi to reflect and recognize the integration of technology into the curriculum. Wherever feasible, such courses will be designated as /T/ courses to identify their technology emphasis.
Goal 2: Integrate instructional technology in the consortium’s pre-service observation and field experiences. These experiences provide a gradual process of immersion in which the pre-service teacher sees and “experiences” the K-12 teaching environment. During these exercises, we will take steps to assure that students receive a triple exposure to instructional technology—(1) seeing how it is used in the classroom; (2) using videoconferencing technology to enrich observations and field experiences, and (3) incorporating technology through moderated chat rooms and threaded discussions to help students share their experiences and insights.

In 1997, IUP received the United States Distance Learning Association award for the best distance learning program in the nation. Funded by a FIPSE grant, this program used two-way interactive compressed videoconferencing. Pre-student teachers at IUP were able to unobtrusively observe classes in progress in K-12 schools. Faculty helped explain what was occurring and pointed out tips and strategies. Following the observations, students were able to talk with the K-12 teachers over the video link to discuss what they had seen and to ask why a teacher used particular techniques and methods. Now that the FIPSE grant has concluded, we have ideas, lessons, methods, and the experience to achieve this second goal.

Goal 3: Provide a variety of professional support of opportunities for faculty and pre-service teachers. A critical factor in introducing technology into any environment is the support of peers and technology professionals. Support will come from “teaching circles” which will provide an opportunity to establish and sustain instructional technology networking and peer mentoring opportunities. There will also be consulting faculty who will be able to provide training and one-on-one assistance to their peers applying instructional technology to teaching and pre-service teachers learning to integrate technology into their beginning lessons. The universities are also working to strengthen their help desk services for faculty and students and to expand basic foundation training through the ADEPTT consortium and instructional programs. For example, IUP’s “incubator” computer laboratory in the College of Education provides valuable professional and technical support and is a program that will grow to help support these efforts.

Goal 4: Enhance the technological infrastructure of the consortium members to better support project initiatives. A lack of sufficient infrastructure is a major impediment to the infusion of technology into the teacher preparation curriculum. Computer labs will be upgraded so that advanced computing skills can be developed among the graduates of the three universities. The enhanced technology infrastructure will allow students to work in a networked environment with student network spaces, as well as network space for courses to work through. Increasingly, school districts are looking for employees who are familiar with a networked environment. The three universities are committed to ensuring that their faculty have adequate multimedia computers to facilitate integration of technology into their courses. Faculty are also actively involved in technology planning. The three universities each have variations of the American Association of Higher Education’s Teaching and Learning Technology Roundtables to encourage faculty input on campus technology development.

The Evaluation Component

Baseline data will be collected on the current use and implementation of technology in the teacher preparation curriculum of the three universities. This will be done by surveys with pre-service students, faculty and recently graduated in-service teachers. There will also be an analysis of syllabi. Building on existing Instructional Technology foundation training, we will offer new workshops on Instructional Technology application and integration. The latter workshops will primarily be in the second year of the project. One-on-one consultations and training will also be provided, and evaluations will be conducted of both group workshops and individual consultation after each session. There will be curriculum revisions, courses enhanced with instructional technology, by the third year.

The data from years one and two will be compared to collected syllabi, surveys and portfolios of year three of the project.

Conclusion

The positive aspects of the model are recognized throughout Pennsylvania and on the national level. Pennsylvania Governor Thomas Ridge has made technology and its use a major initiative in K-12 education. Ridge’s three-year, $132 million Link-to-Learn initiative is aimed at expanding the use of technology in the
classroom, including new and upgraded computers for schools and technology training for teachers. Nationally, the Clinton-Gore administration has pushed for connectivity to the World Wide Web for every American. Indeed, their administration has the goal of making computers, computer related multimedia, and the World Wide Web standard tools for teaching and learning.

The successful implementation of this model will demonstrate that technology can be infused into all areas of the teacher preparation program. The three schools involved graduate 1500 teachers per year. With this model each graduate will be able to utilize technology in their teaching and be leaders for change in the wired and connected school districts which hire them to teach.

The problems associated with this project are of national concern and seem to be increasing in scope. Consequently, this three-phase project will add important information to the literature of technology and its integration into the teacher preparation curriculum. If the model is successful, it has the potential to be replicated at other teacher preparation programs, particularly since it will already have been tested at three institutions with different programs. Thus, other institutions will be moved toward integrating the use of technology into their teacher preparation programs.

References

Preparing Teachers for the Digital Age was funded by a $1.7 million grant from the U.S. Department of Education through the Preparing Tomorrow's Teachers to Use Technology initiative. Matching funds in the same amount were provided by Indiana, Clarion and Edinboro Universities of Pennsylvania and by the Bell Atlantic and Microsoft Corporations.
Increasing Instructional Technology Competencies for Faculty and Students in an Education Preservice Program

Alec Couros
Faculty of Education
University of Regina
Regina, Saskatchewan, Canada.
Email Alec.couros@uregina.ca

Abstract: Education Faculties around the world continue to struggle to develop instructional technology strategies to build and promote their respective undergraduate Teacher Education programs. Successful implementation of instructional technology (IT) is perceived as to allow our revised programs to produce teachers well able to bring success into our 21st century schools. In order for pre-service teachers to integrate technology as a deep and meaningful element of new instructional practices, teacher education faculty need to both model and support technology as an integral part of their instruction. As the pace of technology accelerates further in and with education, our Faculty’s Instructional Technology Committee continues to develop and refine its ‘Vision’ of how the technology of today can seamlessly be integrated into the instruction of the future. Constructed and represented here are specific goals on how our faculty hopes to approach the overwhelming need for instructional technology competencies in our emerging educators. Our Faculty of Education continues its worthwhile struggle to integrate technology into all levels of instruction, into all of its Teacher Education Programs, and in sharing this struggle, we hope to give insight to others in similar circumstances.

Setting the Context

Saskatchewan’s unique demographics, rural economics, and progressive nature, have prompted essential change in the provincial Education system recently. With an inadequate number of graduating teachers each year emerging from either of the province’s universities, a growing number of students in remote rural locations, and a lack of instructional resources and educational dollars in our already crowded urban schools, Saskatchewan Education continually struggles to look for viable options toward more efficient instructional methodologies. As we battle to maintain the integrity of our educational programs, recent reactionary developments have risen from our province’s necessity to compete in a widening global arena.

It is becoming Saskatchewan Education’s mandate to provide the province’s school-aged students with a diversity of educational opportunities effectively leading to their future success in the Information Age. Evidence of this directive is apparent in Saskatchewan Education’s development and creation of the Evergreen Curriculum (http://www.sasked.gov.sk.ca/docs/evergrn.html), a dynamic web site hosting the province’s entire K-12 curriculum and approved educational resources. With the development of the Evergreen Curriculum, all residents of Saskatchewan, Canada, and the world, can view the on-line curriculum documents, analyze lesson plans and resources, and dynamically assess our province’s educational ‘product’. Further evidence of Saskatchewan’s mandate manifests itself in the province’s commitment to Distance Education. Distance Education programs continue to develop in rural and urban settings, and Saskatchewan Education continues to pursue partnerships with its educators, universities, multimedia design companies, and local Tel-Co providers. With both the on-line accessibility of our curriculum resources, and the commitment to further Distance Education programs, we can begin to extrapolate what this will mean for the future of our traditional schools.

It is increasingly clear that the teacher of tomorrow can no longer rely on outdated methodologies to effectively teach the 21st century student. William Clark (1994) states in his article referring to the “high-tech classroom of the future” that the evolution of the classroom “will be characterized by the steady replacement of traditional basal programs by multiple media programs and collections of supplemental
materials. Some of these materials will be classroom resident. Others will flow through various manifestations of the information highway" (Clark, 1994, p. 62). The roles of teachers are changing, as are society’s expectations upon them. Teachers are now expected to incorporate instructional technology into living practice with IT skills leading the way to success for their students. As requests for educational reform increase, comprehensive changes in traditional teacher roles seem an inevitable part of the total restructuring package.

Distance Education, multimedia, web-based learning, instructional technology; these are terms commonly heard by the average teacher, but rarely completely understood. Not only are the technologies themselves misunderstood but more significantly, their underlying pedagogical implications are scarcely realized. Marita Moll, a strong critic of information technology, states “I believe that information technology can be extremely empowering, extremely motivating and extremely conducive to creating new and exciting classroom environments. However, we need to develop a better understanding of how new technologies will effect our learning environment – both positively and negatively” (Moll, 1997). This criticism comes as tremendous amounts of dollars continue to be allocated towards technology upgrades for schools. However, at the same time there are lesser dollar amounts contributed towards teacher training in learning theories, research of instructional technologies, or investigations into technology learning outcomes. Ironically, due to the unprecedented speed of technological change, administrations can only reasonably push for the technologically ‘average’ school. However, in the same push, teachers are left merely adequate in their instructional skills and understanding. Still, the wheels of change roll relentlessly.

As the educational infrastructure continues to evolve in Saskatchewan and the world, Teacher Education Programs are under tremendous pressure to continually improve their ‘product’. Our faculty must continually analyze the successes and failures brought by these times of technology-induced growing pains. Our vision remains strongly founded upon technological and pedagogical diversity. However, vision alone is not nearly enough for change to occur. Collectively, faculty must address the shortfall of technological competencies in both graduating students and faculty members. It is with the cold realization of these deficiencies, that planning may commence toward necessary mechanisms of change. Luckily, and I strongly believe that, “we are fortunate to work in a faculty where collaboration and change are theMaers, Browne, Cooper, 1999)

The above mentioned paper, written by professors from our Faculty last year, details the struggle to produce technologically competent graduates through the University of Regina’s Teacher Education program. The goal at this time, as it continues to be, was to expose all graduating students to a varied representation of educational technology theories, research, resources, and pragmatics. Up until 1998, only the slight majority of students were able to take the offered “Computers in Education” class as an elective. Due to course limitations, many students were unable to fit the class into their programs. With the belief that “offering a single core course in computer technology for education might imply that computers were an ‘extra’ feature in education rather than an integral part” (Stevens, Lonberger, 1999), the Faculty responded with non-credit technology modules that became a requirement for all graduating students. The reasoning for this is to ensure basic computer competency for all emerging teachers of our program. The paper “Pedagogically Appropriate Integration of Informational Technology in an Elementary Preservice Teacher Education Program” (Maeers, Browne, & Cooper, 1998) shares with you those successes.

Faculty Vision and Instructional Technology Innovations

Only one year has passed since faculty members set forth our Faculty’s vision for instructional technology. In part, the visioning process listed key goals in the implementation of instructional technology. Such goals included the role of IT in several of the following areas: addressing diversity and equity issues, continued curriculum support, advanced web-quest & electronic portfolio development, WebCT (Web-based course tools) course development, and the revamping of the Faculty of Education homepage. Only one year later, great successes have been achieved in all of these areas. However, as technological integration undoubtedly is a moving target, our IT goals have also begun to shift towards higher expectations.

Current Goals and Developments
Goals and innovations in a Faculty of Education must be relevant for students and faculty, as there is a strong necessity to acquire skills and learning theory in order to effectively infuse technology into instruction. However, the path from here to there is not an easy one. In collaboration with the IT Coordinator, the Instructional Technology Committee (ITC) is interested in proposing a dynamic set of goals for the Faculty. The following is a short list of the renewed goals formed in an effort to increase technology competencies throughout the Teacher Education Program. Also included are goals which have not yet been proposed, but are being investigated as to their positive effects on the Faculty's IT future.

**Technological Diversity at the Skills Based Level**

Development, enhancement, and stimulation of information technology knowledge and skills of students and faculty in relation to operating systems, software applications, communications software, Internet and library resources, presentation software, instructional design software, and courseware, are to be fully realized. Faculty will also be able to use more specialized software such as test-generators, telecommunications software, grade managers, graphing programs, and databases in the execution of their personal and professional duties including professional development, teaching, research, and service. Both faculty and students will use technology, both hardware and software, as personal and professional tools. This will promote technology integration into the majority of courses, as well as to promote faculty modeling constructivist approaches to instruction. To support this development, the IT coordinator will organize ongoing technical workshops to supplement the instructor's knowledge and skills base. In conjunction with workshops, faculty will receive continuing support in the guise of two dedicated Faculty of Education technicians, and frequent visitations and morale support by the IT coordinator.

**Technology Diversity in Theory and Practice**

Continued development of a theory-based approach to instructional technology implementation is absolutely necessary as a to serve as the backbone to all faculty IT proposals, research, service, and instruction. Moreover, this type of methodical implementation of IT is to be fully modeled, demonstrated, and understood by our pre-service teachers in order for them to take a careful approach to IT integration in their future careers and schools. Faculty and students must continue to consider carefully the works of learning theorists in conjunction with modern practical developers in Instructional Technologies. A communications model is essential here in developing, understanding, and applying theories into personal educational philosophies. This type of theoretical development is well served through continued development of our core classes (ECMP 355) and advanced classes (ECMP 490) in educational technology. Also, already three graduate studies classes have been offered which have an educational technology foundation, and there is continued development towards a graduate studies program specializing in educational and instructional technologies.

**Support of On-Line Course Creation**

Technical and instructional support of on-line, distance related and other, course creation for faculty featuring a variety of HTML editors, and especially WebCT, is strongly supported, and will continue to be supported in our Faculty. Support of on-line course creation tools will be thorough throughout the Faculty and will be adjusted accordingly to the goals and skills of the primary developer (faculty member). This support will include workshops in basic and advanced HTML, HTML editors, and WebCT development. For our technologically more prepared faculty, Java based development will also be offered and supported. Our Education technicians and IT coordinator are dedicated to support faculty ventures in web-based development to support instruction. Ongoing support in this area will lead to greater technological competencies for faculty, and with our careful regard to developmental principles, this will also lead to better, more diverse, instruction for our preservice teachers.

**Essential Partnership with Library Services**

The Faculty of Education has formed a partnership with the Education/Fine Arts library and Instructional Technology services in order to supplement and enhance course development and to provide
basic and advanced instructional support. The Education/Fine Arts library has partnered with the IT coordinator and IT committee to provide the development of web, print, and multimedia instructional resources to supplement both terrestrial, and on-line course development. Also, through this partnership, there has been a provision for the development of a software media center where students and faculty are able to demonstrate the use of a variety of current media resources. In conjunction with this, library services will also catalog and provide educational software at request for faculty’s use in the classroom, and for the students’ use in their field experiences. In return, borrowers are required to both test and evaluate the educational value of the software. This will increase both accessibility and interest of instructional software, as well as providing proper assessment of such software’s validity in formal learning situations.

Increased Exposure to Educational Technology Innovations and Practices

Through the office of the IT coordinator, the Faculty of Education will provide more opportunities for faculty and preservice teachers to be exposed to developmental practices in the areas of educational and instructional technologies. This exposure will be developed through two basic key strategies through on-campus and off-campus experiences. Software and hardware ‘fairs’ will be coordinated biannually. This will allow for the leaders in educational technologies and publishers or developers of educational software to show their ‘wares’ to the eager faculty and students. This will enhance the faculty’s awareness of what innovations exist already and will allow students to experience the innovations first-hand rather than to have had merely a text-book or magazine approach to understanding technological innovation. Also, opportunities will be presented for faculty and staff to view instructional technology strategies in a school setting. This will occur by having either guest speakers (key administrators, educators, etc.) invited to speak about ‘what they are doing in their classroom’ in terms of technology and instruction, or moreso, to have students and faculty visit either on-site or virtually, where instructional innovation is actually taking place. This grounding of theories with practice will give faculty and students a better ‘picture’ of what is already available or what needs yet to be developed, and this will create an opportune environment for developing with, or against, already current technological practices.

Increased Course Development in Instructional Technology

Increased development in core classes of Computers in Education including an advanced class continue to be fully developed. Additionally, the development of instructional technology modules complete with dynamic on-line resources will continue to support the needs of all teacher education students. As the classes in ‘Computers in Education’ are not yet mandatory, the underlying principle of developing the courses and non-credit modules is to provide the opportunity for all preservice teachers to have a strong exposure to technology in instruction. This mandate is due to clear indicators that our school boards look first to hiring teachers who are able to develop innovative instruction in their classrooms primarily based on technology. This need is strongly evident in the requests from school boards, hiring agencies, and educators for graduate classes to be offered in educational technologies. The requests have already spawned three separate graduate courses in IT, and there is definite need to diversify in several more IT related areas. School boards are looking for candidates with a strong IT experience in the classroom, or in a practical setting. We try to offer our preservice teachers the best of both worlds.

Development of an Instructional Technology Development Centre

The development of an exclusive Instructional Technology Development Centre and Sampling Lab, complete with full multimedia authoring capabilities based on high-end multimedia workstations, will soon be fully realized. This Instructional Technology Development Centre will be developed in cooperation and consultation with media experts, instructional designers, and most importantly, experienced educators. The purpose of the center is to give faculty and students first hand experience and the resources to explore multimedia instructional design. The structure of the lab will be continually renewing so as to model most recent instructional technologies. In the development of the center, we will seek partnerships with multimedia design companies such as Macromedia and Adobe. Students will be able to sample, study, learn, and become proficient in specific lateral market software prevalent in the field of instructional and multimedia design. Parallel to this development, the Faculty of Education may seek to include graduate and undergraduate courses specifically geared to providing theoretical and practical
foundations of instructional design. The tandem relationship of both theory in courses, and practical design in the lab components, will further supplement the faculty’s overall IT goals, and will provide many students with a specialized background in one of the key areas of educational technology.

Partnerships with Industry, Telecommunication Providers, and Government Education
The Faculty of Education will explore the possibility of a partnership with Industry, local Tel-Co’s, and Saskatchewan Education, with the purpose of developing a simulation distance education lab. This simulation lab will help to effectively train pre-service teachers in the methodological and practical processes underlying distance education delivery, as well as to help have the students internalize the technical aspects of this emerging technology. Participants will be able to model and experience the benefits as well as the shortfalls of the various approaches to distance delivery. The lab will allow students and instructors to actually simulate both the sending and receiving experiences of a distance education environment. The design of the center will allow for the students and instructors to explore first-hand a diversity of opportunities in distance education fundamentals. Both the traditional delivery model for distance education will be explored, as well as the emerging communications model.

Continual Assessment, Evaluation, and Development of IT goals
The continual assessment of instructional technology needs and goals of the Teacher Education Program, both in terms of faculty and students, is essential. This assessment should be linked explicitly with the Saskatchewan Education needs assessment indicators, as well as with our Faculties’ mandate for continuing excellence in our Teacher Education Program. The faculty must also look towards external sources to develop strategies in terms of instructional technology and related pedagogical practices even those that the local K-12 bodies have not yet embraced. Workshops, instructional strategies, and skills adjustments will be administered appropriately. Also, strong communication between school boards, provincial governing bodies, relevant national and international organizations, and educators is essential to our growth as a respected center for Teacher Education. In light of such rapid change and development in the field, the faculty will allow flexibility in the IT model. The flexibility is warranted in order to adapt to new instructional technologies as they emerge, and to help develop new technologies in teacher education. Inevitably, this will effectively allow for our Faculty to gain a place on the forefront of educational technology and Teacher Education.

Summary
There is no tried and proven method in which to develop technological competencies in our respective situation. In the world of educational and instructional technology, enduring expertise is an exceptionally rare commodity. We are forced to become leaders in our own right, and hope to share our story, whether successful or not, with other leaders and innovators. As our faculty is dedicated to the principles of effective education, they are flexible and accepting of this model of change. There is really no other choice but to remain flexible in this rapidly changing era. However, to be more effective in nurturing change, administrators must still be aware of common principles that apply to all types of education and professional development. We must still provide for our faculty and students a comforting and confident environment for evolution of learning to occur. With the increase of confidence in technology, there will be an unsuppressed, yet educated, growth in enthusiasm for the integration of technology into the classroom. It is when this enthusiasm becomes widespread, that we will see effective change and real integration of technology into the learning environment. However, confidence in technology is not easy to embrace. Confidence comes only after we can develop a significant infrastructure to support both the instructional needs and the technical needs of our faculty, staff, and students. The needs of both groups must be acknowledged through a diversity of approaches to gain an effortless self-assurance in which to succeed. When we are confident enough to accept our failures, we will be confident enough to succeed.

Abstract: The program described below, Learning and Integrating New Knowledge and Skills (LiNKS), addresses national, institutional, and teacher education goals as we prepare pre-service teachers to use a variety of technologies to enhance student learning. LiNKS redesigns the teacher education program within the Professional Development School (PDS) at Texas Woman's University (TWU) to address the technology proficiencies desired by the schools, recommended by the National Council for the Accreditation of Teacher Education (NCATE, 1997b), and delineated by the professional technology associations. The project encourages faculty to explore new technologies and provide a model of technology integration in their curriculum delivery. It also builds the awareness of mentor teachers regarding the instructional possibilities of technology so that these mentors are more open to pre-service teachers who bring technology into their classrooms.

Introduction

The Teacher Education Reform Movement has been at the forefront of debate in colleges of education for many years, and questions about how best to integrate technology
into teacher education programs are often at the center of this debate. Recommendations range from efforts to convince student teachers to use e-mail to programs designed to infuse technology into every aspect of the teacher education curriculum. E-mail, listservs, and electronic dialogue journals are a few of the recent innovations tried by teacher education faculty in attempts to combat the isolation that pre-service teachers often feel. Virtual workshops, out-of-field certification programs, and add-on technology courses have all been implemented with varying degrees of success. Finally, plans to integrate technology throughout the teacher education curriculum have been reported in increasing numbers over the past few years (Drazdowski, 1998; Parker, 1994; Schrum, 1998).

The efficacy of many of these efforts has been called into question. According to Shaw (1998) in his Report to the President on the Use of Technology to Strengthen K-12 Education in the United States, “a large scale program of rigorous, systematic research on . . . educational technology . . . will ultimately prove necessary to ensure both the efficacy and cost-effectiveness of technology use within our nation’s K-12 schools” (p. 115). In spite of these reservations, Shaw warns that “limitations in our current knowledge must not be used as an excuse to allow our schools to fall further behind other information-based institutions” (p. 125). Dusick (1998) and Roblyer (1998), among others, agree. While Dusick provides an egalitarian perspective arguing that computers must be placed in schools so that all students will have access (p. 12), Roblyer basically asserts that technology is here to stay whether or not we are prepared for it: “We have a multimedia future, the task at hand is to become fluent in our new native tongue” (p. 53).

If, as Shaw, Dusick, Roblyer, and others suggest, “speaking” technology is to become as essential as reading and writing, then plans that provide for the seamless integration of technology into teacher education programs seem most viable, at least in terms of society-wide impact. This paper describes one such effort designed to introduce pre-service teachers to educational technology within an integrated context of meaningful learning. This context is a field-based teacher education program, and the technology indicators are tied to specific requirements within that program. The program described below is supported by a U. S. Department of Education implementation grant entitled Preparing Tomorrow’s Teacher to Use Technology (http://www.pt3.org).

The LINKS Program

The Learning and Integrating New Knowledge and Skills (LINKS) Program addresses the four goals of Quantity, Quality, Equity, and Change as we prepare pre-service teachers to use a variety of technologies to enhance student learning in rural, urban, and suburban settings. LINKS redesigns the teacher education program within the Professional Development School (PDS) at Texas Woman's University (TWU) to address the technology proficiencies desired by the schools, recommended by the National Council for the Accreditation of Teacher Education (NCATE, 1997b), and delineated by the professional technology associations. The project encourages faculty to explore new technologies and provide a model of technology integration in their curriculum delivery. It also builds the awareness of mentor teachers regarding the instructional possibilities of technology so that these mentor teachers are more open to pre-service teachers who bring technology into their classrooms.
These efforts are reflective of TWU’s strategic plan as it relates to the preparation of future teachers and support for incorporating technology into higher education instruction and delivery. Technology integration is already an intrinsic part of the TWU PDS as students document mastery of specific technology skills within the context of required coursework. This integration will be further expanded through the implementation of this proposed LINKS program.

Current Technology Integration Program

The current technology integration program was developed based on the findings from the Basic Technology Competencies for Educators (Flowers, 1997) and has been an integral part of the Professional Education Sequence at TWU for the past two academic years. The four cornerstones of the technology integration program are (a) Foundations, (b) Connectivity, (c) Productivity, and (d) Integration. All pre-service teacher education students provide documentation of various skills related to these four areas as they progress through Intern levels I, II, and Residency. A brief description of the four areas and indicators of mastery is provided below. These areas are not intended to be mutually exclusive, rather they are integrated into the context of the field-based experience and requirements throughout the three-semester course sequence.

Foundations

This program component addresses knowledge of computing systems, develops basic skills for computer operation, examines the evolution of technology, and encourages users to begin to think with technology. Additionally, the social, legal, and ethical issues pertaining to technology use in an information society are addressed. Information Technology Service personnel and library personnel provide an overview of University technology resources.

Connectivity

During the beginning of their Professional Education sequence, this program component provides students with the information and skills needed to make both local and remote electronic information connections. Both the University system (Venus) and the use of a World Wide Web browser (Netscape) are utilized by students for e-mail and connectivity projects which include tele-mentoring, e-mailing assignments to liaisons, and communicating with other field-based participants through Web-pages, electronic bulletin boards, Web-based forums, and list-servs. Managing electronic documents and issues of netiquette and confidentiality are examined as well.

Productivity
This program component provides students at both Intern levels the necessary skills for teacher productivity. Intern I level students focus on word-processing, database use, and spreadsheet use. Intern II level students focus on advanced skills for teacher productivity and the integration of these skills into the curriculum. The use of desktop layout, graphics, and presentation tools is addressed at both levels.

Integration

The integration program component is delivered at both the Intern II and Resident levels. These students focus on learning theories and technology integration models, the examination of student technology tools (tutorial, simulation, exploratory, problem solving, and multi-media), and the integration of technology into various content areas. Advanced forms of media including optical technology, Internet resources, and related multi-media hardware and software are utilized in the creation of student projects. The use of global classrooms, on-line education, and distance education is included. Additionally, students learn networking skills, set-up and maintenance skills, and participate in planning for technology at the campus level.

Indicators of Student Achievement

Students in Intern I produce documents related to the development of teacher productivity skills (a parent letter, student database, and grading spreadsheet designed for individual field placements). Students learn how to discriminate between and evaluate various types of software. Students also describe the use of technology at their respective field sites including evaluation of software located at those sites. Students at all levels are required to email requirements and weekly reflections, and they must participate in a bi-weekly desktop conference group that extends discussion related to the required text: Integrating Technology for Meaningful Learning (Grabe & Grabe, 1998).

Students at Intern II and Resident levels produce documents related to the more advanced teacher productivity skills and integration of technology into the curriculum (a newsletter and the use of presentation software for lesson delivery designed for individual field placements). Students describe the technology use at their respective field sites and develop plans related to recommended modifications for a future technology plan at both the classroom and school-wide levels. This plan includes the evaluation of software located at each field site and a plan for implementation at the classroom level. After learning how to evaluate Internet resources, students design a WebQuest using advanced forms of media including evaluated resources. These projects are implemented at the respective school sites utilizing tools mastered in the previous Intern experiences and/or demonstrated during seminar classes conducted at the university. At all levels, students are required to attend a minimum of three lab sessions and six whole-group technology focus seminars which support the development of their skills in the four areas or relate to completion of the required indicators.
Role of Technology Seminar Leaders

This program is not a separate methods course. Instead it is an integrated aspect of the Professional Education sequence designed and delivered by technology facilitators who supports both the pre-service teachers and the instructors of the courses. Technology facilitators (a) provide additional resources and necessary background knowledge for Interns, Residents, and seminar leaders and liaisons through one-on-one support, small-group intervention, and whole-group training sessions; (b) make connections to the field site and provide support for mentor teachers; (c) utilize a course-designed Website for on-line instruction; (d) support desktop conference groups in discussion related to required text readings; (e) develop and conduct technology labs; (f) and document and certify technology competencies of Interns and Residents. As the program has grown to include more Interns and the variability of technology support in the field has increased, curriculum revision is needed to support implementation of this technology vision to a full-scale level at both the University and in field settings.

Proposed Technology Integration Program

The LINKS Program builds on the previously established program through full-scale implementation and is correlated with the PDS field-based education program. The planning for the PDS field-based teacher education program is structured around the Texas-adopted proficiencies for teachers. This includes the proficiencies which describe what teachers must know and be able to effectively demonstrate so that all children have access to quality education (TEA, 1995). The five proficiency domains are (a) Learner-Centered Knowledge, (b) Learner-Centered Instruction, (c) Equity in Excellence for All Learners, (d) Learner-Centered Communication, and (e) Learner-Centered Professional Development. These proficiencies provide the foundation for the Professional Development Appraisal System (PDAS)—the evaluative tool for all Texas classroom teachers.

The LINKS project utilizes this comprehensive and coherent structure to organize the passport tool that guides the pre-service teacher through documentation of technological competencies. These five proficiencies provide a basic structure for the LINKS Technology Passport. Upon declaring an education major (Interdisciplinary Studies) students are given a LINKS Technology Passport to guide them through identifying and documenting technological competencies. The specific competencies in the LINKS Technology Passport are grouped according to two categories—Essential Knowledge and Skills and Expanded Knowledge and Skills. The essential knowledge and skills section reflects the Texas Essential Knowledge and Skills (TEKS) competencies for students in the public schools K-12 (TEA, 1999). Since our teachers are expected to support the development of these competencies by the K-12 student, they must first demonstrate competency of these skills themselves.

The K-12 TEKS technology applications curriculum has four strands—foundations, information acquisition, work in solving problems, and communication. Through the study of technology applications foundations (including technology-related terms, concepts, and data input strategies), learners in public school settings are expected to make informed decisions about technologies and their applications. They learn to identify task requirements; plan
search strategies; and use technology to access, analyze, and evaluate the acquired information. By using technology as a tool that supports the work of individuals and groups in solving problems, students will select the technology appropriate for the task, synthesize knowledge, create solutions, and evaluate the results. Students learn to communicate information in different formats to diverse audiences and to use a variety of technologies. The TEKS technology skills are included in the LINKS project as the Essential Skills to be demonstrated and monitored through the LINKS Technology Passport.

Building on the Essential Knowledge and Skills, and structured through the five proficiencies previously discussed, the LINKS project proposes a second category of technology competency focusing on Expanded Knowledge and Skills. This category is structured through three levels: (a) Productivity, (b) Connectivity, and (c) Integration. Both the Essential Knowledge and Skills and the Expanded Knowledge and Skills are delineated and documented in the Technology Passport.

The LINKS project implements this new technology curriculum founded on current standards which extend beyond productivity and connectivity to problem solving and integration into instruction at diverse levels and in various content areas. Performance in the new curriculum will be documented in the LINKS Technology Passport in which professors at all levels sign off on student mastery and/or performance of skills related to the technological competencies demonstrated as part of their courses. Students will be certified to be competent in these various areas through a series of benchmarks including one-on-one screenings and documentation provided throughout the professional education coursework sequence also recorded through the Technology Passport.

Significance

The National Council for Accreditation of Teacher Education (NCATE, 1997b) in its description of preparing for the 21st Century classroom emphasizes the need for a vision of a teacher education program which fully utilizes information technology. Such a vision requires major adaptations: (a) greater understanding of the impact of technology on our society, (b) new roles as authority over knowledge moves beyond the teacher and the classroom, and (c) emphasis on the ability to organize and interpret information and assess quality of information and sources in a reflective and critical manner. In order to accomplish such a vision, pre-service teachers must participate in courses designed to encourage the development of teachers as fearless users of technology (NCATE, 1997a). These courses must also offer an integrated and collaborative program that seeks to encourage this development through meaningful activities within authentic contexts. Some of these courses will encourage risk taking and lifelong learning through instructional delivery in non-traditional ways such as distance learning and on-line classes. NCATE further recommends that stimulating effective utilization of technology would include integration across all areas of the curriculum in the teacher education program.

"If the role of teacher education programs is to produce teachers who are able to use the new computer technologies, we must take our pre-service teachers from where they are when they enter and advance them to where the technological society needs them to be" (Sheffield, 1996, p. 52). Performance-based programs are measured in terms of competencies or proficiencies (Buhendwa, 1996; Flowers, 1997). Thus, educational needs at all levels can
only be reached when our pre-service teachers are able to model the desired proficiencies identified in educational technology programs designed around an integrated teacher education vision. The LINKS program encompasses the integration of technology use as intrinsic to all courses leading to professional certification as well as within the professional education field-based courses. In the professional education field-based coursework, pre-service teachers complete their documentation of technology skills and knowledge, demonstrate their use in school settings, and utilize a variety of technology tools in teaching, evaluating, and communicating with diverse students in a variety of school settings.

Building Capacity in Wyoming: Preparing Preservice Teachers to Integrate Technology

Guy Westhoff
Department of Adult Learning and Technology
University of Wyoming
United States
westhoff@uwyo.edu

Abstract: This paper is a report on the Wyoming Capacity Building Project. This statewide project involves the State Department of Education, the University of Wyoming, and the seven community colleges in preparing preservice teachers to integrate technology. This project will build a foundation from which several systemic changes can occur within the delivery and curriculum of the preservice teacher preparation program. Three bodies of literature will guide the development of this foundation: the Concerns Based Adoption Model (CBAM), entrepreneurial leadership with technology, and systems thinking. The objectives are related to preparing and supporting UW and community college as they infuse technology into their courses and model the effective use of technology within their classrooms and their teaching methods. The overall goal of the project is to improve the quality of the preservice teacher preparation curriculum with a focus of preparing future teachers to use technology in effective, appropriate, and innovative ways.

Introduction

The over riding goal of this project is to improve the quality of the Wyoming preservice teacher preparation curriculum and prepare future teachers to use technology in effective, appropriate, and innovative ways. This project will build a foundation from which several systemic changes can occur within the curriculum and delivery of the preservice teacher preparation program. These systemic changes will increase the number of technology-proficient teachers graduating from the University of Wyoming who will be able to infuse technology into their curriculum as a tool to improve student learning and achievement. As with any project of this magnitude, change does not come easily and the project team will utilize relevant theories and models from the change literature to guide our processes (Belasco, 1995; Fullan, 1991; Hall & Hord, 1987; Kotter, 1996; Rogers, 1983; Senge, 1990, 1999). Three diagnostic tools from the Concerns Based Adoption Model (CBAM) will be used to manage and facilitate the change processes within this project; Stages of Concern Questionnaire (SoCQ), Levels of Use interview (LoU), and Innovation Configuration Maps (ICM). Additionally, all stakeholders involved in the preparation of preservice teachers within Wyoming are part of the technology project consortium and will be involved in the project activities.

Project Vision

Vision plays a key role within any change effort by assisting to direct, align, and inspire all stakeholders participating in the transformation effort (Kotter, 1996). This vision needs to be imaginable, desirable, feasible, focused, flexible, and communicable. To be successful in transforming the preservice teacher preparation curriculum into a system that will prepare tomorrow’s teachers to effectively use technology, our consortium must create a shared vision of the future of education in a technology rich world. The shared vision of this project can be stated as follows:

To prepare tomorrow’s teachers to use technology in effective, appropriate, and innovative ways through the infusion of technology into the preservice teacher preparation curriculum. These future teachers will have the skills and proficiencies to utilize technology as a tool for improving student learning and achievement.

This shared vision will serve three important purposes for the project consortium. First, the shared vision will clarify the general direction in which to make changes to the preservice teacher preparation program. Second, the shared vision will motivate instructors to take action in the right direction since the benefits and personal satisfactions will be far superior to those available without implementing the changes. Third, the
shared vision will help to coordinate the actions of different instructors, departments, agencies, colleges and the University. This vision will be reviewed and communicated to all stakeholders of this project and will be refined as the project progresses. The project goals, objectives, and activities will support this vision and will help in communicating and supporting the vision to all stakeholders.

A project task force team will be selected to equalize the representation and opportunities for all stakeholders and to ensure the unique needs of each are addressed. Members will be selected to represent the university, community college, and K-12 stakeholders and will include representation from the educational community on the Wind River Indian Reservation. The University of Wyoming (UW) and Central Wyoming College (CWC) are engaged in a project to address the educational needs on the Wind River Indian Reservation. A critical need for the schools on the reservation is to recruit and retain teachers who have ties to the Arapaho and Shoshone tribes. UW and CWC are cooperating in the delivery of an off-campus program designed to lead to certification to teach at the K-6 level. Technology plays an important role in the delivery of this program and having a member from the Wind River Indian Reservation as a member of the project task force will provide valuable insights in equalizing and extending the impact of the project to other rural areas of Wyoming. The task force will have approximately 15 K-12, 11 community college, and 31 university members.

**Project Goals, Objectives, and Activities**

**Goal 1:** Conduct an assessment of current technology uses in the College of Education at UW, the seven community college campuses, and in K-12 Schools within the State of Wyoming.

Objective 1.1 - Develop a rich description of the levels of use of technology within K-12 schools, UW College of Education, and community colleges from the Levels of Use (LoU) interview data collected by the Wyoming Department of Education.

Objective 1.2 - Review the LoU data and compare the level of use of technology in K-12 schools with that of higher education.

The Wyoming Department of Education has collecting data from 112 K-12 educators on their levels of use of technology in their classrooms and is currently conducting the LoU interviews with higher education faculty during the fall of 1999. Additionally, Dr. Guy Westhoff, Assistant Professor in the Department of Adult Learning and Technology, University of Wyoming, will administer the Stages of Concern Questionnaire (SoCQ) to all higher education faculty involved in the preservice preparation program. The SoCQ will be used to identify the technology concerns of college faculty towards integrating technology into their courses and be used to guide activities in support the remaining goals of the project.

A fall Articulation Conference, held in Casper Wyoming during September 1999, launched the project and introduced participants of the consortium to the activities planned for the year. The project team worked with Wyoming educators in identifying national “best practices” and Wyoming practices that should ideally be integrated into the K-12 and teacher preparation programs.

**Goal 2:** Conduct a review of the preservice teacher preparation curriculum and the infusion of technology into these courses.

Objective 2.1 - Review the existing preservice teacher preparation curriculum and identify where technology is currently integrated.

Objective 2.2 - Develop a technology infusion matrix listing all courses within the preservice teacher preparation curriculum and the NCATE, ISTE, and state technology integration standards for teacher technology preparation.

Objective 2.3 - Identify where technology standards are taught across all courses.

Determining the current level of technology integration in the curriculum of courses offered within the preservice teacher preparation program will be accomplished through the activities relating to this goal and objectives. Faculty have been requested to submit a syllabus for each course they teach within the preservice teacher preparation program and to volunteer to serve on a review task force that will be headed by Dr. Ed Paradis, the Director of Teacher Education. The task force will meet five times during the academic year to discuss and conduct the review of the course materials. Results of this review will guide the task force in developing a technology infusion matrix that compares the technology skills addressed in each preservice course to the NCATE standards and the ISTE Technology Standard for Teachers. The task force meetings are planned for dates in September, October, November, February, and April. These meetings will utilize the
technology infrastructure of the WEN and other existing systems and be conducted over the video conferencing systems, as well as face-to-face.

**Goal 3:** Develop recommendations for curricular revisions to improve technology infusion into the preservice teacher preparation curriculum.

**Objective 3.1** - Develop recommendations for revisions to the preservice teacher preparation curriculum to reflect appropriate technology integration.

**Objective 3.2** - Develop an Innovation Configuration Map (ICM) containing observable descriptors that represent what appropriate technology integration in a K-12 classroom looks like.

Data collected from the activities of goal two, review of the preservice teacher preparation literature, and participation in a curriculum and technology conference will be utilized to formulate the revisions to the preservice teacher preparation curriculum. These recommendations for revisions to the curriculum will focus on supporting the shared vision of the project and will benefit from the participation in the curriculum teleconferences and the Connections 2 Solutions conference described in the following section for goal four.

**Goal 4:** Design and develop a professional development program for college faculty to enhance the infusion of technology into the preservice teacher preparation curriculum for the State of Wyoming.

**Objective 4.1** - Identify best practices for integrating technology into K-12 classrooms that support student learning and improved achievement.

**Objective 4.2** - Develop a faculty technology-training program that emphasizes effective and appropriate technology integration techniques and methodologies to enhance the technology integration into the preservice teacher preparation curriculum.

All K-12 educators in the state of Wyoming and UW and Community College faculty involved in preservice teacher preparation programs were invited to the Connections 2 Solutions Conference, sponsored by the WSUP, and held October 20-21 in Sheridan, Wyoming. This conference presented a look at the future of technology in education and allow for discussions with, and presentations by, K-12 and higher education faculty that are using best practices to integrate technology into their classrooms and curriculum. Dr. David Thornburg, Director of the Thornburg Center for Professional Development, gave the keynote address and facilitated one-hour breakout sessions related to four groups: K-12 administrators; K-12 elementary faculty; K-12 secondary faculty, and higher education faculty involved with the preservice teacher preparation curriculum. These breakout sessions allowed faculty to discuss the factors that are most crucial to their level of instruction with each other and with Dr. Thornburg. While there is a great deal of commonality among the technology integration skills and techniques, the individual breakout sessions allowed all elementary, secondary, administration, and higher education faculty to discuss the issues unique to their level of students and their instructional strategies.

**Goal 5:** Implement the professional development program to prepare higher education faculty involved in preservice teacher preparation to utilize and infuse technology into their courses.

**Objective 5.1** - Create a shared vision for the infusion of instructional technologies into college-level instruction within the preservice preparation curriculum that result in preservice students meeting or exceeding national standards.

**Objective 5.2** - Implement the faculty technology training program to provide higher education faculty with the skills and methodologies needed to successfully infuse technology into their preservice teacher preparation courses.

The final goal of the Wyoming capacity building project will be to deliver a professional development technology-training program to the entire faculty involved with teaching courses within the preservice teacher preparation curriculum at the University of Wyoming and the seven community college campuses. This professional development program will be an innovative approach to preparing instructors to infuse technology into their classrooms and become role models for integrating technology to their preservice teacher preparation students. This professional development program will be designed to provide "just in time" technology training for all participants that matches the technology integration skills they currently need to improve their teaching.

The Center for Teaching Excellence (CTE) on the campus of the University of Wyoming will assist with the facilitation of this faculty development program and our corporate sponsors will assist in implementing the one-week professional development program. These training workshops will be delivered at three locations around Wyoming and will include the campuses of the University of Wyoming, Central Wyoming College and
Northern Wyoming Community College. Both community colleges have contributed the use of the technology facilities and training costs at their campuses for the one-week program as matching funds.

Conclusion

Accomplishing the goals, objectives, and activities of this project will assist faculty teaching within the preservice teacher preparation program integrate technology into their classrooms in appropriate, effective, and innovative ways. The natural extension of this project will be the development of a Learning Technology Plan for the preservice teacher preparation curriculum for the State of Wyoming. This proposed plan will assist in moving Wyoming towards a comprehensive effort of improving the preservice teacher preparation curriculum and will guide the development of an implementation plan for the revised curriculum and sustaining the professional development program.

Technology Integration in Colleges of Education: Assessment and Planning

Penny Ann Garcia, Ph.D.
Department of Human Services and Professional Leadership
University of Wisconsin Oshkosh
United States of America
garcia@uwosh.edu

Abstract: Responding to the call for faculty in institutions of higher education to model teaching and learning with instructional technology in undergraduate classrooms, the College of Education and Human Services at the University of Wisconsin Oshkosh submitted a successful application for funding under the auspices of the Preparing Tomorrow's Teachers to Teach with Technology federal grant program. As preparation for this proposal, the current state of the college was assessed using common factors identified in the 1998 Strudler and Wetzel that were identified as consistently moving institutions of higher education towards excellence in technology integration.

In 1995, the Office of Technology Assessment (OTA) published a study of four preservice teacher education programs thought to have exemplary approaches to integrating technology - Peabody College of Vanderbilt University, University of Virginia, University of Northern Iowa, and University of Wyoming. This study by Mergendoller, Johnston, Rockman, and Willis (1994) focused on issues involved in implementing the vision of technology infusion into programs. They noted the following consistent strands across the four universities: leadership at the dean's level to establish technological infrastructure and involve faculty in the use of educational technology; the ability to achieve "the somewhat tricky balance of establishing a culture that strongly encourages faculty technology use, but does not shame individual faculty members who lag somewhat behind" (Mergendoller et. al, 1994 Chapter 10); and preservice teachers at each institution experienced educational technology as an integrated part of their professional preparation across their coursework.

A follow-up study of these programs was conducted by Strudler and Wetzel in 1998 to further delineate the factors that consistently moved sites towards excellence in technology integration. In the recommendations section of their study these factors are enumerated. University of Wisconsin Oshkosh (UWO) used these factors to assist its faculty in determining needs that might be addressed by the catalyst category of the Preparing Tomorrow's Teachers to Teach with Technology federal grant program. A simple checklist was developed as follows:

<table>
<thead>
<tr>
<th>Enabling Factor</th>
<th>Achieved</th>
<th>On-Going</th>
<th>Not Observed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>College-wide factors:</strong></td>
<td></td>

</tbody>
</table>
Provide opportunities for this specialist to work with faculty | X
---|---
Embrace increased needs for access and support as a good problem | X
Provide ample computer access and projection facilities in classrooms | X

**Student learning factors:**

- Have students conduct informal technology inventory at beginning of any field experience | X
- Plan for systematic integration of technology throughout the teacher education program | X
- Consider giving a option of a second tier course for more advanced work | X
- Allow students option of requesting a technology-enhanced placement | X
- Create a field-based component for the required technology course | X
- Seek creative uses of distance technologies | X

Based on this basic checklist of enabling factors, it was evident that the College of Education and Human Services (COEHS) had laid good groundwork for technology-curriculum integration. COEHS at UWO made significant investments in both technology hardware/software and technology integration in the past two years. This focused on the new Classroom of Tomorrow lab, the creation of additional classrooms rich with technology teaching stations, and the successful hiring of faculty who are technology integration specialists with recent, successful K-12 teaching experience. Recently college wide interactions focused on the need for infusion of technology throughout the teaching and learning experience of all future teachers particularly in those courses where students acquire the subject area expertise they will use in their future classrooms and clinical experiences. Experimentation is currently occurring in team-taught social studies and math/science method courses with both curriculum-instruction and technology faculty members. However, this approach is limited by the number of technology faculty available and thus denies many faculty members this support.

COEHS supports the vision that its entire faculty will model new instructional strategies, multiple teaching-learning styles, and content applications that enable them to make full use of modern technologies for improved learning and achievement. To support this vision, the following needs were identified through use of the checklist based on the Strudler and Wetzel study: working with faculty on technology skills and integration strategies, opportunities for staff members who are curriculum integration specialists to work with faculty who desire their assistance, and expansion of the opportunities for tomorrow's teachers to acquire and observe technology-curriculum integration skills. Based on these needs the following program and objectives were proposed and funded under the initial round of the *Preparing Tomorrow's Teachers to Teach with Technology* grant project.

**Project Design: Goal and Objectives**

4. Tomorrow's teachers develop and deliver in their clinicals curriculum projects rich with technology infusion

- 300 students demonstrate technology integration in K-12 classrooms
- Faculty participate in K-12 classrooms
- Students developing leadership roles in clinical settings
- Demonstration of project implementation by artifacts (i.e. projects, simulations, multimedia materials, etc.)
- Written reflection on successes

5. Tomorrow's teachers observe current teachers who model exemplary teaching with technology

- 300 students observe ongoing innovative practice in classroom environment
- Guided observation form completion
- Roundtable discussions with methods classes

6. Tomorrow's teachers develop relationship with on-line mentor currently teaching in field who models exemplary teaching with technology

- Feedback and advice from current practitioner
- Reflection on practice
- Participation level/quality form from mentor teachers
- Count of interactions from website

7. Faculty and tomorrow's teachers will disseminate best practices to larger education audience

- Presentations at state level
- Presentations at national level
- Submission of proposals for presentations or posters
- Presentation/poster artifacts: projects, simulations, multimedia materials, etc.

8. Faculty and tomorrow's teachers collaboratively develop website to meet project needs

- Collaboration between educators in real-life problem centered need
- Website that provides focus for project objectives
- Formative throughout project based on emergent needs
- On-line suggestion/evaluation form

This project involves a consortium representing educators at all levels - postsecondary faculty, tomorrow's teachers, practicing teachers - participating together in a collaborative quest aimed at using new learning technologies for improved teaching and learning. The UWO as Local Educational Agent provides learning facilities, postsecondary faculty, and future teachers. Funding sought under the auspices of the Capacity Building grant is used solely for purposes of improving the teaching and learning of UW Oshkosh faculty and future teachers. However, a vital part of this initiative includes practicing teachers serving as role models in the field. Wisconsin's Cooperative Educational Service Area 6 (CESA 6), representing 42 districts, provides practicing teachers identified as innovative teachers using powerful teaching and learning strategies that incorporate instructional technology. These practicing teachers serve, in essence, as case studies for the undergraduate students in the successful integration of technology into the curriculum. Additionally, they function as mentors in curriculum development for future teachers, and as placement opportunities for clinical experiences. Funding for CESA 6 participation comes from an UW System grant, Wisconsin Regional Instructional Technology Support (WRITS). This grant works with exemplary educators who collaborate to
develop constructivist, problem-centered curricular models designed to be presented as workshops to facilitate preK-12 faculty's understanding of technology/curriculum integration.

A core team of four faculty were selected based on the following indicators: identified as being independently successful in integrating technology into their methods courses, recognized as having worked collaboratively with other faculty and having shared with colleagues both through presentations and publication the results of their technology integration, and demonstrated their commitment to the redesign of the teacher preparation program through active participation in university-wide or college-wide committees, workshops and technology projects. It is the responsibility of the members of this core team to attend regular meetings with the project coordinator, provide technology integration workshops for COEHS faculty who commit to participation in this grant, serve as mentors and consultants on both an individual and group basis for faculty, supervise graduate assistants by acting as liaison with staff identifying needs and work schedules, identify opportunities for project dissemination, organize presentations of students and faculty at state and national levels, and maintain active participation in listserv activities of this grant.

Twenty-five faculty members volunteered to serve as grant participants. This represents almost half of the faculty involved with the teacher preparation program and includes faculty from both the COEHS, and the College of Letters and Sciences. Participants have a rudimentary base of personal computer skills, are faculty currently teaching in those areas where tomorrow's teachers receive their methods, content and clinical experiences, and share a commitment to pursuing new pedagogical learning and teaching methodologies. These twenty-four faculty members have committed to attendance at technology integration workshops as offered by the core team, to the development and deliverance of curriculum projects rich with technology infusion, to sharing and reflecting on questions, concerns and successes of projects with colleagues, to the construction of assignments which require students to develop and implement lesson plans utilizing technology/curriculum integration, and to moderate round table discussions with students after observation of either video or live case studies in technology integration. In the subsequent year, these faculty participants will serve as mentors for additional faculty members in the increased development of enriched technology-curriculum integration opportunities. All grant participants receive a library of resource materials on technology integration and will have input on the creation of a COEHS faculty library of software that will support their redesigned curricular plans (i.e. Tom Snyder cooperative software in the social studies, simulations and dry lab software for science, interactive fiction for language arts, etc.). They and their students will also have the opportunity to present work done under the auspices of this grant at statewide conferences.

The faculty grant participants are supported in their project development by the core team and grant coordinator. A series of four workshops presented by the core team have modeled constructivist, problem-centered curriculum utilizing hands-on approaches, just-in-time introduction of technology skills, and authentic assessment opportunities afforded by technology. Core team members are available to work with faculty members on identifying curriculum modifications that model technology proficient instruction. Additionally, three graduate students are supported by this grant and are assigned to faculty grant participants for one-on-one tutoring and problem solving. Faculty worked during the January 2000 interim to develop activities to be implemented in the Spring 2000 semester. They met individually with core team members twice during the implementation cycle and will meet once at the end of the semester as a group to share reflections, concerns, artifacts and successes of their curricular modification project.

Approximately three hundred students are actively involved in this project. Some represent future PreK-8 and Special Education teachers participating in Clinical A or B which are required block courses that integrate method courses with concurrent field experiences. Other future secondary teachers are participating in their Secondary Learning Community which presents subject area methods classes with concurrent field experiences. Additional future foreign language teachers come to the grant via their clinical and methods experience. These students are the first to experience the results of faculty curricular modifications in an effort to model new technology-rich approaches to instruction that require students to be active participants in learning while drawing on multiple sources of information to solve real-world problems in collaboration with others. They have the advantage of designing technology-rich lesson plans to be implemented immediately in their clinical field settings thus serving as potential leaders in the PreK-12 schools.

It is vital to the success of prospective teachers that they have case studies to observe current practitioners using technology/curriculum integration methodologies and constructivist theory in real world settings. Towards this end, the innovative teachers selected for the CESA 6 WRITS grant will serve as case studies by allowing themselves to be videotaped and subsequently critiqued by prospective teachers and faculty. CESA 6 personnel will also be instrumental in identifying technology-rich sites for student placements to meet clinical field experiences.
Students have the opportunity to work with a mentor via email with practicing educators who currently employ innovative learning theory with technology-rich instruction. All students involved in methods coursework with concurrent field experiences are assigned to a mentor. These mentors may be located in Wisconsin and be participating in the WRITS project but it is equally likely that students may be assigned to an out-of-state mentor. Students may engage mentors in discussions about educational practices, technology integration, reflective practice, or use the mentorship as an opportunity to discuss integrating technology in working with diverse student populations.

All of these various approaches to restructuring teaching and learning at the postsecondary area require a central focus area. To provide this focus, faculty and students will collaboratively develop a website for this project. Responsibility for envisioning the site by analyzing needs and perceived ways the web could meet those needs will lie solely with the grant participants. A storyboard will be drafted to design the site, its pages and purpose. Design and layout issues will be considered. Faculty will use Claris HomePage to develop the core of the site; student consultants chosen from the methods classes will do subsequent completion and revision of the site.

Finally, dissemination of the results of the grant project as a whole and the results of curricular redesign have been considered. An ongoing view of the project through posting of activities, timelines, philosophy, and purpose will be available through its web page linked to the UW Oshkosh site. Proposals for presentations regarding the Capacity Building grant, methodology and outcomes will be submitted at the Governor's Wisconsin Educational Technology Conference and at other appropriate statewide conferences such as Wisconsin Council of Social Studies, Wisconsin State Reading Association, Wisconsin Council of Exceptional Children, etc.

Conclusion

This grant project, Development of Instructional Technology for Tomorrow's Teachers, will enable the UWO's College of Human Services and Education to make significant movement towards addressing both the quantity of tomorrow's teachers who actively participate in coursework enriched with the use of technology and the quantity of today's postsecondary faculty who are integrating technology into their coursework. It will assure the quality of that experience by encouraging thoughtful reflection on both the part of tomorrow's teachers and post-secondary faculty on the role of technology in society, its vital infusion into schools and its fundamental impact on restructuring the traditional model of learning and teaching at all levels. Finally, it will address the issue of equity for students through the preparation of tomorrow's teachers to work in the surrounding 42 school districts representing an area serving a population that is approximately 62% rural in nature, with 11% minority students, 19% low income students, and 7% students with Limited English Proficiency.

Tec to Take: An Innovative Strategy for Supporting Preservice Teachers During Field Experiences

Kathryn Morgan, Professor
Instructional Technology
Minnesota State University – Bemidji
United States
Kmorgan@vax1.bemidji.msus.edu

Abstract: Meeting the resource needs of preservice students during their field experience practica is not a new problem. The tec to take project is designed to provide appropriate resources for integrating technology into instruction by addressing the problem of readily accessible resources for technology enhanced instruction. The project is based on a collaborative model which includes the preservice student, the faculty supervisor, the class room mentor and the school based technology coordinator. The opportunity to check out equipment and software (tech to take) is based on a written instructional plan for the integration of the resources into a field based classroom lesson or unit of instruction.

Introduction

Computer to student ratios have declined steadily from 50:1 in 1985 to 20:1 in 1990 to an estimated 9:1 in 1997, affecting traditional classroom practice and even the culture of the schools. The computer, video, and telecommunications of various kinds are having an impact on every aspect of our society: work, leisure, entertainment, household tasks. These inventions are also transforming the way we approach knowledge and sources of expertise. Today, people are no longer required to read about an event; they can see media versions of it unfold before their own eyes and make their own interpretation. Consequently, the ability to obtain and interpret information quickly and accurately is even more important than in the past.

There is no longer a question about whether the new technology will be used in schools. Nearly everyone agrees that students must have access to computers, video, and other technology in the classroom. Many believe these technologies are necessary because competency in their use is an important feature of career preparation; others see equally important outcomes for civic participation. Most importantly, a growing research base confirms technology’s potential for enhancing student achievement. What is less certain is how and when these technologies will change the nature of schooling itself.

Arthur E. Wise, President of the National Council for Accreditation of Teacher Education states in the Technology and the new Professional Teacher: Preparing for the 21st Century Classroom, 1997:

Two million new teachers will be hired over the next decade. Will these new teachers be comfortable and skilled in using technology? What will it take to transform schools of education so that faculty feel comfortable e-mailing students, using listserves for projects and instruction, and introducing candidates to software that enhances instruction? As technology moves from the periphery to the center in P-12 schools, so must it move from the periphery to the center in teacher preparation.

Teacher education institutions must prepare their students to teach in tomorrow’s classrooms. Rather than wait to see what tomorrow’s classrooms will be like, they must experiment with the effective application of computer technology for teaching and learning in their own campus practice. Today’s teacher candidates will teach tomorrow as they are taught today.

Research has long indicated that future teachers take their cues from the practices they observe in classrooms during teaching practica and internships. If students are taught the latest technology uses as part of their teacher education programs, but don’t see effective technology practices in the schools, they are unlikely to incorporate technology use in their own teaching. Schools are powerful socializing agencies that greatly affect new teachers’ perceptions about what does and what doesn’t work in practice.
The introduction of computers and other technologies into schools is occurring at the same time that three decades of research in the cognitive sciences, which has deepened our understanding of how people learn, is prompting a reappraisal of teaching practices. We know from this research that knowledge is not passively received, but actively constructed by learners from a base of prior knowledge, attitudes, and values. Dependence on a single source of information, typically a textbook, must give way to using a variety of information sources. As new technologies become more readily available and less expensive, they will likely serve as a catalyst for ensuring that new approaches to teaching gain a firm foothold in schools.

Despite the technology changes in society, being a teacher in American schools too often consists of helping children and youth acquire information from textbooks and acting as an additional source of expertise. Teachers are provided role models of this approach to teaching from kindergarten through graduate school; their teacher education courses provide hints for making textbook-oriented instruction interesting and productive, and as teaching interns, they both observe and practice instruction based upon mastering information found in books.

The question raised is "how must teachers adapt to take advantage of technology for instruction? In the 1997 National Council for Accreditation of Teacher Education report on preparing the Professional Teacher for the 21st Century the following paradigm shifts are recommended:

**New Understandings**

Teachers need to understand the deep impact technology is having on society as a whole: how technology has changed the nature of work, of communications, and our understanding of the development of knowledge.

**New Approaches**

Today, teachers must recognize that information is available from sources that go well beyond textbooks and teachers - mass media, communities, etc. and help students understand and make use of the many ways in which they can gain access to information. Teachers must employ a wide range of technological tools and software as part of their own instructional repertoire.

**New Roles**

Teachers should help students pursue their own inquiries, making use of technologies to find, organize, and interpret information, and to become reflective and critical about information quality and sources.

**New Forms of Professional Development**

Teachers must participate in formal courses, some of which may be delivered in non-traditional ways, e.g., via telecommunications; they must also become part of ongoing, informal learning communities with other professionals who share their interests and concerns.

**New Attitudes**

Finally, teachers need an "attitude" that is fearless in the use of technology, encourages them to take risks, and inspires them to become lifelong learners.

More than in the past, teachers must become advisors to student inquirers, helping them to frame questions for productive investigation, directing them toward information and interpretive sources, helping them to judge the quality of the information they obtain, and coaching them in ways to present their findings effectively to others. This will require teachers to become even better prepared in the content of the subjects they teach, and the means by which the content can be taught and learned.

In light of paradigm's stated above, the next question to pose would be "what changes need to be made in teacher education programs to foster the teaching skills for the 21st Century educator?"
Technology can also serve as the catalyst for reconsidering the entire architecture of teacher education: e.g., how, when, and where candidates will acquire the knowledge and skills they need; and the linkage between preservice and in-service professional development. The integration of technology should be accomplished in relation to other efforts to reform teacher preparation, not as a separate reform initiative.

The literature provides an awareness of the pervasive need for a new type of educator. To prepare educators to meet the challenges of the 21st Century classroom will require the development of preservice models that take advantage of community, public school and higher education partnerships in a technology enhanced environment. Research has documented that few teachers fully exploit the use of computer based technologies (Hunt & Bohlin, 1995). The need to be able to understand the compatibility of computer based technologies and newer research based approaches to teaching and learning such as inquiry based learning, performance assessment, and constructivist curriculum are needed for the quality teacher (Bracey, 1993, Campoy, 1992)

**How does the tec to take program facilitate the professional development related to technology integration for the preservice student, the field based mentor and the faculty supervisor?**

The following steps will illustrate the tec to take project process.

**Step one:** A learning community is formed between the preservice teacher, field based mentor, and faculty supervisor (for example a preservice student is linked together with a fourth grade teacher and a university faculty supervisor together they collaborate and identify an instructional topic)

**Step two:** The learning community identifies an instructional topic that would be suitable for the integration of technology into the instruction (for example grade four graduation standard related to a study of States)

**Step three:** The learning community identifies the types of hardware, software, and corresponding workshop experiences that they need to effectively implement the technology enhanced instruction (for example the learning community may decide that an appropriate technology component related to the study of States might be to do a community self study utilizing digital cameras, building of a report web site, and cooperating with another school in another State who might be doing a similar project. To be successful, the learning community may need to complete instruction related to digital cameras, web development, and identification of web sites with classroom link projects.)

**Step four:** Submit a request for a tec to take kit that would include the appropriate hardware and software to accomplish the stated instructional goals of the field based project.

**Step five:** Implement the lesson/unit with a field based classroom (for example, the preservice teacher in collaboration with the field based mentor and the university supervisor would prepare the materials and plan the lesson outlines that would address the instructional needs of the State project)

**Step six:** Assess the student learning as a result of the technology enhanced lesson (for example, the learning community would determine the quality of the learning experience for the fourth grade students. Student satisfaction survey's as well as evaluation of student products related to States would serve as artifacts of the quality and level of student achievement of academic goals)

**Step seven:** Reflection by the learning community of the success of the technology integrated instruction (the learning community would review the student achievement outcomes and the management processes of the instruction. Following this review, recommendations would be made for additions or modifications of the instruction for future planning)

**How does the tec to take process address the new paradigm recommended by the 1997 National Council for Accreditation of Teacher Education report on preparing the Professional Teacher for the 21st Century?**

**New Understandings**
By working in learning communities, the representation of the beginning through the mentor level teacher gives these educators an opportunity to consider alternatives to traditional teaching strategies. The workshops that correspond to the instructional plans provide the opportunity for the educators to learn new skills as a team and apply these skills to an actual classroom experience.

New Approaches

The learning communities will collaborate and review instructional strategies that take advantage of newer instructional technology resources. Because the field based teacher may face curriculum requirement restraints, one of the outcomes of the tec to take program is to support the learning community to identify ways to augment existing curricular goals utilizing technology resources.

New Roles

The instructional technology lessons reflect the consultant, constructivist classroom model. As noted earlier this is the type of instructional model that teacher education programs are advocating in their preparation classes. In order to “break” the cycle of traditional instruction the availability of model field teachers that embrace this approach to instruction is critical for field based placement of preservice teachers. It is anticipated that the tec to take will provide all members of the learning community an opportunity to expand their skills with the student centered style of teaching.

New Forms of Professional Development

The tec to take reflects a continuous need to not only learn how to work effectively with school district curriculum requirements, but also the need to continue to learn how to use new technology based hardware and software. The proposal request process for being able to use the tec to take resources supports professional development by offering software and hardware orientations for the learning communities to assure optimal use of the tools by the educators.

New Attitudes

The learning community model, the use of appropriate instructional technologies, and the ongoing expectation of professional growth is reflective of the career long professional development model advocated by the National Council for Accreditation of Teacher Education as well as the National Teacher Standards Board. The tec to take teacher education program provides a framework for the identification, field testing and reflection of technology enhanced instruction.

Summary

The tec to take program is designed to provide a focus for the creation and implementation of model technology enhanced instruction. Because this approach to teacher education practica is based in a field classroom, several levels of learners benefit from the projects. The preservice teachers has an opportunity to work with real students and utilized recommended teaching strategies and instructional technology resources, the university faculty and field based mentors have an opportunity to work collaboratively in the creation of model field sites for the preservice student and at the same time develop and or expand their instructional technology knowledge and expertise, and most importantly, students in the field based classrooms will have an opportunity to benefit academically from the instructional technology enhanced learning experiences.

Reform in education must begin with the type of educator in the classroom. All of the dollars spent on resources and equipment will do little to alter the day to day realities of the learning process unless preservice and inservice teachers begin to have opportunities to learn “new ways” to conduct the business of education. Initially, the reform will need to be made in the context of the present day to day curriculum. Teachers have minimal time for the inclusion of dramatically new content areas and instructional practices. By developing teacher expertise related to the appropriate use of instructional technology via the...
augmentation of existing practice they will no longer see technology as an "add on" experience rather a natural way to conduct and manage the instructional process. Once teachers gain a comfort level with technology new applications will emerge that transcend the augmentation of traditional instruction.

The tec to take is just one way of providing resources for both the beginning and field teachers. It is the project goal that by providing the hardware, software, and skill development support that the beginning and field based educators will be motivated to try out technology enhanced instructional approaches without the concern of limited resources or lack of knowledge for successful implementation of the instruction. It is the goal of this program to foster a supportive learning community environment that models the continuous professional development of educators. This project is built on the philosophy that we are all collaborative members of a community of learners, all with expertise and knowledge contributions, as well as needs for new knowledge and skills.
Keeping our Perspective: Technology as Tool

Abstract: Technology is prime among educational buzzwords on the cusp of the millennium. Not only have schools scrambled to qualify for beneficial e-rates to support connectivity; a group of Philadelphia educators has sought approval to operate a virtual k-12 educational organization. Despite technology's high profile, just one in five of the 2.5 million teachers currently employed in public schools is comfortable with its use, according to a current U.S. Department of Education finding. Are teacher educators the usual suspects? Just five years ago, NCATE claimed that most teacher education faculty neither modeled technology use, nor taught prospective teachers to use instructional technologies; recent research agrees. The contention in this paper is that, in order to enjoy respect in the academic community, technology must be seen, as neither toy nor trophy, but as a custom tool integral to curricular purpose.

Technology is surely among "the" buzzwords characterizing conversation on educational reform as the century turns. Not only have schools scrambled to qualify for beneficial e-rates to support their connectivity; a group of Philadelphia educators has sought an e-charter, or approval to operate a virtual k-12 educational organization. The White House Web Site features the challenge of technology literacy, and OERI publications include lengthy lists of URLs supporting professional development of educators to promote such literacy.

But, despite technology's high profile on the cusp of the millennium, a recent national survey by NCES (Lewis et al, 1999) found that only 500,000 of the 2.5 million public school teachers currently teaching consider themselves comfortable in using technologies. Are teacher educators the usual culprits? Just five years ago, NCATE (1995) admitted that the "majority of teacher education faculty do not model technology use, nor do they teach students how to use information technologies for instruction." More recent research by Moursund & Bielefeldt (1999), confirms the sense that technology evolves more rapidly than the ability of teacher educators to make meaningful digital applications in their teaching. Yet, McNabb et al (1999), in a U.S. Department of Education technology planners handbook, cite studies which conclude that "the success or failure of technology depends more on human factors than it does on hardware or software." Clearly, our work remains unfinished.

The contention of this paper is that, in order for technology to enjoy the respect it deserves in the academic community it must be seen as neither a toy nor a trophy, but as a custom tool integral to curricular purpose. In this context, the manner in which we employ technology in teacher education is critical, since the admonition to, "Do as I do, not as I say," is ever present. Our mantra, of utilizing best practice research, calls us to honor, for example, active learning, learners' multiple modalities, and coherence between objective and activity. Further, best practice contends that technology is transparent in good learning situations. Freestanding technology study seems wrong-headed; its inclusion should serve the higher purpose of improving learning. Nevertheless, "Many faculty seem to view technology as a separate type of content, rather than as something that should or could be integrated", again according to NCATE (1995.)
Having once required a separate media course of prospective teachers, faculty at our institution have moved their conversational questions from, "What pieces of equipment must students know how to operate?" to, "How do we most appropriately develop preservice teachers' ability to effectively promote learning in technologically rich environments?" The distinction is significant, as is the conclusion of the national working group convened by the Milken Exchange on Educational Technology which emphasized that the teacher's ability to successfully integrate technology relates to knowledge of the learner and the learning environment as well as to technology competence. (McNabb et al, 1999) In our own experience, the primary faculty task seems to lie in defining—and redefining—reasonable competencies for future educators.

With or without technology, we want our future teachers, for example, to conduct research; to engage in situated problem solving; to select learning resources consistent with objectives they identify for their own students; to design learning experiences for students with varied modalities; to promote reflection on their own instructional practice. Insofar as technology can offer expanded opportunity for implementing such goals, it is critical to set technological expectations for the preparation of skilled professionals. The challenge becomes one of recognizing the technology in the true sense of a tool for enhancing human potential.

To illustrate the point, we consider several of the major student objectives, as each is enhanced by technology.

To Conduct Research

It is idealistic to believe teacher preparation programs can provide all the information prospective teachers will need to solve the instructional problems they may encounter in the classroom. It is realistic to expect that future educators will leave teacher preparation programs armed with the skills necessary to fulfill the role of teacher as researcher. In an introductory education course, students gain an understanding of this often unfamiliar role through the investigation of a realistic problem situation. Students are required to seek out additional information on the issues involved. Many different options for obtaining data are explored and discussed but inevitably, someone will suggest searching electronic databases and the web. Using a research question, students design and test searches, a task which ultimately leads to discussion and questions on search techniques and appropriateness of materials. As a follow-up activity, students have the opportunity to attend a workshop on database/web searching techniques.

To Design Learning Experiences for Students with Varied Modalities

"Learning style is the way in which individuals begin to concentrate on, process, internalize and retain new and different academic information." (Dunn et al, 1995). Proponents of the learning styles movement believe, in order to maximize learning, there must be a congruency between the educator's teaching style and the learning style of the student. While research on learning styles has come under criticism, best practice suggest incorporating a variety of strategies into a lesson will enhance the learning experience for all students. Prospective teachers who deliver presentations that incorporate overhead transparencies and/or utilize presentation software or incorporate video clips into a lesson to motivate young students about a topic in science education are demonstrating their knowledge of the importance of making learning more accessible to visual learners.

To Engage in Situated Problem Solving

Given the emphasis on promoting higher level thinking, it is imperative that teacher education programs assure the involvement of their candidates in authentic or contextualized problem solving. While this can be accomplished by such time-tested methods as using written stimulus materials, such as case studies, the implementation of digitized video scenarios created by Vanderbilt University's Cognition and Technology Group offers considerable advantages. Prospective teachers who solve mathematical problems from the Adventures of Jasper Woodbury value such qualities as realistic video stimulus, complex "word problem" content requiring minimal reading skill, and random video access permitting immediate retrieval...
of essential information. Insofar as teacher candidates learn how to utilize this technology, they have mastered an additional resource for promoting problem solving with middle grade students, and not only developed the skill of operating digitized video.

To Select Learning Resources Consistent with Objectives

Evaluation of resources in terms of their instructional fit has long been an expectation for teachers. Professional journals abound with descriptions of trade books that complement thematic study, for example. In its present iteration, this crucial task of professional judgment must embrace not only print and video, but also cyber sites and software. Regardless, the quality of the judgment rendered is prime. Students initially report delight in finding abundant sources of prepared lesson plans on the Internet, but determining what the plan purports to do, for whom, and how well, requires more sophisticated critique. The same principle, that assessment occurs within a context, holds for software review. The action of professionally selecting materials with the best potential for fulfilling learning objectives links us to best past practice, while the introduction of representative new technologies enriches the repertoire of beginning teachers.

In mathematics education, for example, we can provide opportunity for future teachers to examine significant variations. The Math Forum's Ask Dr. Math serves a very different purpose than some of the more colorfully animated commercial sites. Prospective teachers benefit when contrasting the usefulness of LCSI's Logo-based MicroWorlds as a geometric tool for problem solving and creative-critical thinking, against a fact practice staple such as MathBlaster. Similarly, they should be able to discern the advantages of graphing tools in a mathematics situation.

To Promote Reflection on Their Own Instructional Practice

Essential for the success of committed professionals is the habit of self-examination. Teachers must not only plan learning opportunities for youngsters of diverse talents and needs, they must also assess the effectiveness of their implementation. Listening carefully to learners' discourse and studying work products are two of the many ways of gathering useful information. Indeed, analysis of student misconceptions has a long history in providing significant feedback to instructors.

Video technology offers another tool for reflection. We have found that our prospective teachers place real value on the artifacts which video cameras produce. Two upper level courses require oral presentations followed by questions and answers. Peers write informal constructive comments based on criteria specified for this purpose. Having had brief instructor-provided operating instructions, students record their peer's presentation on video, so that the individual has yet another perspective for reflection. Within a week, students submit a written analysis of their work, using both peer and video feedback. Then the instructor adds her evaluation. Invariably, despite acknowledging the increased pressure imposed by the recording, students applaud it as an independent source. In cases of poorly organized presentations, or those in which eye contact was fleeting or absent, the viewer often realizes the weakness before any word from peer or instructor. But in happier cases, students report satisfaction in realizing that they appeared more composed, or more fluent than they expected would be the case. Having seen and heard their work, they often afford more credibility to the insights offered by others!

Final Thought

As we reflect on the competencies we value for prospective teachers we do so mindful of the fact that teacher educators must be committed to modeling appropriate integration of technology. If we design and implement learning experiences that recognize technology as a tool for enhancing human potential, then, hopefully, future educators will begin to "do as we do."

Abstract: This presentation outlines a constructivist approach to educational learning and work for preservice teachers which enables them to move from passive consumers of information to active producers of technological resources for themselves and others. This approach involves secondary methods preservice teachers as critical consumers utilizing a FileMaker Pro™ 3.0 database that has been customized to gather text, graphics, sound, video, and references through the World Wide Web. The preservice teachers then become active producers by applying that information in lesson activities that are made available to others through technology. Mounting lesson activities by preservice secondary teachers from a common site has resulted in a community product or new information bank of over 50 activities in 9 topical areas: English, social studies, science, journalism, guidance, art, math, special education, and business education.

Introduction

In his discussion of the importance and dignity of work, Boyer (1995) states that “life, for all of us, involves producing and consuming” (p. 99). Although it is possible in today’s world for an educator to do a great deal of consuming without producing anything original, teachers need to engage in both activities to maintain self-esteem and to assume their places as professionals in a learning community. Technology helps educators balance producing and consuming through the World Wide Web by giving them the tools “to explore, experiment, construct, converse, and reflect on what they are doing, so that they learn from their experiences” (Jonassen et al., 1999, p. 194).

While World Wide Web tools are very valuable, educators at all levels who use the Internet face an explosion of information for which they need strategies to shape work, save human energy, and focus power. Fortunately, technology users can access such forces through databases or information banks to help them do just that. Information banks, according to Jonassen, Peck, & Wilson (1999), “may include text documents, graphics, sound resources, video, animations, or any other medium of information that is appropriate for helping learners understand the content well enough to be able to use it to solve problems” (p. 199). These information banks supplement the efforts of a human by taking advantage of the superior sort and compile functions of a computer to manage information and to search a topic or keyword in minutes, sometimes even seconds. Beyond speed, the foray of a database also produces work in research and information management by its capacity to move easily among any number of indexed fields.

Approaching databases initially and using them effectively can be daunting for preservice teachers as they struggle to learn and integrate content, pedagogy, and technology all at the same time. Yet Morton (1996) asserts, “computer systems in school should be viewed as structured learning environments with complex and comprehensive capabilities. They should be seen as interactive learning extensions of the children themselves” (p. 417). The same could be said for the computer systems of the children’s teachers. This perspective acknowledges the constructivist nature of a technological learning environment as well as validates
and encourages teachers at all levels to see themselves as active contributors to a community of learners who share knowledge and ideas through the World Wide Web.

Active Production of Technological Resources

This presentation outlines a constructivist approach to educational learning and work for preservice teachers which enables them to move from passive consumers of information to active producers of technological resources for themselves and others. This approach involves secondary methods preservice teachers as critical consumers utilizing a FileMaker Pro™ 3.0 database that has been customized to gather text, graphics, sound, video, and references through the World Wide Web. The preservice teachers then become active producers by applying that information in lesson activities that are made available to others through technology. Mounting lesson activities by preservice secondary teachers from a common site has resulted in a community product or new information bank of over 50 activities in 9 topical areas: English, social studies, science, journalism, guidance, art, math, special education, and business education.

Before we can operationalize the constructivist approach to critical consuming and active producing, we ask preservice teachers to seek World Wide Web resources on a curricular topic in their subject area in preparation for lesson planning and presentation. The information knowledge base available through technology is expanding so rapidly that novice users can easily be overwhelmed. Both teachers and students must understand and feel comfortable with technology in order to tap its strength to address individual needs and specialized lesson activities. McLellan (1996) defines this type of shift as “mass customization—customizing both education and technology to individual learner needs and preferences” (p. 5). At this point in their education, preservice teachers are both learners of content and pedagogy with individual needs, and future teachers who will soon be faced with the individual needs of their own students. Technology is truly valuable only when users, like our preservice teachers, are able to assess and transfer information and processes to new situations.

Following an introductory lesson reviewing navigational strategies using a Web browser, we distribute a handout with the address and brief annotation of a number of search engines and educational sites. As preservice teachers begin to find specific materials, their questions and comments reveal that they are ready to learn how to select and download resources. At this point, we discuss thoroughly how to evaluate the credibility and usefulness of World Wide Web resources. Preservice teachers’ conversations then turn to how they can use some of the materials in their classrooms. By the end of the two-hour session, students report that they feel confident about exploring the Internet for materials to use in curriculum development and teaching, and they are ready for the Three-Step Approach to Information Organization to focus those resources.

Three-Step Approach to Information Organization

The Three-Step Approach to Information Organization blends technology applications with constructivist strategies to enrich both approaches. In theory, constructivism describes the changes in students’ mental schemes that illustrate learning. Planning constructivist activities that involve technology activities requires teachers to consider the following components of practice:

- Lessons should be based on the evolving needs of students
- New information offered within a lesson either confirms or changes students’ current beliefs
- Teachers must value students’ perceptions of and responses to lesson information and activities
- Lessons must establish relevance for current and future use

Today, teacher educators must expect students of education to be intellectuals—problem-solvers who resolve cognitive dissonance, perform authentic activities, and have their efforts assessed in ways that reflects a genuine application. The Three-Step Approach to Information Organization meets these criteria by completing the tasks outlined below.

**Step I—Critical Thinking Assignment:** Students begin this assignment by finding and downloading resources from at least five World Wide Web sites into a Teaching Resources Database that will aid in the development of a lesson activity in their subject area. This assignment reinforces their new skills in navigating and retrieving from the Web, storing, and organizing information. It also helps students understand that quantity does not equal quality, and information does not equal insight.

**Step II—Authentic Activity Procedures:** Constructing meaning involves evaluating information by sorting and sifting, saving only what is important. This authentic activity builds on a process most of us learned
as part of our first research paper assignment—indexing cards. With the help of technology, we can take that process and update it by having students build their own Teaching Resource Database on a hard drive or disk, directly cutting and pasting information from the Web to the database instead of downloading files without careful analysis. The development of a lesson activity using the database makes it personally relevant and a professional resource that one could continue to expand. See Figure 1 to for fields and database layout.

Figure 1: Teacher Resource Database Layout

Using an alternate layout within FileMaker Pro™ 3.0, the student can quickly and simply produce handouts or mini-posters of the materials for teaching.

Step III—Published Products: Performance testing of an authentic activity should be nonalgorithmic, complex, and involve judgment and interpretation (Resnick, 1987). By publishing the product of their searches, preservice teachers are authentically challenged to use World Wide Web resources to create a new resource. This new resource is then available for analysis, comment, and use by other professionals in the field. Like all publication, this step encourages preservice teachers to do their best work because the published resource is also available for potential employers to review at the following World Wide Web site address: http://www.educ.drake.edu/sec_meth/secondary.html.

These published products include the following categories: resources needed, exposition, procedure, interactive learning, critical thinking, possible assignment, and World Wide Web resources used within the activity. The secondary lesson activities can present concepts that might be familiar in new and different ways, but they are all based on resources found on the World Wide Web. For example, one lesson activity, “Adaptation in Arctic Conditions,” explains the concept of thermoregulation with a lab about how to make blubber. Students are divided into cooperative learning groups that explore the insulating effects of blubber in Arctic conditions. Critical questions are provided for students as they consider the concept. In addition, the page includes a complete lab activity outline and corresponding worksheet. Visitors to this page are sent to a number of World Wide Web sites for further information:

Benefits of a Constructivist Approach to Technology

Using a constructivist approach to technology accepts learners as thinkers with valid questions and the ability to create meaning and materials. The benefits of this approach, when properly applied, enrich learning and teaching in the following ways:

- The formulation of questions and assessment of materials can enhance critical thinking and problem solving. Using information obtained from a variety of sources and creating meaningful products to illustrate student learning enables all, teachers and students, to increase their knowledge base and apply that knowledge to new circumstances with emerging technologies.
- Authentic technological activities provide for individual needs and learning styles of students by offering different methods of learning a concept. For example, students might make a video, create an electronic presentation, prepare a concept map, and even use word processing to write a traditional research paper. The important point is that all of these activities are prepared as they would be in a work world.
- Autonomous learning is promoted as students question, explore, and create meaning that arises out of their own unique educational needs and interests. Autonomy is best represented by initiative and creative energy. While technology cannot guarantee that students will succeed, it does motivate them to undertake projects and to persevere in refining them. Such perseverance can then increase self-esteem and satisfaction from intrinsic motivation.
- Collaborative learning in technological situations creates a team atmosphere and produces problem solvers even as it expands human networks. Both Dewey and Vygotsky stress that we naturally learn in social situations. Students working in technology share skills, knowledge, shortcuts, and encouragement with other students on site or with persons across the world through e-mail, chat rooms, and forums.
- Multiple approaches and perspectives allow the student to explore diverse viewpoints and synthesize information critically. Learning with technology reflects the complex nature of knowledge, encouraging the acceptance of knowledge as tentative and tolerance of ambiguity.
- Real-time relevance mirrors our rapidly changing society and its hunger for information about events as they occur. Instant access through technology to newsgroups, electronic publications, and online news reporting provide an active learning environment that facilitate transfer of information quickly.
- Innovative learning environments provide a work-world approach to managing and leading educational innovation. Classroom teachers cannot stay current in all aspects of technology that can be useful to them. They must establish environments where continued learning is modeled and reinforced, and an environment where risk-taking is encouraged.

Hindrances to a Constructivist Approach to Technology

As with any technological process, a constructivist approach to technology can create challenges that act as hindrances in its implementation.

- Time can be a real concern when blending technology with a constructivist methodology. Technology approaches take time to set up and require time to teach both the technological skills needed and the targeted concept. In addition, students require varying amounts of time to construct authentic projects.
- Inequity of resources perpetuates socioeconomic divisions. Lockard, Abrams, & Many (1994) assert that "Computers only call further attention to the fact that schools in the U.S. are anything but equal. Inequities affect everything from basic supplies such as paper and pencils to library resources and even the quality of teachers" (p. 411). The problem is magnified when students from schools with few resources go home to an environment unable to support their technological needs.
• Teachers who have limited knowledge and interest in technology either refuse to use technological approaches or use them ineffectively. Use of technology requires new ways of thinking about instructional delivery. Roblyer et al. (1997) confirms “that properly trained teachers make the difference between success or failure of an integration effort” (p 40).

• Besides the initial cost of establishing technology, schools are faced with continuing cost of repairing and updating equipment and software. Innovations are soon outdated, and newer equipment and software are often incompatible with existing resources.

Conclusion

Preservice teachers with a dynamic need for resources can find or produce a plethora of information. But educators also have a need for a process which enables them to organize and synthesize that information so that it is meaningful as well as useful for current and future projects. The constructivist approach to critical consuming and active producing described in this paper provides proactive procedures for preservice teachers to search, sort, save, synthesize, and create.

Future questions about this approach deal with the ability to sustain and update the site, staying current with database software, and the use of the customized database after students have left the university. We have had contact with former students who are now teachers who look to the Web site for new ideas and indicate that they continue to use the database template that was given to them. Moreover, even if they do not have the same software at their schools, they do have knowledge of the process of evaluation, information gathering, and synthesizing so that they can create their own databases. Using a customized database in a constructivist approach to technology provides a means for students to act as critical consumers and to contribute as producers for the educational community of learners who continue to work with and through technology.

Learning Practices In Amsterdam

Simone Terwindt
Amsterdam Faculty of Education
s.m.m.terwindt@efa.nl

Abstract: The Amsterdam Faculty of Education is developing and implementing a new curriculum concept for professional education, for which it attained the status of "the experimental teacher education in the Netherlands" in 1997. This concept, fitting in the constructivistic learning paradigm, is nicknamed 'learning through producing'. The Amsterdam Faculty of Education (EFA), which attained the status of "Experimental College of Teacher Education" in the Netherlands through a national contest in 1997, is developing a radically new curriculum concept. In this poster/demonstration session a number of concrete results, as well as the basic ideas behind this curriculum innovation, are demonstrated in an interactive fashion.

Introduction

The Amsterdam Faculty of Education (EFA), which attained the status of "Experimental College of Teacher Education" in the Netherlands through a national contest in 1997, is developing a radically new curriculum concept. In this poster/demonstration session a number of concrete results, as well as the basic ideas behind this curriculum innovation, are demonstrated in an interactive fashion. A more extensive presentation of these basic ideas can be read in the SITE 2000 paper "Proving Competence: Integrative Assessment and Web-based Portfolio System in a Dynamic Curriculum", by Douwe Wielenga.

The development and implementation ("expedition", as we call this process) of this new curriculum, is our answer to the challenge of educating teachers for the information society, in which they will have to act as "change agents" of education.

Education should, in our view, take place in a learning environment that reflects the way a professional works: students, like professionals, work together on complex tasks. In doing so, they take control and responsibility of their own work and learning processes. Also, this approach makes learning exiting and challenging: learning can, once again, be fun!

Authentic Learning in Professional Education

At as early a stage as possible, the program should create an environment for students which mirrors professional practices. Learning during the program must be linked as far as possible to useful and responsible work resembling work in the profession for which one is being trained.

In professional practice, teachers have to carry out relatively complex tasks that fit in with the objectives of the school. To be able to do this useful work well, they must be able to use 'two kinds of learning'. They should not only be able to acquire on their own initiative the knowledge and skills they need to do their job well (learning of the first kind), but they should also be able to continue to learn from the experience gained and to experiment systematically with actions leading to improvement or change (learning of the second kind). See figure 1 on the next page.
Both kinds of learning are important in the concept of 'lifelong learning'. Both are 'guided' by the competencies, which the competent and qualified teacher must have.

So the program should offer environments in which students can (and indeed should) put these two kinds of learning into practice connected to authentic practical work, in order to acquire the skills required for the profession. In this concept, named "learning through producing", we integrated ideas on authentic and meaningful learning, first and second order learning, integrated assessment, and portfolio systems. ICT is used, not as an "add on" technology, but as a catalyst of the curriculum transformation. The key building blocks in this curriculum, and the main subject of this session, are "authentic learning practices", which differ radically from traditional courses. Students work together on complex assignments: they provide products or services, preferably for the professional field, schools for primary and secondary education. In many instances, working for schools involves support in innovation and ICT-implementation in these schools. Students acquire knowledge and skills in order to perform the tasks, set in such an assignment. They are being encouraged to take responsibility of their own learning process by basing student's assessment mainly on the quality and usefulness of the products that they make. Of course that assessment is not solely based on products, but explicitly on the proof of professional competence that is given by the sequence of products, feedback and reflections.

Basic characteristics of these learning practices are:
- Students work on meaningful, authentic assignments; someone (e.g. a school) depends on their products! Students acquire the competencies of a professional teacher by working in consecutive learning practices.
- The student takes control of, and is responsible for, his own learning process. Within the framework of the assignment, the student has the freedom to set his own learning aims.
- The teacher (faculty) acts as a coach in both the learning and the productive processes.
- The learning practice encompasses a full learning cycle, including orientation, planning, execution and evaluation activities. Assessment of students is based on their products as well as on their reflections on the learning process.

Examples will be shown at the poster session. Examples can be seen at http://onderwijs.efa.nl. Information in the English language on the expedition of the Amsterdam Faculty of Education can be seen at the Publications part of the home site of EFA: http://www.efa.nl
The Multimedia Content Development Company: The Evolution of a Hands-On Technology Integration Course for Preservice Teachers

Abstract
This article describes a strategy for modeling the integration of technology in the curriculum of ETC 447, Technology in the Classroom, a required course for preservice elementary educators at Northern Arizona University. Preservice teachers engage in a classroom simulation in which they "do" desktop publishing, databases, spreadsheets, and hypermedia development—not just hear about them or complete practice activities. The strategy can be modified and implemented at any K-Higher Ed level. Included are samples of the course materials from the course Web site, as well as examples of student work. Although we are currently using ClarisWorks 4.0 in a Macintosh-clone computer lab, the coursework is platform-free and any of a number of applications can be used.

Introduction and Some History

Don Tapscott, in Educating the Net Generation (Educational Leadership, 1998) recently says of the K-12 environment, Computers alone won't do the trick. They are a necessary but insufficient condition for moving our schools to new heights of effectiveness. We've still got to learn how best to use this technology. And I have become convinced that the most potent force for change is the students themselves. (P. 7)

This, we think, is also true of preservice teacher education at the university level. One of the difficulties in changing the way educators 'do' things may be that our educational system is one in which the new generation of teachers is taught the same way as the last—it is self-replicating. New teachers enter the system from teacher education programs with similar beliefs and experiences as their predecessors; thus, they continue to teach the way they were taught! For change to happen, preservice students need to experience alternative teaching and learning models and strategies as part of their own education.

ECI 447 has been a required technology course for all elementary preservice teachers in the Center for Excellence at Northern Arizona University for over 7 years. It has evolved from a skills-based course where students completed a variety of projects by following instructions in a manual, to a classroom simulation of a Multimedia Content Development Company where teams of students complete a content-centered project in which technology tools are integrated.

At its inception ECI 447 was taught in a lab of Apple II Es which grew, over the years, into first, a lab of hybrid Macintoshes, and now one of 22 Motorola Macintosh clones—equipped with printers, scanners, Proxima display unit, digital cameras—linked together on a network that includes mounted CD-ROM software, student and instructor folders, and fast access to the Internet and WorldWide Web.
become ETC 447 with a prefix that denotes its true goals and objectives, Educational Technology for the K-12 curriculum.

It has been our vision to move from ETC 447 from one in which students followed the traditional computer literacy curriculum of drill and practice routines and activities with little personal engagement in the course materials, few higher order thinking expectations, and, frankly, not much enthusiasm, to one that models authentic practice through hands-on activity and social interaction, enabling our students to "do" technology and "be," for example, authentic desktop publishers and multimedia developers and database managers by using those tools in an environment that promotes risk-taking and personal responsibility for learning. We watched our students plow through the textbook to complete the projects and we graded their papers, and we felt that ETC 447 was hollow: our students gave us good evaluations as helpful and supportive instructors; they reported that they learned a lot, but there was no evidence that they had experienced technology in a way that they could take with them into their own classrooms, the real world, to use effectively—they had only "covered" the material.

Strategy for Technology Integration:
The New, Improved, I Really Mean It This Time, ETC 447

We have spent several semesters struggling with ETC 447 to move it closer to our vision, adding group work here and new activities there, but finally, over the 3-week winter holiday in December 1998 we looked at each other, said "Let's do it!," and spent our semester break completely recreating the course. For the Spring 1999 semester we introduced The Multimedia Content Development Company to ETC 447 students with the following memo taken from the course web site (http://jan.ucc.nau.edu/~cmw447/etc447). This memo serves as the introductory piece for an in-depth 10-week project, and models a contract strategy, both between students, and between instructor and students, in which activities, expectations, and completion dates are noted.

LIZARD GRAPHICS, INC.

MEMO

TO: New Software Development Teams
FROM: Sneak E. Lizard, President and CEO
SUBJECT: Software Development
DATE: 1/11/99

Lizard Graphics, Inc. has decided to aggressively move into the educational multimedia software market. You have been organized into several development teams for the purpose of creating prototypes of some possible software for this purpose. This software should be designed for the K-8 market. The software should follow a specific theme. The exact theme that your team chooses is entirely up to you. Some

FIGURE 1. The Sneaky Lizard Memo

Materials for ETC 447

The first week of class meetings (we have 8 sections of ETC 447 on campus taught by four instructors, some that meet once a week and some that meet twice) was spent introducing the course web site and
carefully examining each document of the Multimedia Content Development Company. The materials that traditionally would be part of a course syllabus are all available at the web site and include

1. the syllabus
2. the competencies (what product instructors expect from each activity)
3. the grading structure for the course
4. the schedule for the semester

At the web site, too, are all project materials, such as
1. the memo that introduces the Multimedia Content Development Company
2. Research Help--lists Web sites for all kinds of research
3. a description of each team member’s responsibility
4. Resources for graphics and educational Web sites
5. Search strategies for “surfing” the Web

Each instructor, that first class meeting, used their own method to place students in teams for the project. ETC 447 classes are limited to 20 students, so teams of 4 were planned. Each student then chose a responsible team position, i.e., the Recorder, who keeps track of what goes on at each weekly meeting of the Team, or the Presentation Coordinator, who is responsible for making sure the final presentation is completed and ready for a wider audience of CEE faculty and students.

FIGURE 2. The Semester Schedule

During that first week, too, each instructor spent extra time with the 4-person teams to review the concept of the project, helping them to decide on a research topic, and answering questions about team-member responsibilities. This proved to be an important element of the introductory process, for instructors and students. We were able to meet and talk with each other in a small group environment: students were able to have discussions with people they were expected to collaborate with, and the instructors were able to put faces with names across a table instead of across a room.

The Multimedia Content Development Company Unfolds

In those small groups the students made their topic decisions and, for the next two weeks, were encouraged to concentrate on their research—on the Web, in the university library, and on CD-ROM encyclopedias available in the computer lab.

Research topics included The Planets, The Four Food Groups, Greek Gods, Animals of Northern Arizona. Time for thinking, planning, and research is often at a premium in the classroom, whether at the university...
or K-12 level. We wanted to model the importance of allowing time for these higher-order skills in order for students to have the best opportunity for success.

In the third week, following their research, the MCDC teams began working on the project. The first activity, using PAINT, was for students to design and create a self portrait. (We use ClarisWorks 4.0, now AppleWorks by Apple Computers, on Macintoshes in our lab, but students are encouraged to recognize the concepts, not the platform, and use other applications and platforms that are also available to them.) These self portraits will be electronically merged to become the cover of their team portfolio. This activity was designed to support and model several levels of learning: the tools available in a PAINT application, the integration of technology in a content-based project, and understanding artistic challenges and possibilities for K-12 classrooms.

![Figure 3. Student Self Portrait](image)

To complete the next activity, students created a slide show using the ClarisWorks 4.0 DRAW application, the storyboard planning for what will eventually be their hypermedia document about the research content they have chosen. They learned the DRAW tools and concepts, how to set up a slide show for use in their own classrooms, and played with design elements such as object placement, color, and text.
Slide Show/Storyboard in Draw: pages 71-102

Using the Draw program in ClarisWorks create a slide show that illustrates the proposed design of your content portion of the new software. The slide show must meet the following criteria:

- Minimum of 3 slides
- Master Page with a border and color background
- Imported graphics:
  - The chosen graphics serve a purpose (specifically relate to the presentation's content)
- Text:
  - All text is easily readable
  - Text of different sizes, colors and styles (e.g., bold, italic, etc.)
- Good design:
  - Colors are coordinated
  - The elements are uncluttered
  - Is pleasing to look at

FIGURE 4. The Slide Show Competency

The completion of the Multimedia Content Development Company project includes the research content and computer-based activities in which students:

- create one-page newsletters about their research for a team prospectus.
- create 10-person databases, with a mail merge of three professors to whom they will send invitations for the final presentation.
- create spreadsheets to explore expenditures for software, hardware, and visiting content experts needed for their software development.
- design and create a 15-20 card team hypermedia document that synthesizes the individual content research and becomes their software, to be showcased at the final presentation.

And, finally, the teams present their completed project to “the company president,” their peers and invited guests—a wider audience. The presentation is both a hard-bound portfolio of completed work, such as their newsletters and spreadsheets, but also an electronic showing of their hypermedia content “software.” Team members are responsible for securing a presentation room, electronic display carts, planning the order of team presentations, and making sure all the technology “works”—everything that must be done in the “real world.” During this presentation teams are also be responsible for videotaping each other for self-critiquing. The constructive self-criticism from viewing the videos allows these preservice teachers a unique opportunity to “see” themselves as presenters and help prepare them for Arizona’s video-based performance evaluations for educators.

Conclusion

A recent article in Education Week (October, 1998) reports that technology can have positive benefits in the classroom, but that too often it is used for the wrong purpose. The researcher, Harold Wenglinsky, an associate research scientist at the Educational Testing Service, used performance data from the 1996 National Assessment of Educational Progress (NAEP) to investigate the relationship between educational technology and students’ achievement in mathematics. What he found, among other things, is that in 4th and 8th grade “students whose teachers had professional development in computers outperformed students whose teachers didn’t.” (p. 13) And, furthermore, eighth graders who used mostly “simulations and applications—generally associated with higher-order thinking” (p. 13), rather than drill and practice, performed better on NAEP than students who did not. In fact, “8th graders whose teachers used computers primarily for “drill and practice”—generally associated with lower-order thinking—performed worse.” (p. 13)
We don't know yet how ETC 447 students will evaluate this innovative course format--only time will tell. But, for us, the “new, improved” ETC 447 not only meets the stated objectives for our technology curriculum for elementary preservice teachers, but satisfies our vision of what that course should look like in order to model good practice in utilizing technology tools for higher-order, relevant, and engaging activities, hands-on technology integration, and be more than “let’s turn the page and follow the steps... drill and practice until you get it right.” From the results of Mr. Wenglinsky’s study, we think we are at least on the right track.

Restructuring, redesigning, and recreating ETC 447 has been time-consuming and labor-intensive. Thinking and planning for meaningful technology integration is a challenging task, but watching and listening to students work together to make a cooperative decision, or engaged with a problem around a computer, it is worth every effort we make. More than that, if we, at the university, preservice level of education, expect to make changes in the way technology is used in the K-12 environment, we must be models for our students, willing to be innovative and risk-taking ourselves, to explore new strategies, methods, and technologies.

References

Acknowledgements

Our thanks to Gary Karcz and Dave Bowman, adjunct instructors at CEE, for their willing assistance in redesigning ETC 447 and implementing it immediately in their course sections. We would also like to recognize George Howington, System Administrator for the computer lab, who always says “yes” when we ask for one more extra drop folder on the network, or access to another software application. And thanks, too, to the graduate assistant and lab techs who support our ETC 447 students during open lab time.

AN INNOVATIVE TEACHER-TRAINING COURSE INCLUDING THE INTEGRATION OF ICT: THE EXPLO PROJECT OF THE ICHTHUS UNIVERSITY

E. Westhoek
Ichthus' Faculty of Education
P.O. Box 23145
3001 KC Rotterdam
The Netherlands
Email: e.westhoek@ichthus-rdam.nl

Abstract: The Explo project of the Ichthus University trains primary schoolteachers with vision and skills in the handling of ICT. Explo is a new, experimental teacher training course, related to the Dutch government's Prommitt program (see also Panel session). Explo is meant to be an educational response to the challenges posed by the knowledge society. One of these challenges is that both pupils and students must be prepared for the learn-as-they-work concept of organizations. Another challenge is that ICT plays a key role in these developments. The first part of this paper explains the view of Explo on the use of ICT in education. The second part deals with the Explo course in detail and gives information on the course program.

The role of ICT in education

Computers are used in education in numberless ways:
• As sources of information, such as educational software, CD-ROMs, on-line catalogs and databases on the World Wide Web;
• As means of communication such as e-mail, electronic news and discussion groups, computer conferencing and video conferencing;
• As tools for making products, such as word processors, data bases, presentation programs, author systems, programming languages, etc.;
• As tools for data analysis and process simulation. ICT applications in education are virtually inexhaustible, but not all applications are equally opportune in each study program, for each student and at each point. Having to make choices, it is important for us to establish the relevance of ICT to education.

The digital world is an extra world

The digital world with e-mail, the Internet, multimedia software and other electronic aids considerably increases the number of ways we process information and communicate. Besides being a playground and a market square, the Internet is used intensively as a working and learning environment. The "web" is not only an oracle, but also a tool to design and construct things. It's not only a means of storage and distribution for educational materials, but also a publication tool for students. It's not only a coaching and consultation channel, but also a virtual space for cooperation and discussion. There are three reasons why education should familiarize itself with this new learning environment, firstly: to teach pupils how to use the possibilities of ICT in a meaningful rather than superficial way, secondly: to enhance pupils' learning competence and thirdly: to prepare pupils for professions in which the use of ICT is increasing.

The computer as the students' tool

In traditional education, lecturers primarily transferred information. Nowadays students can also use computers to gather, order, analyze and edit information, to report on these activities, to simulate processes, cooperate on assignments, communicate about common interests and to exchange information. Explo uses computers especially as students' tools to make the learning process more productive.
Distance teaching supplementing face-to-face instructions

ICT offers new possibilities for distance teaching. Ichtus Hogeschool uses those possibilities for the foreign program for Dutch enrolled students. For Explo, however, where Ichtus deals with young students, priorities are different: the contacts between students, lecturers and fellow pupils are highly valued. The school building is seen as the social meeting point and as the place for face-to-face instructions. Distance learning does not replace these contacts but supplements them: face-to-face meetings are supplemented with electronic work groups, practical training with multimedia simulations, lecturers' consulting hours with electronic consulting hours, searching for information in the library with the consultation of electronic catalogs, etc.

ICT as a component of the teaching profession

ICT is used in all graduate professions. It completely alters the nature of some professions, such as those of publishers or librarians. But there are also professions that until now have been less in the digital forefront, such as the teaching profession. As a result, the digital "tools of the trade" for the teaching profession have hardly been developed. Most of the possibilities of ICT for teachers in elementary schools, secondary schools and higher education remain to be explored. They include better gearing of the study programs on offer to the learning profiles, learning styles and needs of individual pupils (adaptive education), cooperative learning, and ways of learning that are increasingly designed and implemented by pupils themselves.

The curriculum’s three phases

The curriculum is divided into the following three phases:
1. An one-year foundation course, in which students orient themselves to the teaching profession, asking themselves as the most important question: do I want to be and can I be an elementary-school teacher;
2. A main phase (18 months) offering a broadening of the various subjects and themes, the most important question being: what do children have to learn and how do I get them to learn it;
3. A specialization phase, taking another eighteen months, focusing either on the lower grades or the higher grades, the most important question being: what are my educational views and how can I implement them in an elementary school.

Assessments of students' progress take place at the end of each phase.

The curriculum’s five strategies

1. Each year of study consists of four terms, each term having its central theme. Themes are based on students' development from freshman to novice teacher. Each theme is elaborated in tasks, cases and projects, introduced by and evaluated with tutors in groups of 12 students.
2. The internship strategy is closely linked with the theme strategy, since internship assignments, too, conducted in pairs, match the theme of the relevant term. One of the implications is that, in a particular term, students take internships in a particular grade of an elementary school.
3. The skills strategy consists of intensive training directed by a subject specialist. Like the internship assignments, these skills are closely linked with the theme strategy.

4. The reflection strategy teaches the student how to react to his or her development, to strengths and weaknesses and to achieving or failing to achieve certain learning objectives. An important aid in this strategy is the multimedia portfolio, in which students collect their plans, products, assessments and responses coherently.

5. The autonomous-learning strategy, though not linked with the theme strategy, does have a clear structure. As a result of independent-study programs, each student can set his or her pace in acquiring the required subject knowledge. Especially those students who have already completed subject components in their previous education can complete these subjects at a great rate. It is also possible for students to do in-depth analysis.

Variable class size

Students attend lectures and seminars in groups not larger than 60 persons at the most. In lectures, lecturers or guest lecturers give the required information suitable for large groups; in particular, a lecturer will expound on a term's theme from various angles and will give support regarding the contents of independent-study subjects. In seminars, students give presentations about their projects. The teaching of skills is done in work groups of 24. Introductions to and evaluations of thematic assignments are done in basic groups of 12. Students will perform some assignments in groups of 3 or 4. Internships are taken in pairs, and independent study is done individually.

Incorporation of ICT into the curriculum

The incorporation of ICT into the curriculum is based on six viewpoints:

1. To develop wide-range learning competence, students use ICT during the entire program in carrying out their learning activities with increasing command; these are the process-oriented and learning-process-oriented applications of ICT. They are closely linked with the program's concept (learning to learn-as-you-work);

2. To develop vision and skill in the use of ICT in elementary education, ICT-for-elementary education will feature in each theme-term in a way fitting the theme; these are the profession-oriented applications of ICT;

3. To enhance students' practicing and processing possibilities, multimedia software is used, such as "tutorials", training programs, simulations and hypertexts. These are the new learning aids used along with traditional learning aids such as textbooks;

4. To improve the efficiency and effectiveness of (traditional) teaching and learning methods, these are supplemented with and reformed with the use of ICT, and in some cases even replaced by ICT; these are the instruction-system applications of ICT;

5. To test new possibilities, a range of facilities is available on the Intranet; these are the technical applications of ICT for students and lecturers;

6. To monitor learning and teaching, several electronic systems are available, such as the multimedia portfolio, the study-progress registration system, electronic questionnaires for the evaluation of courses and, of course, computer-supported testing systems.

Thematic setup

As was set out earlier, Explo is a four-year thematic program, each year having four thematic terms. Each theme features ICT-for-elementary education in a manner fitting the theme.

1. The first-year theme is "The challenge of the teaching profession", enabling wide-range orientation to the profession. Students acquire basic skills for elementary education, including basic ICT skills. In principle, no special ICT courses are taught, but students make productions (a multimedia handbook for novice teachers), requiring them to learn how to command the entire range of elementary ICT skills. An ICT core item is included in each of the four theme terms of the first year. Moreover, students in the internship school together with children explore an educational aspect of ICT, on which they give a presentation to lecturers and fellow students during the program.

2. The second-year theme is "The class is the world" and emphasizes the relating of items to each other: playing and learning, emotion and cognition, subject matter and the outside world, inside and outside (primary) school. Thanks to the Internet, the class can bring in the whole world and Explo students in the internship schools will see to that as well. Furthermore, ICT is used in reading and arithmetic lessons, in subjects like art and music and subject integration in elementary schools.
3. The third-year theme is "Aspects of the quality of education" and focuses on adapting the study programs offered to the special needs of children with different talents and backgrounds. It deals with "colorful" education, with increasing the number of study programs on offer, and with the diversity in teaching particular subjects and education theory. In this year, students develop their view of the educational value of ICT in elementary schools.

4. The theme of the fourth year is "Schools are made by people". It emphasizes the development of students' individual professional profiles. In this year they take their trainee-teacher internship and students write their "masterpiece" final papers. The theme depends on the specialty selected by each student. The use of ICT to keep in touch with lecturers and fellow students during the long internship term will undoubtedly be a prominent feature.

THE PRODUCING STUDENT: LEARN-AS-YOU-WORK AND WORK-AS-YOU-LEARN, AN EDUCATIONAL PARADIGM FOR TOMORROW’S SOCIETY

E. Westhoek
Ichthus’Faculty of Education
P.O. Box 23145
3001 KC Rotterdam
The Netherlands
Email: e.westhoek@ichthus-rdam.nl

Abstract: In this poster students and coaches show digital products and the digital work surrounding as used in the new course of the Ichthus University. This poster presents examples of the new education model as described in the paper: “An innovative teacher training course including the integration of ICT; The Explo project of the Ichthus University”

Teachers for tomorrow’s society

Explo’s objective is to train students as teachers in elementary education who meet the demands of day-to-day educational practice as well as the requirements laid down in the national statutory professional profile. Central issues are the development of independent learning, learning to learn-as-you-work and exploring the role of ICT in education. Besides profession-oriented training, the program’s objectives are social and cultural training and further development of students' personalities. The program is not at all free from value judgments. On the contrary, Explo aims to make students experience a school as a community, where people, learning together, are willing to accept responsibility for each other and where sufficient challenge is offered besides due care. But teachers for tomorrow's society need to be equipped with more.

Schools in their social context

The educational point of departure is the social and cultural backgrounds of elementary-school pupils and the school’s immediate environment. In the area where Ichthus University is based, this means that both the curriculum and the internship reflect urban problems. The program promotes the students' sensitivity to the social diversity in school classes. Teachers not only transfer culture, but must also be able to criticize the dominant culture. Thus, students are counseled in discovering the values underlying the dominant culture and, consequently, education.

Figure 1. schools in their social context
Basic attitude toward children and education

An elementary school is primarily a community in which children and grown-ups explore the world together. Paramount in the educator’s relationship with the child is the respect for the uniqueness of every human being. For elementary-school teachers it is essential to have ideals from which they want to educate children, share their lives and be their “neighbor”. All that is taught in the school will become meaningful only in such a relationship. On the one hand, we expect our students to be guided by this basic educational attitude when they choose to become teachers. On the other hand, the program enables to further develop this basic attitude.

Generalist teachers

Elementary education demands teachers with great employability. Students taking Explo’s basic program are thus taught all subject areas and take internships in both the lower and higher grades. Consequently, the basic program provides training in the following competencies:

- General teaching competencies;
- Special competencies, such as public community care (in the context of the re-integration of the disabled into non-special education), teaching in a multi-ethnic context, breaking traditional role patterns, handling norms and values, etc.;
- Competencies in school organization;
- Subject-related competencies to meet the requirements for elementary-school subjects.

After two years and a half, students can choose whether to specialize in the lower grades or the higher grades with regard to these competencies.

Lifelong learning

After completing the program, novice teachers will not have completed their development. The exit qualifications of traditional teacher-training colleges are directed mainly toward the starting-level competencies of elementary-school teachers. "Competency for continued development” is nevertheless of the utmost importance: the ability to adequately respond to new developments both in education and in subject areas. This requires that students learn how to respond critically to present-day education and learn how to learn-as-they-work. This means that they learn from their assignments and their internships, from fellow students, books, websites, lecturers, their social and digital networks, etc. In other words, during the program students learn how to become learning professionals.

---

**Figure 1. Teachers for tomorrow’s society**

- Basic educational
  - IT skills and vision
  - Teachers’ qualities
    - Social skills
    - Lifelong learning
  - Generalist
    - Study skills and professional skills
Study skills and professional skills

In all of the program's components, students work on the acquisition of general study skills and professional skills derived from the professional profile. In Explo we especially emphasize information skills in addition to reasoning skills and methodical action.

Social skills

Since teachers work in teams and must be good communicators in all kinds of consultation settings, Explo teaches students cooperation and communication skills. Students regularly work on assignments in small groups, take internships in pairs, participate in discussion-training courses, etc.

ICT in education: vision and skill

In Explo, the development of views and skills is not an isolated activity, limited to any one subject, component or theme. It is integral to all components of the curriculum. In Explo, we wish to train teachers who:

- Learn-as-they-work and are innovative;
- function in a multi-cultural and international environment;
- and in doing so use ICT with vision and skill.

In Explo, five uses of ICT derive from this mission; ICT serves as:
1. A link between learning-as-you-work in practice and learning-as-you-work during coursework (the Internet);
2. An aid in providing adaptive education in elementary schools in a multicultural and international context (multimedia software, the Internet);
3. A means for students to develop vision and skills in the use of ICT in education: "being digital" (a laptop as a mobile toolbox for daily use);
4. A motor for lecturers and students to be innovative colleagues in designing (digital) learning environments (the Intranet to share knowledge);
5. A hub for the exchange of knowledge (website, electronic discussion platform) and to maintain the organization's external contacts (e-mail).

Preparing Technology-Proficient Teachers

Mesut Duran
College of Education
Ohio University
United States
duran@ohiou.edu

Abstract: This study explores the perception of preservice teachers regarding the extent to which their institutions are providing the experiences needed for them to use information technology in their future practice. A major research institution in Southeastern Ohio was selected as the case. Eighteen student teachers within three focus groups—fall, winter, spring—participated in this study. Data collection and analysis were conducted on a continuous basis throughout the 1998-1999 academic year. The study findings indicated that only one course had a primary focus of information technology in the undergraduate curriculum. Preservice teachers experienced somewhat random exposure to information technology in the teaching and learning process in their content and education classes. In field experiences, students viewed only scattered examples of technology use by practicing teachers, and therefore very limited modeling of technology usage. The author recommends increased efforts to integrate information technology into preservice courses and field experiences.

Introduction

The infusion of information technology into the teaching and learning process is challenging to preservice teacher preparation programs. Yet these programs are viewed as the most direct and cost-effective way to prepare the approximately 2 million new teachers who will be teaching in the next decade (National Council for Accreditation of Teacher Education [NCATE], 1997 October).

Although institutions of higher education vary in their specific responses to this challenge, most institutions require at least one educational computing course as a core component of their teacher preparation programs (Leh, 1998). Such courses play a critical role in introducing preservice teachers to fundamental information technology components and skills (Kim and Peterson, 1992). Studies have documented improvement in the amount and quality of coursework in educational computing. However, it is recognized that one required class is inadequate to prepare preservice teachers to use information technology effectively in their future practice (Hunt, 1994; Strudler, 1991; Wetzel, 1993). In addition to educational computing courses, it is recommended that preservice teachers need to observe appropriate models of technology usage in the classroom throughout their university coursework (Huang 1994; Hunt, 1994; Gunn, 1991; Novak and Berger, 1991; O'Bannon, Matthew, and Thomas 1998; Strudler, 1991; Wetzel, 1993). Education faculty need to serve as role models. Their uses of and attitudes towards information technology in the college classroom will strongly influence the implementation of technology by preservice teachers in their future practice. (Barker, Helm, and Taylor, 1995; Huang, 1994; Handler and Marshall, 1992). In addition to the educational computing courses and appropriate modeling throughout the university course work, it is also recommended to integrate information technology into the field component of teacher preparation programs (Gunn, 1991; Novak and Berger, 1991; Strudler, 1991; Wetzel, 1993). As Wetzel and McLean (1997) point out, it is important to place preservice teachers in classrooms where information technology use is modeled appropriately. According to Wetzel and McLean, work in the field is a salient way to help preservice teachers experience deep learning of how to effectively use information technology in their future classrooms.

Today's students live in a global, knowledge-based age, and they need teachers whose practices embrace the best that information technology can bring to learning. Recent federal government estimates suggest that as the number of American students and the demand for smaller student-teacher ratios increase, the education system will be forced to replace nearly 67 percent of its workforce over the next ten years. A large proportion of those new teachers will be recent graduates of colleges of education (National Council for Accreditation of Teacher Education...
This is the time to investigate to what extent teacher preparation institutions are providing the experiences needed by their preservice cadre to use information technology in their future work.

The Study

This study investigates the perceptions of preservice teachers regarding the extent to which their institutions are providing the experiences needed for them to use integrate information technology in their future practice. The specific questions, which guide this study, include the following: (a) What perceptions do preservice teachers have regarding the extent to which educational computing courses are providing the experiences needed for them to use information technology in the teaching and learning process? (b) What perceptions do preservice teachers have regarding the extent to which education faculty are providing the experiences needed for them to use information technology in the teaching and learning process? (c) What perceptions do preservice teachers have regarding the extent to which field experiences with cooperating teachers are providing the experiences needed for them to use information technology in the teaching and learning process?

This study is an exploratory study. In this study, a College of Education at a major research institution in Southeastern Ohio was selected as the case. The study included three focus groups. As Morgan (1998) describes, the focus group is a qualitative research method for collecting qualitative data through group discussions. There are six to eight participants who come from similar backgrounds. Many other variations are possible, however. In this study, all three groups consisted of participants who were student teachers during the 1998-1999 academic year. Only those student teachers in elementary education participated in this study. Group 1 consisting of student teachers in the Fall. Group 2 consisting of student teachers in the Winter. Group 3 consisting of student teachers in the Spring.

In this study, a “maximum variation sampling method” (Schumacher and McMillan, 1993) was used to select the study participants. According to Schumacher and McMillan, maximum variation sampling is a strategy for inclusion within a case that seeks to represent a range of differences of perceptions about a topic among information-rich potential participants. For purposes of this study, the range is being able to use information technology in the teaching and learning process among the participants. To select the study participants with a range of information technology experience, the researcher used an "Information Technology Survey," which was developed based on the ISTE Recommended Foundations in Technology for All Teachers (ISTE, 1998 July). The survey was provided to all potential participants (114) during the 1998-1999 school year. Based on the survey results 18 student teachers were invited to focus group interview participating in three groups. Being a student teacher in different schools and teaching in different grade levels were also considered during the selection of participants. Those who participated in this study were student teachers at 11 different schools throughout the Southeastern Ohio, practicing in K-8 classes.

Data collection and analysis were conducted on a continuous basis throughout the year. The research questions drove the analysis. The researcher analyzed the data question by question, looking for themes within questions and then across questions.

Findings

The findings of the study have been organized into three areas for reporting: (a) educational computing course; (b) education faculty use of technology; and (c) cooperating teachers use of technology.

Educational Computing Course

Only one course—EDCI 203, Technology Applications in Education—had a primary focus of information technology in the undergraduate curriculum. All but two participants took the course as required in their program. Most of the participants strongly felt that the course introduced them to fundamental information technology concepts and skills. However, it was limited to address the task of integrating information technology into the teaching and learning process.

Beth illustrated the feeling of many others as she reflected on her experience:
It was very basic... It pretty much started out with click it twice it's a double click... and really only covered word processing, spreadsheets, database... We viewed some of [educational] software which I think was little bit beneficial just to kind of know what was out there... We did a little bit Hyper Studio... [Concerning using it as a teacher in the process of teaching/learning] it made me not be fearful [of technology] as some of the more experienced or older teachers are. Fearful of it. I wasn't fearful to get on the iMac. As soon as it came in I started playing too. But in terms of integrating into the classroom, it didn't teach me how to do that by any means... View the software, create a program, but now how do you implement it at all. I didn't learn any of that.

"My class was the same," said Jane when she reflected on her experience:

This class kind of got me into it a little more. It was good practice on a computer. The thing that teachers can use like basic Internet functions or electronic mail, spreadsheet, database, we just went through that... Well, like it didn't say if there is one computer in your class how do you teach all the students... That is the thing we need to know.

Stephanie shared the same feeling with her colleagues:

It didn't go into like how to apply it. You know how I would go about using the computer in the classroom or how I would use the research that I found on the Internet to apply it to a lesson or something like that... I didn't get like any of that.

Carmen pictured the feeling of many others as she reflected on her experience:

To me, I am still searching how to use, how to integrate... I would like to have strategies how to use three computers in a class of 25. Or like basic troubleshooting stuff. Like if this little problem occurs here what are the things that you can do... I think it would help us if they could break it down into different parts. Like part of it would be practical hands-on. Like here is how you use everything [tools.] And then talk about how you could apply it to the lessons. How you would manage using computers in the classroom.

The need for instructional support addressing the task of implementing information technology in teaching and learning process was an underlying theme. However, the prevalent feeling was that one required technology course was not meeting the needs of preservice teacher to use information technology in their future practice. Most participants were concerned about the conceptual issues covered in the course. They suggested that in addition to teaching certain technology skills, the course should focus on application of those skills in educational settings, and actual classroom management strategies around the idea of having one or few computers with many students.

**Education Faculty Use of Technology**

The attitude of education faculty towards using information technology in their classroom strongly influences the implementation of technology by preservice teachers in their future practice. However, most participants agreed that they experienced somewhat random exposure to information technology in the teaching and learning process in their content and education classes.

Teresa put it best as she reflected on her experience:

The only class I got anything out of computers was the 203 [technology class.] All my methods, they didn't integrate computers at all. I think it would have been helpful if they would have.

"None of mine were" said Sara when she described her experience:

I think that maybe in my science methods he may have said or maybe even in a couple of other ones, you now do to the Internet and find lesson plan. Just print it off and bring it in... It wasn't anything about how to incorporate it into subject area. It was just to check and see if we knew how to get on the Internet. Just go to this, print it and bring it in. That's it. So I didn't have anything.

Mike described that

It's like you are encouraged but you are not really taught what you really need... It was given just like simple ideas like Internet sites for the class.
John described his experience:

In a couple of my classes I got a list of some good Web sites that I could use. But, my planner had Web sites in it too. I was looking through my planner that other day and I was like oh, Web sites for education.

Bet was concerned experiencing "mixed signal" when she reflected on her experience:

I had problem with faculty not using e-mail or not even having e-mail account...We were supposed to call them. If they had e-mail it would have been very helpful. Makes you want to use it more, too. If your professor is like oh, no I don't have e-mail, just call me. Then you are like okay. I don't have to. Use technology, but don't have e-mail. Don't even bother me with that; it's kind of mixed signal there. Why should I get it then? It's not that important then I don't need it for my class.

A few participants described that they had different experiences. For example, Adam used his experience to challenge his fellow friends:

One of the things that I have done in the classroom teaching [student teaching] wise was with the Geometry Sketch program. But I didn't learn that at all in the computer class 203. I learned that in my 330 A & B for my math major. That helped a lot. So I had that and used that a lot in the math [during my student teaching.]

Melissa described her similar experience:

We used technology in my art class too...We found all the information through the Internet and the library. She [instructor] took us to a class ahead of time to learn how to research, how to e-mail all this kind of things, which was helpful. Then we taught the class. We did some peer teaching with it. We used our lessons that we created. We found the artist and the museum and made a lesson and then we presented it to the class. So it is kind of like you we teaching them and they were learning.

The need for observing technology-using faculty in their curriculum and method courses was a common theme. However, most participants agreed that they have had a few opportunities to observe appropriate models of technology usage in the classroom throughout their university course work.

Cooperating Teachers Use of Technology

Most student teachers found themselves in technology-equipped classrooms/schools during their practicum. However, they strongly felt that they viewed only scattered examples of technology use by practicing teachers.

Jen put it best as she reflected on her experience:

Kids get 10-15 minutes on the corner...and they play some type of game. They are done. It's the next person. So it's never, I have never seen computers incorporated into the curriculum in any way. It's just go do your time, okay your times up and you are off...

Stephanie was agree with Jen when she described her experience:

...Games...They get on computers on free time and play games and stuff. Basically at the elementary school they use shape games and things like that.

Kelly responded to Stephanie's comment when she explained her experience:

Stephanie actually nailed it for me when she said free time because that is when they used it. When they had a free time. Free time and as a reward. It was definitely used as a reward...If you can do this then you can go use the computer. As an instructional tool in the classroom, no...I mean we did not use and we had 5 [computers.] They weren't hooked up to the Internet but they were all working and could be printed from if necessary. I tried to set it up as a center. I had 29 kids in the room so it was very difficult to try to get them rotated through the center. We also did used like CD-ROM encyclopedia once for a big ocean project they did. So they researched their ocean animal or their ocean creature. But very rarely.

Leslie described her experience intensively:
I am just kind of laughing because I am at East [Elementary school] and we have 2 computers in my classroom and I definitely know that my teacher is not comfortable with them because she is always [asking me] can you type up this rubric for me? You seem to be better at it than I am. Like we have these passwords [to access the computer] and she is messing with them. She has broken them three times this quarter already. The kids play games...I have seen them type up a paper once in a great while.

Some participants expressed their concerned about the attitudes of cooperating teachers as well. "I have a barrier," Maria reflected intensively on her experience:

My cooperating teacher is 69 years old. Computers just really started coming, people really started to know how to use them like maybe when we were seniors in high school or even later...So I think that a lot of teachers in the schools are really uncomfortable using computers because they didn't have a class in college. They are really uncomfortable using them.

I have similar teacher said Susan when she described her experience:

...She is perfectly fine not knowing, not wanting to know. She is ready to get retired, and she feels that she doesn't need to learn that.

Few participants expressed positive feelings about what they observed in their field experience. Leslie, for example, described her experience differently:

Actually each neighboring classrooms are joined by a little computer lab in The Plains [Elementary school.] And then each teacher has one [computer.] There is no designated computer time but she does use the computers to supplement her lesson...[For example,] we are going to do graphing today and we are going to do it in your group when they are finished can enter it into the computer or we are going to write poems today and you can make the word problems on the computer to process it. So may be not as much as she should use the computers but she does.

The need for observing technology-using teachers in the field was common theme. However, most participants agreed that they have had a few opportunities to observe appropriate models of technology usage in the classroom where they participated as student teachers.

**Reflections and Conclusion**

As the United State enters the 21st Century, teacher preparation programs across the nation are assessing their capacity to adequately prepare new teachers to embrace the use of information technology in the education of young people who will live in a global, information-based society. While investigating the status quo, recent studies have produced somewhat disheartening data. Relatively few teachers (20 percent) report feeling prepared enough to integrate technology into classroom instruction (National Center for Educational Statistics, 1999 January). In general, teacher preparation programs do not provide prospective teachers with the kinds of experience necessary to prepare them to use information technology effectively in their future practice (Milken Exchange on Education Technology, 1999). Findings of this study are consistent with the mounting evidence that preservice teachers are not being adequately prepared to teach with information technology. Only one course has a primary focus of information technology in the undergraduate curriculum. Preservice teachers experience somewhat random exposure to information technology in the teaching and learning process in their content and education classes. Furthermore, in field and student teaching experiences, students view only scattered examples of technology use by practicing teachers and therefore very limited modeling of information technology. In order to prepare technology-proficient teachers, teacher education institutions should increase the level of technology integration in their own program. In particular, the author recommends, increased efforts addressing the task of technology implications in educational computing courses as well as integrating information technology into method courses and field experiences.

Preliminary investigation of some influences on student teachers' self-efficacy for teaching with computers

Peter Albion
Department of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: Although many teachers now have access to computers for teaching and learning and profess a belief in the value of computers for education the impact on the day to day work in classrooms is still limited. Even where teachers believe in the use of computers and have the necessary technical skills they may be reluctant to implement them in their classrooms. Increasing teachers' self-efficacy beliefs for teaching with computers has been proposed as a means of influencing their behaviour. This paper reports on a preliminary study of some factors that might be associated with self-efficacy for teaching with computers. The absence of significant relationships with factors such as Pupil Control Ideology and Innovativeness suggests that it may be possible to intervene to increase graduating teachers' self-efficacy for teaching with computers.

In Australia, as in the USA, computers are now widely available in schools of all types. The arrangements for access vary. Some schools place the computers in classrooms and others create computer laboratories. Whatever the arrangements in their school, there are now very few teachers who could seriously claim that they have no opportunity to use computers in support of teaching and learning.

There is also widespread support for the increased use of computers among policy makers, educational administrators and the community. In Queensland, the government has provided financial support for Schooling 2001, a policy framework which includes as a goal that "computers should be used in every subject area at every level of education" (Education Queensland 1998).

Despite the levels of opportunity and official encouragement implied by these developments, there continue to be concerns expressed about both the frequency and success with which teachers employ information technology in their classrooms (Cuban 1998). Recent online discussions among students returning from teaching practice have included comments about the limited use being made of computers in many classrooms. However, students observed that even teachers who did not use computers in their teaching expressed belief in the importance of computers in education. Surprisingly, on some accounts the rate of uptake of information technology in classrooms does not appear to be notably higher among beginning teachers than among their more experienced colleagues (Oliver 1993).

Various reasons have been postulated to explain the apparent reluctance of teachers to embrace IT. On the whole teachers appear to share the broader community enthusiasm for IT in education as a "good thing" but they report a lack of confidence in their capacity to use IT effectively for teaching and in many cases attribute this to inadequate preparation (Albion 1996; Handler 1993).

A previous paper (Albion 1999) discussed the importance of teacher beliefs in relation to their adoption of IT for teaching. Self-efficacy for teaching with computers (SETWC) was suggested as an area of belief which was related to teacher behaviour in the longer term, was measurable using existing scales and was capable of being influenced by teacher educators in the context of preservice and inservice courses. Problem-based learning (PBL) has been identified as an instructional design methodology that might offer particular advantages in relation to development of self-efficacy (Albion & Gibson 1998) and a multimedia package using this methodology has been developed (Gibson & Albion 1999).
Factors Influencing Self-efficacy for Teaching with Computers

If self-efficacy for teaching with computers is a significant determinant of teachers' behaviour in respect of teaching with computers and if PBL is an effective instructional design for influencing self-efficacy, then multimedia using PBL as a basis for design warrants investigation as a means of increasing beginning teachers' SETWC. As part of the development of the multimedia package it was proposed to test this hypothesis by measuring students' SETWC before and after the use of the materials.

The Microcomputer Utilization in Teaching Efficacy Beliefs Instrument (MUTEBI) was selected as a measure of SETWC. MUTEBI was initially developed and used in the context of science teaching (Enochs et al. 1993) but it is not specific to that context. It comprises two sub-scales which correspond to the two components of the self-efficacy construct identified by Bandura (1977), namely efficacy expectations, which was labeled by Enochs as self-efficacy (SE), and outcome expectations, labeled as outcome expectancy (OE).

Teachers' beliefs and behaviours in respect of computers do not stand in isolation from their other beliefs. Previous studies have demonstrated that teachers' use of computers may be influenced by, among other things, their beliefs about student centred pedagogy (Honey & Moeller 1990) and their inclinations towards innovativeness (Marcinkiewicz 1994). Moreover, students who reported more custodial orientations on the pupil control ideology (PCI) scale also reported lower self-efficacy for science teaching (Enochs et al. 1995). It is often suggested that the use of computers in teaching leads to more student-centred approaches to teaching. Thus, the possibility of a relationship between PCI and SETWC should be considered.

The effectiveness of the multimedia package in increasing students' SETWC may depend, at least in part, on the existence and relative strength of these other influences on SETWC. Early knowledge of such factors might guide refinement of the materials design. Hence an investigation of the relationships between SETWC and other aspects of student teachers' belief systems is warranted.

Because the multimedia materials were to be developed using an untried design, plans were made to conduct trials of a very early prototype with a small group of students who were representative of those who would use the final product. This group provided a suitable opportunity to trial the instrument that would be used to measure SETWC and to undertake a preliminary investigation of potentially influential factors.

It seems reasonable to assume that positive attitudes towards computers and strong self-efficacy for computer use would be prior conditions for positive self-efficacy for teaching with computers. Scales for the measurement of attitudes towards computers and self-efficacy for computer use have been developed and used with teacher education students (Kinzie et al. 1994). The attitude scale has two sub-scales that relate to comfort/anxiety and usefulness of computers. The self-efficacy scale comprises several sub-scales that relate to categories of computer use including word processing, spreadsheets, databases and so on. Subsequent studies have confirmed the reliability of the attitude scales and of a slightly modified version of the self-efficacy scale comprising seven sub-scales (Albion in press). The scales described in the latter paper were used in this study.

Scales for the measurement of teacher self-efficacy have been developed and used in several published studies. For the purposes of this study the instrument described by Guskey and Passaro (1994) was selected because it was the most recently published validated scale for teacher self-efficacy. It comprises two sub-scales. The internal sub-scale appears to represent perceptions of personal influence in teaching and learning while the external sub-scale represents the influence of elements beyond the direct control of the teacher.

Two other factors were chosen for examination. Pupil control ideology (Graham et al. 1985) is a unidimensional construct which has been found to be related to self-efficacy for science teaching (Enochs et al. 1995). As noted above, PCI could influence SETWC through the relationship between custodial orientation and student-centred classes. It was measured using the instrument published by Graham (1985). Innovativeness has been found to be related to computer use in teaching (Marcinkiewicz 1994). It was measured using the unidimensional instrument published by Hurt et al. (1977).

All instruments used in this study were derived from previously published studies. The body of the questionnaire comprised 134 items representing 15 scales and sub-scales as shown in Table 1. Each item was presented as a
Likert scale item with the extremes of the range identified as Strongly Disagree on the left and Strongly Agree on the right. The number of points on the range for each scale varied from 4 to 7 according to the usage reported by the originators of the scales. Table 2 records the maximum value attainable on each scale.

**Results**

A total of 31 students (25 females and 6 males) who were completing the final year of their Bachelor of Education degree completed the questionnaire. Ages ranged from 20 to 28 years (mean = 21.7, standard deviation = 1.8) with strong clustering around 21 years implying that most respondents had entered the degree program directly from secondary school. As an indication of relative familiarity with computers, respondents were asked to select a category which represented the number of hours they spent working with a computer in a typical week. These data are summarized in Figure 1.

![Figure 1: Distribution of computer use in a typical week](image)

The small sample size precluded reliable factor analysis of the scales and they were assumed to exhibit the characteristics described in the published sources. Reliability values were computed and are shown in Table 1.

**Table 1: Instruments & sources, sub-scales, number of items, and reliability measures**

For each scale, student scores were computed as the mean of the item scores for each student in order to facilitate comparisons. Table 2 shows the means and standard deviations of the results obtained for each scale together with the maximum score possible on the scale as determined by the number of points on the Likert scale.
Scores obtained for the ACT and SCT instruments were compared with the posttest scores reported for a group of first year students in the same program (Albion in press). The only significant differences were for Usefulness (t = 3.11, df = 117, p = .002) and word processing (t = 2.45, df = 115, p = .016). In each case the final year students returned higher scores indicating stronger belief in the future usefulness of computers and greater confidence in their ability to use a word processor.

Pearson product moment correlation coefficients were computed for pairs of measures. As described previously (Albion in press), scores on the sub-scales of the SCT were combined to form a composite measure of self-efficacy for computer use. Results are shown in Table 3.

Table 2: Mean and SD of scores (N = 31)

Table 3: Correlation coefficients for pairs of scales (N = 31)

Discussion

The most significant correlation found was between the SE sub-scale of SETWC and SCT, implying that student teachers who report strong belief in their personal capacity to work with computers are more likely to report
feelings of self-efficacy for teaching with computers. SE is also very significantly correlated with the comfort/anxiety sub-scale of the ACT, confirming that students who are comfortable with computers feel more positive about their ability to teach with them.

Outcome expectancy (OE) on the SETWC instrument corresponds to student teachers' beliefs that, through good teaching, they could increase the computer competence of pupils in their class. OE is significantly correlated with both sub-scales (comfort/anxiety and usefulness) of the ACT and with the composite SCT score. The implication is that graduates who have strongly positive attitudes towards computers and confidence in their ability to use them are more likely to believe that they can transmit those qualities to their pupils.

A significant correlation was found between age and innovativeness. The implication of this is not clear but it may result from older students (maximum age in this sample was 28) being more confident of their personal priorities and being prepared, at least in theory, to consider variations to common practice.

The remaining highly significant correlations are between the two sub-scales of the ACT and between the comfort/anxiety sub-scale of the ACT and the SCT. These relationships have been reported previously (Albion in press). It is hardly surprising that beliefs in the usefulness of computers, which would probably influence patterns of use, should be correlated with feelings of comfort with the technology. It is equally understandable that comfort with computers should be related to confidence in their use as measured by the SCT.

Contrary to expectations based on the results reported previously (Enochs et al. 1995; Marcinkiewicz 1994), neither innovativeness and pupil control ideology was significantly correlated with either sub-scale of the MUTEBI. A significant correlation was found between innovativeness and the comfort/anxiety sub-scale of the ACT. This might be explained in terms of comfort with new technologies being indicative of preparedness to adopt new approaches. The significant correlation between PCI and the external sub-scale of the Teacher Self-Efficacy instrument may indicate an association between a custodial orientation towards classroom management and a belief in the power of influences beyond the direct control of the teacher.

The implications of these findings for attempts to influence student teachers' self-efficacy for teaching with computers through their interaction with a multimedia package remain to be tested in practice.

The factors most strongly correlated with SETWC are comfort with computers and self-efficacy for computer use. These are among the factors that might be influenced by students' working with a multimedia package that presents examples of effective use of technology in teaching together with opportunities to rehearse relevant patterns of thought.

Factors such as innovativeness and pupil control ideology seem inherently more likely to reflect stable characteristics of students' personalities. If self-efficacy for teaching with computers were strongly related to these factors it might prove more difficult to obtain significant increases through the short term use of a teaching intervention such as a multimedia package. The implication appears to be that the use of the multimedia materials may produce the desired increases in self-efficacy for teaching with computers.

sadera@iastate.edu

Abstract: In this paper, the results of a content analysis are presented of preservice teachers’ narratives describing how they would use computers in a classroom to bring about learning. This study is a continuation of an examination of preservice teachers’ preconceptions about the role of the computer in the classroom. Each of the 286 narratives was reviewed and categorized by three instructional technology experts. The results indicate that prior to formal instruction, preservice teachers possess naïve conceptions about effective roles of the computer to support learning.

Introduction

The demand for teachers who can effectively use technology to create meaningful learning environments for students is increasing (U.S. Department of Education, 1999). This fact, coupled with the predicted rate of teacher turnover (Darling-Hammond, 1996), makes the preparation of technology-using teachers among the highest priority for schools of education. Unfortunately, few teacher education institutions adequately prepare teachers to use technology (Quinn & Strudler, 1999; Willis & Mehlinger, 1996; Wetzel & Strudler, 1999).

Effectively preparing teachers who can integrate technology and pedagogy is a complex, arduous task. In part, because preservice teachers often enter instructional technology courses with personal theories about the role of computers in teaching and learning. These theories have evolved from their 12 years of experience as students. When studying about teaching, preservice teachers often use their personal K-12 experiences to understand instructional methods. This perpetuates a cycle in which students who were taught using didactic methods draw on these experiences and personal theories when solving problems in their teacher preparation courses (Niederhauser, Salem, & Fields, 1999; Sadera, 1997).

Preservice teachers’ preconceptions can be inaccurate, incomplete, resistant to change, and affect student learning (Posner, Strike, Hewson, & Gertzog, 1982). In addition, if a student’s existing theories are strongly held beliefs, the student may reject
conflicting ideas presented via traditional instruction and retain their personal theories (Posner et al., 1982). If preservice teachers are to espouse more comprehensive conceptions about classroom computer use, they will need to engage in conceptual change.

The conceptual change theory describes a process whereby rational beings may alter or abandon existing conceptions for ones that are widely supported by empirical evidence (Posner et al, 1982). Conceptual change occurs in four stages through which individuals need to progress to change their conceptions; they are dissatisfaction, intelligibility, plausibility, and fruitfulness.

Although many researchers have examined preservice teachers' perceptions of computers, few have examined preservice teachers' conceptions and conceptual development about educational computing. At the crux of this research study is the Thomas and Boysen Taxonomy for Instructional Computer Use (1984). This taxonomy categorizes classroom computer use based on the student's experience with the subject matter being taught. The taxonomy consists of five categories: experiencing, informing, reinforcing, integrating, and utilizing (Figure 1). Previous research on preservice teachers' technology preconceptions has shown that preservice teachers tend to possess simplistic views about classroom computer use (Sadera & Hargrave, 1999).

By analyzing the content of participants' narratives, this study describes how preservice teachers believe computers should be used in a classroom to bring about effective learning. This study is a continuation of an examination of preservice teachers' preconceptions about the role of the computer in the classroom (see Sadera & Hargrave, 1999).

Research Questions

The purpose of this study was to extend our understanding of preservice teachers’ preconceptions about the role of the computer in the classroom. Three research questions guided this investigation.
Research Question 1: What categories of Thomas and Boysen Taxonomy are the narratives most consistent with?
Research Question 2: How do preservice teachers describe effective uses of computers to bring about classroom learning?
Research Question 3: What do the data suggest about preservice teachers’ preconceptions about the role of the computer in the classroom?

Methods

Procedures To obtain data regarding preservice teachers’ preconceptions about effective uses of computers to bring about learning, the study activities were integrated into an introductory instructional technology course. During the first two weeks of the semester, approximately 300 preservice teachers at a large Midwestern university, were asked to write a narrative in response to the following open-ended statement: “Describe how you would use the computer in your field of study to bring about effective classroom learning”. Part of a larger study (see Sadera, 1997), the responses to this question were gathered in the hands-on laboratory sections of the course.

Data Analysis To analyze the students’ narratives, a content analysis procedure was used. The purposes of the content analysis were to categorize the narratives according to the Thomas and Boysen Taxonomy of Instructional Computer Use (1984) and to characterize the content of the narratives. To complete this analysis, experts in instructional technology reviewed and rated the narratives.

Ten experts in instructional technology participated in the content analysis. The experts received training on the analysis procedures prior to reviewing the narratives. Using the definitions provided by the researchers, the ten experts were to carefully review the narratives and determine the category of the Thomas and Boysen Taxonomy with which each narrative was most consistent. Each narrative was reviewed and rated by three different experts. Using an eight-point scale (Figure 2), each expert reviewed and rated approximately 90 narratives; for the 286 narratives, the inter-rater reliability = .77.

### BACL Rater’s Quick Check Sheet

Original item given to respondents:
Beliefs about effective computer use for learning assignment
Select a discipline (i.e., math, science, English) and describe an example of how you would incorporate the computer into a lesson.

Rating Scale
- E = experiencing
- F = informing
- R = reinforcing
- T = integrating
- U = utilizing
- DA = doesn’t address the question
- 0 = blank or no answer
- 9 = multiple examples of computer use within one answer (not multiple categories)
Results

Two hundred eighty six students completed narratives for the study. Of 286 narratives, 32 were eliminated because the study participants didn’t complete all parts of the original study. The narratives from 28 participants were eliminated because their responses did not address the question; and 26 narratives were removed from the sample because there was no consensus among the experts in the ratings. The number of narratives used in the following analyses was 200.

Research Question 1: What categories of Thomas and Boysen Taxonomy are the narratives most consistent with?

The data analysis indicated that informing and reinforcing were the two most commonly described uses of the computer for effective classroom learning (Table 1). Nearly 60% of the narratives consisted of examples of using the computer to deliver information to students or reinforce previously taught material. Although using the computer after formal instruction was a common example in the narratives, using the computer before formal instruction to set the stage for learning was not. Only one narrative described using the computer to help students develop an understanding of the materials prior to formal instruction.

Nearly 20% of the respondents indicated that having students use the computer to manipulate the subject matter (e.g. write papers, form budgets, access information) would bring about effective classroom learning. Twenty-one percent of the narratives described multiple uses of the computer in the classroom. (The narratives rated as multiple uses of the computer are not analyzed in this paper.)

Research Question 2: How do preservice teachers describe effective uses of computers to bring about classroom learning?

To move beyond the mere categorization of the narratives, the researchers also studied the documents to ascertain their character. The descriptions of effective classroom computer use provided by the participants are consistent with the uses of computers they experienced as students in K-12 classrooms (Sadera, 1997). These narratives provide a great deal of insight into their preconceptions. Below are narratives written by the study participants. Using simple random sampling procedures, the researchers selected five percent of the narratives as examples to demonstrate the preservice teachers’ preconceptions.
Overall, these narratives exhibit rudimentary conceptions of educational computing; furthermore, they tend to be Type I (i.e. using the computer to teach in traditional ways (Maddux, 1984)) uses of computers in the classroom.

In a science lesson, a computer could be quite helpful. I would begin by giving background of the topic (i.e. earthquakes). Then the computer could be used to show earthquakes in a more 3-D way instead of looking at it from a book.

In a math class, I would first teach how to do addition using the chalkboard... Then a couple days later, I would give the students a chance to play a computer game involving addition. This makes learning fun and I think they get more out of it!

English – computers can be used to practice and reinforce what the teacher taught about such things as parts of speech. Students can use computers to publish creative writing stories including graphics.

Math has always been a hard subject for me in high school. I remember in middle school we would always use the computer lab to help us with our math and to introduce us to new things. This always helped me because I am a visual learner and I have to see it being done in front of me at my pace. If I needed to see it being done again, all I would have to do is click a button and I could see it again. This helped me out in a lot of ways and made it seem more like a game than just doing math problems.

To do a math lesson on probability, I might use Power Point. This would help all the students see and figure out the probability of dice being rolled at random. Sometimes seeing things makes it easier to comprehend.

Spanish – perhaps do a matching activity with vocabulary and pictures which keeps a print total for correct answers and rewards the child in the end. Certain games could be used to facilitate the lesson or review for a test.

Science (Anatomy) – You could get a software program that is geared toward scientific learning, and have students explore its features, and have them follow it along with a book.

English writing paper. The kids learn keyboarding skills along with being able to spell. Also they learn and develop skills for good writing.

In the history class I plan to teach, I would incorporate the computer by using websites. In history the more resources you have, the easier it is to gain an overall view of a topic. So I would encourage and demand that my students get information for assignments not only from periodicals but from websites as well.

I might create a lesson in English on finding books on the net. I don’t think computers should be used much to teach a lesson. Too many teachers are taking out the personal aspects of the classroom and turning it into a technology-based center of learning. I think it is important to know how to use a computer, but that is where computer classes come in. Don’t over use them — it’s the easy way out.

Research Question 3: What do the data suggest about preservice teachers’ preconceptions about the role of the computer in the classroom?
The content analysis of the preservice teachers' narratives indicates that preservice teachers possess naïve conceptions of computer use for effective classroom learning. Fifty-eight percent of the narratives described simplistic uses of the computer (as defined by Hooper & Thomas, 1990). That is, the preservice teachers view the computer as a device to supplement traditional teaching methods. Several of the examples included above describe using the computer to complete tasks that are possible without the computer (e.g. practicing addition skills, sustain vocabulary skills, reinforce basic writing techniques, etc.). In addition, several of the examples described using the computer as a device to teach with (i.e. a presentation device).

Twenty percent of the narratives described using the computer as a tool to manipulate subject matter. For example, several participants depicted writing papers, finding resources, and developing spreadsheets as appropriate ways to use the computer to bring about effective classroom learning.

The researchers were surprised at the number of preservice teachers who described advanced ways of using the computer to support learning. To better understand this result, the researchers compared the data of these 39 preservice teachers with the data from the larger study. Specifically, we examined the following variables: experience with computers in education, attitudes towards computers, computer proficiency, and beliefs about knowledge acquisition. No significant differences were found between the two groups.

Conclusions

The intent of this study was to better understand preservice teachers' preconceptions about the role of the computer in teaching and learning. The content analysis procedure was an effective method to characterize the participants' conceptions.

The results of this study are consistent with the larger study of which this research was a part (see Sadera & Hargrave, 1999). Preservice teachers possess naïve conceptions of how the computer can be used to bring about effective classroom learning. Their conceptions are consistent with didactic, objectivist views of teaching and learning and support traditional teaching methods.

Clearly there is an increasing need for teachers who can effectively integrate computer-technology to create meaningful learning environments. Given the results of this study, teacher educators need to devise instructional strategies that will assist preservice teachers in developing more comprehensive views of teaching, learning, and the role technology can play in the classroom.

Flexible Delivery of Teacher Professional Development for Information Technology in Learning

Glenice Watson
School of Curriculum, Teaching & Learning
Griffith University
Australia
G.A.Watson@mailbox.gu.edu.au

Abstract: This paper compares the experiences of undergraduate education students on two university campuses who experienced an introductory information technology subject using different methods of flexible delivery. The paper analyses differences in the perceptions of the students on the two campuses as evidenced by a subject evaluation survey administered in the final week of the subject. Students at this level, express greatest satisfaction with subject delivery when it incorporates adequate human and technological support accompanied by online resource material.

Introduction

Subject delivery is key to student engagement with the subject content. It impacts not only on what students learn but also on their attitudes and beliefs about the subject area. In response to community, commercial, employer and parental pressure, teachers are being required to implement teaching practices that incorporate information technologies. The attitudes and beliefs that teachers have about using information technologies to enhance learning will be influenced by their experiences in their pre-service education degree study. This paper compares the experiences of undergraduate education students on two Australian university campuses who experienced an introductory Information Technology (IT) subject using different methods of flexible learning.

"Flexible learning" is one of those terms that everyone uses but nobody agrees on its exact meaning. For example, Louise Moran (1996) contends that “Flexible learning is multi-dimensional and does not lend itself to a neat, one-line description” while Rachel Hudson et al. (1997) suggest that “There is a confusion in the minds of practitioners between the terms open, distance, flexible and resource-based learning” (p.2). However Peter Taylor and Gordon Joughin (1997) are clear that flexible learning “prioritises learner control over the requirements of institutional practices”. They claim that flexible learning “focuses the design of courses and subjects on how students will engage in learning activities ... and how their participation and learning will be supported” (p.2, emphases in original).

Flexible learning in higher education has been a response to a number of factors. Hudson et al. (1997) include the following: pedagogy, cuts in funding, increasing diversity of students, equal opportunities, labour market requirements, and the demand for transferable skills. But most importantly in these factors have been IT improvements making available a range of delivery genre (including traditional print materials, video, audio tapes, Compact Disc based multimedia, and Internet delivery), and the huge increase in home ownership of computers and access to the Internet.

In the University in which this study was carried out, considerable resources were made available to allow all subjects on a new campus to include Internet delivery and it was strongly suggested (but not mandated) that subject convenors avail themselves of this option. Inclusion of Internet delivery for at least some aspects of the course was further encouraged by the ready availability of high-end computers for student use. This made possible the cross campus comparison of student’s perceptions within the same subject that is the focus of this study.

While there is a fairly large literature on flexible learning and what it entails (see for example McGinnity et al., 1999 and Niklova & Collis, 1998) there has been less discussion on evaluating programs and subjects that employ flexible delivery methods, particularly where on-line (Internet) genres are used. This is probably because flexible learning using on-line facilities is still in its infancy. Diana Laurillard et al. (1997) suggest that “While perhaps the most judicious reason for evaluating an educational program is
to improve it”, there are a number of other reasons for evaluating that might include informing interested
parties, encouraging others to adopt similar methods, throwing light on innovative programs, and
determining effectiveness. To these I would add determining student satisfaction. Students are becoming
increasingly informed consumers of university courses and competition for students between universities is
fierce. Therefore we should not be embarrassed to admit that one of our primary goals in educational
evaluation is to determine student satisfaction and find ways of enhancing it – along with our usual
pedagogical goals of course.

About the Subject

The evaluation that this paper is based on was concerned with the subject Learning with Information
Technology. This is a first semester, first year subject in an initial teacher education program. The subject
is designed to introduce students to aspects of IT relevant to teaching and learning. The subject was
conceptualised in three parts – Concepts and Ideas, Applications, and Developing Assignments. The
students were supplied with detailed Subject Profiles that explained the rationale, concepts, delivery,
timetable, requirements and assessment items for the subject. The subject was taken by 350 students at
Griffith University, Australia, comprising a cohort of 81 students on the Logan campus and 270 students on
the MtGravatt campus. Logan campus is a new campus that specialises in flexible delivery. MtGravatt
campus is a traditional campus that has its origins as a College of Advanced Education. On the MtGravatt
campus the Concepts and Ideas aspect of the subject was delivered via one-hour lectures in a lecture
theatre. In addition a one-hour tutorial in a computer laboratory addressed the Applications and
Developing Assignments aspects of the subject. All aspects of the subject were supported with online
material. On the Logan campus the students had the same online material available to them plus a two-hour
workshop in a computer laboratory but no lecture. The workshop dealt with Applications and Developing
Assignments aspects of the subject. The Logan students had a Book of Readings available for purchase through the campus
bookshop. The Concepts and Ideas section of the subject was studied independently by the students using
the online material and the Book of Readings.

The student populations on both campuses were essentially the same with 86.30% of the Logan
population and 90.91% of the MtGravatt population being female. This is in keeping with the highly
feminised (and increasingly so) nature of the teaching profession in Australia. 58.44% of Logan students
and 57.99% of MtGravatt students are under 21 years of age but there is a significant component of older
students in both populations with 22.08% of Logan students and 19.18% of MtGravatt students being 30
years of age or older. The biggest difference between the two populations was in the number of immediate
family (parents, siblings, children) who had attended university (see Figure 1). At Logan 70.13% of
students had no immediate member of the family who had attended university compared with 46.12% of
MtGravatt students.

![Family attended university](image_url)

**Figure 1**: Number of immediate family who had attended university.
The Survey and Results

The perceptions of the students on the two campuses were ascertained from a subject evaluation survey administered in the final week of the subject. The survey consisted of questions concerned with the subject in general, the format of the subject, and about them as students, as well as a rating for the subject and the tutor and open ended questions concerning the strengths and weaknesses of the subject. The surveys administered on the two campuses were essentially similar with minor modifications to allow for the differences in subject delivery on the two campuses.

Subject Satisfaction

The students were asked to rate the subject from 1 (Low) to 7 (High). A result of 7 would indicate that all students rated the subject High. Table 1 shows the differences in the student satisfaction with the subject on the different campuses. At the Logan campus the subject was rated at 4.70 and at the MtGravatt campus the subject was rated at 3.84. It is clear from this result that the Logan students rated the subject more highly than the MtGravatt students yet the content and assessment of the subject on both campuses were identical. The only difference between the campuses was in delivery.

</table>

Table 1: Difference in subject satisfaction between campuses

General Statements about the Subject

On the survey there were four statements about the subject in general. The students were asked to enter a number against each statement from a rank of 1 to 7, where 1 represented ‘strongly disagree’ and 7 represented ‘strongly agree’. Therefore a result of ‘7’ to a question would indicate that all students strongly agreed with the given statement. The comparative results between campuses for general perceptions about the subject are shown in Table 2.

<table>
<thead>
<tr>
<th>Statement (1 Strongly disagree – 7 Strongly agree)</th>

<td>4.05</td>
</tr>
<tr>
<td>The assessment in this subject was an important part of the total learning experiences in this subject</td>
<td>4.73</td>
<td>4.30</td>
</tr>
</tbody>
</table>

Table 2: Comparative results between campuses for general perceptions about the subject

The first statement was intended to gauge the students’ belief in the relevance of a subject about learning with IT to their professional life as a teacher. The results (5.14 at Logan and 5.12 at MtGravatt) show that the students have a clear understanding that the subject *Learning with Information Technology* was relevant to them as future teaching professionals. There was little difference (0.02) between the two campuses. The second statement on the appropriateness of the subject to the students’ backgrounds was less positive and the Logan students rated this statement negatively (3.5 being the mid-point). There was also greater difference (0.27) between the campuses. As the students did essentially the same work on both campuses this seems to suggest that the students on the Logan campus came into the subject less well prepared with respect to IT skills. This was borne out in the data collected from a survey conducted with these students at the beginning of the semester where they were required to rate their competencies with a range of applications (email, word processing, Web searching, presentation software, spread sheets, databases, desk top publishing, multimedia development and Web page development). In all applications (except for word processing which they rated equally) the Logan students rated their competency lower than the MtGravatt students. With respect to the third statement concerned with gaining competencies for
teaching within the context of the subject, there was strong support (4.58 at Logan and 4.05 at MtGravatt) with a difference between the campuses of 0.53. When read in conjunction with the previous statement these figures suggest that Logan students were more positive about this statement because they learnt more, possible because they knew less to start with, or because the learning experience was more conducive on the Logan campus.

**Statements about Subject Delivery**

The format of the statements about subject delivery was the same as for the general questions, that is a score of '7' would indicate that all students 'strongly agreed' with that statement. Because of the differences between the delivery methods on the two campuses there were variations in some statements between campuses. The results are shown in Table 3.

<table>
<thead>
<tr>
<th>Campus</th>
<th>Statement (1 Strongly disagree – 7 Strongly agree)</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logan</td>
<td>The online Concepts and Ideas material provided me with stimulating ideas and foundation theories about learning with information technology</td>
<td>4.19</td>
</tr>
<tr>
<td>MtGravatt</td>
<td>The lectures provided me with stimulating ideas and foundation theories about learning with information technology</td>
<td>2.82</td>
</tr>
<tr>
<td>Logan</td>
<td>The structure of the online Concepts and Ideas material was easy to follow</td>
<td>4.30</td>
</tr>
<tr>
<td>MtGravatt</td>
<td>I found the online concepts and Ideas material useful</td>
<td>4.26</td>
</tr>
<tr>
<td>Logan</td>
<td>I would prefer to attend face to face lectures rather than have this material presented in online material</td>
<td>4.30</td>
</tr>
<tr>
<td>MtGravatt</td>
<td>I prefer to use the online material than attend lectures</td>
<td>5.31</td>
</tr>
<tr>
<td>Logan</td>
<td>I would prefer to have both face to face lectures and online material</td>
<td>5.02</td>
</tr>
</tbody>
</table>

**Table 3: Results for statements about subject delivery.**

One of the major differences between the delivery on the two campuses was in the presentation of lectures concerned with the Concepts and Ideas of the subject on MtGravatt campus while on Logan the students studied this aspect of the course independently using the online material and a Book of Readings. It can be seen that the Logan students expressed greater satisfaction (4.19) than the MtGravatt students (2.82) but they also expressed a preference for attending lectures rather than having the online material (4.30) and for having both lectures and online material (5.02). In contrast the MtGravatt students expressed a preference for online materials rather than lectures (5.31) and in fact when they found that the lecture material was available online a large number simply did not attend the lectures.

**Statements about Computing Competencies**

The statements that related to computing competencies gained as a result of the subject took the same format as those about the subject delivery and the general statements about the subject. Again there were some differences between campuses because of the variation in delivery. The results are shown in Table 4.

**Table 4: Results of statements about computing competencies.**
The students gained computing competencies during workshops/tutorials and via online tutorials and independent practice. At Logan there was a two hour weekly workshop while at MtGravatt there was a one hour tutorial. It can be seen from Table 4 that the Logan student expressed a greater confidence about using IT in learning. This is important when compared with the lower rating they assigned to their IT competencies when entering the subject. This more positive result is also reflected in their response to the second statement in Table 4 regarding their workshop being a useful experience for learning practical aspects of learning with IT. The negative result (2.34) for the MtGravatt students’ satisfaction with their one hour tutorial makes it clear where the source of their dissatisfaction comes from.

Statements about resources

The survey included statements about resources because there were considerable differences between the two campuses in terms of resources. Statements on this topic took the same format as the previous three sub-sections. The results are shown in Table 5.

Table 5. Results of statements about resources

The Logan students were much more positive about being able to access a computer whenever they wanted to (5.37) compared with MtGravatt students (3.69). The Logan students found their Book of Readings useful (4.71). This was made available to the Logan students because the library facilities on their campus were new and did not have the same book and journal resources of the MtGravatt library. However the MtGravatt students expressed a strong desire (5.04) to have a Book of Readings made available to them as well. Surprisingly the MtGravatt students did not seem to be concerned about the sessional nature of their tutors that resulted in their not being able to have face-to-face contact with their tutor between tutorials. They did have the compensation that as subject convenor I was available to them on their campus four days a week (the fifth was spent at Logan campus).

Conclusions

Evaluating subjects is always a sobering experience for academics – well it is for me anyway. Preparation for this subject had been enormous and had taken over six months. I had the solo task of preparing the Subject Profiles, the Book of Readings, all online material and lectures and then delivered the lectures, took one workshop group and managed four sessional staff on two campuses as well as dealing with all convenorship duties entailed in a subject with 350 students. To say that I was not overjoyed at the outcome would be an understatement, but in some ways I was probably not surprised. For example I was well aware that there would be problems with the lack of computing resources on the MtGravatt campus. This had been the reason that the one-hour tutorials had been scheduled in preference to two-hour tutorials - it had simply been impossible to timetable that number of hours in the available computer laboratories. This of course had the further consequence that there was little available time for students to do independent work in the computer laboratory. This problem is easy to solve by increasing the computer/student ratio and the university has undertaken to do this for the next cohort.

A more difficult question is the value of the flexible delivery. Admittedly, the subject evaluation survey was a fairly shallow attempt to gauge the student preferences with regard to online material compared with more traditional delivery methods such as lectures and tutorials. It did little to gauge the efficacy of the methods with respect to the learning that took place, except in so far as it rated students’ beliefs in their own confidence and competence to use IT in their teaching profession. Certainly there was a more positive result in this regard on the Logan campus but this is more likely to have arisen from the
difference in workshop/tutorial time allocated on the two campuses and the availability of computers for independent practice. The university has considerable investment in the online material that included not only my time in developing the materials, but also the services of the Flexible Learning unit of professional Web designers, programmers and technicians that had the responsibility for Web mounting the subject materials, as well as the infrastructure costs in computers and communication technology. The students clearly valued the online material but only as a suite of possible delivery methods of which face-to-face contact with a lecturer or tutor was the most important. What the online material does is provide a backup for the students where they have chosen to miss lectures for whatever reason and to reassure them that they all have available to them the core of the material regardless of differences between tutors. From the staff perspective, it is an advantage to be able to direct students to online material rather than have to provide personal tuition when special circumstances arise but at this stage the investment in my time comes no where near equalising this advantage.

My limited appreciation of online support for this first year undergraduate subject of internal (that is on-campus) students is not replicated however for post graduate external students. I also convene a Graduate Certificate of Computer Education that I made available via the WWW over the last two years. As a delivery method for these students, online materials have been an unqualified success and the course has attracted students from as far afield as New Zealand and Badu Island (a remote island in the Torres Straight to the north of Australia). It also does not apply to interactive components of the online subject delivery. All subjects I have Web mounted include a Forum (also called a threaded discussion or Web Board) where students can contribute comments or questions and read comments or answers from other students or staff. This has been an very useful for remote postgraduate students and was built into the assessment process for the undergraduate students who are the subject of this paper. Students were required to post their initial thoughts on various aspects of their group project on the Forum and their tutor gave them feedback on a weekly basis. This was a valuable developmental exercise for the students and improved the quality of their projects considerably but it is personally costly on tutors' time and needs to be well managed when used by large numbers of students such as a big first year subject.

So where to from here? With respect to the first year subject Learning with Information Technology, I have implemented changes that will see both campuses having a two hour workshop and a Book of Readings, neither campus will have lectures for the immediate future (a practical decision based on my absence from the university on sabatical) and the computing facilities on MtGravatt campus will be upgraded. With respect to the online material, further developmental work will be directed at improving interactivity as this is where the real power of online material lies. As for research, there is a huge need for in-depth work on the quality of learning that is taking place while students are engaged in interacting with online material, rather than just bowing to student preference or institutional dictates.

How Can Computer Based Visual Mapping Tools Enhance Learning with Pre-service Teachers?

Ian Brown PhD and Brian Ferry PhD
Faculty of Education
University of Wollongong
NSW Australia
ian_brown@uow.edu.au

Abstract:
Visual mapping tools are computer-based and are essentially two dimension and/or three dimension spatial arrangements of text and diagrams. Research has shown that these cognitive tools help teachers link curriculum content to instructional plans. Traditionally, it has been in the area of language and science education. This study extends this notion to include visual arts education. This paper will present the preliminary findings of a funded research study which used a visual mapping tool package in a visual arts studio setting with students training to be non-specialist teachers. The study highlights the benefits of these cognitive tools in allowing students to conceptualise and map their learning processes, while enhancing their visual learning.

Visual mapping tools are computer based, two dimension and/or three dimension spatial arrangements of text and diagrams. They have been used traditionally to link curriculum content to instructional plans, particularly in the areas of science and language. Research indicates that concept mapping is a reflective strategy to promote efficient and meaningful learning by connecting prior knowledge to new concepts. (Novak & Gowan 1984, White & Gunstone 1992, Ferry 1996a).

Concept maps use labelled nodes to represent concepts and lines or arcs to represent relationships between pairs of concepts. Studies by Novak & Gowan 1984; Gallard 1994; Ferry, Hedberg & Harper 1998 contend that concept map structures parallel human cognitive structures as they demonstrate how learners organise concepts. The use of concept mapping strategies with pre-service teachers has been acknowledged in the area of science education where researchers have reported how subject matter knowledge is organised. (Lederman & Latz 1995; Ferry et al. 1998).

While it has been recognised that concept maps act as tools to help learners organise their cognitive frameworks into more powerful integrated patterns, researchers such as Jegede, Alaiyemola & Okebukola (1990), Lederman & Latz (1995) and Ferry (1996b) contend computer based concept mapping goes further and assists pre-service teachers to organise curriculum content into powerful integrated frameworks. Importantly, Ferry et al (1998:2), argue that the process of concept map construction can stimulate a dialectic between curriculum content and pedagogical practice.

This paper takes the notion further and suggests that concept mapping can be employed by pre-service teachers to other disciplines, namely visual arts education, to actively develop understandings, map ideas and conceptualise meanings.

Creating Concept Maps

Six steps are recommended by Holley and Dansereau (1984) for learners to create concept maps. They are: selecting key concepts which is a recognition process which activates relevant knowledge and helps with topic identification; writing of the key concepts; listing the attributes of a key concept; forming spatial relationships which relate key concepts; rearrangement of the spatial representations; comparison of the representation to the text.
White and Gunstone (1992), suggest that a period of direct instruction is necessary for success before employing the process.

The following instructional steps are recommended by White and Gunstone (1992): use a small number of familiar terms with students so they can concentrate on the learning process; modelling by the instructor of the construction process; encourage students to record all possible links; provide constructive criticism by the instructor as it is unlikely that first attempts will produce successful maps; for first attempts suggested layouts are helpful; inform students that there is no single correct answer to the text.

The Concept Map Tool Used in this Study

The concept mapping tool used in this study was created using Inspiration®, using Apple Macintosh™ computers. These computers are used across the campus at the University of Wollongong. The pre-service teachers in this study had at least one course on the application of information technology to teaching and learning (fourteen two hour tutorials during their pre-service teacher training course).

The concept map tool is defined as a cognitive tool in this study. Jonassen (1991:2) defines cognitive tools as generalizable tools that can facilitate cognitive processing. According to Ferry et al (1998:3), cognitive tools are both 'mental and computational devices that support, guide and extend thinking processes of the user'. These tools are 'external to the learner and engage the learner in meaningful processing of information'.

The cognitive tool Inspiration®, allows the user to create a variety of visual diagrams. The four visual diagrams are: concept maps, ideas maps, webs and story boards.

Inspiration® defines:
1. A concept map as a hierarchical diagram used to represent a set of concepts beginning with the most general or most important and then working down to more specific detail. Key concepts are connected with links which may have descriptive words explaining relationships.
2. An idea map is a visual brainstorming technique used to generate ideas and develop thoughts. An idea map has the main idea located in the centre of the screen with sub ideas linked and radiating out.
3. A web has a main idea or core concept at the centre with different categories of information connected to it. Ideas, facts and information are connected to the categories to support them.
4. A storyboard is a visual way to organise projects and displays ideas at the beginning, middle and end.

Method

A number of broad areas for exploration were developed and investigated by the researchers. For the purpose of this paper, the following specific questions are addressed:
1. Do computer based visual mapping tools assist or hinder pre-service teachers to organise curriculum content and knowledge to be effective instructors?
2. When using computer based mapping tools to construct knowledge, do differences exist when applying subject matter knowledge to different subject disciplines, such as Science and Visual Arts?
3. Can the creative process in Visual Arts education be represented and deconstructed as a cognitive framework in the form of a visual map?

During the research study twenty four volunteer pre-service teachers enrolled in their final year of Bachelor of Education (Elementary) training were invited to:
1. compare the use of the visual mapping tool created by Inspiration® to plan instruction in Science and Visual Arts education
2. use the visual mapping tool created by Inspiration® to analyse and deconstruct the creative process

Instruction Provided
Half of the group were given direct instruction in a lecture theatre which contained computer projection facilities, where the program was demonstrated and modelled by an instructor. Half the group were given the User's Manual provided by Inspiration® and worked in pairs to gain knowledge of the package through a self-paced inquiry mode. (Note: the reason for the variation in instructional modes will form the basis for other research outcomes). Each pre-service teacher was allocated a computer but was encouraged to collaborate with their peers when constructing their visual maps.

Data Collection

Data was collected through three main sources, ongoing written personal reflections, analysis of the visual maps produced and interviews. Interview transcripts, written reflections and visual maps were coded and analysed for trends and emerging themes.

In relation to the reflective data, at the conclusion of each stage of the visual mapping process students were required to reflect and comment on their practice.

The reflective practice took three forms:
1. an open-ended reflection where students were asked in pairs to discuss and write about their thoughts and initial impressions concerning the use of the package,
2. an individual reflection where students commented on the use of the package in two situations
   - the visual mapping of prior knowledge of an artist and his/her work
   - the development of a personal artwork
3. a structured reflection where students were asked a number of specific questions (See Appendix 1 for questions)

Brief Description of the Study

Students were given four specific tasks to perform over an eight week period which involved either/or both Science and Visual Arts education.

They were:
1. to plan a short program of work for an elementary class, using the visual mapping tool package Inspiration®, to conceptualise ideas, organise content and knowledge
2. to research and investigate an artist and artwork, gathering and recording as much information as possible
3. to construct a visual map of the information and knowledge gathered in (2) using the visual mapping tool Inspiration®
4. to plan the development of a personal creative response (artwork) using the visual mapping tool Inspiration® to conceptualise and organise thoughts, ideas, materials and processes

Results

The results are organised by the three research question posed for this study. Part 1 presents and discusses the data and helps to clarify understandings on how pre-service teachers use visual mapping tools to organise content and knowledge. Part 2 presents and discusses data on how pre-service teachers use visual mapping tools to organise ideas and deconstruct existing knowledge in the Visual Arts discipline area. Part 3 presents and discusses data on how pre-service teachers use visual mapping tools to conceptualise, organise thoughts, ideas, materials and processes to develop a personal creative response.

Part 1: Do Computer Based Visual Mapping Tools Assist or Hinder Pre-service Teachers b Organise Curriculum Content and Knowledge to be Effective Instructors?

It was clearly evident that all students agreed that the visual mapping tool package Inspiration® assisted them with their organisation of curriculum content and knowledge. The students were able in a
very short period of time in visually representing their knowledge and conceptualising in both subject disciplines. Many students reflected that it provided a clearer way of thinking and more efficient. It allowed the students choice in changing thoughts, conceptualising and recording their ideas. The students unanimously agreed that they would use the package again to prepare and plan their pre-service university course work. Students made positive comments on the transferability to the teaching context. They believed that the visual mapping tools would enhance their abilities to be more effective instructors. These results are congruent with earlier studies conducted by Ferry (1996, 1997) and White and Gunstone (1992).

Note: a number of criticisms/annoyances were raised by the students about specific actions relating to navigation which occurred when using the package. These points will be discussed in detail later in the paper.

**Part 2: When Using Computer Based Mapping Tools to Construct Knowledge, do Differences Exist when Applying Subject Matter Knowledge to Different Subject Disciplines, such as Science and Visual Arts?**

After data analysis it could be concluded that the students felt that differences were evident between the two disciplines when using the visual mapping tool package Inspiration®. Students generally commented that at first differences occurred when planning instruction between the two disciplines, but later when attempting to conceptualise knowledge, greater differences were apparent. This could be possibly be attributed to the nature of the task. That is, in the Science activity and the initial Visual Arts activity, the pre-service students had researched the topic area which was to be visually mapped. While, in relation to the Visual Arts activity, the students were required to gather knowledge about an artist/artwork and visually map this. This required the students to make decisions, find categories, explore ideas, gather like concepts and represent them visually.

It is interesting to note that Inspiration® provides two main views or environments: Diagram view and Outline view. When in Outline view the main idea appears as text at the top of the outline while the supporting topics and subtopics follow in hierarchical order, where notes as text can be added. Students used this mode extensively in this study.

**Part 3: Can the Creative Process in Visual Arts Education be Represented and Deconstructed as a Cognitive Framework in the Form of a Visual Map?**

In this study students were asked to plan and develop an artwork using the visual mapping tool Inspiration® to organise their ideas and thoughts. The New South Wales Visual Arts syllabuses (Years 7-10 and 11-12) broadly organise and describe art practice under the broad headings of three kinds of artworld practice: artmaking, art criticism and art history. For the purpose of this exercise the basic tenets of this syllabus were applied relying on the area of ‘artmaking’.

A characteristic identified in the syllabus for the area of artmaking involves an understanding and application of a process. Students are required to utilise actions of exploring, developing and resolving. For this exercise the visual mapping tool was used at the ‘exploring’ stage of the process.

In this sense, when involved in the process of exploring, students were encouraged to think imaginatively, explore ways of looking, interpreting and responding to subject and forms. Students were required to make decisions about materials they might use or experiment with, the subject matter they might explore and the influences that impact on their ‘artworks’. In other words, butchers paper, scapbooks and pens or visual process diaries were replaced with a visual mapping tool for students to organise their ideas.

From the visual maps provided by the pre-service students in this study and the analysis of the results it appears that the creative process can be represented and deconstructed as a cognitive framework in the form of a visual map. It is the researchers’ belief that the development of and deconstruction/analysis of an artwork is a common practice in art education, but development of and deconstruction/analysis of an artwork using a visual mapping tool is a particularly unique phenomena.
In response to this activity one student stated:

'Inspiration allows the user to think visually, go off in any direction, and follow that idea to its logical conclusion, then come back to a past thought and go off in that direction. This is a great advantage as when someone thinks about a subject or topic they often come up with several ideas to follow, they then go off in one direction, often forgetting about their original thoughts, leaving them with a limited view of their subject. Another advantage is the ability to include notes behind the surface of the concept map allowing thoughts to be explained or expanded upon. Concept maps generally allow people to communicate their ideas to other people, this package helps do this in a very efficient and clear way.'

Other Areas of Investigation/Emerging Themes

This paper has only addressed a small area of the total research project. Other areas presently under investigation and proposed for future research include: the relationship between learning styles and the selection of visual mapping formats; the difficulties experienced in navigation by the pre-service teachers when using the visual mapping package, such as, screen size and printing problems; the problems of visualisation and the need for a package which could import visual or photographic images to enhance the deconstruction process; and the issue of cross-cultural applications when using the packages. In conclusion, further investigation, including the use of hyperbolic trees to present screen data, is being presently explored, as well as research to ascertain whether a particular learner, or learning style is better suited to this method of knowledge mapping.

Conclusion

In conclusion, a number of significant findings have been addressed in this research project. Students all agreed that the visual mapping package has enabled them to:

1. plan more efficiently
2. conceptualise their knowledge and ideas more clearly, allowing them to use the process successfully in two subject disciplines
3. make their thinking processes more explicit.

Abstract: Faced with a 23% population increase during the 1998-1999 school year, the faculty of a small rural K-12 Wyoming school realized that major intervention efforts would be needed to facilitate the absorption of the new students. The plan was to adopt a school-wide code of conduct: the law of kindness, and utilize the involvement of a student teacher in the language arts department, with the promotion of multi-media activities which would encourage students to express beliefs and values about interactions with each other in creative and interesting ways. The student teacher was involved in providing instruction in multi-media applications skills development as well as facilitating student project development. Various computer applications utilized in the classrooms provided the students a creative and challenging medium by which they could demonstrate concepts learned in morals and ethics, through multi-media presentations at a bi-annual celebration of the arts: the 15th all-school Drama and Fine Arts Festival.

Introduction

This project took place in Rock River School, in Rock River, Wyoming. This K-12, isolated rural school had a student population of 116 at the end of the 1998 school year. At the start of the 1998-1999 school year, the population rose to 152. The school was enrolling significant numbers, proportionately, of new students from four different locations, who were all choosing to come to RRS for different reasons. The faculty knew they had to assist with the absorption of the new, diverse student population, or serious fragmentation of the student body would take place. At the same time, the school was notified that it had been a grant recipient of a large sum of money that was intended for the development of curriculum to teach morals and ethics. In addition, the school was notified that a student teacher from the University of Wyoming would be placed with Rock River's language arts teacher. The faculty elected to use the grant initiative as well as the services of the student teacher, as two approaches to solving the problem of helping the new students mesh with the old-timers. Representatives from the University of Wyoming College of Education were recruited to help determine if direct instruction in the teaching morals and ethics through multi-media did have an impact on the students. The student teacher, who had already earned a master's degree in American Studies and was just completing his teacher certification, was most intrigued with the concept of

1374
attempting direct instruction in morals and ethics. The purpose of the research was to
determine whether or not interventions based on direct instruction in morals and ethics,
which were demonstrated through multi-media, had a meaningful impact on a significant
number of the students. The basis of the data collected was transcribed student interviews
and written commentary from student reflections, primarily taken from the language arts
classroom and also from the music classroom. In addition, anecdotal statements from the
principal regarding school discipline were solicited. Also, selected teachers offered
reflections about the impact of the initiative.

Background

Rock River School, a small, isolated rural school in Wyoming was facing a 22%
increase in student population. Large groups of students were choosing to come to RRS
for different reasons. One school located to the north of RRS, in a different county,
closed down and their secondary students were going to be bused elsewhere. RRS was a
viable option for those students. RRS serves as the secondary school for many of the
area ranches, and a group of those students matriculated to the 9th grade (i.e., finished
with their elementary education on site on the ranches). Also, RRS serves as the
destination school for selected K-12 students bused from Laramie, 40 miles to the south,
who want the “small, rural school” experience. Working all of those distinct groups into
the RRS mainstream was going to be a challenge. At this time, as a part of a grant from
Reader’s Digest and DeWitt Wallace Corporation, the school agreed to develop a
curriculum designed to provide direct instruction in morals and ethics. The initiative in
morals and ethics instruction seemed to provide the framework to address the needs. Six
classroom teachers elected to participate in the grant activities: Language Arts, Family
and Consumer Science, Art, Music, and Health. A student teacher from the University of
Wyoming, who was assigned to the language arts classroom, joined the team and
participated in all aspects of the grant initiatives. Through work in using various
computer applications in the language arts classroom, he assisted students in preparing
their multi-media presentations about what they learned about morals and ethics. In
addition, by the time he was done, he used multi-media to prepare his own professional
portfolio that is required by the College of Education as a graduation outcome.

Procedure

Six classroom teachers in the RRS secondary addressed morals and ethics in their
lessons during the year. In the English room, a literature-based approach to morals and
ethics provided numerous examples of stories, plays and essays that raise moral
questions. Students were given the chance to reflect (in various ways) about the moral
questions raised by the literature. The moral issues raised by student publications were
examined. In addition, the students created mini-dramas that reflected the moral and
ethical choices and consequences, and then used them as videos in their multi-media
presentations. The student teacher was instrumental in helping the student write the mini-
scenes, rehearse them, film them, then capture the video to include in their multi-media
presentations. In the Business class, morals and ethics in the workplace were examined.
A first-ever “mock trial” was staged to examine morals and ethics pertinent to business
law. In the Family and Consumer Science class, students were asked to determine how universal values affect their self-concept and personal feelings of self-worth. In Health class, the morality of the drug culture was examined. In Music, through the vehicle of two country-western songs, students examined and reflected on the impact of music that is designed to teach morals and ethics. The two songs are “Don’t Laugh at Wills and “Random Acts of Senseless Kindness” by South-Sixty Five. In the Art class, various unusual cultures were examined for their unique contributions to the human condition.

School-wide Projects Attempted

At four different times during the school year, the entire K-12 student body was called together for projects designed to apply morals and ethics. The first project was building team work, after an especially long and tiresome discussion of the student handbook on the first day of school. The students were placed in groups by random numbers, and those groups comprised the first sports teams of the school year. The second school-wide project was called “adopt -a -disability- for -a- day- and -rel[y- on- a-trust-partner- to- help- you- through- the- day.” The students were paired, and then each set was given a contrived “disability.” Some were partially “blinded” with glasses made from waxed paper. Some lost the use of hands; some were in wheel chairs. Some had ear plugs because they were “deaf,” and some had to wear weight vests with an extra 50 pounds in them. The third school-wide project was “I Am a Member of the Seventh Generation.” The students heard the Native American myth of White Buffalo-Robbed Woman, who in the past had taught Native Americans how important it was to care about future generations, those seven generations in the future. The students were paired with elementary students, and they were asked to get to know children who they didn’t know or who were new to the school. The activity was especially meaningful, because one of the senior boys, the salutatorian of the class of 1999, himself was a member of the Northern Arapahoe nation. He presented the myth of the White Buffalo-Robbed Woman to the students. He was an especially well-liked student who practiced daily morals and ethics with his fellow students, as though they were second nature to him, because they were. The students listened when he spoke, and they took his words to heart. The final project was the 15th RRS Drama and Fine Arts Festival, where students showcased much of the learning that went on during the year, through the performing arts. For example, advanced technology taught by the student teacher in the language arts classroom, was used to showcase the 7th and 8th grade examination of health-related issues. The theme of the Drama Festival was “Teen Choices and Consequences.” The Drama Festival had K-12 involvement.

Tools Used

In order to create the student mini-scenes that were a part of the 4th quarter Drama Festival presentation for the 7th and 8th graders, the student teacher and students used Microsoft Works and Microsoft Word to write and edit the scripts. One critical piece in this entire project was the ability to edit the scripts down to a manageable size. At first
the students had trouble with the editing, but after they saw the size of their video clips, they understood the reason for the critical, discriminating editing. After filming on to tape from a Sony Panasonic Camcorder, the student teacher used Adobe Premier to edit the small scenes. The presentational vehicle used was Hypercard 2.3. The choice to use Hypercard rather than a more difficult presentational package was a conscious one. The students would have to prepare their presentations on LCII and LCIII computers available to them in the school’s one Mac lab. While some applications such as Hyperstudio and Powerpoint were available on some machines, they are not available on all of them. In the next step, the abbreviated, edited videos were added to the Hypercard stacks on the G3 or the Powermac 7500 with a G3 processor, which are located in the English room. The student teacher was able to arrange a workable schedule for each of the 4-member student groups in grades 7 and 8 to get their turn on the two high-powered machines available. While using the tools, the students learned many lessons in group dynamics, collaboration, and team work. The student teacher once told me about some friction among some seventh grade boys, and his response was, “No, you can’t quit the tour just two days before the show.”

Conclusions

In order to determine the success of the instruction in morals and ethics, several procedures were used. First of all, after every school-wide event, students were randomly placed in “debriefing” groups, and with a teacher-leader, their feelings were aired and examined. A secretary for each group recorded observations. Then those thoughts were shared with the K-12 population of the school. Because of the student teacher’s presence in the building, the faculty was able to divide the groups by one additional member, which further allowed the student teacher to be involved in the entire grant initiative. Further, at two times during the school year, Dr. Carol Bryant from the University College of Education came and interviewed a random selection of students about their thoughts on the effort. Those interviews were taped. The six teachers on the grant committee each submitted questions and likely student interview subjects, without collaboration among the members. The interviews revealed that students were really thinking about their actions before they took them, and many commented that they were more aware of kindness and compassion in the school. In English class, end-of-year reflections of the meaning of the initiative became the subject matter for final compositions. The student teacher pre-taught, assisted with the composition, and then evaluated the student written work. During the fourth quarter of the school year, a small contest was organized by the Student Council to determine the students who could demonstrate “random acts of senseless kindness” and be observed by an adult in the building. The senior class won the competition, and then instead of “blowing” the $100.00 cash prize on their senior trip, they elected to host a bar-be-que for the faculty and staff on graduation day. In a closing interview, Principal Charles Cashman commented that serious discipline problems had gone down, and the number of serious suspensions also was significantly reduced from previous years.

During the interviews, students were asked if they thought the emphasis on the Law of Kindness made a difference in the school. Student responses were analyzed for
indicators of change in attitude and responsiveness to the project. Student responses to the questions, as well as personal reflections at the end of the year, were generally positive for the impact of the initiative. Sample comments from the end of the school year included:

SY, 9th Grade: "I also learned to be kinder and to be more patient....but because of this activity, I understand how much the teachers were stressing kindness and I tried harder to be a better person."

MW, 9th Grade: "I have become really comfortable in this school."

BR, 9th Grade: "The grant taught me that kindness is an important element in this day and age. I think almost everyone learned something from it."

However, not all students felt the same.

KL, 8th Grade: "The most important thing I learned this year is that no matter how much teachers preach about kindness, all ages will still be cruel. All year long, the teachers here at RRS have spoken of kindness. Few, if any, have listened."

Further, the integration of multi-media in the English classroom, implemented by the student teacher, created a high level of motivation among students to seriously consider the morals and ethics lessons associated with the grant initiative. When multi-media projects were begun, student discipline incidents diminished, students came in for extra time and assistance, and they were actively engaged in the learning process. The student teacher discovered that the project approach using multi-media was a viable teaching technique that could be managed, even by a pre-service teacher.

Implications of the Entire Initiative

1. The grant monies provided special, unique opportunities for the students and teachers of RRS.
2. The grant initiative did indeed bring diverse faculty members together, out of necessity, to organize the activities. Those who would not normally keep company with each other, found themselves bonding with peers out of their normal group of friends.
3. The student teacher was able to build and maintain relationships with teachers who taught out of his discipline area, who also worked on the grant initiative. The interactions were positive and helped him develop a more global perspective of what the school was trying to accomplish.
4. Direct address of morals and ethics had an impact on many students. However, there is still work to be done.
5. Because of his computer training at the University of Wyoming, the student teacher was able to provide assistance in the classroom with the students with various computer applications in a meaningful way.
6. Student teachers must be trained to integrate various computer applications and technology into daily lessons.
7. Student teachers must be trained in team-building, collaborative learning activities that may be out of the normal range of teacher activities.
8. Student teachers must be trained to use a project approach when appropriate.
9. Student teachers must be trained to use a project approach when appropriate.
10. Student teachers must be able to manage a project approach to various activities and not be threatened by such activities.

11. Student teachers must be willing to spend the time necessary to learn what new information is required of them, regardless of the time it takes.

12. Direct school-wide activities about morals and ethics, including activities to share feelings after an assembly, allow for good interaction among students.

13. Random selection of students for various groups involved with the grant initiative forces students to interact out of their typical groups.

14. The initiative must be continued in future years... students, staff and principal felt that way. Now the education must go on because it is the right thing to do, and not because there is a price tag attached to it.

Selected References

Two distinct sources were used as the foundation for the project. The teachers used these sources as guidance in some of the planned activities with the students.

Brooks, David and Frank G. Goble. The Case for Character Education: The Role of the School in Teaching Values and Virtue. (1998). Brooks provided an answer to the doubters who question “whose values” are to be taught. Brooks identified values common to humanity, that transcended diverse cultures.

Glickman, Carl D. Revolutionizing American’s Schools. (1997) Glickman stressed the importance of fostering democracy in schools and of learning to live productively in society. Glickman advocated that all teachers should examine their practices for democratic overtones.
Preparing Teacher Candidates for the Integration and Implementation of Appropriate Technology: A Triad Approach

Dr. Trena L. Wilkerson
Department of Curriculum and Instruction
Baylor University
United States
Trena_Wilkerson@baylor.edu

Abstract: This paper is a description of initiatives in one teacher preparation program to prepare its candidates for the integration and implementation of appropriate technology. The paper will include descriptions of specific assignments, projects, and learning experiences designed to engage the teacher candidates in enriching technological experiences to enhance their own learning while at the same time serving as a model for teaching. The technology integration approach implemented focuses on a triad model that identifies three areas of technology infusion: communication, productivity, and research/instruction. This triad model demonstrates one approach for designing curriculum and appropriate experiences in a teacher preparation program that provides hands-on experience.

Introduction

Teacher education programs are faced with the challenge of preparing candidates for a technology-rich teaching profession. With innovations in technology growing exponentially and current research in teaching and learning advancing, the challenge can be quite daunting. Accreditation agencies such as the National Council for Accreditation of Teacher Education (NCATE, 1997) and discipline specific organizations such as the National Council of Teachers of Mathematics (NCTM, 1989) have proposed guidelines for preparing future teachers in the use of technology for instruction. These guidelines emphasize the importance of the appropriate use of technology for teaching and learning in both content and pedagogical studies for teacher preparation.

The International Society for Technology in Education (ISTE, 1996) proposed educational technology foundation standards in three areas: Basic Computer/Technology Operations and Concepts, Personal and Professional Use of Technology, and Application of Technology in Instruction. ISTE advocates that teacher candidates should be able to use a variety of software and technology tools to communicate, solve problems, and support instruction in their grade levels and subject areas. These guidelines provide a framework for teacher preparation programs and higher education faculty to build exemplary certification programs to prepare future teachers for the appropriate use of technology.

In 1996 President Clinton and Vice President Gore unveiled the Technology Literacy Challenge (U.S. Department of Education) that advocated a 21st century where all students in the United States would be technologically literate. The challenge outlined four goals to address an aggressive technology vision. The goals focused on teacher training and support, computer access, internet accessibility, and appropriate integration of instructional software. Woven into those goals were strong implications for teacher preparation programs to provide innovative technology instructional experiences for its candidates.

At present most preservice teachers know little about how to use technology effectively for instruction (Willis & Mehlinger, 1996). A recent survey of teacher-preparation institutions conducted by the International Society for Technology in Education, commissioned by the Milken Exchange on Education Technology (Moursun & Bielfeldt, 1999) revealed that teacher preparation programs do not provide their candidates with sufficient experiences to prepare them to use technology effectively in their classrooms. The greatest problem lies not in the availability of technology, nor in the actual technical use of the
technology, but in the integration of technology in curriculum and instruction. The survey further found that most preservice teachers do not ordinarily use technology during field experiences and that university faculty do not model the use of technology routinely. The report proposes a more integrated model for the effective use of technology in instruction with both student teachers and faculty applying integrated technology.

The University of Georgia's efforts to integrate technology into their teacher education program (Schrum & Dehoney, 1998) demonstrate that with support, modeling, and proper training preservice teachers can experience success in using technology. They found that attitudes toward the use of technology improved and confidence in their own abilities to use technology increased. The preservice teachers also were able to articulate potential uses of technology for their future classrooms. Efforts such as this indicate that teacher education programs must move to a level of integration of technology for their candidates to be prepared to use technology effectively for instruction.

This paper will describe initiatives in a university teacher preparation program to prepare its candidates for the integration and implementation of appropriate technology. Descriptions of specific assignments, projects, and learning experiences designed to engage the teacher candidates in enriching technological experiences to enhance their own learning while at the same time serving as a model for teaching will be included.

The Triad Model

The technology integration approach implemented focuses on a triad model that identifies three areas of technology infusion. The triad categorizes the three areas as communication, productivity, and research/instruction. The triad model (Fig. 1) applies to discipline specific methodology courses, general curriculum courses, and practicum experiences such as student teaching. Over the past four years modifications and revisions based on ongoing research in classroom practice have provided an experiential foundation for the integration of technology in both coursework and field experiences of teacher candidates.

The teacher candidates engage in authentic learning experiences where technology is a tool among many other resources that is provided as a venue for learning. The triad model is used to illustrate that the three components of communication, productivity, and research/instruction are interrelated. Linkages between the triad components are essential for the understanding of the model and the true integration of technology in instruction.

![Figure 1. TRIAD MODEL: INTEGRATION OF TECHNOLOGY IN A TEACHER PREPARATION PROGRAM](attachment:figure1.png)

Communication Component
Appropriate use of technology can facilitate communication between and among various groups involved in teacher preparation programs. Both e-mail and video conferencing were used as tools for communication between preservice teachers, university instructors, and curriculum experts. Preservice teachers at the university used e-mail as an avenue for communicating with their peers located at the same university, as well as with other students involved in teacher preparation at universities in other states. These experiences began with direction from the instructor with various guidelines for implementation. The students began to branch out on their own and use the e-mail vehicle for continued collaboration and support. Results showed that the students continued the dialogue more within their own university than across states. Future collaboration with teacher preparation candidates in other locations needs to be more structured with sufficient time given for the communication.

The use of e-mail also facilitated communication between the preservice teachers and the university instructor. Not only were there required assignments such as reflective journaling while completing field experiences, utilizing e-mail communication but the e-mail vehicle continued to be used by the preservice teachers as a means of support for both course work and field experiences. It was found that this means provided immediate feedback for timely communication. After the field experiences and course work many students continued to make the connection with the instructor through the use of e-mail. This has given them useful support and feedback.

At the university a video conferencing session was held with one class of preservice teachers enrolled in a secondary mathematics methods course. The group participated in a discussion with the author of the text used by the students in the course. The class prepared for the experience by developing questions and topics to engage the guest curriculum expert dealing with issues related to the text and course. The guest author made a brief presentation, addressed various questions from the students, and engaged the students in a discussion of current topics in the field of mathematics education. The students noted that this experience not only gave them an opportunity to interact with an expert in the field whom they might otherwise not encounter personally, but also modeled a use of technology that they may use in their own classrooms in the future. The preservice students were able to relate both technical and curriculum issues in utilizing such technology.

Both the experiences of e-mailing and video conferencing provided a wide range of opportunities for the preservice teachers to engage in professional dialogue with colleagues. They were able to identify benefits and issues related to the use and implementation of such technology for their own future use as teachers. Communication was modeled through an integrated approach.

Productivity Component

According to Forcier (1996) the computer can be seen as a "multifaceted tool" (p. 2) and serve both teacher and student as a productivity tool. His reference includes both personal and instructional productivity for the user. In the Triad Model productivity refers to personal productivity and support of instruction. Actual classroom instruction is addressed in the third component of the Triad Model - research/instruction. Computer technology was used by the preservice teachers at the university for personal productivity in the form of word processing, e-mailing, and presentation software packages. While word processing is possibly the most common form of productivity software, the preservice teachers were required and encouraged to combine it with the use of digital camera images and scanned images to enhance their documents. The preservice teachers began to find creative uses that saved them time and produced more professional materials. As they became more comfortable using the technology, they were able to initiate its use as needed without an actual assignment by the instructor.

Other examples of student use of technology for productivity were through the selection of multimedia presentation software packages such as Power Point and HyperStudio when given assignments such as personal literacy portfolios or group project assignments. As an example, preservice teachers enrolled in a graduate curriculum course were given an assignment to develop a personal literacy portfolio addressing multiple literacies. They were instructed to use a presentation medium of their choice. Many produced
effective presentations utilizing a wide range of technology tools. When assignments such as this were given so that an option of type of presentation was allocated, many students in the teacher education programs chose to use computer technology. The students cited as reasons for their choice ease of use and more appropriate format for their content or topic.

Research/Instruction Component

A third component of the Triad Model addresses the use of technology for research and instructional purposes. As preservice teachers begin to integrate university course work and field experiences it is important for them to explore the role of technology in this capacity. Opportunities to use internet resources and educational instructional software are essential for their development as effective teachers. Preservice teachers at the university participated in a Web Quest as a model for integrating internet resources, curriculum content, and research. The results of their experience were presented through multimedia presentations. Others were able to implement particular instructional software packages in their classrooms as student teachers. One such student teacher was able to have extensive experience using Geometer's Sketchpad with students. This experience was very successful in part because the student teacher had worked with the software in the university courses and then had it modeled by her supervising teacher with students. This multiple, integrated approach provided a strong foundation for effective use of the instructional software.

In a secondary mathematics methods course students were assigned a project based on the book G is for Googol (Schwartz, 1998). The project required the use of a Power Point presentation that would relate appropriate mathematical content to secondary students based on the information in the book along with other sources and activities. Students connected literature, technology, and mathematics content addressing both research and instructional ideas.

Preservice teachers became more critical users of instructional technology through these experiences. They also expressed renewed interest in applications of various technology resources that they had experienced in their course work at the university. Some preservice teachers expressed frustration when appropriate technology was not available in their field experiences. More importantly, they were disappointed when the technology was available, but was not utilized and modeled by their supervising teachers.

Conclusion

Teacher education programs must meet the challenge of preparing teacher candidates for the effective use of technology for instruction. The three areas of communication, productivity, and research/instruction addressed in this model provide a foundation for such a program. All three areas are essential and are interrelated in their use.

It is critical that teacher candidates actively participate in an engaging technology model that prepares them for their future as innovative, effective classroom teachers. In establishing expectations for accredited schools of education, NCATE (1997) advocates that teacher candidates complete experiences that use technology in their content areas along with experiences in the use of technology in instruction, assessment, and professional productivity. The triad model described in this paper is built on such expectations. This triad model demonstrates one approach for designing curriculum and appropriate experiences in a teacher preparation program that provides hands-on experience.

Abstract: Two innovations, performance assessment and information technology advancements, provide the prospect for wide-scale use of electronic portfolios as an assessment tool. In a time where national and state standards are recognizing and incorporating technology literacy requirements into preservice teacher education, electronic portfolios offer benefits beyond their ability to easily manage and store data. There is evidence that using hypertext and multimedia tools to create a presentation of one’s competency involves a range of higher order complex thinking skills. Putting the process of assessment in the hands of the student, portfolios produce tangible evidence of a preservice student’s ability to connect theory to practice to create meaningful learning experiences for their students. As technology tools and skills become more commonplace, and the expectation of technology literacy more universal, electronic portfolios can serve as authentic assessment tools that provide a rich repository of information about teaching and learning.

Introduction

Portfolios represent the next logical step in applying performance assessment to constructivistic learning theory (Boulware & Hold, 1998; Richards, 1998; Barrett, 1999; Read & Cafolla, 1999; Tichnor & Sipek, 1999). According to constructivism, the learner plays an active role in knowledge building leading to deeper understanding and retention of this knowledge (Bruner, 1986; O'Neil, 1992, Leeman-Conley, 1999). Portfolio assessment models rely on the learner as an active player in representing what they have learned through a purposeful collection and explanation of their work (Wiedmer, 1998). Portfolios offer an on-going and summative documentation of a person’s knowledge, creativity, and personal perspectives.

In 1991-1992, Vermont became the first state to use portfolios on a state-wide basis for assessment of math and writing ability of 4th and 8th graders (O'Neil, 1993). In 1995 this was extended to a results-orientated program approval process for teacher certification, evaluation by portfolio, placing this evaluation in the hands of the institutions of higher education that serve those pre-service students (VISMT, 1995).

As states, districts, and schools are adapting portfolio assessment strategies, corresponding problems associated with issues of storage, organization, dissemination, and inter-rater reliability are emerging (O’Neil, 1992; Barrett, 1998). How do we manage all this new information? How do we allow a personalized representation of knowledge yet develop uniform criteria to fairly assess it? How can we facilitate connections and reflections between theory and field experiences and how can we be assured the learner can present their knowledge to an array of audiences?

Some solutions to these problems seem intertwined with our struggle to define and implement technology literacy standards for pre and inservice educators. (National Council for Accreditation of Teacher Education, 1997; International Society for Technology in Education, 1999). There is added value in using new technology to document pedagogical competency through electronic portfolios. Electronic models streamline storage, facilitate dissemination, organization, and easy updating of documentation (Wiedmer, 1998). Portfolios can be easily shared for feedback, models distributed to students, and the electronic nature facilitates documentation for research about patterns of what creates a good educator. There is evidence that electronic portfolio construction helps students focus more on the content and connections of theory and practice than traditional paper-based models. Hyperlinking
allows the student to connect course work, applications, ideas, and themes through a network of designed nodes, assisting them in reflection and enlightenment (Jonassen, 1996). Multimedia features support multi-intelligence theory allowing expression in text, video, animation, and sound (Moersch and Fisher III, 1995). Student’s portfolios can be richer, sharing work otherwise not possible and presenting what they’ve learned and who they are as a teacher in a creative, personal representation. Finally, there is no better way for students to document their technological competence than to create their final assessment using a hyperlinked, multimedia based instrument.

The Portfolio Process

To respond to the 1995 Vermont State requirement for teacher certification, the Elementary Education Program at the University of Vermont encourages students to use the power of multimedia to construct electronic portfolios. Beginning in their first year, students enroll for a required technology course: Computers in the Elementary Education Classroom. In this class students learn basic computer skills and applications, and discuss technology-related issues. One third of the class is dedicated to teaching HyperStudio, the software used for building portfolios. At this stage, students are taught how to use the program’s multimedia and hypertext tools to allow documentation of their work with children, coursework, with artifacts from their first year as a preservice student. They are encouraged to select particular products that showcase their learning, and in a caption, provide the context of their document and justify their selection with a reflective statement. They are taught how to design their presentations to include easy navigation, facilitate the reading of large text fields, scan, and work with digital photographs. They learn how to plan their presentation through story boarding and how to organize their information with sensitivity to layout techniques, color, and design.

Barrett (1998) has developed a matrix to help educators decide which portfolio tool meets their needs. These include a range of HTML and multimedia solutions corresponding to the level of technology proficiency and student-teacher control. Our interests were in creating a student-centered model and after exploring a number of programs, we selected HyperStudio. The program is popular in our neighboring schools, easy to use and yet provides sophisticated features that offer flexibility for students to control what and how they represent their learning. The program is self-sufficient with built in multimedia tools and a player readily available on the Internet in Mac and Window platforms to permit final products to be seen on almost any computer. The program allows for easy importation of text and sound and graphic files from many formats. QuickTime video and slide shows can be brought in, animations constructed, and final products uploaded to the internet, saved to a variety of media, or mailed via FTP (file transfer protocol).

Students’ electronic portfolios are maintained on the College of Education and Social Service’s server for easy access throughout the students’ academic and professional course work. All residence hall rooms are networked with access to the College’s server and a computer facility, The Technology for Teaching Lab. This is a college-based lab supervised by a full time technology coordinator and staffed by workstudy students who support faculty and students working on computer based assignments or projects or exploring technology tools. Most of the workstudy students are pre-service educators and have completed the required computer course and are thus familiar with the applications and student assignments. The lab has scanners, a writeable CD-ROM, and computer with the capacity to convert video movies into digital ones for incorporation into electronic presentations.

The use of HyperStudio to develop teaching materials is a new assignment recently introduced into a third year elementary education course in the inquiry block, an interdisciplinary based methodology course in science, social studies and art. In this assignment students develop a multimedia stack as one activity in a student constructed science center. Students build these around science content, set them up and leave them in their field placement classrooms for two weeks. Science Centers must be self-sufficient with activities and assessments about science content and processes. Creating a multimedia based resource helps preservice students demonstrate their ability to develop grade-appropriate content, organize information in a logical interesting way, and use technology tools to present this to an elementary audience. It also reestablishes student’s familiarity with HyperStudio, preparing them for their senior portfolio experience.

While students complete their internship in their final year of our program, they participate in a one-credit portfolio course where they are given specific direction and skills related to assembling their final professional portfolio. At the University of Vermont, professional portfolios must be organized as a text, via themes of practice with student selected documentation that describes them as an emerging teacher. State and Program criteria are located in appendices and cross-referenced to the documentation. Students collect, select, and connect the artifacts. Documentation is captioned to explain the context and relevance of the evidence and invites the pre-service student to reflect about how it translates to a meaningful learning experience for their students. Pre-service students are
expected to relate educational theory to practice drawing upon their coursework, fieldwork, and community experiences to create personal profiles.

Portfolios showcase learning and demonstrate professional competency and electronic portfolios facilitate this process and scope of expression. Evidence includes a rich assortment of artifacts: papers, homework, video, pictures, projects, diagrams, notes, animation, student voices, and music. In constructing their portfolios, students learn from the process and product as well as demonstrate their ability to use integrated technology. Beginning portfolios electronically in their first year ensures students possess the technology skills they need to succeed as undergraduate students at the university, in their field placements, and as prospective teachers. This serves as a vehicle for infusing technology throughout their college and field placements and begins their documentation of their education and professional competence.

Advantages

Teachers and administrators who have used electronic portfolio documentation have reported they make it possible to portray one's educational philosophy by helping them summarize their beliefs and attitudes into a compact multidimensional product (Wiedmer, 1998). Electronic portfolios demonstrate organization and presentation skills, facilitate the ability to make cognitive connections between themes, and offer multimedia for a rich choice of expressive modes. There is also evidence that in creating multimedia-based hypertext presentations, students practice complex thinking and express creativity (Jonassen, 1996).

Management

Electronic portfolio construction offers several advantages over traditional paper-based models. Distribution of portfolios to faculty and potential employers becomes simple with the ability to save to disk, CD-ROMS, and Zip and super disks in both Macintosh and Windows formats. Products can also be uploaded to an Internet site or e-mailed to facilitate the ability for graduating students to seek employment in diverse and distant communities. In a study of school administrators' reactions to electronic portfolios, portfolios were found to be powerful marketing tools during the interview process demonstrating technology expertise, presentational organization, content and pedagogy (Giuliano, 1997). Numerous copies can be easily and inexpensively duplicated, offsetting the risk of loss of the singular paper based format. They are easier to share making it possible for students to see a variety of exemplars and helping students "stand on the shoulders of giants" so they see other perspectives of teaching and learning and challenge their own practices and beliefs. Electronic portfolios are easy to edit permitting a continuity of documentation of growth with the control of distribution in the hands of the student. Yates (1999) reports that substantial revisions involve reflection on course content encompassing processes like reordering and reevaluating, resulting in new insights. If left on a server, assessment can be formative with a stream of faculty-student and student-student interactions that fine-tune the portfolio. Electronic documentation also provides a reservoir of data about the teaching learning process that with analysis and organization offers an opportunity to understand what constitutes a good teacher and good teaching.

Interactive Multimedia

Multimedia refers to communication from more than one media source such as text, audio, graphics, animated graphics and full motion video. (Sharp, 1999). In the past we have made presentations using different media but we had to combine slide projectors, cassette players, video players, and overhead projectors to achieve these effects. The change lies in a combination of all these different media handled by just one machine, the computer. The computer injects a level of interactivity into multimedia permitting an element of input via keyboard, mouse, and voice. Multimedia features allow students to include sound, graphic, and video components, in addition to traditional textual data. According to multiple intelligence theory, not only do all individuals possess numerous mental representations and intellectual languages, but individuals also differ from one another in the forms of these representations, their relative strengths, and the ways in which (and ease with which) these representations can be changed. (Veenema and Gardner, 1996). Multimedia encourages a richer and more accurate presentation and interpretation of what one has learned. Multimedia presentations are more engaging because they stimulate many senses at a time something many believe is essential when working with today's video and net generations (Jonassen, 1996). Preservice teachers have included video clips that demonstrate portfolio criteria, scanned copies
of student work, and voices of children reading. In constructing multimedia portfolios, students are actively engaged in creating representations of their understandings and have a variety of tools to use to make that representation accurate and unique (Jonassen, 1996). Educators who compiled their own portfolios noted growth in their self-confidence, collegiality, and sense of personal empowerment (Wiedmer, 1998). Portfolios materialize as creative personal products that represent a formative and summative assessment of progress as well as a clear picture of creativity, organizational ability, and pedagogical knowledge.

Hypertext and Hypermedia

Normal text is linear, proceeding from beginning to end. Hypertext presents information in a nonlinear fashion, without a predetermined sequence. Barnes (p. 29, 1994) describes it as “interactive reading” because students experience the text as part of a network of navigable relations instead of a linear sequence of ideas. The reader finds the experience more personally meaningful because they have greater control over what is read and the sequence in which it is read. Its organization is not imposed by the author (Jonassen, 1996). Hypertext is more closely related to how the human mind operates, by association, snapping from one item to another creating trails of information, suggested by the association of these thoughts (Bush, 1945). Hypertext usually refers to an environment limited to textual jumps from one chunk of information to another. Hypermedia extends this concept to include additional forms of media that may be linked as well so that text may link to a bird’s song or hear a student read. It may link to a video of a student teaching a lesson or a scanned image of a science test. The hypermedia component fosters connections between course work, concepts, and applications because it allows the individual to designate links between ideas and themes. It cultivates the development of association of content, theory, and practice helping students become thoughtful problem-solvers. Because the architecture of hypertext is open, the same set of data can be organized in many different ways to reflect different conceptual perspectives and orientations that facilitate the production of personalized products. One of the notable initiatives of the 1990’s is the development of the World Wide Web. To those not familiar with a hypertext retrieval system, this may present a barrier (Barnes, 1994). As authors of a Hypermedia product, students become proficient hypermedia users in “a new kind of literacy prompted by jumps of intuition and association” (Heim, 1993, p.30) and a kind of literacy imperative for an educator to understand and demonstrate.

As a Mindtool

Jonassen (1996) describes mindtools as applications of computers in schools as tools for engaging learners in constructive, higher order thinking activities that help them become self-directed critical thinkers. In designing Hypermedia presentations, students are engaged in complex thinking skills and decision making: evaluating, analyzing, connecting, elaborating, synthesizing and imagining as they conceptualize and design their presentation. Adding hypertext capabilities creates another dimension of organization and interactivity, creativity, and complexity. Electronic Portfolios represent a challenging assignment that engages students in management, research skills, organization, presentation skills, and reflection. They select the multimedia tools they will use and essentially have carte blanche in representing what they know about teaching to faculty and potential employers. They must make numerous decisions about what to include, synthesize themes and help the viewer see their constructions. They use the technology to create: diversity and coherence, visual and textual balance, and stillness with movement. Learners are more mentally engaged in developing materials than by studying materials and the diversity of tools enables the student to express abstract concepts with concrete representations. According to Jonassen (1996, p.209), “...Hypermedia is the most compelling and potentially effective of all Mindtools” because of richness of representational forms available in designing with multimedia. The process of using this tool augments portfolio assessment by presenting a learning experience in itself.

Computer Literacy

In using electronic portfolios, students are demonstrating their ability to manage their information with a computer, and use some complex applications and sophisticated techniques to prepare their products. They work with different graphic file formats, import data from a variety of applications, perform screen dumps, scan and crop photos, digitize video, create slide shows, and insert sound. HyperStudio has built in hyperlogo scripting capabilities allowing students to include fairly sophisticated programming techniques. Students learn to correctly name and connect their files, save them to a server, disk, or CD-ROM, or e-mail as an attachment or upload them to the Internet. They use graphic tools, Internet resources, peripheral devices and constantly problem-solve using
technology tools to produce tangible evidence of their ability to teach in twenty-first century classrooms.

Obstacles

There are some obstacles associated with electronic portfolio assessment to consider. Constructing any portfolio is a time-consuming process. Students begin with collecting and labeling artifacts, looking for patterns that express their educational philosophy and then need time to process these into coherent themes. It also takes time to translate all into an electronic format. Photos need to be scanned, videos digitized, and there is a limited amount of equipment available. Students attend to this assignment at the end of the semesters resulting in wait time for some equipment. Portfolios are also time consuming to grade and faculty have to know how to access these presentations and use hypermedia tools to understand the student's theme development and documentation. Although using a network can facilitate communication and exchange of documents, it can represent some interesting challenges in running software and saving files. Files get corrupted, the system crashes, and data is lost and retrieving and reconstructing it is not always possible.

One must have hardware capable of handling multimedia software with the ability to input and record sound and video. Lots of storage space is also advisable. Although students begin portfolios in their first year, they forget details and many need to work on them in a supported atmosphere and finally, although this is becoming less of an issue, there are still some schools that do not have the technology to view electronic portfolios.

Conclusion

New technologies have historically helped us do things better, and to do things not possible before. The printing press allowed books to reach the masses and cars enabled easier travel. Technology advancements in terms of the multimedia computer offer an assessment tool more aligned to accepted educational learning theory. Electronic portfolios can serve as an authentic assessment tool that provides a rich repository of information about teaching and learning. Electronic portfolio documentation using hypermedia software offers better management, storage, and distribution with the added value of providing a tool that promotes higher order thinking and creativity. Electronic portfolios offer a formative and summative assessment tool that simultaneously demonstrates technology skill. Putting the process of assessment in the hands of the student, portfolios produce tangible evidence of a student's ability to connect theory to practice and use new technology tools in the process.

Development of a Personal Electronic Profile for Pre-service Teachers

Gerald Ehli
School of Education
Northern State University
United States
Ehlig@wolf.northern.edu

Harold Sorknes
School of Education
Northern State University
United States
Sorkness@wolf.northern.edu

Abstract: As part of the pre-service teacher education program for the elementary and secondary education program at Northern State University, students were required to develop an electronic personal profile. The purpose of the project allowed pre-service teachers to become more proficient in the use of technology and also to communicate a personal profile to their future mentor teachers, K-12 students, and future employers using an electronic medium. The product they developed may also be included as part of their professional electronic portfolio.

Goals of the Project

During the past two years education faculty at Northern State University have emphasized the use of technology in the courses they teach and through the activities and projects required of pre-service teachers in completion of their program. With this project implemented as one part of their Instructional Technology class, students developed a personal profile of themselves using Microsoft PowerPoint as the software for producing the product. Microsoft PowerPoint was selected since it was most readily available for use by students in our computer labs and by the school districts in the regions they will practice teach.

The goals of the project were to:
1) Develop skills in the use of Microsoft PowerPoint in order to create classroom and professional presentations for their students and colleagues.
2) Create a presentation, which profiles information about their personal lives that reflect their interests, achievements, family, and community.
3) Enhance collaboration between pre-service teachers at Northern State University and K-12 teachers, students, and administrators.

Content Criteria of the Project

In order to communicate the requirements of the assignment, it was decided we would model them by creating a personal profile of ourselves for demonstration in our classes. We decided that even though each profile would be unique it should include minimum criteria and components.

The criteria we decided on should include:
1) A recent personal picture.
2) A favorite elementary or secondary school experience.
3) A memorable childhood experience.
4) A teacher or experience that inspired them to become a teacher.
5) A hobby or pet.
Technology Components of the Project

Technology components and skills we wanted to have our students demonstrate through the creation of the portfolio included:

1. Producing an organized and motivating personal profile demonstrating appropriate visual, oral and written communication skills.
2. Utilizing a digital camera, computer scanner, and "Internet", to import and transfer pictures, music, sound effects, and graphics into their personal profile.
3. Creating "Internet Links" which will enhance the information presented in their profile.
4. Demonstration of equitable, ethical, and legal use of technology resources by following copyright regulations related to the use of electronic media.
5. Demonstration of these on Microsoft PowerPoint, which allows the use of a variety of texts, fonts, colors, layouts, sounds, images and special effects to create motivating and unique presentations.

Teaching the Lesson

Anticipatory Set

We introduced the lesson by stating the purpose, goals, and components of the project. It was suggested they create a storyboard which includes the texts, pictures, and special effects for each frame prior to creating the presentation. An example of the instructor's storyboard was distributed to the students.

Modeling the Lesson

We loaded our personal profiles and presented it to the class discussing various aspects included for each frame. This seemed to motivate the students and generated many questions.

Instructional Input and Guided Practice

We had each student load PowerPoint and they began to develop example frames using a variety of formats, texts, colors, sound and special effects as they were being demonstrated. A Microsoft PowerPoint Tutorial was distributed to students and reviewed to assist students in solving problems they might have while creating their portfolio.

Checking for Understanding of the Lesson

We had students practice by creating several frames implementing different presentation strategies. We answered their questions and demonstrated things that were confusing to the entire class or we had forgotten to cover during the instructional input stage.

Assessment of the Lesson

In order to assess the project we decided that we would create a rubric, which would include the criteria and the project technology components. The only additional requirements was that each student would also showcase the personal profile to the entire class during our showcase day and create a printout of the frames to be submitted with their CD ROM for grading purposes, see [Table 1].

Evaluation of the Project

Informal interviews with the students indicated the project was a very enjoyable and positive experience. Students were anxious to show them to their cooperating teachers and students during their field experiences. They also stated they planned to incorporate the electronic version in their professional electronic portfolio or the printout version in their paper professional portfolio. The only negative responses pertained to the significant amount of time required to locate personal pictures and Internet sites for pictures, music, and sound effects to create their
presentations. As instructors, we found this to be a very successful and useful project for our pre-service teachers and plan to continue and refine the project during future semesters.

Personal Electronic Profile Rubric

- Introduction and conclusion frames with a recently scanned photo and e-mail address. (15 pts.)
- Elementary or secondary education experience that inspired you to become a teacher. (15 pts.)
- Enjoyable childhood experience with your family or friends. (15 pts.)
- Past or present hobby or pet. (15 pts.)
- A personal or professional achievement. (15 pts.)
- Experience which reflects your local community or home. (15 pts.)
- Internet links to sites, which enhance the information presented. (15 pts.)
- Use of sound, music, or animation. (15 pts.)
- Creative design, unique details, or interesting facts about you. (15 pts.)
- Presentation utilized correct grammar and is appropriate for your goals for your grade level audience. Includes a printout with rubric attached. (15 pts.)
- Total Points (150 pts. possible)

Table 1: Rubric distributed to students and utilized to evaluate their personal profile.

Abstract

The purpose of this article is to present a model for integration of technology into teacher preparation. A four-course block of elementary teacher certification courses serves as the context for this study, as well as a university-based summer camp for the requisite field experience component. Investigators analyzed purposes for technology integration into the curriculum of the methods courses and the students' use of technology in the field experience as they worked with children ages 6-11.

In his 1997 State of the Union Address, President Clinton issued a "Call to Action" that included as a priority improvement of the quality of teachers in every American classroom. President Clinton's speech reflects the rhetoric of concern over the condition of education and the nation's need for excellent teachers. The nation requires teachers with the knowledge, information, and skills necessary to prepare students to live and compete in a complex international marketplace. This means, students must be knowledgeable in a broad base of disciplines, technologically literate, and autonomous learners.

Definitions of good teaching range from those that focus on what should be taught and how knowledge should be imparted to the kinds of knowledge and training teachers should possess. Two broad elements emerge as characterizations of teacher quality: (1) teacher preparation and qualifications, and (2) teaching practices. The first refers to preservice learning and continued learning. The second refers to the actual behaviors and practices that teachers exhibit in their classrooms (U.S. Department of Education, 1996a). These elements of teacher quality are not independent; excellent teacher preparation and qualifications should lead to exemplary teaching behaviors and practices.

Using a nationally representative survey of full-time public school teachers of core subjects or self-contained classroom, the National Center of Educational Statistics (NCES) (1999) included indicators of preservice and continued learning (e.g., degrees held, certification, teaching assignment, professional development opportunities, and collaboration with other teachers). The survey indicated that currently less than half of American teachers report feeling "very well prepared" to meet some classroom challenges, specifically feeling 'very well equipped' to integrate technology into classroom instruction (20 percent). White (1996) advocates that technology can facilitate preservice teacher understanding of and engagement with problem solving and critical thinking skills facilitating their development of desired teaching behaviors and practices.

We teach how we're taught. In this era of constructivism, preservice teachers continue to enter teacher education with the belief that teaching is all about the transmission of knowledge rather than interaction and construction of knowledge (Brazee & Kristo, 1986, Shor & Friere, 1987). As undergraduates, they attend 'lectures' and respond to tests about these lectures in their core requirement classes. They encourage their teacher training supervisors to observe them on days they're really teaching (lecturing) rather than those days where students are actively involved with activities of a constructivist nature. They don't perceive these strategies as teaching, limiting their ability to spark fresh insights in their own students (Holt-Reynolds, 1991). Field experience is carefully guarded as a special event rather than an integral component of teacher preparation. Use of technology is covered via stand...
alone courses that are taken out of the context of teaching and with the leap of faith that it will be accommodated into the daily life of the student. Is there any reason to believe that preservice teachers can be prepared to create constructivist classrooms that prepare their students to live in a complex international marketplace carrying with them this nonconstructivist experience?

To develop technology-using teachers, preservice teachers must experience demonstrations by their professors, integration of technology into daily activities, and application of technology into their class projects and field experiences. Technology also supports the reflective practice essential to the development of a constructivist teacher (White, 1996). Camp Paw Print was developed as a constructivist field experience requiring the use of daily interactions with technology through the preservice teachers' own instructional experience, as well as their planning and preparation for the camp.

**Methodology**

This paper reports the outcomes of the preservice elementary methods students taking a block of courses that were richly infused with technology as tools of instruction and communication and integrated into the context of science, mathematics, social studies, and language arts content and pedagogy. The culminating field experience gave rise to observations, measurements, and analyses of these preservice students as to their abilities to use various types of technology. The role that technology took in their instruction of children ages 6 to 11 years and the way that they learned to use technology in instruction was significantly increased from the limited impact of the stand-alone course previously taken as a core requirement.

Observational data was recorded through anecdotal record by preservice teachers regarding each child's interactions with the instructional materials, other children, and the ability of each child to meet instructional objectives. Graduate students collected observational data through the course of the summer semester about preservice teacher level of technological literacy. Professors of the methods courses collected observational data on preservice teachers during the camp regarding their planning of integrated, content-rich and technologically supported experiences and implementation of instructional plans, their interactions with the children, and their ability to problem solve events and situations that emerged. The graduate students and one of the professors kept Field Notes of the camp that were analyzed for significant patterns in technology use and implementation and authenticity of application.

Interview data were collected by the graduate students from SHSU methods' students regarding their understanding of the events of the camp/field experience and their beliefs about the use of technology. Student products were collected daily by the children and reviewed with the children by the preservice teachers for evidence of the child's having met the instructional objectives.

Methods students and campers participated in pre and post test technology attitude surveys that were analyzed by the graduate students.

Each preservice instructional team prepared daily assignments for themselves regarding who would carry out instructional duties, who would provide support, who would be taking the camper kid-watching notes for the day, and who would record through digital video or still pictures the events at the center and/or computer laboratory.

Graduate students and professors analyzed the threaded message boards used by preservice teachers and children for type of response, reflective nature, and cognitive connections between instruction and life experience. Follow-up data regarding use of technology during student teaching, feeling of preparedness to student teach, and unfulfilled plans for instructional strategies in their first position as teacher were collected from preservice teachers during a Camp Paw Print reunion during their student teaching semester.

**Findings**

**Modeling Technology Use for Instruction**

Integrating technology into the day to day instruction of the methods courses was important in the overall modeling of technology as an instructional tool. Threaded message boards were used by students to
respond to their reading assignments. Each student was required to respond to the reading assignment with a question about the reading, a quote from the reading, and a comment about the thrust of the chapter. They were required to respond to at least two of their colleagues' postings and to everyone who responded to them. Other uses of the threaded message boards included the posting of responses to current issues in education or demonstration video-tape/video disc of classrooms. Posting of products, such as lesson plans or unit outlines, allowed all students in the class to review each student's work and their approach to a given topic. Students commented that they took greater care with the content and composition of their responses when realized that the other students and their professors would be regularly reviewing their work and responding to what ideas they had put forward.

Other uses of technology were the use of web pages that were developed to support daily lessons and the course. Daily lesson pages included links to threaded message boards that students would respond to after participating in a class activity, links to web sites that offered supporting material to the lesson, and links to common pages that contained planning in progress for the field experience camp, Camp Paw Print. Course support web pages included the syllabus, e-mail links to all members of the class, an announcements page, links to support to the course (e.g., lesson plan pages, professional organizations, Texas Education Agency, State Board of Educator Certification). These web sites contained a schedule for each day and the topics of discussion, including the reading assignments. Students could access the course support pages from their homes if they were absent from class and work on the materials that would be due when they returned or to see what changes might have been arranged. In addition the sites included links to questions for discussion and instructions for classroom activities. Sites also included links to children's books on line or reader's theatre scripts. These sites were used as sources of children's literature for classroom study. In addition, literacy events were constructed around web sites that contained content related to the upcoming field-based thematic-unit of study—Hawaii.

E-mail was the official method of contact between students and professors, and all students in the course were required to correspond with their professors and their team members in this way. Each student had a campus computer system address, but could use their home e-mail address if they desired. Professors accessed e-mail often and were able to respond to messages frequently. This approach was much more consistent and responsive than telephone calls.

Integration of Technology into Preservice Teachers Field Experience Lessons

During the field-based learning experience, Camp Paw Print, preservice teachers were required to integrate technology into their lesson plans. Before their participation in technology-enhanced methods, students greeted this requirement less than enthusiastically and in some case with hostility. They felt underprepared and overburdened for this requirement. However, as the short, summer semester progressed, and students became more adjusted to responding to their reading assignments on threaded message boards, reading and responding to their classmates' work, checking the course web site for the daily schedule and related resources and activities, they became less vociferous in their complaints. By the time, they began teaching, they had put up web pages for their teaching teams with links to their own lessons and resources. They were comfortable and proud of this technology-resources, and many students voiced their opinion that they would not want to teach without access to the 'net.

Preservice teachers integrated technology into their lessons for the following purposes:
- Building Community and Getting Acquainted
- Creating Environment
- Investigation
- Activating Existing Schema and Creating Prior Knowledge
- Inquiry
- Applying Concepts
- Connecting to Culture
- Modeling
- Responding to Literature
- Dialoguing with Experts or a Virtual Community of Learners
Building Community and Getting Acquainted

Preservice teachers used technology to get acquainted with students and build a sense of classroom community. A graduate student intern set up threaded message boards, and preservice teachers created questionnaires for campers to respond to on-line. Campers typed out the answers to the questions—sometimes on their own, or with the help of the preservice teachers, and mini biographies of each students' background and interest became available to campers, preservice teachers’ and professors. In this way, technology was used as a literacy event, a team building activity, and as a way to create community.

Creating Environment

Technology was also integrated into the classroom environment to set mood and tone and contribute to a cultural understanding of the environment being studied. Pictures of Hawaii were projected through a computer-enhanced projection unit to give a display Hawaiian land, sea, and beach landscapes and create a scenic effect of being in Hawaii. In addition, digital pictures from Hawaii were captured from the web and put in a Power Point slide show presentation which was then used in a "look out the window" flight simulation for campers' who participating in a flight simulation from the mainland to Hawaii. Once again, the pictures helped support an understanding of what the journey would be like as well as what the experience of flight was.

Investigation

The science center became the focus of several technologically enhanced lessons. One lesson in particular used the web as a resource of information for the scientific principles that support flight. Preservice teachers created a web site that utilized the nonlinear nature of hypertext to allow a camper to create an investigation of flight. Campers were to select an icon of an airplane to learn about flight, then could select one of several entry points to learn about the kinds of flight and principles of flight. Students then created their own objects to fly and experimented first hands with the principles of flight by trying to fly their objects.

Activating Schema and Creating Prior Knowledge

For a literacy event, preservice teachers used the web as a resource for students to learn about volcanoes prior to campers reading the book Dear Katie, The Volcano is a Girl by Jean Craighead George. To prepare for the reading, campers filled out KWL charts, listing what they knew about volcanoes prior to viewing the web site and what they wanted to know about volcanoes. Campers then viewed http://volcano.und.nodak.edu/, a web-based volcano site. They returned to their KWL charts to write what they learned about volcanoes after viewing the web site and then with their prior schema activated and/or new schema created, they read the story, Dear Katie, The Volcano is a Girl.

Inquiry

Preservice teachers developed an Internet-based inquiry lesson on Hawaiian animals. Campers worked with partners and/or a preservice teacher to explore the site to finding information on the kinds of animals that live in Hawaii, where they live in Hawaii, what foods they eat, and the classification to which they belong/ (mammal, bird, reptile, etc. and why) This information was charted by teams and brought back to group discussion and hands-on activities.
Applying Concepts

Preservice teachers developed a problems-based math lesson in which campers would use hands-on activities and web sites in order to understand the relationships between shapes and mathematical language. Preservice teachers displayed various triangular figures and elicited camper response about the properties of these shapes (3 sides, 3 corners, angle, straight rather than curved.) Then distributed pattern blocks to each student. Then had students explore ways to make triangles with the pattern blocks. Then students went to the Internet to "build triangles" on a tessellation site (http://www.forum.swarthmore.edu/sum95/suzanne/active.html).

Connecting to the Culture

In order to relate to the sounds and rhythm of the Hawaiian language, students went to a web site and entered their name. The site contained a translator program that translated the American names into the Hawaiian equivalent. Students then displayed their Hawaiian names beneath their American names on their name tags.

Modeling

After studying and Internet-based lesson on states and their flags, preservice teachers used the Internet to have campers research information about symbols in general. After some discussion, each camper chose a flower as their symbol, and then they printed pictures of flowers and then took them back to the Social Studies center and drew their own rendition of the flowers. In addition, students viewed Hawaiian children hula dancing from video and then followed the video teacher's instructions and learned to hula along with the video.

Responding/Dialoguing

Threaded message boards were used for campers to write responses to literature they studied. In addition, they used e-mail to contact experts in areas they were researching.

Conclusions and Implications

Preservice teachers arrived in the summer methods block with varied computer skill and lukewarm attitudes about the use of technology. Most of them had experienced the use of e-mail. A number of students knew they had e-mail addresses, but couldn’t remember the predictable username or password that they had been assigned when they had taken the required computer science course. Some were known only as default user.edu when they could not recall how to set the preferences for their account. And, a few students were quite fluent with e-mail and Internet use. It was evident that the knowledge and application of the requisite stand-alone computer science course had not developed expected schema for the preservice teachers.

None of the students had experience in developing web-based instructional materials or participating in threaded-message boards as an integral part of class. The preservice teachers were able to develop their own threaded message boards to review student writing and explanations at the literacy center. While type of technology to be used during the camp was not defined, the preservice teaching teams were all able to incorporate instructional technology on a daily basis. A problem that developed early in the camp program was the need to schedule specific times for various computer stations for each center so that all teams and children could have the access they desired. The types of technology that the preservice teachers wrote into their plans was the technology that had been modeled and used consistently during the methods courses.
Children typically wrote more on the threaded message boards and expressed greater interest in the reading of responses of their peers in this medium. The parents of the children requested URL's for the writing sites to view their child's writings and responses. The campers' interviews and attitude surveys revealed high interest in working with technology and increased time on task for content projects enhanced with technology. In addition, critical thinking was regularly employed in the context of problem solving, and the use of technology was a significant factor in providing information resources for analysis, and a means of graphically organizing their products. Campers and students reported an appreciation for being able to print out resources for home use, and an appreciation for the aesthetics of their own final products which were printed or displayed through a light projection unit.

Preservice teacher development was significantly more learner-centered than in those field experiences where the preservice teacher worked in an established classroom. The preservice teachers had to work collaboratively to develop much more of the operating procedures, curriculum, and supervision infrastructure than the traditional field experience students. This group of preservice teachers than in typical sections of methods block expressed a stronger camaraderie.

Seven of the twenty-five preservice teachers gathered for a reunion in October of 1999, the fall semester following their field experience. They expressed a strong appreciation for their methods and field experiences, particularly in the areas of collaboration, classroom management, and integration of technology in curriculum The seven students were teaching in four different school districts, and each reported that technology was not typically being integrated into classroom curriculum. All seven of the preservice teachers indicated their mentor teachers had expressed interest in learning technical skills from them with software and basic computer skills. Two of the preservice teachers had mentors that used a computer inside the classroom for record keeping. The preservice teachers reported that their own technology expertise had increased as a result of the constant integration of technology into their methods’ block, and that after using it in field experience, it was an easy transition to use it in their student teacher placement. They felt disappointed that more technology equipment was not accessible to them in public schools.

Implications

Technology-enhanced instruction should be regularly integrated into preservice teachers coursework, both in the College of Education and the College of Arts and Sciences.

Technology-enhanced instruction should incorporate the same features that make technology useful into today's world—collaboration, rapid access to information, ability to input information and disseminate quickly, global connectedness.

Field experiences must offer an opportunity for preservice teachers to integrate technology as well as pedagogy which is consistent with current real world experience.

References

Abstract: The Infosphere represents a global resource that can be applied to the teaching/learning environment and utilizes the computer as a mediator of communication. How can such resources be incorporated into the classroom? What are the effects of computer-mediated communication on the teaching and learning processes. How do students and teachers react to computer-mediated communication. This paper begins the process of understanding the effects of technology on communication by examining student and pre-service teachers reactions to the use of computer-mediated communication.

Problem/Concept

Presently myriad opportunities exist for educators to utilize technology to support teaching and learning. Typically these opportunities are presented as pieces in a puzzle and not integrated into the whole school/curricula culture. Yet, schools exist within an increasingly global culture—one that is united by new technologies, transported by the Internet and the World Wide Web. Computer-mediated communication through its ability to access global information makes possible a new and potentially more unified culture. Dr. Boris Berenfield, metaphorically describes this culture as the Infosphere "(implying) the growing unity, interdependence, and accessibility of information produced by humankind" (Berenfield, 1996) and encompassing technological and informational resources. How does the Infosphere change the nature of how students find, access, analyze process and exchange information? How can the Infosphere change the nature of how we teach and learn? How does the Infosphere change what we understand about teaching and learning?

This paper describes a beginning, the application of Infosphere resources to the teaching/learning process and the way in which students and pre-service teachers react to the process. The project was concerned with:

- Determining the impact of educational-oriented computer-mediated communication on student attitudes toward technology?
- Determining the impact of computer-mediated communication on student attitudes towards communication and collaboration?

Theoretical Basis

Vygotsky believes that "culture is the product of social life and human social activity" (1986, p.168). Michel Foucault addresses this issue of culture in the context of discourse. He believes that learners create knowledge with language, and, while solving open-ended problems, they are created as thinkers by the language they use within a particular discourse (1971). Traditionally education has been representative of its geographic social, political and cultural environs. Also traditionally education has assumed there is a fixed body of knowledge which can be transmitted from educators to learners. But in Infosphere, knowledge is transmitted, analyzed, and in many cases, transmuted so quickly that it is continually evolving. No longer, can knowledge be
thought to be a static entity dispensed by educators. Instead now, many educators believe that thinking takes place in communication, in an act of knowing in which the learner assumes the role of knowing subject in dialogue with the educator” (Freire, 1988, p.403-404).

With computer-mediated communication, an opportunity exists to open the boundaries of classroom communities whose discourse is not limited by time or space, or by the tradition of a fixed body of knowledge. Words become tools, in this medium, and this helps accomplish the work of learning—mobilization of thinking. Furthermore, Banks posits that when thinking takes place in communication, and that when learners’ home cultures are honored and validated, a dialogue will open up fixed boundaries so that “students can freely examine different types of knowledge in a democratic classroom where they can freely examine their perspectives and moral commitments” (Banks, 1993, p.6).

Educators using CMC have an opportunity to situate their curriculums in the context of real life problems. They use collaboration between students, educators, and professionals in a variety of disciplines, and they utilize a wealth of informational resources, none of which are limited by geographical time/space boundaries. Educators who use language to mediate problem solving through the Infosphere have the ability to not only supply information through technological means but also the potential to impact the culture—the values, ideologies and social context of the populations they serve. The Infosphere resides in and informs that social context.

Methodology

In the summer of 1999, 24 students enrolled in a block of elementary methods' courses. The students were involved in a five-week project designing and implementing Camp Pawprint, a summer camp for elementary school children. The project consisted of the development of curriculum, lesson plans and teaching materials centered on a Hawaiian theme. The students were expected to integrate technology into the curriculum design and also utilize technology as a management and development tool. Much of the material was developed using standard office applications. The worldwide web was utilized as a major data and image resource and both email and threaded message boards were used to communicate among students and between faculty facilitators and the methods students.

Once the curriculum and materials were prepared, the students acted as facilitators in the summer camp. During the methods course and the summer camp both quantitative and qualitative data was gathered, including:

1. Computer-mediated communication, primarily in the form of threaded message boards used as a medium for discourse in the learning/teaching process. The threaded message board provided the opportunity for sequenced multimedia communication in both asynchronous and semi-synchronous modes. The content and structure of communication through the threaded message boards be analyzed to ascertain how the process impacts both learning and teaching. The threaded message boards provided data from both the methods course pre-service teachers and the Camp Pawprint attendees.

2. Pre-post surveys of methods student and camper participant attitudes toward technology. The analysis of these surveys was used to identify changes in attitudes as a result of exposure to learning-oriented, computer-mediated communication. Pre-post surveys of methods student and camper participant attitudes toward technology were used to identify changes in attitudes as a result of exposure to learning-oriented, computer-mediated communication. The results were discussed in the evaluative narrative and then the resulting attitude data was mapped to the perception data.

Analysis

Data was collected from 12 students enrolled in EED 560, elementary teaching methods and SED 560, secondary teaching methods. In addition data was collected from 24 elementary school students enrolled in Camp Pawprint. The generation of 1747 messages in 29 message boards used by 38 users. The average length of message was approximately 67 words with the longest messages being initial postings (new questions of items for discussion) and responses being somewhat shorter. The graph below illustrates the distribution of message length.

The messages boards used by the methods students had a life of about eight weeks, those used by camp Pawprint, about two weeks. Threads within each message board had duration of about 5 days with an average 8 hours between postings.
Message Board Content Analysis

Threaded message boards served multiple instructional purposes in the Spring 1999 Secondary Methods Block which was taught as a Distance Education Course via the web. They provided a mechanism for the professors and students to:

- Organize information about the structure and content of lessons
- Post expository assignments discussing the application of theory to classroom practice
- Report primary data collected
- Post lesson plans and construct instructional strategies
- Summarize and reflect upon assigned readings from texts and journals
- Evaluate textbooks & class assignments
- Participate in book club discussions
- Present persuasive arguments on educational issues
- Analyze educational issues and current events
- Simulate classroom practices through role-play, etc.

The professors for the methods-on-line class published web pages to deliver information about the structure and content of the course, but the threaded message boards became the forum for students to interact with the professors and other students in the class. In a typical lesson, a professor posted:

- General information, which consisted of the dates and times the assignments were due for any particular class meeting
- Questions which guided student inquiry into the lesson
- Introduction into the topic, which provided a basis for linking student prior knowledge to the topic to be studied
- Threaded message boards for students to respond to the readings and discuss their responses with each other or post other instructional activities

Attitudinal Analysis

An instrument designed to measure attitudes toward computing (Cooper, 1997) was administered to the students enrolled in the Elementary and Secondary methods courses at the beginning of the course and at the end of camp Pawprint. The instrument evaluated student responses within the framework of Bloom’s (1956) taxonomy of educational objectives (Affective Domain). The instrument provided data on five aspects of affective response:
Receiving (items 6, 19, 25, 26)
Responding (items 13, 19, 22, 27)
Valuing (items 2, 5, 8, 12, 21, 24, 25)
Organizing (items 3, 7, 8, 10, 11, 14, 16, 18, 20)
Personal (items 1, 4, 6, 8, 16, 13)

Figure 2: Methods Students Attitudes toward Computing

With only 12 respondents in the sample, it was not possible to perform a statistical comparison between the pre and past data. However there did not appear to be any major differences between the pre and post scores. A comparison was made between the post scores for the Methods course students and data previously collected for CS 138 students, students enrolled in the freshman general education computing course. While no statistical results could be obtained due to the nature of the instrument, it does appear that the Methods students had a more positive attitude toward computing as measured on four of the five subscales.

An instrument measuring affective response to computers was administered to the camp Pawprint students before and after the camp. The instrument measured positive and negative attitudes. Comparison of pre (top bar) and post (lower bar) responses are shown below.

Figure 3: Pawprint Students, positive attitudes

Again, while no statistical analysis can be performed it appears that while the positive attitudes were somewhat lower after the camp, there were more marked reductions in the negative attitudes displayed by camp Pawprint students.
Figure 4: Camp Pawprint. Negative attitudes

Conclusions and Implications

How does the Infosphere change the nature of how students find, access, analyze process and exchange information? How can the Infosphere change the nature of how we teach and learn? How does the Infosphere change what we understand about teaching and learning?

The Infosphere can be the nexus of thought and language that teaching and learning occurs. Threaded message boards offer these points of connection in public space. In this setting of the Infosphere students find, access, analyze, process, and exchange information.

Teaching and learning is changed by the way students and professors participate in a cyber class. Students can not sit passively and observe discussion, but rather must be active participants in the discussion. They must be ready to defend their work with logical and rational reason, and they are exposed to ways educators react to a given problem in multiple educational contexts:

- Professors must design and organize the course around real problems that connect course content to student schema in a meaningful ways. The professors' roles should be that of orchestra director and facilitator—participating in the on-line community's conversations by questioning, extending, and challenging.
- Students engagement in the course is enhanced through interaction with the text and lesson assignments and responding electronically to what colleagues and the professors post on the threaded message boards.

Threaded message boards provide public space for students' publishing their understandings of educational theory and practice. Their work is not limited to being acted on by the instructor; rather, they must be ready to defend their work to their colleagues. Primary research can be disseminated more rapidly by being published on the threaded message boards thus increasing the impact of the research.

Threaded message boards provide a public forum to publish lesson plans to an audience of their peers. The public nature of this forum increases student accountability extending it beyond the scope of classroom practice and the evaluations of their instructors. Cyber book club discussions posted on the threaded message boards open boundaries of traditional teacher-directed assignments, allowing students to discuss books an pertinent issues in a manner consistent with real world dialogue. Threaded message boards offered a public space for analysis of events in popular culture, which affect education and society. Students can offer reasons and pose solutions to current dilemmas and reality check them against their peers' understanding of society and the values. Threaded message boards offered a medium for role play and simulation. In this medium, students could enact how they would respond to an educational problem and then view how their colleagues might respond.

Preliminary results indicate that a majority of students' attitudes toward technology were positively influenced over the course of the semester after a period of initial resistance. Communication and collaboration between university students, university students and professors, and campers increased beyond the traditional classroom boundaries as a result of participation in computer-mediated communication.

Cold Computers and Warm Hearts:
Using Group Process Techniques to Facilitate the Development of Educational Technology Skills While Conducting Pre-Service and In-service Training

Dr. Beverly J. Hagen, Professor, 
School of Social Work, 
University of Nebraska at Omaha, USA, 
bhagen@unomaha.edu

Abstract: Individuals who select teaching as a profession tend to be high on the scale of incorporating personal interaction into learning situations. They are usually people-focused with less interest in machines. Computers, on the other hand, offer an isolated, somewhat sterile environment in which the individual is learning techniques that are quite different from his/her educational experiences in the past. It seems, therefore, an oxymoron to expect teachers to work alone as they attempt to learn how to use teaching technology tools. Integrating a group process-oriented pre-service or in-service experience with mastering computer technology skills builds upon the very strength most teachers bring to the profession.

Introduction

According to a study published in 1999 by the U.S. Department of Education, only 20% of teachers considered themselves well prepared to integrate technology and learning in the classroom. Ellsworth in a 1997 publication suggested that universities are failing to provide adequate technology training, particularly in the area of using the internet, for students who plan to become teachers. The need for experienced teachers to keep up with advances in technology through in-service training has also been discussed by authors such as Melheim (1997).

The complications involved, however, in increasing the percentage of teachers who feel prepared to use technology in the classrooms are many. Of major importance in determining in-service training needs is the assessment of skill and knowledge levels, either through asking the teacher to complete a needs assessment, or via another variety assessment such as a discussion group meeting with faculty and the prospective group facilitators.

Levels of Technology Skills and Knowledge

Differences in understanding and skill levels vary greatly among faculty, ranging from never having touched a computer to sophisticated knowledge of the use of complicated multimedia systems. Levels of accomplishment, however, may be grouped according to the following system:

Teacher understands computers, how they work, basic operating systems, and peripherals.
Teacher knows about other learning experiences available through computer technology and software including the internet, distance learning, using a PDA, as well as other technological information systems.
The teacher is able to match the learning needs of the students to available technology.
Teacher knows how to use software, knows what is available in their area of teaching, is able to integrate material seamlessly into classroom teaching in a manner that supports and enriches the curriculum.
Teacher is aware of the student's role in using technology in a creative way as part of both their group and individual learning projects.
Basic computer skills including understanding the computer operating system, how to use folders and files, word processing, spread sheets and data basis are generally taught in most educational institutions. These competencies are expected of beginning teachers. Knowledge and skills in these areas are often an important criteria for hiring in many school systems. Teachers who have been part of the system for several years, however, may not have had the same educational opportunities provided in most colleges and universities today, and therefore may need to catch up with their younger cohorts regarding basic computer use and even more sophisticated skills.

The expectation that experienced teachers learn advanced skills implies the anticipation for changes in instructional strategies developed throughout years of teaching experience. The resistance to learning computer technology may well be partly due to this realistic concern.

For other teachers who have mastered the basics of computer technology, the added pressure of in-service training in more complex areas, particularly those having to do with the successful integration of technology with curriculum and student needs, may be threatening as well.

Finally, the time needed to carry a full time teaching workload along with the expectation that the teacher acquire or refine computer or other technological skills may be overwhelming to the busy teacher.

It seems reasonable, therefore, that various incentives be available to those who are willing to update their technology skills. These might include bonus pay, an extra hour per week of prep time, paid in-service workshop opportunities either within the system or in the community, and of course ESUs needed for teacher certification.

The Value of Group Process in the Learning Situation

Teaching skills or specific informational areas in groups is the cornerstone of most school systems. Whether called classes, seminars, workshops, or any other name that implies people getting together to accomplish a specific task, groups of students are generally brought together to engage in the learning exercise. When a teacher or facilitator receives training in a certain area, he or she is much more likely to feel prepared to use the information and skills acquired during the training. If properly done, the teacher may even feel a sense of excitement regarding a new strategy for instruction.

Kelly, in a 1999 article, described how a teacher training session on Microsoft's PowerPoint was instrumental in her developing an approach to teaching students to use a presentation program for their own work.

The group process, however, is often devaluated or ignored in learning situations. Content rather than process is stressed, thereby losing the advantage of one of the most productive aspects of partnership in groups. It is my contention, therefore, that the integration of group process theory with content by a facilitator with experience in dealing with group dynamics, would enrich the learning experience for most participants. Johnson et al., (1987), while discussing the research of Lewin, (1951) states: "His research demonstrated that learning is achieved more productively in groups whose members can interact and then reflect on their mutual experiences." Such emphasis on group process during the course of a computer technology workshop or seminar has the potential to improve the group's learning experience by:

- Openly addressing resistance to learning
- Developing a trusting, helping atmosphere in the learning situation,
- Forming bonds that would continue to provide a source of help, even after the seminar is over.
- Extending leadership opportunities to all group members according to their knowledge and skills related to the subject at hand.

With these advantages in mind, the logistics of group process as integrated into this specific learning experience will be explored.
The Pre-Group Planning Stage

The concept of group stages or phases and the group processes involved in each stage has been embraced by many writers and researchers. The pre-group phase, group planning and formation, is devoted to the development of goals and objectives and their integration with the skill levels of the participants for whom the group is planned. As Toseland et al., (1997) suggest, during the planning stage, the group leader focuses on both the task to be accomplished and the level of knowledge and skills of the potential participants. Is the workshop to be devoted to learning basic computer skills, more complex technological strategies, or something in between? The answer to these questions lies both in the targeted membership population as well as the knowledge and skills of the facilitator of the workshop or seminar.

The next step is acquiring information regarding the targeted audience. Is there a need for teachers who have been in the system for many years to catch up or even begin learning basic computer skills? Does the school system have several new teachers who have mastered the basics of computer use, software, and internet use, but who are unsure as to how to assimilate these areas of knowledge and skills into the curriculum they are expected to teach? Or would the school system administrators rather group the participants according to curriculum areas rather than skill attainment? Answers to these questions having to do with group formation will determine the number of groups needed as well as the information and practice that should be provided. As was stated previously, information may be obtained though needs assessment questionnaires returned by faculty members several weeks prior to an in-service training session, or, when possible, through meetings of the faculty of a specific school or district.

Preplanning has been completed when: the workshops have been organized during times convenient to a sufficient number of participants; the grouping of appropriate skill levels concluded; an appropriate number in each group has been selected; and the availability of adequate technology teaching resources has been assessed.

Group Stages and the Learning Process

When a group actually begins, the first stage of group process is an orientation to the purpose and goals of the group as well as a "getting to know you" opportunity. During this early stage in the process of a short term group, it is common for participants to be uncertain as to what will be expected of them, what kind of behavior they will experience from other group members as well as the paradox of impatience and hesitance (Corey et al., 1997). The activities of group members as they become acquainted and learn to trust each other, although somewhat time consuming and often disparaged by group members themselves, pays off later when the need arises for trust and cooperation rather than competition or judgmental behavior. This is particularly true when one of the goals of the group is to help the members work together both inside and outside of the group to improve their skills and share their experiences in building technology strategies for their classes. One group activity usually found to be successful in helping members get to know each other consists of asking the group members to form dyads with someone they do not know well, with the purpose of interviewing the person regarding their technology skills, and then introducing them to the rest of the group members. Another exercise that also works well involves each group participant standing behind his or her own chair, playing the role of a relative or close friend who would relate details about themselves (the group member) that would be important to the task at hand. These activities work best when the group facilitator starts the exercise, illustrating both the logistics and the information about the participant that would be most helpful in the learning situation.

During this initial stage, and also during a second stage sometimes classified as a stage where differences are worked out, the group considers whether the goals of the group fit their needs, and interests. These considerations often have to do with inclusion/exclusion, that is, each member contemplates whether or not this group will meet his or her needs. As this occurs, care must be taken by the learning group facilitator to help those who feel they must exclude themselves to either find a more suitable group, or to reassess their abilities to learn the material to be presented. A clear understanding of the skills that will be taught and the expectations in terms of time and achievement will often help those who feel initially overwhelmed by the experience to
stay with the group. On the other hand, understanding the purpose and scope of group goals will be helpful to the potential participant for whom the information would not be useful, or would be redundant because of the technology knowledge and skills group the member already possesses.

Once the member configuration of the group is established, the goals and expectations clearly explained, and the participants relatively comfortable with each other, the group is ready to work. At this point, it is helpful to attempt to match those who seem to catch on more quickly or have more beginning skills with those who are more hesitant to try something new or ask questions of the facilitator. Hopefully, the setting for the workshop would be a computer lab with availability of a well-maintained computer for all participants. As the workshop continues and the facilitator gets to know the abilities of the participants more fully, the buddy system suggested above can easily be inaugurated with a change of seating arrangements. In an ideal situation, several facilitators per workshop would be available so that questions and problems could be solved more quickly, consequently keeping the group together in their skill development as well.

As the learning group moves toward a more trusting and cohesive level, each member will be more willing to ask questions, even those that may seem "stupid" or embarrassing. Since members have learned to know each other well enough to be aware that they are each nearly the same stage in the learning process, much less competition or threat of being seen as inadequate will be present in the group. The group members will have had an opportunity to observe the leader's behavior as well. As they experience the technical skill of the leader as well as his/her warmth and interest in each participant, the group members will be more likely to ask questions of the facilitator, no matter how simplistic or elementary the questions may seem to the participant.

As the workshop is drawing to a close, emphasis on the future will be part of the natural progression toward group termination. A review of the material covered and how it might be used by the participant either personally or in the classroom would be indicated. The need to practice that which was learned should also be accentuated. Facilitators must emphasize that practice should begin as soon as possible, since new ideas and skills may quickly be forgotten as the participants focus on other aspects of teaching when the workshop experience is over.

The possibility of getting together informally with the group or several members of the group after the workshop for socialization is often a pleasant ending to the experience. Group members being available to each other, and the availability of the facilitators through offering continued aid for questions or problem resolution (particularly if they are part of the staff of the school system of the participants) could provide an excellent continuing resource for those who attended the workshop. The possibility of another in-service training opportunity might be discussed as well, focusing on perceived needs in the present, or more complex issues anticipated in the future. Finally, a questionnaire, assessing the value of various areas of the experience should be distributed and completed by participants as part of the workshop.

Using the group process as a teaching tool to "warm up" the technology experience requires that the group facilitators be trained in the knowledge and skills needed to lead small groups as well as the technology skills needed to fulfill the goals of the workshop. Even though these facilitating skills may require extensive knowledge and training in various domains, some of which may seem unrelated, the enrichment provided by the technology learning experience combined with the relationships developed during the group experience has the potential to provide major rewards for both participants and group facilitators.

Abstract: This study focuses on ways to connect field experiences to academic theory and reflection through email correspondence. The assignments given by the university instructor were designed to facilitate the students' reflections on observations in the classroom. The instructor hoped that her responses would mentor the students to be reflective about their observations.

Introduction

Feiman-Nemser and Buchmann (1989) report that students come to their education courses with the belief that academic theory and reflection have no relevance to becoming a teacher, and that experience in the classroom will be the primary source of growth in becoming a teacher. Research clearly documents that beginning teachers are seeking "recipes" that will tell them exactly which action to pursue and in what manner they ought to do that to be seen as the "effective" teacher. Additionally preservice teachers tend to believe that there is not much to teaching (Britzman 1991). Preservice teachers have been watching teachers for years and they believe they know what their teachers will do before they do it. Preservice teachers may think they have seen all there is to see and know most of what there is to know about teaching. Further, according to Britzman, most preservice teachers feel disrespect toward university instruction that attempts to teach them about teaching. They feel that "practice" alone is what they need.

The irony is that preservice students' frustration with university coursework in teacher education is gaining strength just at a time when the evidence clearly indicates that the difficulty of being a good teacher is increasing (Bullough & Gitlin 1995). Preservice teacher beliefs about the complexity of teaching need to be exposed. When field experiences are linked to academic theory and reflection,
students begin to question their previously held beliefs about teaching and rethink their practice (Wentworth & Hansen 1999). Reflection and the linking of field experiences to theory require a lengthy time commitment of both faculty and students. Field visits are difficult to arrange and do not accomplish the important goals of reflection or linking of theory and practice. Even when students are seen in the field by their university instructor, conversations are often short and deal with a specific event of that day. These constraints are not conducive to serious reflection on the practice of teaching.

Research evidence in educational change theory (Fullan 1993, 1999) suggests that doing things the way they have "always" been done by the majority of teachers will not help solve the problems of education. A model of teacher education that has students learning to teach primarily from already practicing teachers, or learning practice from practice, is a model of simply reproducing education as it currently exists. Teachers need to learn from their experiences and transform both their own practice and serve as leaders in helping their colleagues transform their practice as well. Thus, as teacher educators we are in a quandary. How do we mentor preservice teachers to be reflective about their practice while they struggle to succeed initially in the classroom? Email correspondence may facilitate reflection on practice.

Email correspondence has been cited as an important contributor to educational practice, allowing participants to share reflection with others. Several research studies focus on electronic networks in university settings and report that motivation and comfort level with computer networking are factors that influence students’ use of email networking (Feenverg & Gellman 1990, Kimsky 1991). Grandgenett & Harris (1994) reported that number of years of teaching influenced university faculty members’ use of computer networking. Gender, age, and previous computer experience are factors in the preservice teachers’ use of electronic communication (Downes 1993). Norton & Sprague (1997) report that on-line mentoring for lesson planning was equal to that of face-to-face mentoring with a peer. This study endeavors to analyze the value of email correspondence as a mentoring tool for university advisors of preservice teachers during an early preservice field experience. The assignments given by the university instructor were designed to facilitate the students’ reflections on observations in the classroom. The instructor hoped that her responses would mentor the students to be reflective about their observations.

Methodology

The university instructor began an 8-week “exploration of teaching” course with discussions of student beliefs about teaching and what the preservice teachers might observe as they spent several weeks working in the schools. The students were then assigned to a school where they would act as a teacher’s aid for four weeks. They were required to email the university professor once each week. Four topics, lesson planning, evaluation, NCTM questioning, and difficult students, were suggested for email topics. The topics were defined and discussed during the opening weeks of the course. The students were also required to collect data for a mini research project while in the schools. The email messages could discuss any problems with the collection of this data.

The university professor set a goal to reply to each email message within a 24-hour period. She attempted to encourage the students when they seemed frustrated, respond to questions in the emails, and ask questions that would spark further reflection from the students. She also reminded them of their data collection responsibilities and of future campus meetings. Following the field experiences the preservice teachers returned to the university for several seminars. The first day was one of unpacking the field experiences. The university professor used the emails as a beginning point to discuss several of the topics initiated in the first two weeks of class. Then the students were assigned to groups to present the data collected in the field. These groups were used for further data collection on the value of the email mentoring.

Each group participated in a focus group interview (Glesne & Peshkin 1992, Connaway 1996) within the week that they returned from the schools. Each focus group consisted of 4 to 7 students. Interviews lasted from 30 to 40 minutes and were audiotaped. Seated around a conference room table, students responded to questions posed by a moderator. Questions for the interview were formulated by the authors in an attempt to gather data concerning the following: 1) the quality of communication and connectedness between student and professor via email during field time, and 2) to what extent the weekly
email helped the students to connect with what they learned in the university classroom with what they learned in the field. During the interviews, the moderator augmented the questions to produce more in depth student response.

Results

The 24 students in the class sent a total of 81 email messages. Two students sent five emails messages; nine students sent four; nine students sent three; and four students sent two messages. Forty percent of the email messages were answered by the instructor within 24 hours of when they were sent; 11% within two days; 20% within three days; 1% within four days; and 15% within five days. (The majority of the responses sent five days after they were received were sent to first email messages that were received very early in the first week of the field experience. The instructor had not expected email to come that early so she did not begin responding until the end of the week.) Fourteen percent of the emails were not answered at all. All of the emails were coded for the topics suggested by the instructor during the first weeks of the course, lesson planning, evaluation, NCTM questioning, and difficult students. Almost every student sent an email discussing classroom questioning (25% of all emails) but not all of these focused specifically on the NCTM questioning. Evaluation was also covered by most students (24% of all emails focused on evaluation). Twenty-one percent of emails were listed by the students as dealing with lesson planning. Only 15% of the email messages were focused on difficult students. The other 15% of emails were on other topics. Each of these topics will be discussed to see if the emails help the students connect discussions in class with field experience. Selected email comments and replies will be included.

Questions

Connection to the importance of NCTM questions provided the most thoughtful responses in the emails of the students. During the focus group interviews many students commented that they remembered discussing questioning during university seminars and then seeing questioning in the classroom. The university professor discussed the point of the ineffective and often-posed question to students, “Do you have any questions?” Due to the class discussion prior to the field experience, the majority of the students noticed a “red light” when the cooperative teacher posed this question followed by the lack of classroom response.

In the emails, students commented about the importance of posing questions to students that helped them focus on understand the instruction. They also saw questions as a tool for helping students in the classroom remain focused:

“She will occasionally ask the ‘Does anyone have any questions?’ question, but it is after she has covered all the preliminary questions. If she doesn’t have any response, she will call one of the students names, usually one of them with a perplexed look. She asks the students to explain a certain concept. This seems like a great approach, because she can see if they are understanding.” (C. E. 17 September 1999, 16:29:18)

“I noticed that one specific teacher always asks the question ‘Any questions?’ Not once in the three days that I went to that class has any student ever answered that question.” (T. P. 20 September 1999, 13:45:37)

“The hardest thing that I found while taking questions from the students was figuring out how much to tell them in my answer and how much I needed to leave for them to figure out. I found it was good to use an example similar to the problem they are struggling with but that wasn’t the exact one in the assignment one.” (N. F. 20 September 1999, 15:01:25)
Evaluation

In their emails to the professor, students seemed to define "evaluation" as quizzes, tests, grading homework, and assigning grades. Typical emails about evaluation detailed breakdown of points per quiz/test and percentage assigned to in-class participation. The following email from a student about his cooperating teacher's breakdown for a final grade is a typical example of what student email about evaluation stated: "The final grade in her class is due to 20% homework, 20% quizzes [sic], 10% participation [sic], and 50% tests." (J. R., Report on Evaluation, 1 October 1999, 19:18:36)

Emails on evaluation tended to be qualitatively superficial, focusing on procedure rather than their own point of view or their cooperating teacher's philosophy. Occasionally, students would reflect that they were thinking about more than just grading procedures, such as this students' comments about her cooperating teacher's use of a test written by textbook publishers:

"Also, the test was one of those tests that comes from the book and the questions were pretty confusing. A lot of kids didn't read the directions very carefully and so they lost a lot of points. I don't think that the test accurately represented how well they could do that math, it just showed who could read the directions the best. I think that when I teach I will try to avoid using standard book tests as much as possible." (J. G. Re: Evaluation, 24 September 1999, 2:42 PM)

One student did have a notable exception. She discussed the use of alternative assessment even though she did not use that term: "I also like how instead of tests, for some sections, she gives them projects that test their skills." (J. H., Week #3, 1 October 1999, 14:48:30)

Difficult Student

Emails about a difficult students varied from describing groups of students that were challenging to teach to details about one student with whom preservice teachers tried to establish good rapport. Some emails described the willing student having difficulties with the complexities of mathematics; others talked about rebellious youth that were resistant to learning. These emails tended to be more qualitatively thoughtful. Emails about "the difficult student" often contained realizations about teaching, "all the students aren't easy to teach, even in the advanced classes. Some really require extra time and attention." (L. T., Re: Difficult Student, 4 October 1999, 4:29:12)

Communication about "the difficult student" also tended to be more story oriented, student oriented, and contained emotion as they reflected on who they were teaching. Often they also expressed aspirations like this email:

"It's really a challenge to love these kids despite their actions. I've gained a ton more appreciation for my junior high/high school teachers. Teaching is really a thankless job. Kids go on and graduate and leave, sometimes saying nothing to you about your influence. . . I really hope to be a good teacher. One who inspires, looks for the best, is respected and loves her students no matter how they do in math." (B. M. Re: Weekly Report, no date).

Lesson Planning

Many of the email messages about lesson planning were more about classroom instruction than actual planning. An idealized view of lesson planning widely held by college professors is that of the classroom teacher intently at work at her or his desk during planning period, surrounded by resources from which to glean ideas for instruction. Add to this picture several teacher colleagues with whom to discuss both the content and the pedagogy for previous and upcoming lessons, and one has the reality of planning for mathematics instruction in China as reported by Ma in her recently heralded book, Knowing and Teaching Elementary Mathematics (1999).
Neither version of lesson planning appears to be the reality for the secondary teachers to whom the students were assigned during the course under study. No students reported collaborative planning among mathematics teachers. Further, no student reported on the actual planning process. Rather, students appeared to infer from classroom instruction the nature of the teacher’s planning for that instruction. For example one student reported the following:

“I feel that my teacher, . . . , does a very good job of lesson planning. Each class starts with a warm-up. Which [sic] is a review of the day before. They go over the warm-up and then go into the next days [sic] lesson. She gives the class the objective before she starts the lesson. She introduces new ideas and has the kids help her in developing the idea. Then she has the students either go to the board and work problems, or just work out of the book as a class.” (A. D. 24 September 1999, 3:49:29)

Other students mentioned similar lesson routines, and most reported that the teachers they observed relied heavily on the mathematics textbook:

“I got to talk with the teacher about how she does her lesson planning . . . . She does her lesson planning just from the book mostly. She doesn’t [sic] write anything down, but just from observing her I can tell that her objective is internally set to help the students understand and have a concrete view of the math.” (A. L. 24 September 1999, 4:17:43)

In at least one instance, the student inferred from a discussion with the classroom teacher that that teacher viewed lesson planning as unnecessary:

“When I asked my teacher about lesson planning he did not have a very specific answer. He more or less just comes to class and decides that day what to have the kids do. He does have a set routine the students follow and sticks to it well. Most days the students are just given a lecture and then given an assignment from the book.” (J. C. 23 September 1999, 8:36:26)

In summary, little information was included in students’ email reports regarding the actual process of lesson planning. Students appeared to infer the planning process from the lessons they saw implemented, and most lessons reported were described as routine and highly textbook dependent.

Conclusions

The email correspondence seem to keep the students connected to the instructor during the weeks they were in the field and facilitate the connection of field experience and university coursework. Many of the students were surprised that the instructor responded to the first email. They were pleased to have feedback from their university instructor. Their emails seem to be more thoughtful the next week, perhaps because they knew the instructor would respond to them. Almost every student reported on three or more of the suggested topics. Very few asked questions or discussed problems with the data collection responsibilities. The university instructor commented that very few of her questions to the students were answered directly the next week. Instead the student reported on a different topic.

Email correspondence seemed to facilitate the connection of field experience and university coursework. Students seemed to reflect about the practice they observed in the classroom. However some reflection seemed to be more focused than others. Some topics seemed to be more clearly defined in the early weeks of the course so the preservice teachers were able to discuss them more deeply in their email messages. In this course evaluation and difficult students were fairly well understood by the students. Many of the email messages focused on procedural issues of evaluation, lesson planning, questioning and not theoretical issues. The instructor tried to ask questions to the preservice teachers to help them reflect about their observations, but few of these questions were answered the next week. The preservice teacher just went on to the next topic. Lesson planning and questioning were less clearly understood so the email
messages were less reflective. The instructor needs to be aware that careful discussions about topics for email messages will aid in the depth of reflection of the students as they work in the field.

Further research on the use of email correspondence will be useful in learning how to have preservice teacher reflect on theory and practice as they begin their work as a teacher. While this study focused on the connection of students to instructors, others could look at reflection when students communicate with each other. Additional work could consider allowing students to select their own topics to discuss. Email correspondence does show promise as a way for university work to connect with field experience.

New Meets New Year Two: Integrating Technology into Inquiry-Based Teacher Education

D. Michele Jacobsen
Assistant Professor, Faculty of Education, University of Calgary

W. Bruce Clark
Associate Professor, Faculty of Education, University of Calgary

ABSTRACT: What happens when an inquiry-based teacher education program encounters a province-mandated Information and Communications Technology (ICT) curriculum? This paper reports on the second year of technology integration efforts in an inquiry-based teacher preparation program. The first three sections provide the context for this endeavor and review strategies employed in the first year of targeting technology professional development in the new Master of Teaching program at the University of Calgary. The final section describes current integration strategies, professional development, and integration projects that are underway for year two of new meets new. Keywords: pre-service teacher education, technology integration, problem-based learning, needs assessment, program development.

TEACHER EDUCATION TRANSFORMED

Teacher education programs in this century have generally been organized around an applied science model within which discrete courses are framed by philosophical and theoretical content, and these in turn are followed by short-term “practice teaching” in schools. Beginning in 1996, the University of Calgary embarked on a course of action to discontinue its teacher education programs formed in the conventional mould, and to replace them with a program in which the elements of the professional degree program are integrated, the learners are treated as professionals-in-the-making, the richness of pedagogical knowledge is acknowledged, and cooperative problem-solving is valued. In this new Master of Teaching (MT) program, “courses” in the traditional sense have disappeared to be replaced with professional, case, and field seminars, independent studies, and extensive field experience. The scope of “field” has been extended beyond schools to include a requirements that every student spend a block of time in some alternate educational setting, e.g., zoo, art gallery, museum, prison, special needs facility, social agency, human resources department. Students spend approximately equal amounts of time on campus and in the field from the first day in the program, and the one experience is expected to inform the other.

The campus elements of the program include case, professional, and field seminars. Much of the “academic” content of the program is carried by a series of cases with which students must wrestle, research, take positions toward, and defend their stands. There is a logical progression of series of cases encompassing learners and learning, teachers and teaching, curriculum contexts and issues, living cases from the field during their most intensive field experience, and ethical cases (broadly defined). Each case encompasses far more knowledge than any one student can deal with in the time given—hence the incentive for cooperative endeavors. Team work and collaborative inquiry and problem solving is encouraged, valued, and rewarded. Field seminars provide a forum for the exchange of ideas and experiences gleaned from the variety of educational settings in which a group of students find themselves, not to mention dealing with many of the pragmatic issues which characterize the lives of teachers and students. Professional seminars offer students an opportunity to critically reflect on themselves as teachers-in-the-making, to pursue topics and skills of particular interest, and to engage in the many debates that surround the nature of education and teaching. Now in its fourth year, the MT program has clearly demonstrated its capability to prepare teachers who are energetic, reflective, cooperative practitioners capable of solving problems, confronting new challenges, and taking and defending
positions on complex issues. The move away from courses taught by specialists has not been without its challenges, however, and one of the first to rear its head was how to re-examine the integration of technology.

THE MT PROGRAM MEETS NEW PROVINCIAL TECHNOLOGY CURRICULA

Concurrent with the changes in teacher education at the University of Calgary is the introduction of a new curriculum by Alberta Learning (the provincial department of education), *Information and Communication Technology, Kindergarten to Grade 12: Interim Program of Studies* (Alberta Education, 1998). Best described as a requirement to teach technology across the curriculum, this approach emphasizes the seamless relationship between technology and the subject disciplines, the process nature of technology itself, and the co-existence of knowledge, skills, and attitudes (KSAs) for technology alongside those for subject areas. The emergence of this new technology curriculum follows in the wake of technology competencies that have been published for beginning and experienced teachers.

Our efforts to design professional development for technology integration are further motivated by a specific requirement that teachers develop competency using communications technology in order to qualify for teacher interim certification. Provincial legislation, in form of the Alberta School Act and specifically the Ministerial Order #016/97 Policy 4.2.1., defines the following technology requirement for teacher interim certification:

> Teachers who hold an Interim Professional Certificate are expected to demonstrate consistently that they understand: j) the functions of traditional and electronic teaching/learning technologies. They know how to use and how to engage students in using these technologies to present and deliver content, communicate effectively with others, find and secure information, research, word process, manage information, and keep records (Alberta Education, 1998b).

From the point of view of teacher education in Alberta, it is not only desirable that our students become familiar with the content of the new technology curriculum, it is the law.

A considerable amount of research and careful thought went into transforming teacher education at the University of Calgary. What now needs to be considered carefully as this new program evolves is how to address the needs of students to gain the technology competencies and thinking skills required for interim certification. The Master of Teaching program accepts 400 students per year, which translates into approximately 800 students in progress each year. The MT program must address technology in education BUT it must do so within the structure of the new program—the reintroduction of courses is not an option.

TECHNOLOGY INTEGRATION STRATEGIES: YEAR ONE

The authors were charged with the task of developing a framework that dovetails technology with the MT program. We determined it necessary to conduct a needs assessment to identify present technology skill levels and areas of highest need. To this end, we distilled the required
learning outcomes of the Alberta curriculum into a competency set that served as the basis for an online survey of students in program. Survey information was used to identify areas upon which we should concentrate our professional development efforts. A complete set of survey results has been published on the World Wide Web (Clark & Jacobsen, 1998). Comparison of 1998 survey findings with Ott's (1996) findings from education students in 1995 permitted us to draw some conclusions about the differences in clientele and entry level skills. For example, more MT students have a computer at home than did students in 1995 (i.e., 84% versus 67%), all of our students hold at least one prior degree (i.e., compared to 20% in 1995), and students entering our program have a higher degree of prior experience with word processing, email and spreadsheets. In brief, our needs assessment told us that with regards to previous computer experience, our students reported the most expertise with word processing, e-mail and WWW browsing and searching. However, a percentage of students also reported having "none" or "a little" word processing experience (9.5%), electronic mail experience (25.5%), and WWW browsing and searching experience (33.3%). Skill areas we targeted for immediate professional development support were those with which a majority of students reported having "none" to "a little" expertise. The high need areas included: accessing library resources using the WWW, spreadsheets, database creation, presentation software, and WWW page creation and editing.

Technology professional development was provided for students in three areas of the MT Program: weekly lecture, a technology skill and integration workshop series, and in professional seminar. As part of their campus experience, MT students attend a weekly lecture series on topics identified with each thematic unit. In order to focus on the integration, communication, decision making, and problem solving aspects of educational technology, the authors prepared and presented two of the winter session lectures for first year MT students on integrating technology. We organized a series of technology workshops to provide skill and integration training in four "high need" application areas: (1) presentation software, (2) web page design, (3) spreadsheets, charts & graphs, and (4) databases for social science. Upon completion of the workshop and a project, such as a web page with internal and external links and graphics, students are presented with a certificate for their teacher portfolio.

INTEGRATING TECHNOLOGY INTO PROFESSIONAL SEMINAR

The first author experimented with integrating authentic technology requirements into the full year Professional Seminar (prosem) she taught with 21 students. The basic intent of prosem is to promote self-conscious learners and teachers. More specifically, prosem opens a space in which students become aware of the differing, sometimes competing sets of values and beliefs that support and frame different kinds of educational practice. Students are encouraged to see teaching and learning from multiple viewpoints— to understand the complexity and contradiction inherent in these perspectives, to be able to choose and generate multiple possibilities for action, and to see what one's choices both allow (legitimate), or disallow (suppress). The instructor structured prosem using the following five components: (1) Weekly readings with required written interpretive and critical responses, (2) Group discussion/debate, and individual and group presentations, (3) Generative discussion periods for articulating and examining lived experience, (4) Biography of Learning / Independent Inquiry / Scholarly Writing workshop sessions, and (5) Individual consultation / feedback sessions. Student assessment was narrative, and was based
upon participation and contribution to weekly seminar, responses to required readings, creative writing and narratives, two independent inquiries, and three biographies of learning.

Given the goal of creating a collaborative on-line community of scholars, students took on the task of learning how to publish and exchange the results of their written coursework and investigations using individual World Wide Web homepages. Students met with the instructor for additional hands-on instruction both before and after scheduled seminar time, and on alternate days, in order to develop their skills in HTML and web publishing. Eventually, all students learned how to find resources on the web, create new HTML documents, convert existing word processed documents into web pages, incorporate graphics and links, and upload their web pages to a public web server. Some students learned how to convert and upload PowerPoint presentations to their web sites, to construct animations, and incorporate sound and video into their web documents.

This experiment with integrated technology requirements in professional seminar worked. We created images of how students in the MT Program can work with technology and web-based environments to create scholarly electronic communities. The integration of technology into prose also assisted us in better defining the challenges ahead as we work to integrate technology across the Master of Teaching program. The additional time required to prepare for and to integrate technology in this one course, and the ability and skill levels required of the instructor, lead us to conclude that issues of faculty workload and professional development requirements will be primary considerations in drafting plans for faculty-wide integration. Several additional hours per week over an entire semester, for both faculty and students, is a significant commitment to ask of people. Therefore, we will have to focus carefully on the learner outcomes the faculty plans to target and realize that any and all integration efforts will require that individuals invest time in their own professional development and instructional planning in order to yield the expected returns. Even with years of educational technology experience and bushels of enthusiasm and commitment, the lived curriculum with regard to technology integration can be anything but neat and tidy! Computers freeze, network connections are busy or go down, the projector bulb burns out, floppy disks and hard drives die, and students ask questions that cannot be answered on the spot. However, in the midst of all of this apparent chaos, students create amazing and extensive projects, develop remarkable technology skills, discover the fallibility of technology, overcome some of their technology-related fears, and invent neat ideas for technology integration in their future classrooms. The challenge will be to convince our colleagues to persevere in spite of these expected, and often inevitable, technology glitches and failures, and provide the necessary support and just-in-time training as they work toward meaningful integration of technology into learning goals and processes.

NEW MEETS NEW IN YEAR TWO

A number of recommendations, in the form of goal statements, were made to the Faculty of Education Curriculum Planning Committee as a result of our first year technology integration efforts and literature on technology integration, professional development, and ICT leadership (Jacobsen, 1998; Stein, Smith & Silver, 1999; Yee, 1999): (1) take steps toward the ubiquitous integration of technology into the MT program, (2) plan for and support faculty members'
professional development for technology integration, (3) create an electronic communication medium for all MT students and faculty, (4) disseminate instructional materials about technology access and requirements, and (5) offer an extended MT technology workshop series in 1999/2000.

TECHNOLOGY INTEGRATION COMMITTEE

The first recommendation was to reconceptualize the end goal of "ubiquitous integration of technology for learning" from being a sole responsibility of the "educational technology folks", and repositioning it as a faculty-wide vision and commitment. The new provincial curriculum requires all teachers to integrate technology across the K-12 curriculum. Technology as process is every teacher’s responsibility. Therefore, technology integration efforts on campus should be undertaken by faculty across all curricular specializations, rather than relegating it to the technology specialists. To this end, one of us has formed and now chairs a Faculty of Education Information and Communications Technology (ICT) Integration Committee. When selecting potential committee members, careful consideration was given to appropriate representation and diverse membership. A goal was to promote a faculty culture that explored fundamental teaching and learning issues, rather than emphasizing the adoption of technology for technology sake, so it was important to solicit and include views from both adopters and non-adopters in the faculty, in schools, business, and government about the relative advantages of technology for teaching and learning. Therefore, the committee includes Faculty of Education colleagues with expertise in areas other than educational technology, colleagues with expertise in educational technology, the Director of the Doucette Resource Centre, individuals from Calgary-area school boards, a member from the Galileo Educational Network, an individual representing Alberta Learning and the leading author of the new Information and Communication Technology Interim Program of Studies for Alberta, and an individual from industry with technology expertise.

The committee's goal is to create a shared vision by working to establish a Faculty Wide Technology Integration Plan. This document will provide a flexible and responsive plan that will guide rather than constrain integration efforts that are in alignment with the University Technology Integration Plan and the teacher certification requirements of Alberta Learning. An outcome of this Technology Integration Plan will be to address the second goal, that of determining the technology professional development requirements of faculty members, and developing appropriate strategies access to technology, training, and support. In order to realize the potential benefits from technology, the faculty as a whole needs to find ways to encourage and assist faculty members with the adoption of technology for a variety of teaching, administrative, and research tasks. Without attention to the human infrastructure, nothing of value will be achieved with the technological infrastructure (Jacobsen, 1998).

SPECIAL TOPICS SEMINAR FOR SECOND YEAR STUDENTS

An opportunity for advanced technology infusion in the MT Program has presented itself in the form of the second year special topics seminar. In their final semester, second year students enroll in a special topics seminar which allows them to extend and deepen their understanding about a particular aspect of education. A list of diverse topics for special seminar is made available to students in semester three, and students indicate their preferred topics. A special
topics seminar entitled "Integrating Technology Across the Curriculum" has attracted 45 second year students for the Winter 2000 semester. The normal class size for special topics seminar is 15 students. Instead of offering 3 separate seminars, the first author and two colleagues with expertise in educational technology have been afforded the innovative opportunity to team teach a combined seminar with all 45 students. Goals of this seminar include: (1) investigating fundamental teaching and learning issues that surround the use of information and communications technology in educational settings, (2) examining both the potential and the limitations of educational technology use, (3) providing a forum for discussion of conceptual issues related to educational technology and the Alberta Learning Technology Outcomes, (4) participating in a collaborative, electronic community to publish, exchange and consider emerging ideas, (5) engaging in practical exercises that have classroom application for student learning, and (6) acquiring some proficiency in the use of various computer applications. A component of the seminar will be to critically analyze, build and extend upon innovative professional development strategies described by Stein, Smith & Silver (1999) with regard to technology integration, and approaches to ICT leadership outlined by Yee (1999). Students will be responsible for producing a portfolio demonstrating advanced technology understandings and skills. Portfolios will be assessed by the seminar leaders, along with student-selected peers, public school and university faculty members.

EGALLERY: ELECTRONIC PUBLICATION OF EXEMPLARY STUDENT WORK - http://www.ucalgary.ca/~egallery

The third goal, to create an electronic communication medium for faculty and students, has opened a space for an innovative publication medium for student work. A number of faculty members, teachers, and two second year MT students have formed an editorial team and have created the EGallery, a web-based peer-reviewed publication of exemplary student scholarship. EGallery's mission is to provide an electronic medium for international publication and consideration of exemplary scholarly work produced by Master of Teaching students in the Faculty of Education. The editorial team seeks submissions of critical essays, independent inquiries, and biographies of learning from first and second year Master of Teaching students. All submissions are subject to a peer review process.

To get to the stage of a full-scale launch of the EGallery, a number of different development tasks needed to be undertaken by the editorial team. We needed to: (1) discuss and develop a mission statement, (2) define our intended audience, (3) outline our purpose, (4) establish publication and submission guidelines, (5) establish a review process and criteria, (6) consider how we might involve others, (7) consider who might become reviewers, (8) design advertising and promotion strategies, (9) canvas for academic and financial support, (10) establish an e-mail account and web page directory on the University of Calgary server, and (11) design and develop the website.

Development work has also included, not exclusively: (1) designing HTML documents and graphics for the core website, (2) designing and publishing paper-based promotional materials, (3) formatting and publishing the first two submissions for review, (4) creating a review form that will e-mail results to the editors, (5) inviting others to become part of the editorial team, (6) inviting peers and students to become reviewers, (7) fielding numerous questions from peers and...
students, (8) recording and discussing suggestions and advice from others, and (9) editing, refining, and maintaining the web site.

There are some technological and infrastructure requirements to consider when launching an online publication of this type. The EGallery website is hosted on a University of Calgary public web server, and linked to the official Faculty of Education website. The editorial team considered it crucial to have both the Dean and the Associate Dean's public support of the EGallery, and sought their advice and advocacy. The Department of Teacher Preparation in the Faculty of Education has generously supported EGallery by providing photocopying for promotional materials.

We have published a prototype issue of the EGallery with two exemplary independent inquiries about teaching mathematics. Our immediate goal is to publish the first issue of EGallery in January 2000 with six exemplary pieces of student scholarship. Our future plans are to fully explore how EGallery can become an active and inviting space for critical discussion among experienced educators, faculty members, and student teachers about educational issues and topics. We plan to investigate how the editorial team might facilitate ongoing and sustained conversations that build and extend upon issues raised in the published work.

TECHNOLOGY HANDBOOK

The fourth recommendation was based upon an observed need for instruction, access, and support materials that students could access for individual training and support needs. Plans are underway for the creation of a technology handbook for faculty members and students. This document will be available on the Faculty of Education web site as both HTML and PDF documents, and will provide useful information about technology integration activities, professional development, and resources. A preliminary list of topics and resources that will be addressed in the Technology Handbook are: 1) requirements and expectations for technology integration by Alberta teachers for Interim Certification by Alberta Learning, 2) where to access and how to print Alberta Education online resources (PDF files) and curricular documents, 3) how to get e-mail account and how/why to use it (i.e., communication with faculty, peers, cooperating teachers), 4) how and why to sign-up for list server, and 5) the URL for Faculty of Education web site and description of relevant online resources.

MT TECHNOLOGY WORKSHOP SERIES

We have organized an extended MT Technology Workshop Series for the 1999/2000 instructional year that includes instruction in getting started with technology, personal writing, communication and research skills, creating computer-based slide presentations, and graphics creation and integration. A fundamental goal for all of the workshops is to provide images of how the new ICT curriculum might be lived out in the classroom with students.

The first workshop was designed for beginners who wanted to develop a better understanding of computer terminology and components, to navigate basic operating system features, to word process, save to disk, and print a basic document, to access technology resources in the faculty, and to set up an email account with the university. The second workshop was developed for
beginners who wanted to refine their writing, communication and research skills using a computer. The workshop was designed to help students to develop general word processing skills (i.e., new, open, save, print, page numbers, double spacing, formatting, insert clip art, and so on) for their major writing assignments, to use email to communicate with others (i.e., instructors, partner teachers, and peers) and to exchange attached files, to use various search engines to locate research information on the World Wide Web using a browser, to download and open Curricular documents, such as the Technology Outcomes document, from the Alberta Learning Website (Alberta Education, 1998). The third workshop was designed to provide instruction on developing computer-based slide presentations. Students learned how to create PowerPoint presentations using the Wizard feature, design a new presentation from blank slides, develop a new presentation using the color templates, add graphics and special effects, and most importantly, explore how presentation software can be used for writing and research in the classroom with/by students. The fourth workshop built upon skills learned in the first three workshops. Students learned how to integrate graphics into word processing and presentation documents, to create graphics using a flatbed scanner to digitize photographs, drawings, and other media, to use a spreadsheet to create simple charts and graphs, and to create drawings and figures using draw tools. Students also learned how to download images from the World Wide Web for use in word, presentation, and web documents.

Three additional workshops will be offered in the Winter 2000 instructional session: database design and integration, manipulating numerical data using spreadsheets, and web design and HTML.

Teachers Learning about Software Implementation

Alex C. Pan
The College of New Jersey
pan@tcnj.edu

Abstract Knowing how to integrate computer resources into curriculum is far more important than finding what resources are available, where the former requires the knowledge and skills of evaluating, planning, designing, and enforcing. Most teachers today, however, lack knowledge of and experiences with software implementation. This paper describes an experience of 23 teacher education sophomore students observing school children exploring the Magic School Bus CD-ROMs and discusses several related issues, including students’ perception, children’s performance, the usefulness of the software programs, and other issues.

Introduction

Throughout many years of working with teachers, I have heard many teachers ask, “What computer resources or software are available for my teaching?” Surprisingly, very few teachers have asked, “How can I best use the existing computer resources for my teaching?” Although most teachers are eager to know what resources are good for their class to use, it would be improper to assume that teachers already know how to integrate existing resources in their curriculum and they only need to know what resources are available and how to acquire them. By talking with school teachers on various occasions, I found that many teachers have faith in computers and believe computers can enhance content teaching and learning although these teachers did not have experiences using computers in teaching, nor did they know exactly how students would react toward the computer resources being used in any given situation.

Knowing how to integrate computer resources into curriculum is far more important than finding what resources are available, where the former requires the knowledge and skills of evaluating, planning, designing, and enforcing. As Dias (1999) indicated, although electronic resources are widely available, how software may be best integrated into curriculum still remains a puzzle among most teachers. Oftentimes, teachers are unaware of the students’ needs when assigning computer-related learning tasks for students to complete.

To help preservice teachers better understand the actual use of computer programs for teaching and to help some local elementary school children gain a better understanding about what it is like when learning in a college computer lab, a special arrangement was made to invite local elementary students to the College of New Jersey campus. Forty-five children in grades 1 through 5 from a professional development school in Trenton, NJ, came to the college. The sophomores in the Analysis of Teaching class met with these elementary school students in a campus computer cluster. The children were given an opportunity to explore the Microsoft Magic School Bus CD-ROMs, and the college preservice teachers observed and helped them with this experience. The preservice teachers gained more sophisticated understandings of how
children approach software as they observed and documented this experience. After elementary students had a good time learning while playing on computers, they were asked to share how they felt about the software and what they enjoyed most about such an experience.

Based on the results of the children's visit and exploration on the software, this paper explores various issues with reference to the following questions:

1. How did elementary students react toward the Magic School Bus software?
2. Are there changes in preservice teachers' perceptions about how elementary students would perform or benefit from using the software program before and after this experience?
3. Do elementary students prefer the use of the Magic School Bus software for learning to the traditional classroom instructional approach?
4. Do elementary students' attitudes change after they explore the software?
5. Do college students perceive the use of such a program superior to the traditional approach of instruction?
6. Are there any differences in performance between the younger students and the older students?
7. How well do the preservice and inservice teachers know about software implementation?
8. Under what circumstance will elementary students benefit from the software?
9. What did the preservice teachers learn from this experience?

Magic School Bus Series

The Magic School Bus (MSB) CD-ROM programs, designed and developed jointly by Scholastic and Microsoft, are based on a series of books and video tapes that center on science explorations in various topics, including exploring the ocean, inside the earth, the human body, the rainforest, and the Solar System. This highly interactive program series features Ms. Frizzle, a teacher who, with the help of a magic school bus that can go anywhere and do anything, provides her students with outrageous field-based science experiences. The CD-ROMs attempt to simulate journeys presented in the books and tapes and to engage children actively in science through various activities. The design of the series is based on Ms. Frizzle's teaching approach: exploring, getting messy, and finding solutions to problems encountered by students. The CD-ROM programs are intended for teaching and learning with the constructivist's approach.

The visit of school children

Forty-five children in grades 1 through 5 from Christopher Columbus School, a member school from the Professional Development School Network, in Trenton, came to The College of New Jersey. Twenty-three college sophomores in the Analysis of Teaching class met with these elementary school students in a campus computer cluster. The children were given an opportunity to explore MSB CD-ROMs, while the college students observed and documented them as they did so. These children later shared how they felt about this trip and what they have learned from using the Magic School Bus CD-ROMs.

The procedure
Prior to the children's visit, the sophomore students rated the MSB software based on their own observations and perception. During the visit, each sophomore student observed two pairs of school children who explored the software together for two one-half hour periods. The children were randomly assigned to work in pairs on one of the MSB CD-ROM titles for a half hour, then worked on a different MSB CD-ROM title for another half hour. After the observation, the sophomore students rated the MSB software again and wrote reports describing their observations. In addition, before and after the elementary students' visit, sophomore students were surveyed about their perceptions and attitudes concerning the usefulness of using the MSB programs for teaching and learning. The sophomores were encouraged to answer the question, “Did the children succeed in using and learning with the Magic School Bus software?” The Columbus School children were also asked to share what they perceived about their Magic School Bus experience. The data collected are primarily from the sophomore students' pre- and post-survey as well as their reports about their perceptions and findings from observing children using the software.

Results

This paper addresses some key issues related to appropriate software implementation. Derived from careful observations of how college students interacted with the elementary school children on the computer tasks, how sophomore students interpreted their observations, and gathered from the pre- and post-surveys conducted with all participating preservice teachers, some interesting findings are worth noting. Many preservice teachers didn’t actually learn how to integrate software into instruction until they had a chance to interact with both the software and students. As a result of this experience, many preservice teachers developed a different perspective about the best way to implement software in teaching. Through an informal discussion with the two teachers of the students in this study, it was determined that they had an incorrect notion about how their students would react toward the software and how the software may be best used to enhance teaching and learning. Like many others, these two teachers assumed that having students learn with software would automatically result in positive learning outcomes. A further report of the findings is presented below.

Sophomore students' attitudes

In general, students held good faith in software and advocated the usefulness of the software. Although a few sophomore students expressed different concerns of the software implementation after they observed these children exploring the software, there were no significant changes in their general attitude toward this particular software or toward the general use of educational software for instruction. This may be partially due to the insufficient amount of time allocated for children to use the software for learning, and partially because there are no lesson plans or other activities to go along with the software; it became impractical to assess the value of the software when it is irrelevant from the intended learning contents.

Sophomore students' beliefs

As evident in their observation reports, most sophomore students believed it was worthwhile to use software in instruction because:
Learning with CD-ROMs vs. learning with Ms. Frizzle

It is interesting to compare a regular classroom setting with Ms. Frizzle’s class. Many sophomores can easily identify some major differences, including the language used by Ms. Frizzle, the efforts for the class preparations, the concept of student safety, the flexibility of class time and activities, and the passion for new knowledge. Students were also encouraged to compare learning with CD-ROMs with learning with Ms. Frizzle. Most students considered the similarity between the two, while some students pointed out some differences. These comparisons are listed below.

- “Ms. Frizzle rarely answers the children’s questions directly; she allows them to learn hands-on. Similarly, the software gave little instruction; the children have to figure out how to use it.”
- “The CD-ROM offers an independent learning experience for children, in which they are free to explore and learn on their own. This is similar to Ms. Frizzle’s methods in the cartoon classroom. She is not concerned with telling children things; rather, she favors a method where children discover things for themselves, with very little direction from their teacher.”
- “The teaching that is embodied in the CD-ROM is different from that of Ms. Frizzle. Although it encourages independent learning and allows children to explore different areas, it keeps them in a controlled environment and constantly spits out facts. Ms. Frizzle’s mantra is ‘take chances, get messy, make mistakes.’ When interacting with the CD-ROM, I realized

Sophomores’ observations about children using the MSB software

- The CD-ROM offered little direction. Some children could navigate with ease, but others required extensive guidance. Most observers felt this impaired learning.
- Younger children generally liked the software more than did older ones and were excited by the sights and sounds they were able to create.
- Children were engaged with the video game-like activities and had little interest in the facts.
Only a few children took an interest in the game around which the software was organized. There was little knowledge embedded in the games, and few children could identify anything they had learned. While some activities had more learning than others, all had some educational value.

Children were generally good at sharing the mouse and working together. Children tended to click around, avoiding difficult activities or those that involved a lot of information.

A half hour was not enough time for children to become engaged with the software.

How would sophomore students use the software for their future teaching?

Elementary students were frequently carried away by the bells and whistles presented in the software and ignored the intended learning content. Simply putting students to work on a computer program does not necessarily guarantee learning success. Sophomore students suggest implementing the software for teaching:

- as the primary source of instruction for older children.
- as an introduction to a unit.
- as a supplement to a unit once children knew the basics.

Children’s reaction toward the visit

The children shared their perceptions with us and almost all of them gave positive feedback regarding their experience. Most children were excited to have an opportunity to visit the college computer lab and work with college students. They were strongly motivated to explore the CD-ROM programs and thought this experience was fun. Although most children had encountered some difficulties in figuring out what to do in the program at various stages, they did not seem frustrated. In fact, many children seemed to pay more attention to running the MSG programs rather than focusing on the learning contents.

Implications

- Software integration is complex. Know it well, pilot it on children, and use it appropriately.
- Time pressures may make it difficult to use software effectively.
- Preservice teachers believe that learning should be fun.
- Preservice teachers equate constructivism with hands-on learning and don’t see a difference between Miss Frizzle and the CD-ROM.
- Preservice teachers like the idea of software but are afraid of its random quality.
- Preservice teachers are technophilic.

What did the sophomores learn?

- They found that children are fast in catching up with new computer applications. It took adults longer to figure out something in the program than children.
- It is important to find appropriate software to supplement teaching. Not all the materials are good for instructional needs.
Putting students in the computer lab to explore the Web or software applications will not automatically help students learn better. Lesson planning is essential to ensure the success of the software implementation. To maximize the learning, teachers should relate the learning contents with the computer programs as well as with students’ prior experience.

When applying software in the school, there may not be sufficient hardware or software resources. The cooperative or collaborative learning setting is beneficial to engage students in learning from each other.

Software implementation requires time. It will take plenty of time for teachers to prepare the lessons. It will also require much time for students to explore the programs. Not until they can manage the program well enough will they be able to engage in active learning through activities.

Summary

Knowing how to integrate computer resources into curriculum is far more important than finding what resources are available, however, most teachers lack knowledge of and experience with software implementation. By inviting some elementary school children to The College of New Jersey to explore the Magic School Bus series, sophomore students developed a better sense of software implementation while observing children using the software. They also developed a better understanding about some other related issues which are essential for software implementation in the classroom.

Abstract: California legislation recently mandated that credential candidates meet specified technological competencies before being recommended for a California State Teaching Credential. This paper describes how a large teacher preparation institution and an innovative alternative to certification offered by the California State University system are responding to this legislation. Faculty involved in the implementation efforts discuss issues and challenges faced and share examples of information technology infusion in a variety of teacher education courses.

Technology Infusion in the Credential Program at CSUF—Roy M. Bohlin

As a result of recent legislation in California, the faculty at California State University, Fresno were faced with a dilemma of how to make sure that our credential graduates met specified computer competencies. There are several ways in which technology competencies can be implemented into a teacher credential program, but some of these were not an option for us. Because our current credential program doesn’t allow room for additional courses or credit hours, we had to find a way to infuse technology into the overall program. For us the greatest barriers to the infusion of computer experiences include the following:

- Many part-timers teach many sections of our core courses on a rotating basis.
- In spite of a new technology enhanced building with four complete computer labs, many sections are assigned outside of our building and many classrooms do not have a computer and/or an internet connection.
- Many of our faculty were not comfortable with moderately high levels of computer usage.
To address these problems, the Dean and Department Chairs first identified several key courses to be the focus of the infusion efforts. These courses in which the major infusion responsibility would be placed were:

- Curriculum and Instruction
- Mathematics in the Elementary School
- Psychological Foundations
- Teaching Reading.

I was asked to coordinate the effort to infuse technology into our credential program, while focusing on these courses. The process of getting faculty onboard was begun by holding a meeting in which key faculty were asked to help make decisions about content and timing for a weeklong workshop during the summer of 1999.

Because the reading faculty were already saddled with their own competencies, the reading course was done separately. Their infusion was coordinated by a member of that department, who had previously worked on Web-enhancements in several courses.

A weeklong workshop was scheduled in June and 12 faculty were able to participate. They all had some familiarity with both word-processing and e-mail. During this week faculty were:

- Introduced to the new labs, computers, and network
- Familiarized with several applications (e.g., PowerPoint, Netscape Navigator and Composer, HyperStudio) and search engines (e.g., Metacrawler, HotBot, Sherlock)
- Shown model examples of how technology can be used in student-centered higher-order thinking lessons
- Provided with the opportunity to meet with exemplary technology using teachers, technology coordinators, and other resource people to discuss what students need to know and how we might better prepare future teachers to use technology
- Given time to thoroughly examine and discuss the content of their courses to make decisions about how technology might be best used to achieve their curricular goals.

Stipends were provided to the participating faculty. The feedback from the participants was very positive. They enjoyed the opportunity to learn about infusing technology into teaching and they also enjoyed the opportunity to meet with other faculty and discuss many different issues related to their courses.

Two matrices were developed during the week, one for the Multiple Subject and one for the Single Subject programs. Faculty selected those competencies that fit the needs of their students and the content of their courses. The selected competencies were identified as being either primary or secondary responsibility in each course. Actually, very little negotiation was needed to cover nearly all of the competencies with these selected courses. The few that did remain “unclaimed” were added to either the general curriculum classes or as part of the field experience courses.

Individuals from each of the four courses volunteered to serve as leaders in the fall, to pilot the full infusion plans developed by the teams. The others agreed to try infusing one or two of the new assignments or lessons. I met with the course leaders and talked with their team members late in the semester to discuss progress and to help participants move through a formative evaluation process. The revised plans are being implemented in Spring 2000 semester. Additional stipends were not available for this continued planning and work, so the effectiveness of this part of the process was very limited.

Also during the 1999-2000 academic year, I am planning several follow-up workshops and professional development experiences aimed at helping faculty to gain more knowledge and confidence of computer use. Some of these experiences will be coordinated with a grant that will provide some support and small stipends for faculty. Additionally to help provide technical support while faculty are teaching, a lab support person is scheduled to be available to help with hardware and software problems three evening a week. He has also helped faculty by teaching some of the technical skills to students in some of the classes.
Designing Meaningful Activities for the Elementary Curriculum and Instruction Course—Robin T. Chiero

The newly adopted technology standard mandated by California states that credential candidates must “demonstrate knowledge and use of computer-based technology to enhance and support teaching and learning”. There are a number of competencies that indicate that this standard has been met. One of the courses designated to address a number of the competencies was the course titled “Curriculum and Instructional Methods in the Elementary School.” In this course students explore a variety of topics, issues, and instructional strategies related to curriculum theories and practices in the elementary school (K-8), and learn how to plan lessons and create instructional units.

One section of the course was selected to serve as a pilot to integrate activities that would enable students to meet the competencies. The students in the course were in a cohort program designed for “re-entry” students (students going in to teaching from another career). Consequently, the students were, for the most part, older than students going directly into a credential program after completing their undergraduate work. There were 24 students in the course, sixteen females and eight males. Results of the pilot will be used to provide information necessary to revise activities and ensure that they can be consistently met across all sections.

There are, in a sense, two perspectives of technology integration in such an effort. First is the use of technology in the curriculum course so that students see the advantages technology can have for their own learning. Second is the issue of providing them the knowledge and skills for using technology in their classrooms. A group of professors who teach the course met to determine what activities would be. Table 1 shows the competency and the corresponding activity.

Table 1. State-mandated Competency and Corresponding Activity
Goals of Designing Course Activities

Three major goals in designing the activities were to (1) provide opportunities for students to demonstrate their competency; (2) design activities that are relevant to course content; and (3) model appropriate use of computer-based technology in the classroom. To meet the first goal, students had opportunities to demonstrate their competency in a number of areas. For example, a major assignment in the course is to create a two-week interdisciplinary instructional unit. Included in the requirements for the unit were to use a spreadsheet as part of the assessment component, to incorporate text and graphics into a letter to parents describing the unit, and to incorporate technology into unit lessons. Although students did not have hands-on practice, electronic portfolios as a means of assessment were discussed. In addition, the course web site supported a Bulletin Board where students could discuss topics covered in the text and pose additional questions. Also available at the course web site was the syllabus and course materials based on lectures and class activities.

Challenges and Opportunities

One major challenge encountered was one that has historically been a major obstacle to computer integration—that of access. The cohort program is a site-based program and all classes are held in a portable classroom at an elementary school site. This was the first year at this site, and for the first several weeks there were no computers in the classroom. Eventually three computers were made available for the portable, but without Internet access and without a projection device. The logistics of borrowing a projector from the School of Education and taking it to the site were difficult. Another access challenge was access to software. The computers supplied had limited productivity software installed, but had no educational software for students to examine and evaluate. These circumstances limited the amount of modeling that could be done in the course.

Another, and perhaps more important challenge was to design activities that demonstrated the true power of the computer to support teaching and learning, not merely activities that added to the demands of the course. In this pilot, although activities provided students the opportunity to demonstrate their competence in a number of areas, the activities need to be revised somewhat to show how computers can support the teaching and learning process.

An unanticipated opportunity arose as a result of the coming accreditation visit the School of Education and Human Development will have next spring. Each program is to create a visual display that describes the program. The program coordinator and I decided that this would be a good opportunity to model the use of a multimedia program to convey information. One assignment was adjusted to allow additional time to create the project. As a whole group we decided what major topics we wanted to include. I presented a brief introduction to PowerPoint. Students then were divided into groups with each group taking a topic. Groups designed their slides on index cards before going to the computers. Then they entered the information on slides. Due to time constraints, we didn’t have time to complete the final product during class time. An indication of their interest was that many students requested they be able to finish the project, as they had a particular vision of what they wanted to convey. We have set aside a date during the winter session where they will be able to complete the project.

Conclusion

Despite the challenges encountered during the pilot course, students indicated positive attitudes regarding the importance of incorporating computer-based activities used in the course. Early in the semester, one class session was held in a computer lab on the University campus so students could practice accessing the course web site and other Internet sites and so they could explore some of the educational software programs available in the labs. The bulletin board was widely used throughout the semester, not only to respond to questions posed about text material, but also to discuss student teaching experiences, ask questions, and share ideas and resources. With the access to computers problem solved from the start of the semester, other more sophisticated issues could be more satisfactorily addressed. Activities incorporated in to the pilot need to be revisited to ensure that they not only address the competencies, but that they model the strengths of technology in supporting student learning.
Technology Infusion in an Elementary Mathematics Methods Course—
Carol Fry Bohlin

At California State University, Fresno, all Multiple Subject Credential Students are required to take CTET 121, a three-unit course in mathematics teaching methodology for the elementary school classroom. Following the one-week Technology Infusion Workshop described above, I completely restructured my assignments to provide multiple opportunities for my students to become comfortable using technology as a resource for their current and continued professional development in mathematics education. Eleven assignments were developed that incorporated the following technology competencies: the student (a) is familiar with a variety of computer-based collaborative tools (e.g., threaded discussion groups, newsgroups, list servers, online chat, and audio/video conferences); (b) demonstrates competence in the use of electronic research tools (e.g., access the Internet to search for and retrieve information); (c) interacts with others using email, and (d) demonstrates knowledge and understanding of the appropriate use of computer-based technology in teaching and learning. A number of other competencies were also addressed to a lesser extent in the assignments or by the guest speakers—elementary teachers who provided an inspiring vision of the range of possibilities for technology’s effective use in the K-6 mathematics classroom.

All students were required to have an email account. Those who did not already have an account were provided with a free University account prior to the second day of class, at which time the class met in a computer lab for hands-on experience with e-mail, Web browsers, spreadsheets, databases, and word processing programs. A discussion was held about attaching files, hot links, characteristics of various e-mail programs, Netiquette, and various differences between Macintosh and MS-DOS computers. During this first class session, the assignments were discussed in depth, and I demonstrated how to join a listserv. The class met in a computer lab the following week and was given a handout of “Must-See Web Sites for K-12 Mathematics Teachers.” They explored sites such as the National Council of Teachers of Mathematics, the California Mathematics Council, the California Department of Education (with links to the California Mathematics Content Standards, to the California Mathematics Framework, to the list of recently-approved mathematics textbooks, and to schools’ scores on the Stanford Achievement Test (SAT 9), Eisenhower National Clearinghouse, EducationNews.com, and The Math Forum.

The students were also added to my personal distribution list—“OMEN” (Online Mathematics Education News) to help keep them apprised of the latest developments in mathematics education at the local, state, and national levels. They will remain on this list following the completion of the course.

Assignments

All course assignments were submitted to me via email; one assignment had to also be distributed electronically to all students in the class. Each assignment was required to contain a concluding paragraph where students reflected on the assignment (e.g., its value, what they learned, ease of completion), their feelings about using e-mail and other computer applications, their thoughts about the class, and anything else they wanted to express. Below are very brief descriptions of the assignments:

(1) **Statewide Test Results**—Students looked up the SAT 9 (Math) and Math Augmentation test scores for a selected school at the STAR Web site [http://star.cde.ca.gov](http://star.cde.ca.gov). They then interviewed teachers and administrators at the school about steps that were being taken to address student performance on these tests.

(2) **Report on Classroom Technology Use**—Students interviewed a teacher from each of three different grade levels at an elementary school to see how these teachers infuse technology into their mathematics curriculum. Students are given a number of issues to address in their paper.

(3-5) **Online Article Reviews**—Students went to the National Council of Teachers of Mathematics (NCTM) Web site for three months (September, October, and November) and selected an online article from one of the four NCTM publications to discuss and critique.

(6) **Listserv Membership**—Students joined a mathematics education-related listserv (e.g., math-teach, TIMSS-Forum, AMTE, or NCSM) and wrote a report summarizing their experience (discussions, etc.). They were encouraged to participate in the discussions, and over half of the students elected to do so.
(7) ENC Web Site—Students became familiar with all aspects of the Eisenhower National Clearinghouse (ENC) Web site (http://www.enc.org). ENC publishes an outstanding magazine, ENC Focus: A Magazine for Classroom Innovators. Students signed up for a free subscription at http://www.enc.org/focus/. They also wrote a critique of an article in each of several issues of ENC Focus.

(8) “Ask Dr. Math”—Students submitted a math-related question to “Dr. Math” at the Math Forum site (http://forum.swarthmore.edu/) and reported “Dr. Math’s” response.

(9) Search Engine Exploration—Students picked a math-related topic (e.g., Fibonacci numbers, pentominoes, tessellations, division of fractions, Platonic solids, etc.), and used MetaCrawler, Ask Jeeves, HotBot, and AltaVista search engines to investigate sites related to their topic. They wrote a report comparing and contrasting each of these search engines.

(10) Web-based Lesson Plan—Students went to the “lessons” portion of the SCORE-Math Web site (http://score.maths.k12.ca.us/). The site contains teacher-developed, Web-based lessons that are linked to the California Mathematics Content Standards and the NCTM Standards. The students developed their own Web-based, standards-based lessons and shared them in class. Students were also invited to submit their lessons to the SCORE-Math site, and received $200 if their lesson was accepted.

(11) “What I'll Remember Five Years From Now”—Students mentally projected themselves into the future to reflect upon what they will recall from CTET 121. I have found this assignment to be one of the most valuable for me as an instructor, and the students appreciate the opportunity to reflect on the semester and see what aspects of the class stood out in their mind and what knowledge and meaning they constructed from the class.

Reflections

The reaction to the assignments and the focus on technology has been overwhelmingly positive. Having assignments submitted electronically allowed me as an instructor to hold an ongoing dialogue with my students; to develop a more interactive, personal relationship with them; to provide feedback to them as they completed their assignments; and to mentor them on various matters. Virtual office hours were thus “24-7,” which students greatly appreciated. Throughout the semester, the students’ comments on the assignments indicated an increasing confidence in their computer skills and their excitement over the power of the Internet for information-gathering. Their assignment reflections included the following:

- This assignment inspired me to think about how to include technology into my classroom. I think it is easier for me as a student teacher because I can start thinking of ways to integrate the Web, computer software, and email into my curriculum before I have my own students. By reviewing the math standards now, I can look for innovative ways to teach this information. For teachers that haven’t incorporated technology into their curriculum, it is more difficult for them to either enhance or replace their existing materials. I’m excited about all the possibilities for using various technologies in the classroom. It is not only a more visually stimulating way to learn but it is also a necessity to be successful in this society.

- I am becoming more confident in myself in using the computer, and found that I don’t have a feeling of dread in using technology in my classroom.

- I cannot believe the amount of useful information that is available through the Internet. The unlimited amount of resources have given me a sense of empowerment in teaching math in innovative ways.

- I would like to thank you for these interesting assignments you have given us. I don’t know where else I would have found all of these things that you can do on the computer.

- I thought this lesson was a lot of fun to create. I didn't realize how useful the Internet could be for making math lessons, or any other lessons. I searched the Internet for different sites to incorporate into my lesson and I found these to be the most useful and easy to use for the lesson I created. After doing this lesson and all of the previous assignments, I am feeling much more comfortable using the Internet and e-mail. I look forward to trying to implement it into my classroom when I teach.

Postscript

This is the first semester that technology has been infused into CTET 121 in any significant way. Prior to this semester, I only had students surf the Web for Web sites that they felt would be useful for K-6 teachers. (They also gained experience with using calculator technology, using the TI Math Explorer to help develop mathematics concepts.) Hence, the planning and implementation was time-consuming and involved much experimentation. In addition, organizing and responding in a timely fashion to all of the students’ comments and
papers electronically was quite a challenge! However, the many benefits to the students and the close relationships that were developed made the efforts worthwhile.

In the future, I plan to develop a course that incorporates more math-related software and one that is Web-enhanced, as many of my colleagues have done. Such a course will include threaded discussions, online calendars, chat rooms, online resources and lessons, and other elements of an interactive, virtual learning environment that helps students see the possibilities of how technology can, as David Thornburg has said, “prepare our students for their future, not for our past.”

Sparkles and Blemishes: Integrating California’s New Technology Competencies into a Fifth Year Secondary Credential Program—Susan Harris

Educational decision-makers in California are anxious to equip beginning teachers with all the skills and competencies necessary to be “successful” teachers. They need opportunities to learn about the social and psychological foundations of education and the generic teaching skills related to instructional planning and management. They need content knowledge as well as knowledge of content-appropriate pedagogical strategies. They need opportunities to apply what they are learning during an extended student teaching experience. Because they need specialized training to meet the needs of California’s ethnically and linguistically diverse student population CLAD (Cross-cultural Language and Academic Development) competencies were added to the mix. Now we are asked to ensure that “candidates are able to use appropriate computer-based technology to facilitate the teaching and learning process” as well. Required competencies have been defined in a developmental sequence which assumes that some basic skills would be acquired prior to admission, and that other more sophisticated competencies would be developed after initial credentialing. Nevertheless, at the basic credential level we are left with a very substantial number of competencies which are to be integrated into a teacher preparation curriculum which is already bursting at the seams.

This case describes my attempt to pilot integration of selected competencies (general or specific) in a secondary general methods course taken currently with initial student teaching. To organize this discussion, I have provided the competency, followed by piloted strategies for implementation. The case concludes with a discussion of “sparkles and blemishes” I encountered during this effort.

Guidelines require that, prior to issuance of the Preliminary Credential, each candidate demonstrates knowledge and understanding of the appropriate use of computer-based technology in teaching and learning. To document achievement of this general competency my students developed: (a) web-based lessons which stressed higher-order thinking skills and caused students to use information not easily available from other sources; (b) lessons to teach secondary students to evaluate web resources; and (c) lessons which required middle or high school students to use HyperStudio to demonstrate their learning. They completed and reflected upon an Internet tutorial on Visual Literacy and used related principle when developing student handouts, transparencies, and other course materials. They used computer-based technologies to prepare all course assignments including a professional portfolio. While they all successfully completed the technical requirements for these assignments, few were able to actually teach and reflect upon the success of the lesson so questions of “appropriate use” remained unanswered. Would it work with “real” kids? Would students achieve the desired learning outcomes? Important issues were also raised: What reality should they design lessons for, the ideal or the real? Is it appropriate to design lessons for students which will not be taught either because the necessary hardware/software does not exist or because the school/department priorities dictate otherwise? Should a cooperating teacher be excluded from having a student teacher because s/he has few, if any, technology resources for teaching, or is lacking the skill to model effective use of what does exist, even though s/he is an excellent model in other respects? Clearly these are important questions which need answers.

This first “specific” competency addressed requires that each candidate uses computers to communicate through printed media. This was a fairly easy competency to achieve, as students were already required to prepare assignments using wordprocessing or other appropriate computer programs. Specific assignments included computer generation of a student handout and preparation of an overhead transparency (or PowerPoint slide) which incorporated text and supporting graphics. Scanners, digital cameras, and the Internet were used to “capture” images for inclusion in curriculum materials. They created an AUP (Acceptable Use Policy) to guide
student Internet use in their classrooms. Finally, students used Excel to chart, analyze and present student test data. While students found the content of some assignments to be challenging, student valued the utility of application programs and most were sufficiently skilled so that actual preparation was fairly easy.

The third specific competency, each candidate examines a variety of current educational digital media and uses established selection criteria to evaluate materials, was also easy to address but addressing a related standard, each candidate chooses software for its relevance, effectiveness, alignment with content standards, and value added to student learning, was much more challenging. To demonstrate these competencies, students evaluated selected digital media, including web sites, and reflected upon appropriate criteria for evaluating different media. While I could and did require students to include an annotated bibliography of technology resources in interdisciplinary units, there was no assurance these materials would be available to teach the unit. In most, if not all cases, good content/topic specific software at an appropriate academic level was not available for my students to review or to use in their student teaching. Another thing disturbed me as well. Too many students maintained that real teachers would not go to such trouble in evaluating curriculum materials. This belief apparently was supported by many cooperating teachers. It is true that many teachers do not really evaluate materials they order. It is also true that thousands of dollars are wasted because they later discover that these materials do not meet their needs, or that they lack the proper hardware to use the media ordered. Again, there is a good bit of tension between the real and the ideal in terms of student and teacher perceptions.

Integrating the next standard, each candidate is familiar with a variety of computer-based collaborative tools, was also a challenge for me. I required that all students obtain e-mail accounts and many students did communicate by e-mail with each other or with me but their willingness to do so was dependent upon having access at home. While some did, many did not. As a class we participated in an "on line" video conference with a local superintendent of schools. Students were thrilled to have their questions answered "on line" but most felt the conference was slow and somewhat boring. While they saw the potential in having virtual guest speakers visit their classes they tended to believe that maintaining student attention would be problematic. They did recognize, however, that involving their students in such a conference might be a useful strategy for encouraging them to read and write. The examples and opportunities I provided were not sufficient to convince my students that these tools would be particularly valuable in helping their students learn. I need to try some new strategies. I need to see it work in a real classroom.

Integration of the last two standards, each candidate demonstrates an ability to create and maintain effective learning environments when using computer-based technology, and each candidate analyzes best practices and research findings on the use of technology and designs lessons accordingly, was also problematic. I could not require that student implement lessons using technology in their student teaching assignments (although ultimately this seems the only way to demonstrate achievement of this standard). I did, however, model lessons with them that required cooperative and collaborative strategies while using technology applications. We also explored how technology could/should be used for supporting the learning of Second Language Learners and considered how technology could support implementation of SDAIE (Specially Designed Academic Instruction in English) strategies. I am not at all convinced that students know what "best practice" is in their specific discipline or as applied to the learning of specific students. I am not sure I know. I even wonder if we have an adequate research base to guide their choices.

To summarize, my students and I accomplished a lot this semester. First the sparkles. They became more knowledgeable about and proficient using a variety of technological resources. They learned to access valuable resources on the Net and recognized potential classroom uses. They identified "increasing computer skills and competencies" as being an important goal for their own professional development. And now the blemishes. The additional demands placed on them to integrate technology into assignments created considerable stress and a negative attitude for some students. While they appreciate that technology might enhance their teaching and their students' learning, they are cynical about the reality. Few are convinced that integration of technology with their students in their subject area is viable. Two assignments in another credential course reinforced this view. They were to interview an instructional leader at a local school site regarding availability and use of technology for instruction; they were also to observe a teacher in their content area effectively using technology to help students meet subject matter standards. The results were dismal. Most principals had only limited knowledge of how computers were being used in their buildings; most could not suggest a technology-using teacher to observe. Few students were able to locate good models of teachers using technology within their subject area.
Technology standards require that students be placed in field experiences with teachers who are modeling such skills. I wonder where we will find them! Piloting technology integration was stressful for me as well. I have more questions than answers. Integration requires that all faculty participate. I wonder how we will encourage them to do so, and who will provide the resources necessary for them to do a first class job. Yes, in the best of worlds, beginning teachers should know how to use appropriate computer-based technologies to facilitate the teaching-learning process. I just wonder if we should expect them to do everything at once.

CalStateTEACH: An Integrated Curriculum Approach
Empowering Teachers in Training through Technology—Jean M. Casey

A somewhat different approach to integrating technology into a teacher preparation is CalStateTEACH. CalStateTEACH is a new alternative path to the California Multiple Subject teaching credential with a CLAD (Cross-cultural, Language and Academic Development) emphasis. It is an 18-month program that culminates in a preliminary credential and 39 semester units of credit. The CalState TEACH approach is field-based, learner-centered, outcome driven, and is built around a set of activities and organized study that relies heavily on the school site as a learning environment. Technology is used to build an electronic community of support for the Intern as well as give them appropriate experiences to use technology successfully in their classrooms.

CalStateTEACH model

In the Cal StateTEACH approach, intern students do not have to attend classes at the university. They are in cohort groups of 20 and each group has a Learning Support University faculty member who visits their classroom monthly and communicates daily with them via e-mail and the Internet. They also have an Adjunct Site Faculty (a classroom teacher with at least 3 years of teaching experience) as a mentor at their school. They receive a kit of videos, texts, and software as well as complete Study Guides for the program. Upon successful completion of the program they receive a preliminary California State Credential.

Districts with Emergency Permit teachers in the CalStateTEACH program have certain commitments, including:

• Inform emergency teachers; show the program Overview video, and distribute applications
• Sign the Terms of Agreement with the university
• Identify Adjunct Site Faculty support teachers at each school site to work with the Intern Teacher(s) and university faculty member

Students in the first cohort 1A started the program September 7, 1999 with September 27, 1999 being the last possible date to enroll for fall 1999. Cohort 1B will begin in January, 2000. The earlier participants apply, the more help we can give them toward passing their MSAT before school begins.

Curriculum

The curriculum is unique in that it is an integrated, spiral curriculum progressing in four stages. The first stage is 15 weeks, stage two is 17 weeks, stage three is 17 weeks, and stage four is 23 weeks. Vacations and breaks are interspersed throughout the program. The curriculum includes the normal Multiple Subject credential coursework plus the infusion of CLAD, mainstreaming, and technology curriculum.

The heart of the CalStateTEACH approach is its high quality academic and student support material using a variety of media. The quality curriculum, designed by 30 distinguished teacher educators in the California State University system, includes videos of the best mentor teachers in the nation, the latest texts, CD-ROM, cassettes, and access to university experts via the Internet. Students can study at the place and time of their choice, but not at their own pace. Students are guided and supported by an extensive instructional support system provided by faculty members who work with a small group of students in personal meetings and visits, in small groups, and on-line.
Features & Benefits

There are several features and benefits to the CalStateTEACH that make it particularly appropriate for teachers working with an Emergency Permit.

- The Emergency Permit teacher does not have to spend time driving to a university in the evenings.
- Most assignments pertain directly to the emergency or Intern teacher’s classroom.
- Emergency teachers communicate using e-mail, the Internet, and online discussion groups.
- One university faculty member, who visits Interns at their school, conducts Saturday workshops and tailors the 18-month program to meet specific classroom needs.

Specifications

The high standards of this program have been approved by the California Commission on Teacher Credentialing. To complete the credential program, the Intern teacher will need a B.A. or B.S. degree; pass the CBEST and MSAT tests, and pass the summative assessment in all four stages of the program. Just because they are employed on an emergency credential does not mean that the participant will successfully complete this program. Program assessments help insure quality teachers.
Technology in the Teacher Education Classroom: Six Categories of Practice

Priscilla Norton, EdD
Graduate School of Education
George Mason University
Fairfax, VA USA 22508
pnorton@gmu.edu

Abstract: Technology has the potential to make teacher education a more robust enterprise but not because we learn to make a Web page or use WebCT or create spreadsheets. Its potential for our practice lies in understanding the ways in which technology can solve our problems - the ways in which it can help us resolve the conundrum posed by the often competing need to meet standards, promote new notions of learning and teaching, and use technology. This paper discusses five categories of technology practice that solve teacher educators' problems by: 1.) helping students prepare for class, 2.) supporting students' grasp of concepts through collaborative meaning-making, 3.) publishing and sharing insights, 4.) promoting resource-based problem-solving, and 5.) modeling how theory translates into practice. Descriptions of each category are presented.

Teacher educators are challenged by a conundrum. Their students, perspective teachers, must be prepared to enter practice able to cope with the complex dynamic of state standards (often accompanied by high-stacks testing), new notions of learning and teaching (ones not part of their own educational experience), and the press for teaching students about and with technology. Practicing teachers who return to higher education classrooms often do so because they seek to resolve the pressures of coping with these seeming contradictions. Teacher educators are not immune to the pressures of these competing challenges either for they too are asked to meet standards or competencies mandated by state legislatures and professional organizations while helping their students understand and put into practice emerging knowledge. And, they too are encouraged and/or required to make technology a part of their practice.

There is a pervasive national notion that somehow technology has the potential to improve education - to solve instructional demands. Yet, higher education's response to that notion is all too often expressed as the need to put syllabi on the Web, to beef up presentations with PowerPoint, or to deliver courses on-line. Thus, university faculty, in general, and teacher educators, in particular, ask or are asked how to make a PowerPoint presentation, how to create a Web page, or how to use WebCT or TownHall. Yet, these are the wrong questions. Rather, before we seek information on how to use these and other technologies, we ought to be asking: What are the educational problems that technology might help solve?

The Problem is Recognizing the Problem

Educators have traditionally adopted tools and strategies, writes Cuban (1986), only when those tools meet the challenges and problems they encounter, not because someone says to use that tool (Cuban, 1986). The criteria educators use relates not to available technology but to the problems they perceive as they seek to meet educational mandates. Thus, when the mandate for education is perceived as the need to get a batch of students to absorb certain knowledge and habits of practice in order to meet a set of standards and/or competencies, educators adopt strategies that enable them to teach a prescribed content and to show tangible evidence that students have performed satisfactorily. Educators have learned to ration their time and energy to cope with these demands and pass these practices to succeeding generations of educators. A collection of
teaching practices has emerged as resilient, simple, and efficient solutions. Technologies, no matter how appealing or lauded, that do not serve these goals are quickly rejected.

So, for example, teaching the entire class at one time is an efficient and convenient use of an educator's time. Lecturing, recitation, seatwork, and homework drawn from texts are direct, uncomplicated ways of transmitting knowledge and directions to groups. The tools that educators add to their repertoire are ones that are simple, durable, flexible, and responsive to teacher-defined problems. A chalkboard becomes an integral component of classroom practice because it solves the problem of writing, erasing, and keeping material as well as the problem of providing ready and simultaneous access for all students. A textbook becomes an integral part of classroom practice because it solves other instructional problems. It is portable, compact, and durable. It can be read for hours or a few minutes, skimmed or read carefully. All students can be assigned the same sections to be mastered individually as well as independently of class time. It travels easily.

Projectors, radios, television, and especially computers do not easily solve these problems. They are sometimes scare, sometimes undependable. Educators are not always skilled at using them. They have few, if any, experiences seeing others use these tools to promote learning. Thus, writes Cuban (1986:59), for many educators, "the simplicity, versatility, and efficiency of those aids such as the textbook and chalkboard in coping with problems arising from the complicated realities of classroom instruction far exceed the limited benefits extracted from using machines."

Educators confronted with new technologies are thus inclined to do one of two things: reject a new technology or adapt that technology to serve already recognized problems. PowerPoint supports classroom and conference presentations. The Internet becomes one more source of information to which students can be referred when writing research papers. Databases are collections of library resources or student records. Email serves to support dialogue with colleagues or to support the student advising load. Study of the role of technology to support K-12 classroom instruction is relegated to a separate course, and teacher education proceeds much as it always has. These uses of technology support the teacher educator's work, but they do not challenge time honored instructional practices in the teacher preparation or graduate level education classroom.

Still, there are some educators who do use a variety of tools as part of their instructional repertoire. There are educators, for example, who believe that films, television, and Internet resources enhance textbook reading. There are educators who are deeply concerned over visual illiteracy and seek to use television to enhance critical viewing skills. There are educators who believe that using camcorders to produce video helps students understand not only content but the anatomy of the media. There are educators who believe that teaching students to express content understanding using desktop publishing and web page designs value these tools' capacity to help students structure and communicate their knowledge using multiple forms of representation and non-linear patterns. There are educators who view television, camcorders, and a variety of computer tools as vehicles to motivate student learning, to supply relevant and meaningful content, and promote students' ability to reason and solve problems. "In effect, the practical criteria these teachers use in deciding what is best for them and students are broader than ones used by their colleagues" (Cuban, 1986).

**Technology as Part of the Teacher Education Classroom**

If technology is to have a role in the teacher education classroom, and more importantly, if technology is to make learning to be a teacher a more robust experience, teacher educators must stop asking questions about technology and start focusing on the problems which challenge teacher education. The remainder of this paper addresses six problems that confront teacher education and the ways in which technology offers solutions.

**Preparing for Class**

In the teacher education classroom, time limitations are perhaps the educator's greatest challenge. Many teacher education classes meet only once a week. Others meet for one hour, three times a week. A class is generally bounded by either a ten week quarter or a sixteen-week semester, making contact time with students only 48 hours if no holidays interfere. This time is precious, and the broad agenda necessitated by the complex and robust array of competencies, standards, literature, and activities places extraordinary demands on this time. There just never seems to be enough. Certainly, students are expected to spend considerable time in preparation for class. Yet, that time generally focuses on independent research and reading. Occasionally, students can...
Another group of students was asked to use NetMeeting (http://www.NetMeeting.com), an online writing tool, to create a reader’s theater to demonstrate the debate between advocates of phonics and advocates of whole language prior to class. They presented these reader’s theaters during the next class period. As students watched the performances, they were asked to note common threads and to look for discrepancies. Three, after reading Howard Gardner’s The Unschooled Mind and discussing the book using email, students were challenged to invent a school, create a desktop published brochure, and a one minute video advertisement. As students and the instructor reviewed the materials, they looked for reflections of Gardner’s ideas as well as aspects of the “school” which contradicted Gardner’s ideas. There were many rigorous debates. Four, after reading Vygotsky’s Mind in Society, students were challenged to use a graphics program to create a map of
Vygotsky’s mind modeled after the maps in Hampton-Turner’s Maps of the Mind. Five, after reading Gilster’s Digital Literacy and participating in a threaded discussion using TownHall, students were asked to use graphics and word processing programs as well as a large piece of butcher paper and markers to redesign the book cover. Students were challenged to complete their redesign in such a way that educators would be encouraged to read the book and see the relationship between the book and their practice.

Resource-Based Problem Solving

There was a time in the life of teacher educators when our central problem was selecting the right textbook and identifying the appropriate body of knowledge that informed the topics of the courses we taught. Our work focused on using the library and keeping abreast of the textbooks and journals published in our field. Education seemed a relatively straightforward, clear-cut domain. We could anticipate that our students would enter classrooms where textbooks were available to teachers with teacher’s manuals to guide their practice. But the world of information has changed, as has the complexity of teaching and learning. No longer is it clear exactly what knowledge students will need. Neither is it clear which resources will best structure their practice nor can we guarantee what problems they will encounter during their life as practitioners. Those entering teaching today must become problem solvers, and they must be able to solve those problems within the context of an ever-growing knowledge base. Teacher educators must find ways to help those entering practice and those currently practicing use the plethora of resources – online, offline, in their communities, and among their fellow educators. Today’s teacher educators must ask: How can we help students become resource-based problem solvers?

Two examples will serve here to illustrate the ways in which technology can support resource-based problem solving. The first example rests on the work of Bernie Dodge (http://edweb.sdsu.edu/webquest/webquest.html). While it is clear that one important skill is the location of resources either using library databases or “surfing” the web, what is more important is using identified resources to solve problems. The WebQuest is an Internet based instructional strategy that sets a context, identifies a problem, clearly specifies an outcome or product, and provides links to resources necessary for solving the problem. While this strategy has become extraordinarily popular among K-12 educators, it has the potential to serve teacher educators as well. The author teaches an introductory course to Secondary Education licensure students called The Culture of Teaching. One of the important course topics focuses on the legal parameters surrounding educational practice. In addition, these students do not take a course in educational technology. Rather, technology is embedded throughout their coursework. A WebQuest was created to engage students with the ethical and legal issues associated with the attendance of AIDS students in high schools (http://mason.gmu.edu/~mballard/WebQuest.htm). This WebQuest asked small groups of students to create an “AIDS policy” for their school. Links were provided to legal sites, sample policies from other schools, and to sites containing medical information about AIDS. After students had completed their policies and shared them with other groups, groups of four students were presented with other legal issues related to such areas as special education and discipline. They created their own WebQuest, locating both text and Internet resources. Classmates then solved each others’ WebQuests. In this way, it was possible to help students explore the legal issues associated with teaching and to teach them about the WebQuest as an instructional strategy.

A second example of resource-based problem solving is a graduate course created by Evelyn Jacob. The course, Education and Culture, is designed around a Cultural Inquiry Process (CIP). In teaching the course, Jacob and Ruess (In Press) had identified two problems. One, since the body of relevant cultural research was not organized around addressing practitioner’s puzzlements, it was necessary to “cover” much research before practitioners had sufficient information to use the CIP in their own practice. Second, although post-course interviews supported the content of the course, students expressed a need for support to continue using the CIP. Jacob and Ruess created a course web site (http://classweb.gmu.edu/classweb/cip/index.htm). This web site presents the six steps of the CIP and, for each step, provides links to information supporting each step, research related to using cultural perspectives to develop educational interventions, and sample CIP Cases. Additionally, a mechanism is provided for small groups of students to support each other in implementing the process and in seeing a variety of potential perspectives related to individual puzzlements. Students who have finished the course are encouraged to return to the site, using both the text and interpersonal resources of the site to solve their instructional problems.
Publishing and Sharing Insights

In the traditional teacher education class, knowledge resides with the instructor. The purpose of the class is to transmit the instructor's knowledge to students. Student knowledge is tested by objective tests, research papers, and various other, generally written, assignments. The flow of learning is from the instructor to the whole class and back to the instructor, student by student. Decisions about appropriate instructional strategies and technology use, in particular, center on supporting this flow. Instructors solve teaching problems by choosing lectures sometimes supported by PowerPoint presentations, projected Internet sites, and notes or diagrams on chalkboards. Instructors additionally ask students to respond with written tests, prepared presentations, and research papers. Sometimes student work is supported by word processors and Internet references. If, however, the teacher education classroom is to honor students as teachers and teachers as students as well as the social construction of knowledge, the flow of learning from the instructor to students and individual students to the instructor must be reframed. The problem facing teacher educators is not how to support this flow but, rather, how can the flow of learning be shifted from instructors to students toward students, supported by instructors, creating, publishing, and sharing insights?

Secondary education students completed a field experience, shadowing a high school student for a day. When they returned to class, they were asked to divide into groups of three and challenged to reflect on their field experience, identifying five generalizations about the school lives of high school students. They then created a five slide, PowerPoint presentation – one for each generalization. Instead of presenting their slides to the class, groups rotated around the room, examining each others’ presentations and noting similarities and differences. A final list of generalizations was created by the class and posted. Each week as students and the instructor explored high school students' development and learning, they returned to the generalizations to see if they could further elaborate meanings and explanations associated with their observations. Their midterm exam centered on returning to their original PowerPoint presentation and building links from each slide to student generate explanations, text-based resources, and Internet sites. Most groups added additional generalizations that their continued learning experiences demanded. In this way, technology supported the shift from the instructor as the holder of knowledge to students as creators and elaborators of their own knowledge.

The final examination for a graduate cohort studying technology and learning was structured so that assessment was not based on individuals demonstrating mastery of the course content but, rather, on students collaborating to apply their knowledge to the creation and publishing of a learning product that reflected the principles they had studied. Together, students analyzed the commercial product, Hooked on Phonics, including a copy of one of the Hooked on Phonics television commercials. The product was discussed in terms of the learning philosophy underlying the product’s design as well as the design of the box and promotional materials. Students were randomly assigned to groups of four and challenged to create the perfect educational software program, reflecting the ideas and theories they had encountered during the course. Among the many tools that supported students were graphics programs, word processors, glue, and colored pencils. The final product was to be the software’s packaging and a desktop published brochure explaining the power of the software. Groups switched finished products and used word processors to write a comprehensive analysis of the ways in which the product reflected learning principles as well as to point out conflicts with theories or to recommend elaborations.

Modeling Theory to Practice

The most powerful model of teaching for teachers comes from their own experiences as learners. Thus, if one’s learning experience happens only in a teacher-centered, print-based classroom, one is likely to teach in that way. If teacher educators perpetuate that learning experience, the traditional image of instruction persists and is reinforced. If we, as teacher educators, use technology only to give better lectures or as additional sources of literature for research papers, perspective and continuing teachers will have no better image of the role of technology for teaching and learning. If, however, teacher educators seek to identify and understand newer instructional problems and then choose to use technology in ways that solve those problems, they offer perspective and continuing teachers images of both new instructional problems and new uses of technology. In all of the examples above, technology use did not focus on the "hows" of using technology. Neither did it focus on modeling the use of technology within the K-12 curriculum. Rather, technology was used to support students' own learning. It was used to solve authentic teaching and learning problems.
Second, using technology to address the problems of supporting preparation for class, assisting students to grasp concepts and collaboratively create meaning, promoting resource-based problem solving, and creating, publishing, and sharing insights represent solutions to teaching problems reflect newer understandings of learning that are constructivist, social, and distributed. They reflect instructional choices that not only use technology to support learning but convey an alternative version of teaching and learning. Teacher educators must be careful not to talk one talk and walk a different walk. They must be careful not to advocate a particular vision of teaching and learning while practicing a different vision. Using technology to solve the problems described above allows teacher educators to solve the last problem – modeling theory to practice.

Conclusion

Cuban (1986) characterizes education’s history with technology as proceeding through four phases: enthusiasm, scientific research, disillusionment, and teacher bashing. As teacher educators, we have experienced and sometimes contributed to the enthusiasm for the electronic technologies. We are cognizant of and have contributed to the research associated with technology. Yet, our slowness to use technology to support our own teaching – promoting technology by word more than deed – has made it difficult for entering and continuing teachers to use technology to support their own teaching. Today’s disillusionment with technology centers not only on problems of access, maintenance, and cost but jeopardizes efforts to realize the potential of technology. Some have begun to question technology’s role in education, citing teachers’ lack of use. Policy makers have begun to lean toward such technology applications as large, integrated learning systems and teacher-proof, “how to” curriculums. Teacher educators have the responsibility to carefully rethink instruction, identify relevant problems, and find ways to solve those problems by making wise use of technology and conveying a vision of educational practice consistent with newer understandings about teaching and learning.

Abstract: This paper is a report on the rationale, design, development, and evaluation of Videos in Technology Integration (VITI), a video-case based, multimedia CD-ROM intended to provide teacher educators with concrete examples of exemplary technology integration. A review of literature shows that it is important that exemplary models of technology integration be incorporated into teacher education programs. However, video-case methodology specific to the area of teacher educators' technology integration had not been addressed. Inspired by the dedication to help teacher educators meaningfully integrate technology into their classrooms, the CD-ROM is an initiative in modeling exemplary technology.

Introduction

The Center for Technology in Learning and Teaching (CTLT), located in Iowa State University's College of Education, is dedicated to helping educators provide students with technology-enriched environments that enhance learning at all levels. In keeping with this commitment, Videos in Technology Integration (VITI), is a video-case based, multimedia CD-ROM designed to provide higher education instructors with concrete examples of exemplary technology integration.

Background/Purpose

Although the potential for technology use in teacher education programs is strong, few models exist for teacher educators who desire to use technology to facilitate learner-centered environments. As a result, many teacher educators who would like to integrate technology into the learning environment lack the knowledge to do so. Ultimately, such a lack of knowledge on the higher education level results in a lack of and/or ineffective integration of technology in the K-12 classroom. Because effective and appropriate technology use is not demonstrated for pre-service teachers, many lack the knowledge to effectively use technology to create a learner-centered environment. Therefore, it is important that we incorporate exemplary models of technology integration into teacher education programs.

While teacher educators who desire to use technology to facilitate learner-centered environments would benefit from models of exemplary technology integration, they possess such divergent backgrounds and expertise that traditional staff development does not meet the needs of all involved. To address the complexity of modeling technology-integrated learning environments for teacher educators, current research in instructional design suggests using video-case methodology.

The video-case methodology was inspired by the North Central Regional Education Laboratory's (NCREL) Learning with Technology, which features video and written cases designed to help teacher educators reflect and facilitate discussions on uses of technology in their classrooms. Furthermore, such methodology has been used extensively for professional preparation in business, medicine, and law (Hasslebring, 1994) and is equally, if not more, appropriate for teacher educators due to their expressed need to connect to real classroom environments. The video component provides a rich environment where participants observe the uses of technology and the effects it has on students and the teacher. The hypermedia component, which consists of linking text, graphic art, sound, and video, allows the user to control when and how these elements are delivered.

The video-case methodology, presented in CD-ROM form, allows anchored instruction, which provides a situation in which users share a common experience (Hasslebring, 1994). Within this shared experience, the user is able to reflect and develop his/her own meaning contingent on past experiences and ultimately transfer the learning to new and developing situations in his/her classroom environment.
A review of literature (Office of Technology Assessment 1995) indicates that video-case methodology specific to the area of teacher educators' technology integration has not been designed, developed, implemented and evaluated. Therefore, the purpose of this project was to create a multimedia CD-ROM that incorporates video cases featuring exemplary technology integration by teacher educators to be used by teacher educators.

The context of this paper includes a description of the design process, the CD-ROM, and the status of a preliminary summative evaluation.

Methods (The Design Process)

To complete the study, a multimedia research team was assembled. The research team consisted of higher education faculty, graduate students, and pre-service teachers of various ages, gender, ethnicity, and socio-economic background. The diversity of the research team assisted cross-validation among data sources, data collection, time periods, and theoretical schemes. The team members volunteered their participation according to their interests in and/or connection to technology integration in the classroom. For example, most of the higher education faculty participants had expressed the need for such a modeling program because of their past experiences with technology integration. Due to their participation in a mentoring program (Thompson, Schmidt, & Hadjiyianni, 1995), these faculty members were able to gain knowledge of appropriate and effective technology integration into their classrooms, and as a result, now serve as the subjects featured in Videos in Technology Integration. Other participants involved in constructing the CD-ROM had a background in the areas of video photography, instructional design, and research methods.

The research team conducted structured interviews and observations of faculty members who exemplified model technology integration to gain perspectives of teacher educators on technology integrated learning environments. The selection of featured faculty members was determined by their reputation for technology integration in their teaching.

The selected faculty participants (previously described) of the video case multimedia project were video taped in their technology integrated classrooms. The video showcased the faculty participants, the classroom set-up, and the administered lesson. The collected video footage was then edited into vignettes to make up the major component of the multimedia program. The editing was done through Adobe Premiere. The video was edited and categorized into peer debriefings, interviews, reflections, mentoring, and information on relevant reference materials. Then, the vignettes were labeled and assembled in a way that would allow the viewer to gain an understanding of how technology is integrated to facilitate a learner centered environment. Ultimately, the vignettes, linking text, graphic art, and sound were comprised into a user-friendly multimedia program using Authorware and burned onto a CD-ROM.

The CD-ROM

The CD-ROM, entitled Videos in Technology Integration (VITI), features a total of nineteen video vignettes highlighting technology-integrated lessons, and instructor and student interviews. Menu bar buttons and clickable text allow the user to navigate through the multimedia program. Current features include:

- a concept/navigation map that allows the user to have an overview of the product's totality
- an introduction/welcome that contextualizes the program by giving background, purpose, and general description
- a list of the featured content areas
- titles of the featured video vignettes and their descriptions
- video vignettes featuring exemplary technology integration

Currently, the program has three major content areas: Math with Anchored Instruction: The Jasper Woodbury Series; Math with Distance Education: The Iowa Communications Network; and Reading and Language Arts with PowerBooks. Users can access the video vignettes by selecting a content area and then clicking on a video vignette title. The titles are worded in the form of questions that might be common among users.

Math with Anchored Instruction: The Jasper Woodbury Series

What is the Jasper Woodbury Series?
Why would I use this?
How does it support learning?
How could I use this?
What are the strengths and challenges?
How do students respond?

Math with Distance Education: The Iowa Communications Network
What is the ICN? Iowa Communications Network
Who uses the ICN?
How might I benefit?
How might students benefit?
How do students respond?

Reading and Language Arts with PowerBooks.
Why use Powerbooks?
Who uses them in class?
What should I know?
How does it support learning?
What are the strengths and challenges?
What are the students' responsibilities?
How do students respond?

The question formatted titles contextualize the content, prompt users to discuss issues surrounding technology integration, and act as navigational tools and cohesive elements that allow the vignettes, collectively, to tell a story. When users select a vignette, they are guided through the video by a higher education instructor whose narration addresses the question embedded in the vignette title.

The CD-ROM is formatted for Macintosh. The recommended minimum configuration is Power Mac, System 7.5 or higher, 16 MB RAM, thousands of colors, monitor resolution of 800 X 600 or higher, 2X CD-ROM drive, and Quicktime 3.0. No installation is necessary. To run the CD, the user can simply place CD-ROM in the CD-ROM drive and double-click on the VITI icon.

Preliminary Results

In Spring 1999, the current version of the CD-ROM was assessed by twenty-five faculty members of the Iowa Association of Colleges of Teacher Education (IACTE) via the Iowa Communications Network (ICN) as an anchor of the Videos in Technology Integration Iowa Discussion. The Iowa Discussions through the ICN was aimed at fostering conversation and interaction between Colleges of Education in the state of Iowa. Topics of discussion included: uses of video cases in teacher education; the current state of technology use in teacher education programs in the state of Iowa; and visions of future possibilities of technology in teacher education. The institutions represented were University of Iowa, University of Northern Iowa, Iowa Wesleyan, St. Ambrose, Graceland, Clark, Grinnell, Upper Iowa University, Loras, William Penn, Dordt, Central, Drake and Simpson (Long, S. & Thompson, E. A., 1999).

In addition to taking part in ICN sessions, involvement in the Iowa Discussions consisted of reviewing the CD-ROM and completing a survey. The surveys were aimed at gathering information about teacher educator's beliefs about technology and teacher education and those of their institutions, and their reactions to the CD-ROM. Participating faculty members received the CD-ROM either via the IACTE conference or by mail (Long, S. & Thompson, E. A., 1999).

While the ICN sessions were successful, currently, the analysis of surveys is in its preliminary stages (Long, S. & Thompson, E. A., 1999).

Implications
While the CD-ROM features a number of video vignettes, the CTLT hopes that VTIJ will continue to grow and evolve, collecting more video of exemplary technology integration and spanning across many more content areas.

In conclusion, because no policies for continuing educators' knowledge of technology integration have been predetermined, educators are finding themselves ill-prepared to ready students for the "real world" in which technology plays a major role. Therefore, the preliminary results of the project are significant. The program has potential for widespread impact on classroom technology integration, and can be useful to educators and policy makers. It is our hope that ultimately the multimedia program will have a sequential effect on classroom technology integration. The program can serve as a model for teacher educators who can in turn model exemplary technology integration to their pre-service students. These students can, subsequently, effectively and efficiently integrate technology into their K-12 classrooms.

Abstract: This paper describes the development of CD-based video clips and case histories to be used in a course in instructional technology. The videos illustrate real K-12 teachers using technology in real teaching situations. The video clips and case histories are used to help preservice teachers better conceptualize how to use technology as a learning tool. The process of video development and use of the videos in teaching is described. Initial student reaction to the videos has been positive.

Tomorrow’s technology-enhanced schools will require that teachers be prepared to use and integrate digital instructional technologies (DIT). National and local standards, such as the National Mathematics Education Standards (National Council of Teachers of Mathematics 1989) and the National Science Education Standards (National Research Council, 1996), require that preservice teachers learn how to use technology effectively as learning tools in teaching. Currently, the lack of real-world classroom models that use DIT as learning tools for instruction inhibits beginning and advanced students from implementing digital technology effectively into instruction. Preservice teachers come from classrooms in which they have used DIT mostly for low level educational purposes such as drill and word processing. Thus, few preservice teachers come to college with experiences or schemata that allow them to conceptualize how to teach effectively using DIT.

The Course
At Iowa State University, preservice teachers take CI 201, Introduction to Instructional Technology typically as sophomores and before they have completed teaching method courses or teaching practica. CI 201 teaches basic technology skills in the context of using the technology as a teacher and encourages preservice teachers to incorporate technology as learning tools in the future teaching. We currently use the Grabe and Grabe (1998) Instructional Technology Book and emphasize the Grabes' ACTIVE model in the course. The Active Model argues that technology should be used in a manner such that the learning tasks are:

- **Active** - tasks require cognitive behaviors that emphasize the transformation of information into personal knowledge,
- **Cooperative** - tasks require meaningful interaction among students,
- **Theme-based** - tasks are flexible and multidisciplinary based on an organizing theme,
- **Integrated** - tasks emphasize content area knowledge and use technology tools to encourage learning this content in ways that are meaningful, and
- **Versatile** - tasks make efficient use of technology skills and develop those that can be applied repeatedly.
- **Evaluation** - Finally, evaluation tasks allow the assessment of the student's ability to use the knowledge and skills we want them to learn.

By emphasizing the use of technology for learning tools and the ACTIVE model, we hope to lead future teachers towards constructivist uses of technology that promote knowledge development that is meaningful and transfers to new situations.

CI 201 is a large course. Two sections of 150 students meet twice a week for lecture and once a week for a 3 hour lab. Departmental faculty teams provide the lectures and teaching assistants working under the direction of the course lecturers teach the laboratories. Most of the student assignments in the course ask the preservice teachers to demonstrate use of technology skills by using those skills to create technology-based lesson that they will use with their future students. Throughout this course, preservice teachers design and develop technology-based lessons and projects targeted to the specific classroom situations in which they intend to teach.

We schedule CI201 early in the preservice teaching sequence to provide students with technological skills that can be used in later methods, technology, and practica courses. This early exposure to a technology in teaching course compounds our students' difficulties in developing models of effective technology use in education. Most students have not yet begun to think about themselves as teachers and they have not yet incorporated contemporary teaching models into their thinking. This lack of prior experience and teaching knowledge makes it difficult for them to conceptualize and imagine effective learning-tool teaching uses for technology that they can incorporate in their own teaching.

### The Videos

To address this issue, we have begun to develop videos of exemplary uses of technology in real classrooms. Funding provided by ISU has allowed us to videotape teachers in Iowa who are using technology effectively as learning tools for their students. Modeling is known to be an effective method of teaching (Pressley & McCormick 1995). According to the report, *Teachers & Technology: Making the Connection*, "Video can extend the range of student observation into the classrooms with the best teachers, wherever they are located. Whether live broadcasts from a classroom or tape, they can provide teacher education students with models of effective teaching and the opportunity for reflection on what constitutes good teaching" (Office of Technology Assessment, 1995, p. 166). The videos developed in this project present our preservice teachers with authentic PreK-12 learning situations that integrate technology.

Our project had one overriding goal: To develop a collection of digital video segments to be used in teacher education courses, primarily CI 201, that exemplify PreK-12 classroom situations in which teachers and students effectively use DIT as learning tools. These videos show PreK-12 students using technology; and include interviews with teachers and students describing their uses of technology for learning and teaching. The interviews ground the teaching situation in a meaningful context. The teacher is asked about the overall place of the videotaped activities in the overall curriculum and about the goals and purposes of the lesson and the technology activities. Interviews with the teachers' students present the students' conceptualizations and reactions to the learning situation including the use of technology.
Two types of uses for the videos are planned and partially implemented. One use is to prepare short segments on CD that can be used in a large class to illustrate particular points. The second use is to provide students with longer video cases on CD that would be used as part of outside of class case history or problem-based assignments. Both the nature of the videos and the uses we plan and are implementing are different from the standard videotapes commercially available and their typical use. Commercial tapes are typically long sequences that tell a cohesive story. They often relate tangentially to the specific goals of a given lesson. Rarely can an instructor use a video to present several short examples of a particular teaching approach or concept. In their typical use, the content as discussed in class is often distant in time from the examples provided in the tape. Instructors may show a video to introduce a unit that may last for several class periods. Students are expected to remember the examples in the video as they encounter the concepts and schemata taught in the unit. This elapsed time weakens the instructional effectiveness of commercial videos.

As conceptualized, the proposed videos would include both longer sequences and short, specific examples aligned directly with specific course concepts that can then be integrated into a lecture or class discussion. For example, given appropriate videos, an instructor could illustrate a discussion of the pedagogical value of using a hypermedia program to produce collaborative reports with:
- a short (2-5 minute) sequence showing a 3rd grade team in the process of developing a social studies hypermedia project, and
- a middle school math class creating a hypermedia report involving graphics and algebraic prediction equations based on a water quality study they have done in their local environment,
- a high school English classes hypermedia project on major authors and works of the cultures of the students in the class.

These multiple examples would be timely to the on-going discussion. They would provide students with models appropriate to their intended teaching level. Presenting multiple examples of to be learned concepts and schemata facilitates learning (Andre 1997). Providing models with which students can readily identify also facilitates learning (Pressley and McCormick 1995). Thus, this use of video segments should help preservice teachers better understanding effective technology integration into teaching processes and strategies. Such a use of technology would provide just-in-time instruction to support preservice teacher learning.

Learning would also be reinforced through the case examples provided to students on CD. These case histories would contain multiple segments of video that would cover more completely a whole unit involving technology. The segments would contain examples of students using the technology, interviews with students about their use, interviews with the teacher explain the goals and purposes of the unit, interviews with the students about their overall reactions to the unit, and examples of student produced materials. As part of laboratory and take-home assignments, preservice teachers would be asked to review and analyze the case. The preservice teacher would be expected to identify strong and improveable points, to suggest revisions in the unit, and to consider how the approach might be adapted to his or her own teaching. Discussion time in laboratory sections would allow students to present their case analyses. Our plan for producing video cases, described below, would provide multiple examples across grade levels of learning tool uses of technology. Having example cases closely related to the preservice teacher's intended grade level and subject matter facilitates the effectiveness of the cases.

**Video Development**

To develop the videos, we contacted teachers and administrators and located a cadre of teachers spanning PreK-12 grades who were willing to participate in these videotaped cases. Permission to video and release for future use of the videos for teaching purposes was obtained from school district personnel, parents of students in classrooms being videotaped, and the participating students where this was an age appropriate question. Four specific topics of instructional technology use in classrooms were targeted:
1. PreK-12 student use of the World Wide Web for research, project development and computer mediated communication, and Web page development tools;
2. PreK-12 student production of hypermedia projects;
3. PreK-12 student use of integrated software programs (i.e., desktop publishing, databases, spreadsheets) for interdisciplinary research and writing projects; and
4. PreK-12 student use of software to develop problem solving and critical thinking skills.

Specific grade levels (e.g., early childhood education, elementary, middle, and secondary education) were targeted in each of the four targeted topics for video development. Approximately 1 academic year was...
spent in collecting the original video samples. A digital video camera was used to create the videos. These original videos were reviewed by the senior faculty and graduate students involved in the project and segments were identified for editing into the videos to be used in CI201.

As noted, two types of edited sequences were identified. The first consists of relatively short sequences (several seconds to a few minutes) that illustrate particular teaching points. These shorter sequences will be used in lecture to illustrate effective technology uses. In some cases, these shorter sequences were combined into a video case history. Students in CI201 will analyze these case history as part of laboratory or homework assignments. Both the shorter examples and the video cases will be prepared on CDROM and made available to students in the course.

The following paragraphs describe two of the instructional activities that have been videotaped in classrooms.

- Second grade students design and produce electronic portfolios using mPOWER with the assistance of 8th grade students enrolled in a multimedia development course. The purpose of the project is for the 2nd grade students to visually represent and document what they have learned in 2nd grade by producing a multimedia portfolio. This project involves 8th grade students who provide one-on-one instruction on how to use a multimedia program to elementary students. After receiving initial assistance from the 8th grade students, the 2nd graders work independently on their portfolio in their classroom for the rest of the school year. This collaborative multimedia development project supports the districts' learner outcomes in the areas of collaborative learners, responsible communicators and problem solvers.

- In a sixth grade language arts class, students work in collaborative groups as they plan and publish newsletters that document people and events during various decades of the 1900's. During this four-week instructional unit, each 6th grade student has 24-hour access to a portable laptop computer for gathering research, importing graphics and writing notes and articles for the newsletter. Video clips of this classroom showed students actively engaged in a learning activity where they are learning and applying language arts skills throughout the writing process.

Initial Use

Editing of the videos onto CD is proceeding. Initial uses of some of the videos clips provided informal support for the concepts. Preservice teacher reaction to these initial uses have been quite positive. Use of the videos is perceived by the preservice teachers to help them better conceptualize ways to effectively use technology in real teaching situations. In the presentation for SITE 2000, we will describe the development process in more detail and illustrate the available videos and CDs. In addition, student reactions to the use of the videos will be described.

ABSTRACT
Today, more than ever before, field experiences are an integral part of teacher preparation programs. As the accountability movement promoting performance-based assessment grows, teacher educators are looking for opportunities to integrate real-life experiences into their programs. This article describes a videotaping program at the University of the Incarnate Word designed to provide accurate data to preservice teachers regarding their performance in actual classroom settings. This videotape technology provides the opportunities that prospective teachers need to effectively reflect and assess their development toward mastery of state-mandated competencies.

Today, more than ever before, field experiences are an integral part of teacher preparation programs. These field experiences provide authentic contexts in which preservice teachers gain the knowledge and skills necessary to integrate theory with practice. It is believed that prospective teachers should learn to systematically observe, recognize, and practice teaching behaviors prior to entering the teaching profession. However, field experiences alone are inadequate for the transformation of preservice teachers into practicing teachers.

The importance of developing in new teachers the ability to self-assess and reflect on their practice of teaching is well documented in the literature (Koorland, Tuckman, Wallat, Long, Thomson, & Silverman, 1985; Moore, 1988; Struyk, 1991; Jensen, 1994; O'Donoghue, 1996; Holodick, Scappaticci, & Drazdowski, 1998). In addition, research clearly reveals that preservice teachers reflecting upon teaching can enhance their repertoire of pedagogical knowledge (Freiberg & Waxman, 1988). Reflection and self-assessment of teaching performance must accompany meaningful field experiences in the schools for the continued growth of preservice teachers to occur.

In order for preservice teachers to effectively assess their own teaching, accurate data must be collected, analyzed, and interpreted. While data provided preservice teachers should come from a variety of sources, one tool for data collection is the use of videotaped teaching episodes to foster self-assessment and reflection. Since the videotape can be stopped, reversed, and fast-forwarded, it is possible for the preservice teacher to focus on specified aspects of the lesson. However, simply videotaping preservice teachers and having them assess their teaching performance without established structured procedures will be ineffective (Holosick, Scappaaticci, and Drazdowski, 1998).

State-Mandated Beginning Teacher Competencies

The State Board of Educator Certification (SBEC) was created in 1995 by the 74th Legislature to govern the standards of the education profession in Texas. In 1997, SBEC approved and adopted Teacher Proficiencies that reflect the skills and knowledge needed by beginning teachers to enhance student learning. In addition, SBEC developed competencies to reflect mastery of the Teacher Proficiencies and
created state-mandated exams based on these competencies. These proficiencies, competencies, and exams are integrated into the teacher preparation program approval process in Texas. All teacher preparation entities are held accountable for the performance of educators who complete certification requirements from the entity.

A high priority in the University of the Incarnate Word (UIW) teacher preparation program is for our preservice teachers to meet the state-mandated competencies. Videotape technology, while not a new or innovative technology, has proven to be an effective tool to help our preservice teachers meet the competencies and make the transition from preservice teachers into practicing teachers.

**Videotaping Program**

Structured procedures and activities were established by the education faculty at the University of the Incarnate Word, utilizing videotape technology in field experiences throughout the teacher education program. These procedures and activities, used as benchmarks in the program, require preservice teachers to videotape a lesson in their field setting for two semesters prior to student teaching. Each semester, the student and faculty view the videotape and assess the student’s teaching performance relative to the state-mandated competencies established for beginning teachers in Texas. These competencies, used by every teacher preparation program in Texas, are designed to ensure that new teachers have the knowledge and skills to teach in Texas public schools. The student is required to view the videotape, reflect on teaching behaviors, mark the professional development competencies observed in the lesson, and give an example of the behaviors illustrating the competencies listed in Table 1. At the end of the semester,

### Professional Development Competencies

**Domain I: Understanding Learners**

01: The teacher uses an understanding of human developmental processes to nurture student growth through developmentally appropriate instruction.

02: The teacher considers environmental factors that may affect learning in designing a supportive and responsive classroom community that promotes all students’ learning and self-esteem.

03: The teacher appreciates human diversity, recognizing how diversity in the classroom and the community may affect learning and creating a classroom environment in which both the diversity of groups and the uniqueness of individuals are recognized and celebrated.

04: The teacher understands how learning occurs and can apply this understanding to design and implement effective instruction.

05: The teacher understands how motivation affects group and individual behavior and learning and can apply this understanding to promote student learning.

**Domain II: Enhancing Student Achievement**

06: The teacher uses planning processes to design outcome-oriented learning experiences that foster understanding and encourage self-directed thinking and learning in both individual and collaborative settings.

07: The teacher uses effective verbal, nonverbal, and media communication techniques to shape the classroom into a community of learners engaged in active inquiry, collaborative exploration, and supportive interactions.

08: The teacher uses a variety of instructional strategies and roles to facilitate learning and to help students become independent thinkers and problem solvers who use higher order thinking in the classroom and the real world.

09: The teacher uses a variety of instructional materials and resources (including human and technological resources) to support individual and group learning.

10: The teacher uses processes of informal and formal assessment to understand individual learners, monitor instructional effectiveness, and shape instruction.

11: The teacher structures and manages the learning environment to maintain a classroom climate that promotes the lifelong pursuit of learning and encourages cooperation, leadership, and mutual respect.

**Domain III: Understanding the teaching environment**

12: The teacher is a reflective practitioner who knows how to promote his or her own professional growth and can work cooperatively with other professionals in the system to create a school culture that enhances learning and encourages positive change.

13: The teacher knows how to foster strong school-home relationships that support student achievement of desired learning outcomes.

14: The teacher understands how the school relates to the larger community and knows strategies for making interactions between school and community mutually supportive and beneficial.

15: The teacher understands requirements, expectations, and constraints associated with teaching in Texas, and can apply this understanding in a variety of contexts.

### Table 1: Professional Development Competencies

| Texas Education Agency | BEST COPY AVAILABLE | 1457 |
students are required to compare and contrast their two videotaped lessons, reflecting on ways to improve their instruction and make decisions accordingly. An education faculty member also views the videotape, marks the professional development competencies he/she observed in the lesson, and gives an example of the student’s performance illustrating the competencies. A feedback conference is scheduled between the faculty member and the student to discuss the videotaped lesson relative to the state-mandated competencies.

Conclusion

Through the utilization of videotape technology, preservice teachers are able to use videotapes to record their performance in the classroom. This videotape can later be used for discussion and formative development. After viewing the videotapes and reflecting on their demonstration, prospective teachers begin to realize that improvement is always possible and indeed necessary, even in the best of circumstances.

Abstract: The integration of technology throughout the curriculum of both K-12 schools and higher education is widespread throughout America. There are over 1.6 million computers in American schools today (Rosenthal 1999). Millions of dollars are being spent on educational technology (Bull, Nonis, & Becker, 1997), as educators strive to establish a reasonable ratio of computers to students—some (Smith, 1999) suggesting as little as one-to-four, respectively. The preservice teachers enrolled in the Technology-Based Teacher Education program at Lehigh University partner with experienced inservice teachers for a semester to work towards the educational goal of integrating technology into an established curriculum. Preliminary analysis of survey and interview data suggests the partnership may accelerate the professional development of new teachers and provide a support structure for experienced teachers who are beginning the integration process. Both inservice and preservice participants expressed perceived benefits from the project.

The systematic introduction of technology into classrooms has become an increasingly important school reform issue since the 1980's. Recently, the integration of technology into established school curricula of both preservice and inservice teachers has emerged as a focus for colleges of education and K-12 schools. Understanding the role of technology integration within K-12 classrooms is vital to the professional growth of both novice and experienced teachers. Technology resources are requiring educators to rethink how they teach. Educators must focus on integrating technology into the school day: using technology to communicate, to think and to learn (Dwyer, 1996).

Technology as a Tool
Technology—particularly, computer-based applications and software—is emerging as a viable instructional tool for many inservice teachers (Conte, 1998). However, some educators simply have not adopted technology as a tool to use in their curriculum. Lack of comprehensive training is the number one reason why teachers are not using technology in their classrooms (Sykes 1997). Insufficient time and non-existent or inappropriate incentives hinder teacher inservice work (Smith, 1999). If educators are to recognize technology as useful for effective teaching, then staff development should begin with the establishment of underlying philosophies and goals for the use of this technology. Curriculum orientations should guide the goals on how technology should be used. Once a philosophy has been adopted, then the inservice teacher needs relevant and ongoing instructional support (Bull, Nonis, & Becker 1997). On-going staff support and encouragement is key to teachers use of technology in their curriculum (Conte, 1998). Sometimes teachers are unaware of what technologies are available in their schools, or of how to
take advantage of them when they obtain them. Therefore, when a teacher is willing to give technology a try having onsite support is key. Teachers who come across problems while teaching with a technology, and have support, are more willing to keep trying. Sadly, the opposite is true. Teachers lacking support and encouragement will more likely give up a technology enriched lesson when it goes awry (Conte, 1998). Schools must devise strategies for strengthening capacity within their own ranks in order to sustain their efforts and continue to grow (Maddin, 1997).

Preservice Teacher Education

Our preservice teachers must be skilled and supported in using technology, as well. Presently, thirty-eight states have technology requirements for teacher preparation programs (Rosenthal, 1999). Studies document that preservice teacher technology education has not kept pace with the changes that have affected the quality and quantity of technologies (Anonymous, 1999). Many preservice teachers find that the experience of using a computer is lacking for practical purposes (Laffey & Musser, 1998). Schools of education often overlook the very basic needs of their preservice teachers. According to Rosenthal (1999) only two of the thirty-eight education programs require actual evidence of proficiency in the use of technology in teaching for certification. Through her research Rosenthal (1999) presented several areas in teacher preparation programs that lacked initiative to fulfill these requirements. For instance, many teacher education programs lack the hardware and software necessary to incorporate technology into the teaching agenda.

Some education faculties have not been provided the training they need to use technology effectively. Other higher education faculties have little understanding of the changes technology is bringing to the K-12 classrooms and have not adjusted their own teaching methodologies to reflect these changes. This lack of modeling to preservice teachers provides little support of the use of technology to enhance teaching (Anonymous, 1999). According to a recent study conducted at the University of Michigan several factors deter the growth of preservice teacher education programs. For example, a lack of a written, funded and updated program will ensure little future growth. Finally, many preservice teachers who work in schools for field experiences do not typically work with master teachers who can provide them with support and information on the use of technology.

Technology-Based Teacher Education Program

The Technology-Based Teacher Education (TBTE) Program at Lehigh University is addressing this need of preparing teachers with the belief that modern technologies can and should be used as an educational tool. The TBTE program weaves technology throughout the course work and experiences of the preservice teacher. This ensures that the preservice teacher has a broad and meaningful understanding of how technology, teaching and learning interact. It is the programs belief that technologies—such as computers and the Internet— are more likely to succeed when their use addresses actual needs, encourages the development of a professional community and is grounded in sound theoretical understandings (Nonis, Bronack & Heaton 1998). One area that TBTE stresses with its preservice teachers is field-based experiences. Preservice teachers enrolled in the Seminar in Elementary and Secondary Education regularly work in classrooms with inservice teachers. In addition to working with an inservice teacher, these preservice teachers are actively observing experienced, model teachers.

Seminar in Elementary and Secondary Education

The Seminar in Elementary and Secondary Education course is designed to be the first course perspective teachers take as they begin the 5-year BA/MEd teacher education program at Lehigh University. The course outline touches on several basic elements of teaching, both from the historical model and the present day perspectives. The discussion-based format allows students to share their ideas, interests and concerns regarding education today as they plan to become our future teachers. In addition to the discussions and weekly readings that are assigned to each student, the last hour of each class is spent in a “Tech Talk.” Tech Talks range from learning about email and word processing documents, to databases and digital cameras. Each student is responsible for demonstrating competency in using that specific technology by the end of the course. The objective of the Tech Talk is to introduce to these preservice teachers the varied technologies, both hardware and software, available to them as future educators. This knowledge base also assists them in their field experience work via the Lehigh/Moravian Partnership.

The Lehigh/Moravian Partnership

The students enrolled in the Seminar in Elementary and Secondary Education course at Lehigh form a partnership with Moravian Academy—a K-12 Independent School—to address the needs of both preservice and inservice teachers. The partnership provides a variety of opportunities for both the preservice and inservice teachers. First, the preservice teacher spends quality time observing, interacting and conversing with an experienced
The preservice teachers use a Web-based journal form on the course website to share their reflections with the course instructors via field notes for each visit to their classroom. These notes asked the individual students to reflect on the topics discussed, technologies explored, and ideas generated. The field notes allow the preservice teachers to contemplate, reflect, and share concerns about their experience and serve as an on-going update for the instructors on the progress of each preservice-inservice dyad. Second, the preservice teacher work in an environment where technology is available throughout the school. The preservice teacher has an opportunity to see how technology is used in an actual classroom setting. Third, the partnership experience provides an opportunity for inservice and preservice teachers to collaborate on technology integration within an existing curriculum to solve real educational problems. Through conversation, observation and experience the inservice teacher learns more about new technologies and techniques available for teaching.

The Lehigh/Moravian Partnership is overseen by a faculty member at the university and administrators from Moravian Academy and is coordinated by a doctoral student who is a former teacher at Moravian Academy. The coordinator decides on placements for each team and meets with both the preservice and the inservice teachers when necessary. Placement depends on the academic interest and grade level that most interests the preservice teachers. Schedules of both the preservice and inservice teachers are considered, as well. Each semester begins with a gathering of both groups for introductions and orientation to the project. The preservice teachers spend a minimum of 20 hours observing and working with their mentor teachers. The objective for the preservice teachers is to observe and work with an experienced educator. The preservice and inservice teachers decide together upon an area of the established curriculum where technology can be embedded to enhance the learning experiences of the students in the class. The preservice teacher is then responsible for researching and finding appropriate technologies to address the stated needs.

Toward the end of the semester, each preservice teacher is responsible for developing and delivering a final project. The project involves teaching a technology-rich lesson to the students—in partnership with the inservice teacher. The projects vary. Some use the digital camera to incorporate photos into writing samples and slideshows. Others use a specific piece of software—such as Hyperstudio or Powerpoint—to complement a part of the existing curriculum. The inservice teachers provide informal feedback to the students during the presentation. At the end of the semester, each inservice partner provides more formal feedback to their preservice intern through a course evaluation. Finally, the preservice teachers present an overview of their lesson to their peers during their Seminar class. Included in their overview presentation is a written description of the lesson and example of the project.

### Formal Evaluation

Data from the first partnership cohort was collected at the end of the Spring 1999 semester from both the preservice and the inservice participants via a 12-item end-of-course survey. Each participant was asked to respond to the Lehigh/Moravian Partnership Feedback Form, a five-point Likert scale questionnaire concerning issues of guidance, structure, professionalism, and benefit of the program. Results in each category are displayed in Table 1, below:

Table 1: Results of End of Course Survey—Preservice and Inservice Participants

An independent t-test was conducted to investigate differences between the inservice and preservice participants with regard to the four factors. No significant differences were found between groups (p < .01). It is important to note that, given the small number of participants and the exploratory nature of this initial study, the results of the t-test must be viewed as prefatory.

Further data gathering is in process as the partnership continues to develop. In Fall 1999, a second cohort of inservice/preservice dyads was begun. The inservice and preservice teachers were asked to respond to the
Technology Teacher Survey once at the beginning of the semester and again at the end. Sample statements for this survey were divided into several categories: technology skill and knowledge, enthusiasm regarding technology, challenges implementing technology and confidence using technology. This survey targets the overall use of technology in the classroom. The data from this survey will add further to our growing understanding of the impact and effectiveness of the Lehigh/Moravian partnership.

Conclusion

The goals of the Seminar in Elementary and Secondary Education course and the Lehigh University/Moravian Academy Partnership includes the development of techniques that help emerging teachers close the gap between the potential of technology and its realization by teachers in their own classrooms. Certainly the experiences of both the preservice and the inservice teachers varied depending on the match made between the two and the expectations that each group had going into the partnership. Generally speaking, however, each pair succeeded with the overall objective: integrating a new piece of technology into an established curriculum. Some had more success than others with the working partnership created within each team. The field notes provide an outlet for the preservice teachers to express concerns. The inservice teachers used meeting time and emails to communicate concerns or problems.

Several modifications arising from what we have learned from the first cohort have already been initiated in the second group. For example, a more formal email system is now available for those inservice teachers involved to communicate with the coordinator on a more regular basis. Other suggestions made from the final evaluation by both the preservice and inservice have led to modifications in what technologies are covered and what initial skills are targeted as primary. By the end of the Spring 2000 semester, over 40 preservice teachers will have had the opportunity to work closely with experienced educators via the partnership. Many of the inservice teachers who took part in the partnership were only marginally facile with technology at the start. Yet, by the end of the course, all the inservice teachers had adopted some form of technology as a tool for both their own teaching and their students' learning. For most, this was a remarkable paradigm shift that will affect their practice to the ends of their careers.

The authors would like to thank the administration and faculty of Moravian Academy for their gracious support of this pilot program. Additionally, the authors would like to acknowledge the time and effort of the preservice participants.
Abstract

Integrating technology into the curriculum sounds simple. We've talked about it and have been "work-shopped" on it since the early 1980's. But, as educators, what have we accomplished in those years? This paper will share one teacher educator's experiences from germination of ideas to the implementation and success of using student interns (pre-service teachers) as models for the integrative use of technology in the learning/teaching process.

Introduction

Integrating technology into the curriculum sounds simple. We've talked about it and have been "work-shopped" on it since the early 1980's. But, as educators, what have we accomplished in those years? Many educators have taught courses and presented workshops but little has changed. What has been happening in most schools (if anything) is just more of the same - instruction delivered and practiced - now by both teachers and computers. There have been some changes in certain areas of the curriculum, in some parts of the country but not enough to equal the amount of money and time that has been spent by school districts and the state and federal government.

When you walk down the hallways of most schools - both K-12 and higher education - one still sees the teacher as the center of the classroom. Teacher talk is still the strategy that dominates most classrooms today.

Changes are beginning to occur, though slowly (Parker, 1996).

With over thirty years of educational experience – twenty-two years as a middle school educator, I decided about twelve years ago that a different approach was needed if technology integration was to make a difference in the learning environment of our K-12 schools. The approach that it utilized most often in teacher training in use of technology, is learn the technology and then the educator uses it in their learning/teaching environment. Much of the technology "in-service" has been working with the tool, not how to use it in the learning/teaching process. But, little integration has occurred using this model. Educators need to see it being used in the learning/teaching process (Beck & Wynn, 1998). I believe that learning to use technology in the learning/teaching process is more a change in the way we see students learn than in the actual use of the technology itself. It is the shift from teacher directed to student directed learning that may be the actual problem that needs to be solved.

Most of the teachers in today's educational settings received their knowledge and skills in teaching years before the utilization of technology became a reality, and years before much of the research on how
students learn became known to us. Thus, it stands to reason that not only do educators need to learn about technology but also about new learning theories and models.

I became aware of the need for a different approach when I was asked to speak to a group of pre-service teachers at my undergraduate alma mater. It was then that I realized that a new group of educators, ready to take on the responsibility of being educators, had no more experience using technology in the classroom than the teachers already in schools. Teacher education programs were failing to help the situation (of integration of technology) in any way. They were graduating students with little or no knowledge of the use of technology in the learning/teaching process. Much of what was being taught was the same as when I had graduated from the institution some 20 years ago. Following this realization I studied other teacher education programs around the nation and found that my alma mater was not alone. Most of the teacher education programs were not addressing the issue of technology integration nor the ideas of active learning.

It was then that I began to see a plan for how teacher education could make a difference in the unending pursuit of utilizing technology in the learning process. It was then that I realized “an” answer to this long and enduring problem of the lack of technology integration. Start at the pre-service level and have these students become the “models” of the integration of technology in the learning process.

It took a few years, but I am now involved in doing just that. Pre-service teachers involved in the teacher education program where I now facilitate the learning process are the “technology integration models” for their mentor teachers in their K-12 field-based experiences.

As part of this program, students are taught by the professors to integrate technology into their lesson units and plans. This is modeled by the professor and in turn modeled by the student interns during their field-experience. In this paper I will describe how pre-service students are playing an integral part in technology integration truly happening - with the excitement of learning by student interns, mentors and K-12 students soaring.

The Process

Besides my enlightenment that teacher education can play a major role in the area of integrating technology, there are a few other details that help me work with the students in our teacher education program to become the “integration of technology models.”

First, my doctoral study in Educational Systems Design made me aware that teacher educators have not been an integral part (if any) of school change and/or restructuring. As part of one of my comprehensive exam questions, I looked at a study done by Dr. Alison Carr (1996) that looked at refereed articles written by “systems thinkers” dealing with school change. In the thirty-five articles that were designated as such, only two mentioned teacher education. Neither of these articles dealt with teacher education in any detail.

This was an affirmation of my beliefs on how we, as teacher educators, may be missing the boat with technology integration, as well and school transformation. In teacher education we have a chance to begin to make a difference in schools - yet we are rarely involved in the change efforts in the K-12 arena.

Second, my assignment as an Associate Professor in residence in a K-6 school has given me the opportunity to “see” first hand how teacher education students can make a difference in the integration of technology into the learning process. I spend four full days a week in a K-6 school that was built three years ago. This school was designed by a group of teachers in the district who are now teaching there. The school is a neighborhood school, not a magnet school, yet it has an emphasis on the use of technology in the learning process. All teachers in the building were hired from within the district with the knowledge that the university would be an integral part of the learning environment, that teacher education classes would be taught in the university classroom (built as part of the new school), and that university professors would be available for training and support of their efforts. I was hired to work with them on a daily basis.
Sounds great. However, in practice not all went as well as we had hoped - at the beginning. First we needed to work through the K-12/higher education rift that is evident in most areas of the country. This takes time and patience. Then it was finding time for me to work with the teachers - before school, during school, after school - time - the unending push for more time.

A year ago, our teacher education program became completely field-based. Our students are spending over 50% of their time and work in the K-12 classrooms. I saw a possible answer to the on-going problem of time for training and team teaching. Instead of one person (me) trying to find the time to work with each of the teachers, my students now do this work.

During our class time - I model, we plan, we collaborate, and we prepare lessons that involve the integration of technology into the curriculum. This year has been a wonder - my students, their mentor teachers, and their K-6 students have been involved with many lessons and projects that support the new state curriculum standards AND integrate the use of technology AND everyone involved is thrilled with the results. This year professors at the other PDS sites are using this same process.

Third, the university received a state grant that has helped us restructure our teacher education program. The teacher education program is now completely field-based, all classes being taught at one of the seven PDS sites. Most of the money received from the grant purchased hardware and software (a university classroom lab and additional computers being placed in classrooms where interns are working with mentor teachers), and a professional development library ($10,000 per PDS site) for the seven professional development schools (one high school, one junior high school, and five elementary schools) where we teach our courses - one being the elementary school where I reside.

Before you start thinking - of course this would work with all of this support - I believe that this project can be replicated with the resources that most teacher education programs and school districts now possess. A change in the collaboration efforts between the university and the school district need to be solidified (little money needed for that), classrooms in school district buildings where teacher education classes can be taught need to be made available, and the technology resources of the K-12 schools need to be utilized as part of the teacher education program. Much of what will be mentioned in the remainder of this article can be done with one computer in a classroom that has Internet capability and is hooked to a large monitor or projector for full class or group viewing.

Model/Learner Project

This project emphasizes the use of technology in the K-12 field-based teacher education courses. As mentioned earlier, teacher education students at all seven professional development schools must integrate technology into the lessons taught as part of their internship. Thus, they are modeling, for their mentor teachers appropriate ways to integrate the use of technology into the curriculum. Reciprocal teaching (Palincsar, & Brown, 1984) occurs when the mentor teacher models for the interns various teaching strategies, classroom management strategies, lesson planning, and other essential components in the everyday learning environment. Both interns and mentor teachers team plan and team teach lessons using technology as an integral part of the lesson.

The integration of technology in the learning/teaching process takes on an apprenticeship model (Collins, Brown, & Newman, 1989) of learning. The apprenticeship moves back and forth from intern to mentor teacher as lessons are planned and taught, by the mentor teacher, in a team teaching environment, and intern-facilitated lessons. “In the apprenticeship model the learner sees the processes of work. In the traditional apprenticeship, the expert shows the apprentice how to do a task, watches as the apprentice practices portions of the task, and then turns over more and more responsibility until the apprentice is proficient enough to accomplish the task independently.” (Collins, A., Brown, J. S., & Holm, A., 1991). During their apprenticeships, both the mentor teacher and the intern learn new ways of facilitating learning,
using active learning processes as well as integrating the use of technology as a tool in the learning/teaching process.

Some examples of the intern modeling for the mentor teacher include:

1. Interns (pre-service teachers) use one computer in a classroom - utilizing a large screen monitor for full class instruction.
2. Interns use the Internet as a motivating factor at the being of a unit or lesson.
3. Interns use the Internet as an integral part of a lesson - student interns develop webquests and web pages as part of a course in the teacher education program.
4. Both interns and mentor teachers participate in collaborative on-line projects such as AfricaQuest, GalapagosQuest, AsiaQuest (Classroom Connect), Earth Day Project, Hundred Day Project, Jamestown, M&M Project, Problem of the Day, and many more.
5. Interns use of SmartBoards for full class instruction. Many of the mentor teachers have the availability of this hardware but have not used it until the interns demonstrated its use in a lesson they taught.
6. Both interns and mentor teachers use on-line field trips to enhance a unit or lesson or in preparation for a real-time field trip.
7. Use of PowerPoint by interns, mentor teachers, and students to present information, including use of Internet sites.

Conclusion

These projects serve as an on-going professional development for both interns and mentor teachers in the integration of technology into the learning/teaching process. The projects are always changing as new ideas, new sites, new technologies (digital cameras with video capability) are added to the teacher education program.

In the past two years I have witnessed what can happen to the learning process of interns, mentor teachers and K-12 students as technology plays a more important role in their instructional lives.

I challenge each and everyone of us, as educators, whether we be K-12 educators, teacher educators, or administrators, to model for learners the integration of technology into the active learning process. As Collins, Brown, and Holm state it:

Apprenticeship is the way we learn most naturally. It characterized learning before there were schools, from learning one's language to how to run an empire. We have very successful models of how apprenticeship methods, in all their dimensions, can be applied to teaching ... they help point the way toward the redesign of schooling... as well as improve the ability to learn throughout life.

The use of the apprenticeship's four basic aspects of modeling, scaffolding, fading, and coaching can, and I believe will, lead us to a dimension of learning that we all strive.

Abstract: Partnerships between universities and local K-12 school districts provide learning opportunities for university professors, K-12 students and teachers, and pre-service teachers enrolled in undergraduate programs. This paper describes a partnership between a southwestern university and a local K-12 school district. The partnership was designed to enhance computer competence and confidence in 250 middle school students, build an ongoing relationship between the university and the local school district, provide opportunities for pre-service teachers to observe best practices in technology integration in K-12 educational settings, and allow a university professor to conduct a qualitative research project.

Introduction

Partnerships between universities and local K-12 school districts provide learning opportunities for university professors, K-12 students and teachers, and pre-service teachers enrolled in undergraduate programs. This paper describes a partnership between a southwestern university and a local K-12 school district. This partnership was designed to:

- enhance computer competence and confidence in 250 middle school students;
- build an ongoing relationship between the university and the local school district;
- provide opportunities for pre-service teachers to observe best practices in technology integration in K-12 educational settings; and
- allow a university professor to conduct a qualitative research project.

A K-12 teacher and administrator initiated a partnership with the state university in which a K-12 teacher and a university professor collaborated to team-teach classes to middle school students. These students were bussed to the university campus where they spent approximately ten hours in a technology-rich environment. The students completed web-based research projects and then created multimedia projects summarizing their research. Undergraduate university students observed the team-taught classroom and gained insights into best practices of technology use in K-12 education. The university researcher conducted a qualitative study on the middle school students’ understandings of technology. Data sources included an open-ended survey, observations, document review, and focus groups. This paper describes the process of establishing this partnership, the participants, the workshop model, and benefits to each stakeholder group.

The Process of Establishing a Collaborative Technology Partnership

A partnership between a southwestern university and a local K-12 school district seemed advantageous for all stakeholders: middle school students could benefit from use of computer facilities at the local university, K-12 administrators could satisfy parents’ desire for greater access to technology for their children, undergraduate students studying to be teachers could observe K-12 technology integration on their own campus, and a university researcher could conduct an extensive study on middle school students using technology. Since this
partnership was beneficial for all involved, establishing the alliance was straightforward. Each stakeholder outlined goals and objectives to other stakeholders, and during several collaborative meetings, they developed a workable plan for this collaborative technology partnership. Details about stakeholders and the semester-long development process for this project are outlined below.

**Participants and the Workshop Model**

The primary participants in this project were a teacher from the participating K-12 district, a university professor serving as teacher-researcher, approximately 250 middle school students from a local K-12 school district, and undergraduates enrolled in the education certification program at the university. Middle school students were enrolled in classes for gifted and talented students in twelve elementary schools throughout the district. These students visited the university four times for two-and-a-half hours each visit. Students were predominantly Caucasian; approximately 20% were Hispanic, 3% were Asian, 1% were Native American, and 1% were African American. They had a mean age of 12.5 years. Socioeconomic status varied widely among the middle school students.

This project was grounded on the following assumptions:
• learning is an active process facilitated by the creation of an environment that encourages risk-taking and creative and critical thinking;
• teachers strive to create such environments to facilitate learning and provide opportunities for self-reflection and evaluation;
• learners learn by doing;
• learning is social and is fostered by collaboration; and
• technology is a tool for facilitating learning rather than the focus of learning.

Benefits to Participants

The project was designed to benefit many stakeholders. Documented benefits to each stakeholder group are described below.

During their four visits to the university computer classroom, the middle school students spent approximately ten hours in a technology-rich environment. Through completing a WebQuest on cloning and creating a PowerPoint presentation to share their research findings, they enhanced their skills in:

• using the Internet as a research tool;
• using the Internet as a tool for enhancing multimedia presentations;
• working collaboratively and reaching consensus;
• designing multimedia presentations using PowerPoint;
• delivering multimedia presentations to share their research with peers and parents.

The middle school students also became familiar with a college campus and became aware of higher education opportunities at the local state university.

University and K-12 administrators established both a workable model for K-12 – university partnerships and an on-going partnership. This partnership resulted in:

• increased goodwill between the two institutions;
• increased enrollment of K-12 teachers in graduate classes in educational technology courses at the university;
• increased access for K-12 students to computers and pedagogically-sound practices that integrate technology into the established K-12 curriculum;
• happier K-12 parents because of increased student access to technology;
• on-going dialog about ways to continue and expand this partnership.

University undergraduates studying to be K-12 teachers observed their university professor and a middle school teacher using technology in theoretically grounded and pedagogically sound ways. Student observations were meaningful as they involved good teaching practices in which technology was a tool rather than the curricular focus. Through a series of observations followed by class discussions, they were able to:

• provide a pedagogically sound argument for using technology in elementary or secondary classrooms;
• describe their view of the learner and the learning process;
• describe the categories of software best suited to their view of the learner and the learning process;
• describe best practices for using technology in elementary or secondary classrooms;
• describe the supports and obstacles to these best practices.

Finally, a university professor was able to conduct an in-depth and on-going qualitative study of middle school students’ understandings of technology. By using open-ended surveys, observations, document reviews, and focus groups, the professor examined the changing relationships between gender and understandings and uses of technology. The results of this research are forthcoming.
Conclusion

Partnerships between universities and local K-12 school districts are advantageous to all stakeholders. This collaborative technology partnership:

- provided a workable model for K-12 – university partnerships;
- established an on-going relationship between the university and a local school district;
- opened the way for future partnerships with other K-12 school districts;
- enhanced the computer competence and confidence in 250 middle school students;
- provided opportunities for pre-service teachers to observe best practices in technology integration in K-12 educational settings; and
- allowed a university professor to conduct an in-depth qualitative research project.

As indicated above, all stakeholders benefited. In addition, a viable model for K-12 – university partnerships was developed and fine-tuned. This model can be used in the future with other interested K-12 districts in the area. As more partnerships are formed, all partners should seek funding to support several aspects of the project including student bussing, substitute teachers for K-12 teacher participants, and graduate research assistants. The university should continue to contribute the computer classroom and the time and efforts of the university teacher-researcher. Finally, future partnerships should strive to attract corporate sponsors so that K-12 educators, university educators and corporations are working together to optimize educational opportunities for learners at all levels.

Changing Preservice Teacher Education: A New Paradigm Integrating Technology

Henry D. Dobson, Ph.D.
Professor, Educational Technology
Bloomsburg University of Pennsylvania
United States
hdobson@bloomu.edu

Abstract: This paper will describe a project that was designed to create teachers for the 21st century by raising the minimum technology requirements in their course of study. This project required future teachers to apply their technology skills in the classroom at K-12 partner schools by creating an electronic portfolio with a set of technology-based classroom activities. This project directly served approximately 76 preservice teachers, 80 classroom teachers in 16 school districts, and a significant number of university faculty. The preservice teachers involved in this project volunteered to take an additional six credits in advanced technology that included topics related to instructional design systems and virtual learning communities. The preservice teachers were trained to use the most sophisticated technology tools for research, information analysis, and problem solving in all content areas including special education. This paper will present the why, how and the where changes occurred during the initial phase of this project.

Introduction

Currently every teacher education student is required to complete one three-credit technology course. This course is designed to ensure that every pre-service teacher receives a baseline of experiences using computer hardware and software for professional productivity, research, and classroom presentations. Students learn to use computer technology for desktop publishing, database management, spreadsheet analysis, and simple multimedia applications. They learn to evaluate software in a variety of curriculum areas, use e-mail, and use the Internet for communications and research.

The Project

This systematic initiative has four closely related educational objectives. First, the project ensured that all preservice teacher participants develop the knowledge and skills to integrate technology into their teaching and learning processes. Second, the project ensured that the K-12 cooperating teachers enhance their knowledge and skills in integrating technology into their own curricula. Third, the project provided opportunities for the university faculty to increase their knowledge and skills in the use of technology in their own teaching. Fourth, the project established a state-of-the-art technology resource center for use by preservice teachers, inservice teachers from surrounding school districts, and university faculty.

The first objective of the project was met by having three members of the School of Education designed two, three-credit courses that provided the educational opportunities for the preservice teachers to master the advanced technology competencies stated at the end of this paper. At the completion of these two technology courses the preservice teachers are required to demonstrate or provide documentation that they have mastered the 48 advanced technology competencies reflecting national educational standards. The content of these courses focused on the use of technology to improve student learning in the K-12 classrooms and reflect specific activities related to grade levels and content areas. The courses were team taught by three members of the School of Education who have specific expertise in the major content areas.

The second objective required recruiting schools and cooperating teachers for the project. During the summer of 1999, a week long workshop was conducted for the participating inservice and preservice teachers. The workshop included hands-on technology based activities and training to help their student teachers apply the advanced competencies in actual classroom settings.
The third objective was met by having university faculty from specific content areas participate in workshops for the inservice and preservice teachers. The university faculty provided examples of how they have integrated technology into their instructional practices.

The fourth objective required the development of a technology center with advanced technologies that included over 30 multimedia stations with Internet access, scanners, digital cameras, CD recorders, and a variety of special education assistive devices. The center is equipped with wide-bandwidth communication lines designed for desktop videoconferencing. The technology center provides opportunities and resources for students, faculty, and inservice teachers to develop projects that promote the integration of technology into their curriculum. The project incorporated an extensive web-based component (http://planetx.bloomu.edu/center) that contains activities, resources, a newsletter, and examples of projects created in this program.

The key to the success of this project is the inservice teachers who acted as mentors for the student teachers participating in this project. In the initial phase of the project, the preservice teachers met with their respective mentors to design technology-based units and supporting lessons that match the existing curriculum being taught by the inservice teachers. During the second phase, the preservice teachers researched, designed, and tested their activities in the technology center. In the last phase of the project, the preservice teachers incorporated their technology-based activities into their student teaching experiences.

The two, three-credit advanced technology courses are currently an elective option for the university's teacher education program, however, it is the intent of the project that these courses will become a requirement for all entering freshmen in the School of Education.

Advanced Technology Competencies

For each of the following statements, code in True for your Yes response and False for your No response on the accompanying answer sheet. For each True response you must be able to document or demonstrate your knowledge and skills associated with that particular statement.

1. Can you identify and use computer and related technology resources for facilitating lifelong learning and emerging roles of the learner and the teacher?
   Yes ______ No ______

2. Can you compare and contrast current instructional design principles, research, and appropriate assessment practices as related to the use of computers and technology resources in the curriculum?
   Yes ______ No ______

3. Can you design, deliver, and assess student learning activities that integrate technology across disciplines for a variety of student grouping strategies and for diverse student populations?
   Yes ______ No ______

4. Can you identify and report on the responsible, ethical, and legal use of technology, information, and software resources?
   Yes ______ No ______

5. Can you identify and report on the basic principles of effective instructional design associated with the development of multimedia learning materials?
   Yes ______ No ______

6. Can you create and produce simple hypermedia/multimedia products that apply basic effective instructional design principles?
   Yes ______ No ______

7. Can you select and use appropriate tools for communicating concepts, conducting research, and solving problems in subject areas and grade levels?
   Yes ______ No ______

8. Can you organize and implement collaborative technology-based projects and team activities?
   Yes ______ No ______

9. Can you collect and evaluate examples of emerging programming, authoring, and problem solving environments?
   Yes ______ No ______

10. Can you create and initiate online workgroups to build a collection of knowledge on specific topics?
    Yes ______ No ______

11. Can you design and publish simple online documents presenting information that include links to critical resources?
12. Can you design, develop, and produce instructional units that involve compiling, organizing, analyzing, and synthesizing of information and that uses technology to support these processes?

Yes No

13. Can you conduct, evaluate, and report the research associated with online resources of information that support and enhance the k-12 curriculum?

Yes No

14. Can you identify and describe strategies to support the development of school and laboratory policies, procedures, and practices related to the use of technology in those environments?

Yes No

15. Can you research, evaluate, and produce recommendations for purchasing instructional software and hardware to support and enhance the k-12 curriculum?

Yes No

16. Can you design and write recommendations for the organization, management, and security of hardware and software in different learning situations?

Yes No

17. Can you identify strategies and product documents for troubleshooting and maintaining various hardware and software configurations in a variety of instructional settings?

Yes No

18. Can you select and configure a complete computer system and install the operating system and a minimum of one application package?

Yes No

19. Can you identify and use information access and telecommunication tools to support research and instruction throughout the k-12 curriculum?

Yes No

20. Can you use and demonstrate distance learning delivery systems including computer, audio, and video conferencing?

Yes No

21. Can you create and present a multimedia presentation using advanced features of a presentation tool and computer projection system?

Yes No

22. Can you install, configure, and demonstrate the use of mass storage devices?

Yes No

23. Can you identify and describe software currently used in classrooms and administrative settings?

Yes No

24. Can you investigate and recommend in writing, purchasing strategies and procedures for acquiring administrative and instructional hardware and software?

Yes No

25. Can you identify and classify adaptive assistive hardware and software for students and teachers with special needs?

Yes No

26. Can you evaluate and report on the technology concepts and skills being taught in a k-12 setting?

Yes No

27. Are you familiar with methods and strategies for teaching technology concepts and skills in a laboratory and classroom setting?

Yes No

28. Can you identify and upgrade technology supported curriculum to reflect on-going changes in this area?

Yes No

29. Can you design, produce, and demonstrate integrated technology-based activities that involve teaming and/or small group collaboration?

Yes No

30. Can you identify and present activities and resources to support regular professional growth related to the use of technology in the classroom?

Yes No

31. Can you describe student guidance resources, career awareness resources, and student supported activities related to technology?
32. Can you compare and contrast national k-12 technology standards with benchmarks set by state and local agencies?
Yes___ No___

33. Can you identify and critique professional organizations and groups that support the field of educational technology?
Yes___ No___

34. Can you design and produce a set of assessment strategies and methods that will evaluate the effectiveness of instructional units that integrate technology?
Yes___ No___

35. Can you summarize and apply principles and practices of educational research to educational technology?
Yes___ No___

36. Can you summarize and report major findings and trends related to the use of technology in education that support the integration of technology in the k-12 environment?
Yes___ No___

37. Can you apply theories of learning, teaching, and instructional design and their relationship to the use of technology to enhance learning?
Yes___ No___

38. Can you describe social and historical foundations of education and how they relate to the use of technology in schools?
Yes___ No___

39. Can you design and produce a research project that includes an evaluation component of a specific technology in the k-12 classroom?
Yes___ No___

40. Can you demonstrate the use of more than one authoring environment?
Yes___ No___

41. Can you describe and analyze accepted principles of strategic planning to facilitate curriculum designed for teaching with technology?
Yes___ No___

42. Can you identify and evaluate national, state, and local guidelines for developing curriculum plans for technology integration?
Yes___ No___

43. Can you demonstrate methods for teaching hypermedia development in a problem solving format?
Yes___ No___

44. Can you demonstrate methods for teaching at least one authoring program?
Yes___ No___

45. Can you demonstrate methods for teaching the use of media-based tools – television, audio, print media, graphics?
Yes___ No___

46. Can you observe and compare strategies used in educational technology in a variety of authentic educational settings?
Yes___ No___

47. Can you develop and teach a series of lessons that apply technology to support learning?
Yes___ No___

48. Can you document and assess a significant field-based activity involving experiences in instructional program development, staff development, resource management, and managing change related to technology use in schools?
Yes___ No___

Acknowledgement

This project was funded by a grant from the Link-to-Learn Integrating Technology into Teacher Preparation Program, Pennsylvania Department of Education.
Using Technology in Field Experience in Regular and Special Education

Cindy L. Anderson, Ph.D., Department of Elementary, Early, and Special Education, Southeast Missouri State, USA, clanderson@semovm.semo.edu

Kevin M. Anderson, Ed.D., Director of Instruction, Kenosha Unified School District, Kenosha, Wisconsin, USA, keanders@kusd.edu

Abstract: Preliminary results of a study designed to measure the effectiveness of two Funding for Results grants at Southeast Missouri State University are shared. These grants allowed the purchase of computer equipment and software that was used by Block III regular education and additional computer equipment, assistive technology and software that was used by Block IIIA special education students. Each of these groups used these supplies on their field placements. The study, using a pretest-posttest repeated measures design, was intended to measure the awareness level of both the preservice students using the equipment and the cooperating teachers working with the students. Results outlined in this paper summarize preliminary results as case studies of four students who described the impact of the technology on their field placements.

Introduction

Schools today are preparing the employees of the future. Projections for the year 2000 indicate that five of the ten fastest growing job areas will be computer related (College Planning Network 1996). Today's school students must be trained to function in a rapidly changing world, a world in which the amount of information at least doubles every 5.5 years (Naisbitt 1994). To be well-prepared, students must be trained to use technology and to access, search, and evaluate information. Schools have recognized this need and have increased their investment in technology for the last several years, with a recent ratio of students to computers at 5.7 to 1 (Market Data Retrieval 1999).

At the same time technology is increasing in the schools, the population of experienced teachers is declining. An estimated 2 million new teachers will be hired in the next decade (National Council for Accreditation of Teacher Education 1997). Schools of education have a valuable opportunity to fill these openings with teachers who are trained to use technology successfully. Indeed, teacher education institutions are recognizing this need. Seventy-six percent of education professors surveyed by the Office of Technology Assessment (1995) agreed that technology plays an important role today and eighty-two percent felt it would continue to play an important role. Yet, in a recent survey of graduates of teacher education institutions, more than fifty percent of the graduates felt that they had been poorly prepared in the use of information technology in the classroom (Barksdale 1994). In a review of literature on information in technology and teacher education, Willis and Mehlinger (1996) concluded that while many students received coursework in information technology, little training in technology was tied to or required in field experience.

The National Council for the Accreditation of Teacher Education (NCATE) recognizes that teachers must be trained to use technology. To meet this need, NCATE collaborated with the International Society for Technology in Education (ISTE) to spell out minimum technology skills for all beginning teachers. The Council for Exceptional Children is currently working with members of their Technology and Media (TAM) Division to outline minimum assistive technology skills for
NCATE's list of competencies for beginning special education teachers (Lahm & Nickels 1999). NCATE recommends that schools of education infuse these technology skills into their regular operations.

ISTE has researched how teacher education institutions can successfully accomplish training preservice teachers to use technology. In a survey of teacher education institutions, the International Society for Technology in Education (1999) verified the Willis and Mehlinger (1996) results. Their survey found that most teacher education institutions do not routinely use technology during field experience. Their survey determined, however, that the use of technology during experiences is more highly correlated with successful technology integration than separate technology course requirements.

The need for preservice teachers to use technology in their field experience situations was the basis for this study. In 1997 and 1998, a $25,000 multi-year Funding for Results grant, "Enhanced Technology Experiences for Block III Elementary Education Students," provided educational software, laptop computers, and projection hardware for preservice teachers to take into the field during their Block III (third year) field experience placement. In 1999, another $25,000 Funding for Results grant, "Integration of Assistive Technology into Teacher Preparation", provided software, laptops, projection equipment, and assistive technology for preservice teachers in special education to take into the field for their Block IIIA (third year) special education field experience. This study is designed to measure the technology knowledge of both preservice teachers and their cooperating teachers in the field placements where the technology is being used. It further assesses the attitudes of both the preservice teachers and the cooperating teachers toward the technology being used in the field experience.

The Study

The state of Missouri has developed Funding for Results grants for the purpose of enhancing university classroom instruction. Portions of these grant monies are provided to each public university in the state. At Southeast Missouri State University, a committee decides which grants will be awarded each year with preference, in recent years, given to grants designed to improve experiential learning. The two grants involved in this study, “Enhanced Technology Experiences for Block III Elementary Education Students” and "Integration of Assistive Technology into Teacher Preparation" were designed to allow students to integrate technology into field experiences even when the field experience placement did not have a computer in the classroom.

The Funding for Results grants allowed the purchase of equipment that Block III regular education field experience students and Block IIIA special education students were able to take to their classrooms. This equipment included laptop computers, projection devices, and software for both grants. In addition, the Block IIIA grant allowed the purchase of software and hardware designed for students with disabilities. A survey instrument was designed for both field experience placements to be administered to both preservice teachers and cooperating teachers at the beginning of the semester and at the end of the semester. This survey instrument was designed to measure the awareness of instructional technology, software and hardware, and attitudes toward technology use in the classroom. Researchers designed the survey instrument to help answer several questions of both regular and special educators:

1. Will the use of this technology during the field experience improve the awareness of
technology that is available for instruction?
2. Will use of the technology improve its infusion into classroom instruction?
3. What is the teacher's opinion toward infusing technology into the curriculum?
4. Will the knowledge of the operations of computers and peripherals improve?
1. Are the teachers disseminating their new knowledge?

Additional questions were asked of the special education students:

6. Are the teachers more aware of methods for using technology in assessment?
7. Are the teachers more aware of technology that is available for students with disabilities?
8. Do the teachers feel better prepared to make recommendations for technology for students with disabilities?

The study used a repeated measures design, with a survey instrument administered at the beginning of the semester and a posttest survey at the end of the semester. Researchers predicted that each of these questions would show a positive increase as a result of using the materials and equipment purchased with the FFR grants. To measure the change, survey instruments were administered to both pre-service teachers and inservice teachers. The survey instruments were the same except that the special education students and teachers had questions about assistive technology that the regular education students did not have. The survey instruments were adapted from the instrument used by Blackhurst (1988).

The Results

While the posttest survey results are not yet available at the time of this paper, a structured interview was administered to four students, two from Block III and two from Block IIIA. These interviews provide a formative report on the anticipated results of this study. This paper is a description of their experience in using the FFR grant equipment as reported in four case studies.

Regular Education

Regular education students at Southeast Missouri State University proceed through a structured block program that involves numerous field experiences. At each level, preservice teacher participation and responsibilities in the classroom increase, so that by the time they student teach, pre-service teachers have spent over 250 hours in a classroom. Students involved in this study were part of the Block III level. Block III is the final level of instruction and field experience placement before pre-service teachers begin student teaching.

The Funding for Results grant, “Enhanced Technology Experiences for Block III Elementary Education Students” provided four laptop computers and two projection devices for students to use in the field. In addition, the grant purchased several software packages to take to their field placements. These software packages were in the area of mathematics, science, and social studies, as well as tool packages such as Microsoft Office, The Cruncher, and The Graph Club.
Regular Education Case Study 1: Annie

Annie was a junior at Southeast Missouri State University. She was placed in the professional development section of Block III, spending about 250 hours in the classroom during the semester. Annie was placed in a regular 4th grade classroom in a small city setting. Her students came from a generally lower socioeconomic level, with several minorities represented.

Annie used the computer technology in 4 lessons. During these lessons, Annie used web pages she had previously downloaded as the basis for a Missouri history scavenger hunt. A video projector was used for large group searches and students worked in pairs for small group work. She had previously shown the students how to conduct web searches, so they were fairly comfortable with the process.

Annie reported that she was already a competent computer user, having worked for the university computer development center helping faculty and students. She strongly felt that technology benefits students, saying, "My students were legitimately interested in learning when the material was presented in a multimedia format. It may not have provided new information, but it provided the excitement associated with learning."

Annie reported that she used a laptop, LCD projector, scanner, layout software and the Internet while teaching the students. She reported that use of the equipment helped her to better integrate technology into instruction by facilitating the development of student storybooks, integrating use of the Internet by using an Internet scavenger hunt, and incorporating an instructionally appropriate software package such as Hyperstudio. She further reported that she has shared her new knowledge at technology conferences and with teachers in the field who asked general questions about the technology. She learned to identify software for its clarity of instruction, its player control, and its fidelity in situations that were designed for the classroom. To maximize the integration of technology into the schools, she suggested the use of prolonged exposure for students and lots of teacher training involving meaningful skills.

The impact of the technology on the classroom teacher where Annie worked was evident in the post-instruction assessments conducted by Annie and her cooperating teacher. Students who had not previous shown much interest in social studies lessons were excited and motivated to complete their searches. According to the cooperating teacher, the fact quiz given several days after the searches also showed a greater degree of correct knowledge than usually was shown by previous classes. This teacher also commented that she planned to use similar techniques in her classes in the future.

Regular Education Case Study 2: Shannon

Shannon was a junior at Southeast Missouri State University. She was placed in the professional development section of Block III, spending about 250 hours in the classroom during the semester. Shannon was placed in a regular 4th grade classroom in a rural setting with very few minorities.

Shannon used the computer technology on 2 occasions. She had not felt that technology benefited her students much until she used PowerPoint with the students. She saw how much more students were motivated by the technology when it was used beyond the normal drill and practice mode. "The kids were so excited when the computer was used to present their lesson materials in a
new way. They also got to use a CD-ROM to further research the topic they were currently studying. This was much more meaningful than sitting at the computer to do daily math and reading work."

The impact of the technology on the classroom where Shannon worked was evident in the excitement generated during the discussion of the social studies topics covered by her PowerPoint presentation. The students also completed a fact book based on the presentation, working in small groups. The cooperating teacher commented that the students seemed to remember the facts more quickly than was usual in her class. She also noted that she would like her school to obtain a video projector for the elementary teachers to share since it made using the computer with the whole class much more effective.

Shannon reported that she used a laptop, LCD projector, CD-ROMs, overhead projector, and a TV-VCR while teaching the students. She noted that the equipment provided with the grants helped her to know more technology available for integration into instruction, but that she still did not know everything that was available. She reported that she improved her knowledge of the computer operations necessary to set up a presentation, but that setting up the equipment still was somewhat confusing to her. She had shared her lesson with other preservice teachers in her Block III class and received favorable responses. Shannon shared that she had learned to value software for its ability to stimulate students' minds. To maximize integration by teachers in the schools, she suggested not overusing technology, but using it meaningfully starting in the early grades like kindergarten or first grade and making equipment available for all classrooms.

Special Education

Special education students at Southeast Missouri State University proceed through a structured block program similar to the one in regular education with field experience at every level. In addition to classes with the regular education students, the special education students have a semester block with special education methods courses, Block IIA. The field experience placements during this semester occur in a special education classroom.

The Funding for Results grant, "Integration of Assistive Technology into Teacher Preparation", allowed the purchase of five laptop computers and one projection devices for students to use in the field. Several items for students with disabilities were purchased: Intellikeys, Don Johnston Key Largo, adapted toys, software made for students with learning disabilities, an augmentative speech device, switches and switch adapters. In addition, the grant purchased several instructional software packages not specifically made for students with disabilities to take to their field placements. This software was in the areas of reading, writing, mathematics, science and behavior.

Special Education Case Study 1: Stephanie

Stephanie was placed during her special education Block IIA semester in a K-6 learning disabilities classroom in a small city, middle class school. She used the computer technology each time it was available and all four occasions when her college supervisor made a formal observation. She had already used technology in the classroom, but this semester, she reported that she saw its expanded value in the area of writing for students with disabilities. She saw how students with learning disabilities who have a large oral vocabulary and lots of creativity could transfer what they want to say to paper without being hindered by poor handwriting.

Stephanie was convinced during this experience that the students benefited from technology and actually had opportunities to see observe its benefits. She was working with a second grader who spelled "center" as "senter" during a writing lesson. Using a word prediction program provided
by the grant, the second grader was trying to type the word. This word prediction software, Co-
Writer, generates a list of ten words starting with the letter that was typed. The students can run the
cursor over these words to have the software read the words. When the second grader could not find
"center", she asked if the word began with a "c", discovering her own mistake. When told so, she
finished the writing selection.

Stephanie stated that she was aware that computer technology could also be used for
assessment. She said that she knew that a spreadsheet could be used to report behavior charting and
that a multimedia authoring programs like Hyperstudio could be used for portfolios. Her chance to
use these packages during this activity was limited though by her teacher who did not permit her to
participate in reevaluations and Individual Educational Planning (IEP) meetings. However, she felt
more able to make IEP recommendations for students with mild disabilities who benefited from
software that bypassed reading and writing deficits.

Stephanie's technology skills were competent before this semester, but she gained the
knowledge of setting up the projection device and became the computer technician for others in the
class. She still felt a bit uncomfortable with the Macintosh operating system and chose to use the PC
system for all her activities. Stephanie reported that she used the IBM laptop and projector, along
with word processing software, word prediction software, spreadsheets, graphs, and IEP software
and math software. She reported that the equipment provided with the grants helped her to know
more technology available to be integrated into instruction for students with disabilities.

Stephanie was able to use the special education technology and software in several lessons.
One of her lessons required that students write a paragraph about themselves. Only one of the four
students wrote more than the minimum amount of sentences. When given the chance to use the
computer, they each added more to their stories. They were motivated by the computers and felt that
it was so easier to write using the computer.

Stephanie's final lesson with the computer used word prediction software again, but this time
added Inspiration to generate character or story maps. Students created a story map with Inspiration
and turned their map into an outline. This outline was then incorporated into a story that included
digital pictures. They had fun using the hardware and software, stating that they did not know that
writing a draft could be so much fun. Their results were well-written stories that Stephanie found
were longer than their hand-written stories.

As a result of participating in the grant, Stephanie developed standards that she felt defined good educational
software. She reported that good software needed to be self-explanatory, modifiable for different learning needs,
educational and fun. Stephanie's recommendations for a district developing a plan for integrating technology included
planning for a variety in software and hardware and having technology available for all students and teachers.

Stephanie was very involved in dissemination of what she learned through using the
materials of the grant. She was asked to present her students' computer products to the
administrators and to teachers in the elementary building where her field experience placement was
located. Her teacher requested that her special education director purchase the equipment and
software after seeing the results that Stephanie obtained with the students. In addition, she was
invited to co-present with the grant author to an audience of special education teachers,
administrators, and Missouri Department of Elementary and Secondary Education employees where
she demonstrated the technology and explained how she used the software and hardware with her
students.

Special Education Case Study 2: Laura
Laura was placed into a K-6 grade mixed disabilities classroom in a small city school district but in a building with primarily lower socioeconomic students and several minorities. She used computer technology in several lessons during her field placement. She reported that she felt much more knowledgeable about technology for students with disabilities than before this semester, although she felt that she still needed information for disability areas such as visually impaired, hearing impaired and physically disabled. She felt that computer technology that has been created for students with disabilities could benefit not only these students, but also those without disabilities. She noted that it could increase their academic performance and allow the students to meet their maximum potential. At the same time, she felt that some technology could be inappropriate for students with disabilities. "However, throughout this semester, I have seen students with ADHD and BD sit at a computer for the whole class period and not be disruptive, work diligently, and complete a productive piece of work. I feel that these students would not have finished the assignment if they weren't allowed to use technology in producing their assignments."

Laura felt that she could make recommendations about technology for students with disabilities because she had the opportunity to use the software and hardware and incorporate it into lessons. She also became aware of how software could be used to score an assessment and create a portfolio, although she had not had a chance to try them in a full classroom.

Laura had an opportunity to disseminate information about the computer technology, sharing information with peers and with teachers in the public schools, including schools outside of her field placement. She shared a variety of the software with her cooperating teacher and was asked by other teachers in the building to share it with them also. In addition, they asked her how they could apply the technologies in their classrooms. Her student teacher supervisor for next semester asked to see the equipment over winter break after watching Laura present it to local special education teachers, special education administrators, and Department of Elementary and Secondary Education staff members.

Laura feels competent now to infuse this technology into instruction. She used a talking word processor with a student in mathematics who benefited from hearing the math problem spoken. She also combined several packages into a lesson on Huck Finn. First her students used the Classic Adventures CD-ROM to read the book and took the quizzes that were included in the CD-ROM. Next, they used Inspiration to create a semantic map of events in the chapter. Finally, they would use Write OutLoud with their semantic maps and outlines from Inspiration to write a report over the chapter. They asked her if they could print out the quizzes from Huck Finn to help them.

Laura reported that she was able to improve her operation of a computer and learned to connect peripherals like a projector and Intellikeys keyboard to the computer. She also used a talking word processor, Write OutLoud, IEP software, scanners, printers, a LCD projector, and a digital camera during this experience. She learned to identify good software by its student friendliness and its educational value. She also valued appropriateness, effectiveness, and cost efficiency. She looked for software that was motivating, provided feedback, and adjusted its rate of difficulty. To plan technology's effective use in schools, she learned to research new software packages to make sure it met student needs, taught what the teacher wanted, adjusted ability levels and was not biased. She recommended that assistive technology be interchangeable to increase its usefulness and that teachers be inserviced and encouraged to use the hardware and software.

Preliminary Conclusions
This study was undertaken to investigate the results of using technology with regular and special education students in an elementary school setting. Preliminary results indicate several findings:

2. Preservice and cooperating teachers were not comfortable integrating software and hardware into classroom lessons but improved their awareness, opinion of, and ability to infuse technology into instruction.

3. Preservice and inservice teachers disseminated the knowledge that they gained about technology.

Additional conclusions for special education indicate:

4. Preservice teachers were aware of some technology applications for assessment, but improved their knowledge through grant activities.

5. Preservice teachers were somewhat aware of technology that is available for students with disabilities, but improved this knowledge with grant activities.

6. Teachers, both preservice and inservice teacher, improved their ability to make recommendations for assistive technology for students with disabilities.

Discussion

NCATE (1997) has recognized the need for technology literate teachers to fill the need for a world that is demanding technology-trained workers. This study investigated the use of technology by both special and regular education students provided by two Funding for Results grants. Preliminary results of the study were reported through four case studies of preservice teachers, two in special education and two in regular education.

Results of these case studies indicated that all four preservice teachers improved their awareness, opinion, and ability to integrate technology into teaching. These results agree with the ISTE study (1999) that indicated a positive correlation between infusing technology into current courses in teacher education and successful integration. This awareness extended to an improvement in knowledge of assistive technology for students with disabilities for special education majors. This ability helps in making recommendations for assistive technology for the Individual Education Programs of students with disabilities.

Preliminary results indicate that both the preservice students and cooperating teachers shared their knowledge with other teachers. This ability to disseminate technology expertise was identified by Blackhurst (1988) as a recommended technology skill for teachers. This study seems to indicate that infusion of technology into field experience provides a method of making teachers aware of both of new technology and successful methods of infusing it into their teaching, providing them with the motivation to share this information.

This study investigated effects of one semester's use of technology provided by two FFR grants. Further research to determine the long term effects of these grants would be to follow up the students as teachers to determine if they continue to infuse technology into their own classrooms. Additional follow-up research on the cooperating teachers' classrooms is also recommended, to see if they continue to apply the methods observed and used during this semester.

Abstract: This paper provides a model for revising curriculum and training faculty to integrate technology into instruction while meeting new NCATE standards for teacher education units. Identified as key partners in this project are the undergraduate teacher education faculty and students, student mentors, technology staff, faculty and students in K-12 partner schools. The three-year plan, designed during the Summer 1999 with implementation beginning Fall 1999 is a work in progress. Key components include needs assessments, establishing a knowledge base, program redesign, professional development, fearless faculty, faculty accountability, tech support, teacher education students, and project evaluation.

In the 1990s school districts in the United States have invested billions of local, state, and federal dollars to equip schools with computers and advanced telecommunications equipment. During this same time period higher education institutions have scrambled to advance their own technology infrastructures. In many instances, technological advancement in higher education has proceeded unevenly, with Colleges of Education hard pressed to match the resource bases of such Colleges or Schools as Medicine, Engineering, or Business. This is an unfortunate situation given the critical need for "Teachers...to understand the deep impact technology is having on society as a whole...[especially when we wish them to develop] an attitude that is fearless in the use of technology" (NCATE, 1998, pp. 5-6).

In 1996 a joint AACTE/NCATE data collection project (Persichitte, Tharp, & Caffarella, 1997) assessed the level of technology use by schools, colleges, and departments of education (SCDEs). Too few students are expected to use computers, televisions and VCRs to share information in their campus classroom settings. Students do not use SCDE Web sites to obtain assignments and syllabi, implying that SCDE faculty are not making best
use of the available information infrastructure...it appears that the majority of faculty have not reached a comfort level beyond basic user skills with...information technologies. Willis and Mehlinger (1996) have succinctly summarized the literature on technology and teacher education when they say "Most pre-service teachers know very little about effective use of technology in education and leaders believe there is a pressing need to increase substantially the amount and quality of instruction teachers receive about technology" (p. 978). This conclusion, coupled with the fact that the number of schools in the United States having access to the Internet has increased from 35% in 1994 to 89% in 1998 (NCES, 1999a), while classroom teachers in the United States are "least likely to report being very well prepared for activities...integrating educational technology into the grade or subject taught" (NCES, 1999b, p. 74), leaves the inescapable conclusion that Colleges of Education must in turn assume greater responsibility for the development of technology skills among their own faculty members and America's future educators. As Rosenthal (1999) points out, "Bringing the existing teaching force up to speed [technologically] is a massive task...[but it is] a problem that will be greatly exacerbated if the teachers entering the profession have not been adequately prepared to use information technologies [italics added]" (p. 22).

The general image of technology and teacher education described above characterizes, to some degree, the current situation in Wichita State University's College of Education. Until about a year ago, the College was essentially "on its own" to provide the technology and staff development necessary to bring faculty and staff into the personal computer age and to provide appropriate learning experiences for students. During the 1998-1999 academic year the College Technology Committee completed a technology mission, vision, and commitments document that incorporates recent International Society for Technology in Education Standards (ISTE, 1999) and current and draft standards of the National Council for Accreditation of Teacher Education (NCATE, 1998). During this time, the College's Technology Committee also completed a needs survey of all faculty and staff in the College of Education.

Though we face many of the obstacles to preparing technologically proficient teachers including lack of equipment, faculty training, technical support, and funds (among others), we have mapped out a 3-year plan to increase curriculum integration in our undergraduate teacher education program which has already culminated in three grants submitted and funded. These grants will provide (a) portable projection units and laptops, (b) a SMART Board, and (C) faculty development support through Expanding our Curriculum Integration through Technology Education (EXCITE).

The purpose of this paper is to share a model for revising curriculum and training faculty to integrate technology into instruction while meeting new NCATE standards for teacher education units. Identified as key partners in this project are the undergraduate teacher education faculty and students, student mentors, technology staff, faculty and students in K-12 partner schools (2 private and 8 public schools). The three-year plan was designed during the Summer 1999 with implementation beginning Fall 1999. The following design and process is a work in progress. Some steps in the process have been completed, others are in progress, and still others are yet to come.

EXCITE Project Design

Technology Plan
The College of Education was the first college unit on campus to develop a technology plan based on mission and goals statements. Both faculty and student goals were identified and developed within this plan. Action plans were also developed to provide a support structure for student access and integration of technology into instruction. The mission and goal statements of this plan can be found at http://education.twsu.edu/technology/plan.htm

Needs Assessment

A survey of classrooms used by the teacher education program was conducted in the fall of 1999 to determine hardware and software needs. At that time COE faculty members were scheduled to teach 63 courses in three different buildings. The survey revealed that only one classroom in the three buildings was connected to the campus network and another was being remodeled to include a network connection. Only one program had access to a portable projector. A portable electronic lectern was planned for one of the buildings. The College maintains one computer lab for student use with 20 Macintosh G3s, three Gateways, and a G3 server. A larger computer lab is available for all university students in a building not used by the College of Education. The university library has a small computer lab open for student access to the Internet. Neither of these labs can be used for instruction. As a result of this survey, the College of Education Technology committee submitted and received a grant to purchase 5 portable projectors. Our goal is to have as many classrooms equipped with appropriate equipment as possible and where equipment is not available, to have at a minimum video players, laptops, and portable projector units available.

COE faculty have participated in two separate needs assessment. The first needs assessment, completed in Spring 1999, determined the level of familiarity with technology, the frequency of use, the perception of potential of the technologies, and the amount of training received and needed. Table 1 shows the most frequently used tasks for which faculty use computers. (See more results on-line at http://education.twsu.edu/technology/needs.htm)

A second assessment, the Profiler Online Collaboration Tool, developed by Technology Assistance for Kansas Educators (http://www.taken.org). This assessment is designed to determine the level of technology integration achieved by each faculty member. The Profiler was also administered to the student mentors along with a basic skills assessment. Partner school faculty also completed the Profiler.

Table 1: Faculty reported use of computer technology in Spring 1999.

| Knowledge Base | Durning Fall 1999 a subcom |
several professional organizations including the International Society for Technology Education (ISTE), National Council for the Accreditation of Teacher Education (NCATE), and Kansas State Board of Education (KSBE), as well as student outcomes for the local school district, Unified School District (USD) 259. The committee recommended to the Undergraduate Teacher Education Programs Committee the endorsement of the ISTE standards as the basis for our program goals, major topics, and outcomes. Following their endorsement in October, 1999, the standards were presented to the entire teacher education faculty in December for their endorsement.

**Program Redesign: Integrating Technology**

Teams of faculty work together in each Block (semester) of the undergraduate teacher education program, coordinating instruction, curriculum, and field experiences beginning in the Preprofessional Block (second semester of the sophomore year), and concluding with Block IV (second semester of the senior year). All sections of any one course in the program are taught from a common syllabus outline, the complete syllabus filed in the departmental office each semester. Following a review of those syllabi in Fall 1999, Project EXCITE facilitators will meet with each set of Block faculty to determine what types of activities they required of their students and the variety of instructional approaches used. During this meeting Project EXCITE facilitators will suggest ways that technology might support faculty instruction and student learning. The ideal progression would be that faculty would try the suggested strategies and if they felt they were appropriate, the additions would be made to the common syllabus outline which would be approved first by Block faculty, by department faculty, by the Undergraduate Teacher Education Committee, and finally by all teacher education faculty. At that point, the technology outcomes would be integrated into the undergraduate teacher education curriculum in a meaningful way, not as an added-on and isolated course.

**Professional Development**

Concurrently with program redesign specific to technology, and beginning in Spring 2000 faculty teaching required courses in Block II and all methods instructors (Block III) will participate in professional development designed to build skills in integration of technology into the curriculum, including use of the Internet and multimedia presentations. Key faculty from partnership K-12 schools and university student mentors will also attend the professional development activities. Fall 2000 will see these outcomes extended to all elementary, fine arts, music, physical education, English, math, science, social studies, and foreign language methods courses. Finally, in Fall 2001, outcomes for student teaching will require the use of technology in instruction.

As a partner in the EXCITE grant, Apple computer agreed to provide training workshops and server space for sharing Units of Practice developed by faculty and classroom practitioners. Student mentors and faculty were shown how to access Apple's Units of Practice and other educational resources. The format provided by Apple's units will be used to create a model for additional lesson plans.

To provide students and faculty authentic learning experiences with a variety of technologies EXCITE set out to involve faculty in instructional projects with partnership
schools and to build awareness of how technology is used in the schools. Our goal is to develop online models and videotapes of how partner schools use technology with their students that may be used in methods courses. Video conferencing and discussion forums to enhance communication between teacher education students and partner school students is encouraged.

Three public school Professional Development Schools (a high school, middle school, and 3 elementary schools) a middle school, two elementary schools, and 2 parochial elementary schools become partners of the COE in developing technology-rich environments. A list of "experts" will be developed using the Profiler to assist faculty and mentors in integrating technology into instruction. One elementary school is a computer magnet school. The teaching staff from that school are able to provide model lessons for methods classes. On-line chats will be developed between teacher education students and classrooms to explore how technology is used in the schools. Teachers from partner schools receiving professional development take the information back to their schools to (a) model the use with their students, (b) teach to their students, (c) train other faculty, and (d) provide support to university students assigned to them. Student mentors are assigned to each of the teams of block faculty as they work to integrate these new technologies into the existing program.

Fearless Faculty

The COE Technology Committee and Professional Development Committee worked with Project EXCITE personnel to plan and promote inservice for faculty based on identified faculty needs with the intent that we could develop technologically fearless and competent teacher education faculty who are capable of modeling and integrating technology into their instruction. A partnership with Apple Computer provided a series of workshops on integrating technology and developing multimedia for teacher education faculty and community school partners. In order to involve teacher education faculty from content areas such as music, math and art as well as classroom practitioners in the training, a meeting was planned that engaged all partners in the teacher education program in a discussion of how technology is being used, how it should be used, and how the partners could work to combine resources to meet our goals. Inservice was planned and implemented to include school practitioners as well as university faculty. The COE Professional Development Committee conducted their own survey of faculty needs and used the results to establish a series of workshops for faculty interested in online instruction and projection devices such as the SMART Board. To monitor faculty involvement, needs, and attitude, an electronic faculty log was initiated in Fall 1999.

During the fall semester, 1999, a multimedia cart was introduced to faculty who were in turn encouraged to use the various components of the cart in instruction. Faculty had support from tech staff in preparation and set up—but were encouraged to "go it alone" during instruction. Weekly logs from faculty included comments such as

"I do want to say that I was so encouraged to be able to make the mobile cart work perfectly the first time—in front of a class of 50! Whew. Everything went without a hitch on the PowerPoint presentation."
I tried an FER #2 presentation in CI 430 that had a PowerPoint presentation, video clips, CD-Rom resource evaluation and then showed students what the format of their paper would look like in an APA Format. Before I started, I got hives when I realized that I didn't have a back up plan for the lesson in case the cart crashed. When it was over I got a migraine—relief of tension. But I DID IT!!! And it was great! I'm ready to do it again!"

Other informal on-line comments indicate that after some initial scouts (those sent to find the various types of technology that could be used), a few explorers (those sent out to see if it is really true) emerged:

"[One member of the tech staff indicated] she would like us to encourage totally electronic portfolios. Let's mention this to our advisees as an option. Who knows what wonderous things we may get!

(Thinking about the all-electronic portfolios...I feel like we're hanging on to a rock...tetering at top of Niagara Falls...and we're all about to get inundated with a [another] new gush of water (technology) forcing us over and down into the abyss below! I hope you all have on your lifejackets*!)

Faculty Accountability

Just how will faculty be accountable for the integration of technology throughout the pre-service program? Within the undergraduate teacher education program several program safeguards are already in place. Syllabi are filed each semester in departmental offices and are then checked against the program document for consistency with the program document. Technology integration can easily be seen by the course purpose, major topics, learning outcomes, and schedule of instruction and assignments. In addition, as part of Project EXCITE, faculty were asked to fill out an electronic log weekly that asked them to (a) describe any activity that modeled the use of technology for instruction, required students to use technology within the class time, or required students to use technology outside of class time to complete assignments, indicating any activity that is something new you have tried for the first time; (b) describe any activity that you would have liked to use but did not have the training, the software or the hardware necessary; (c) list any professional activities related to technology they participated in and how they thought they would use the training in their own teaching; (d) acknowledge any help they received from tech support staff, student mentors, faculty, secretaries, etc. and if so, from whom they receive help and for what purpose; and (e) tell us anything else they would like to share related to technology in their instruction?

Tech Support

The COE supports a full-time Coordinator of Educational Computing who provides instructional support for faculty and students interested in integrating technology into their instruction, and a full-time Technical Staff person who provides full-time technical support for faculty and students. The Tech Staff person supervises three part-time student assistants
based in the computer lab who serve as teaching assistants and technical support for students and faculty.

Teacher Education students were invited in Fall 1999 to submit applications to the EXCITE Mentor Program which will pair them with faculty based on faculty requests for assistance. Students applied for the mentor positions on-line and faculty submitted their requests for assistance on-line as well. Six students were selected and trained to provide assistance and training for faculty. The EXCITE grant provided $12 an hour for student mentors to work with faculty which created an additional 60 hours a week of assistance and support for faculty who want to integrate technology into their instruction. Student mentors receive training and experience they can use with faculty and in their own fields of study. This mentor program is intended to provide ongoing support for faculty beyond inservice and workshops offered by the college and the university.

Students

The primary focus of all grant activities is the enhancement of the undergraduate teacher education program. We hope to develop technologically proficient students. Students see teachers model appropriate use of technology in the courses, complete assignments in coursework using technology, and teach lessons to peers on campus and to students in schools. Competencies for knowledge and skills will be within meaningful components of instruction. Necessary changes in methods courses and evaluation instruments will follow.

Evaluation

As part of the current assessment process in teacher education, students use a professional portfolio to interpret their philosophy and pedagogy and provide evidence they are approximating and eventually accomplishing the goals of teacher education (Pothoff, Carroll, Anderson, Attivo, & Kear, 1996). The professional portfolio begins in Block I and is assessed each semester. Self-selected entries, teaching evaluations, and the list of relevant courses all provide potential resources of information about the use of technology in learning and instruction. In our previous research in the area of integration we found that "only our most intense and obvious efforts at modeling integration are successfully encouraging preservice teachers to submit integrated portfolio entries." (p. 57) It is our hope that modeling effective use of technology in instruction will have a significant impact on student use, which will be documented in their portfolios.

Other assessment activities include documentation as well as quantitative and qualitative evaluation components. Evaluation planning, implementation, and oversight are coordinated by the College of Education's Coordinator of Educational Assessment and Associate Dean for Administration and Graduate Program Support.

Conclusion

The model presented in this paper for revising teacher education curriculum and training faculty to integrate technology into instruction while meeting new NCATE standards for teacher education units may not be appropriate for every college of education. However,
it may offer insight into problems and suggestions for solutions that fit with other teacher education programs. Developing fearless faculty is a lofty goal, but once faculty become leaders, their students will be empowered to be leaders and advocates for change in schools.

The Viewing and Doing Technology Project: Preparing Tomorrow’s Teachers

Liz C. Stephens, Ed.D.

Southwest Texas State University
San Marcos, Texas USA
LCS@tenet.edu

Abstract: Southwest Texas State University’s (SWT) Center for Professional Development and Technology (CPDT) is a university-school partnership that involves 20 school sites and more than 300 preservice teachers. With funding support from the US Department of Education, the SWT CPDT is developing a model for preparing future teachers to use technology by helping university faculty integrate it into courses preservice teachers take. The model, titled the Viewing and Doing Technology Project, recognizes the knowledge and talents of faculty members who use technology and establishes themed workshops during which faculty share their expertise and help other faculty members to expand their knowledge.

Introduction

Southwest Texas State University’s Center for Professional Development and Technology (CPDT) is an award-winning program that has been in existence since 1992. The university-school partnership is a vigorous one that continues to grow. Of the 20 school sites where university interns and teacher educators are assigned, five are secondary level. This project will focus one site, Hays High School, in order to establish a model by which all 20 sites can provide the optimal learning experience for preservice teachers.

Despite the strength of the field-based program, the infusion of technology is inadequate or lacking in the delivery of instruction by teacher educators, university instructors in departments outside of the School of Education, mentor classroom teachers at the sites, and cooperating teachers in the student teaching setting that follows the 9-hour field-based experience. Reasons for the deficiency are lack of development opportunities, poor equipment, and inadequate communication among stakeholders.

In order to best prepare future teachers to use technology, all stakeholders in the teacher preparation arena (university faculty, cooperating teachers, in particular) must model the use technology in effective and appropriate lessons. This became the primary goal of the Viewing and Doing Technology Project (VDT)—a one-year systematic effort that is funded by a $115,000 grant award from the US Department of Education. SWT and Hays Consolidated Independent School District, one of the members of the CPDT Consortium, matched the grant award, bringing the total funding for the VDT Project to $230,000.

The VDT Project was designed to ensure that interns observe competent to exemplary uses of technology in the delivery of instruction at both the university and the school level. The goal of the project is to enlist the cooperation of all stakeholders in a collective effort to provide a technology-rich learning environment for preservice teachers. Five objectives support the goal is attained: (a) support SWT education professors as they infuse technology; (b) use videocase methodology in classes and professional workshops; (c) collaborate with disciplinary departments to restructure courses; (d) provide professional development opportunities for cooperating teachers in high schools where preservice teachers will engage in student teaching; and (e) seek and acquire recognition and financial support from the Hays County community.

The outcome of a year of professional development activities will be the establishment of a model for the preparation of new teachers and the means for disseminating, expanding, and sustaining the model. The model will provide preservice teachers multiple opportunities to view appropriate and meaningful uses of technology in
instruction as well as to provide authentic opportunities for practicing new skills and strategies. This paper will describe each of the goals and anticipated outcomes of the VDT Project and provide a mid-year evaluation of the success of this effort.

Goal 1: Support SWT Education Professors as They Infuse Technology

Seven workshops were scheduled in the 1999-2000 academic year for the ten faculty members who teach in the field. Because the faculty are off campus Monday-Thursday, they have few opportunities to share knowledge and expertise. The seven workshops were designed to carve out a dedicated time for sharing. They were scheduled on a Friday in each of the following months: October, November, December, January, February, April, and May.

The ten faculty members who make up the VDT Team were invited to conduct one or more of the workshops and were interviewed to determine the expertise of the member and to select a topic for the assigned workshop. Six members agreed to conduct one or more workshops. Topics include putting courses online, creating web forms/surveys and using database programs to analyze input, doing a WebQuest project, writing/editing/revising papers collaboratively using a word processing program, creating interactive multimedia products, and using videocase methodology to teach preservice teachers.

The anticipated outcome of the workshops are the following: (a) all courses will be available online, (b) web sites will include forms or surveys for students to complete, (c) preservice teachers will be required to use multiple features of a word processing program to edit and revise writing, (d) WebQuest projects are included in the list of projects for each VDT Team member’s course, (e) all VDT Team members use multimedia and require their students to do so, (f) all VDT Team members use videocase tools to teach classes. Outcomes are to be measured by examining each VDT Team member’s syllabus for the Spring 2000 semester and for the Fall 2000 semester. The syllabi should show evidence of incorporation of the skills/strategies learned through the workshops.

In addition to the workshops, members of the VDT Team will receive "just-in-time" technical support from two graduate assistants who will be on call Monday-Friday from 8:30 a.m. to 3:30 p.m. These assistants will travel to the various school sites, if needed, to help solve technical problems and to teach the faculty member how to use particular software programs.

Goal 2: Use Videocase Methodology in Classes and Professional Workshops

A software program tentatively titled Classroom Windows (CW) is being developed specifically for the VDT Project. CW is a version of another software application, Literacy Education: Application and Practice (LEAP) (Stephens 1995), which has been re-purposed to fit the needs of the VDT Project.

LEAP is a videocase-based interactive software program designed and developed to use in university courses and professional development workshops that deal with methods for teaching reading and writing. LEAP was constructed according to the precepts of cognitive flexibility theory (Spiro & Jehng 1990). Users of LEAP are guided through short videocases, or minicases, of classroom teachers in naturalistic settings. Minicases can be explored from multiple perspectives through built in navigation routes in the software program. As in LEAP, CW will provide minicases of teachers and their students using technology in high school classroom settings. CW will provide guided exploration of the minicases as well as links to the World Wide Web and a threaded discussion group. The minicases will show teachers at Hays High School using technology with sophomore, junior and senior level students. Three teachers have been videotaped; their tapes will be edited and prepared for insertion into the CW software structure.

CW is still in production. The final version will be available on CD-ROM in late Spring 2000 and will be distributed to the ten VDT Team members for use in their classes. The anticipated outcome is that the team members will use this tool in Fall 2000 semester courses.
Goal 3: Collaborate With Disciplinary Departments To Restructure Courses

The rationale for expanding the professional development beyond the College of Education is that all of the secondary teaching methods courses are taught outside of the College of Education. It is critical, then, to insure that preservice teachers are exposed to effective application of technology in their disciplines and that they are required to practice using it within those classes.

A one-week summer workshop is scheduled in mid-May 2000 for 10 faculty members in the various colleges at the university. Five technology proficient faculty members within these colleges have agreed to conduct workshops that resemble the workshops conducted in the College of Education. One member will conduct a full-day workshop on each of the five days. The topic will be determined by the member’s expertise and interest. Each of the five has been requested to bring one member of their staff whom they think would benefit from the experience.

The anticipated outcome of the summer workshop is that the information/skills shared each day are incorporated into the Fall 2000 semester syllabus of each attending member.

Goal 4: Provide Professional Development Opportunities for Cooperating Teachers In High Schools Where Preservice Teachers Will Engage in Student Teaching

Preservice teachers who are enrolled in the classes taught by the faculty members who attend the academic year workshops and the summer workshops will be placed in a student teaching setting in the Spring 2001 semester. If the cooperating teacher with whom they will work is not proficient with technology or not interested in integrating it, then it is likely that both student teacher and cooperating teacher may find the experience unproductive. To help prepare the student teaching environment for a technology-proficient teacher in training, eight cooperating teachers will be invited to enroll in a summer course at the university; tuition and fees will be paid by the VDT Project.

The anticipated outcome of this goal is that the eight cooperating teachers will support their student teachers in the Fall 2000 and Spring 2001 semesters as they both explore ways to integrate technology in the middle school or high school classroom.

Goal 5: Seek and Acquire Recognition and Financial Support from the Hays County Community

To assure a positive impact of the VDT model and to justify the energy, effort, and funding spent on the model, a continuity plan is vital. A team of faculty members is exploring the further development of the VDT Project. Plans for disseminating information, acquiring more funding, and enrolling more faculty members in professional development activities are being made. A promotional videotape will be distributed to possible funding sources as well as interested institutions in the community. Papers will be presented at conferences such as this one. Proposals for funding will be written in the Spring 2000 semester. Outcomes from the previous four goals will be reported in all of the materials that are written/developed for the continuity plan.

The anticipated outcome of this goal is that the VDT model is revised and refined and that funding and support is made available for expansion. Five of the field-based blocks—all at the secondary level—are involved with the VDT Project this academic year. It is hoped that the remaining 15 field-based blocks—all at the elementary level—will benefit from the next level of the VDT Project.

Conclusion

The VDT Team and all supporting individuals have dedicated much time and energy to the attainment of the five goals of the VDT Project. To date, evaluations of activities indicate that the model has been effective in helping
faculty members become more comfortable with technology. By June 2000, indicators will determine what components of the model need to be revised/restructured. By December 2000, the full impact of this model on how well new teachers are prepared to use technology will become evident. In informal interviews the VDT Team and others who support it have indicated that they are confident that the model will have a positive impact on both faculty and students.

Acknowledgements

The VDT Project has been supported by funding received from the US Department of Education, Southwest Texas State University College of Education in San Marcos, Texas, Southwest Texas State University Office of Research and Sponsored Programs, and Hays Consolidated Independent School District in Buda, Texas.
The purpose of this paper is to share the findings of a study that examines issues regarding K-12 integration of Internet instruction. The main thrust of this project involves the development of a comprehensive educational internet database dedicated to assisting preservice teachers entering the K-12 classroom to incorporate Internet resources via the creation of WebQuests based on the model developed by Bernie Dodge (1999).

**Introduction**

**The Cognitive Domain**

Educators continually strive to find ways to create learning situations that exercise higher level thinking skills. Bloom, Englehart, Furst, Hill & Krathwohl's (1956) taxonomy of educational objectives for the cognitive domain classified goals of an educational system into six objectives: knowledge, comprehension, application, analysis, synthesis and evaluation.

According to Bloom, et al. 1956), the first three levels of the taxonomy set up the foundation for higher-order thinking skills. Knowledge includes "those behaviors and test situations which emphasize the remembering, either by recognition or recall, of ideas, material, or phenomena" (Bloom, et al., 1956, p. 62). This objective also applies to transfer of learning in that the learner has to relate to and make judgments in terms of answering questions or problems at the time of testing that are posed in a different form than that of the original learning situation. Comprehension involves "the grasp of meaning and intent of the material" and application concerns "remembering and bringing to bear upon given materials the appropriate generalizations or principles" (Bloom, et al., 1956, p. 144).

Generally, higher-order thinking skills reside in a learner's ability to analyze, synthesize and evaluate concepts and information. Analysis involves breaking down material into its constituent parts to determine relationships between the parts. Analysis can be considered a prelude to evaluation and is
considered an important objective in the fields of science, social studies, and the arts, among others. As an objective, Bloom, et al. (1956) divides analysis into three levels: identifying or classifying elements of a communication, determining the explicit relationships among the elements, and recognizing organizational principles and structure of the communication as a whole.

The next educational objective that is considered to be indicative of higher-order thinking skills is that of synthesis which Bloom, et al. (1956) defines as "putting together of elements and parts so as to form a whole" (p. 162). Synthesis is a process of combining the elements in such a way as to create a pattern or structure not seen before. This category of the cognitive domain is thought to constitute creative behavior. According to Bloom, et al. (1956), the main difference between synthesis and the categories of knowledge, comprehension and application is that the first three objectives deal with "working with a given set of materials or elements which constitutes a whole in itself" whereas synthesis involves drawing upon "elements from many sources and putting these together into a structure or pattern not clearly there before" (p. 162). Synthesis can be classified in terms of three sub-categories evidenced by their products: a unique communication, a plan or set of operations, and a set of abstract relations.

Finally, the last educational objective that is indicative of higher-order thinking is that of evaluation which is defined as "the making of judgments about the value, for some purpose, of ideas, works, solutions, methods, material, etc." (Bloom, et al., 1956, p. 185). Generally, evaluation involves a combination of all of the other educational objectives. It is also crucially linked to the affective domain and can, therefore, be regarded as indicative of motivation. Further, evaluation may be the last step in the domain, but it may lead to acquisition of new knowledge, re-evaluation of prior knowledge comprehension, or further analysis and synthesis. The evaluation component is composed of two components: judgments in terms of internal evidence and judgments in terms of external criteria. A major goal of our educational system is to expand a learner's existing and potential knowledge base by operationalizing and integrating knowledge, comprehension, and application with analysis, synthesis and evaluation to engender higher level thinking skills.

The Affective Domain

According to Gagne & Driscoll (1999), the most fundamental element to learner motivation is the "desire to enter into the learning situation." The cognitive domain is intertwined with the affective domain. According to Krathwohl, Bloom & Masia (1964), the most sought after kinds of affective domain objectives are interest and motivation. It is the motives, drives and emotions of the affective domain that are the predominant factors in the achievement of cognitive behavior. Achievement motivation results from positive affect and takes "the form of building upon self-discovery as a means of fostering interest in learning material" (Krathwohl, et al., 1956, p. 58). Krathwohl, et. al's (1964) taxonomy of educational objectives for the affective domain fits well with a widely-known model of motivation - Keller's (1979) ARCS model. The four basic elements of the ARCS model are: Attention, Relevance, Confidence and Satisfaction. Learner attention may be captured by colorful graphics, animation or music. Relevance might be garnered by relating the topic to be studied to the learner's personal goals or lifestyle. Learner confidence may supported by providing an opportunity to demonstrate what they have learned to peers. Learner satisfaction can be enhanced by providing meaningful opportunities to use the newly acquired knowledge or skill gained as a result of the learning experience. The purpose of the ARCS model is to make theory and research findings in the field of motivation applicable to classroom instructional settings.

As further support for considering both the affective and cognitive domains, research on learning and motivation has found that motivation increases an individual's energy and activity level (Maehr, 1984, Pintrich et. al 1993; and Vernon 1969) and promotes time on task in terms of initiation of certain activities and persistence in those activities. While motivation directs an individual toward certain goals, it is also dichotomous in that when people exert effort toward some goals, they often must direct it away from others (Csikszentmihalyi & Nakamura, 1989). Additionally, motivation affects learning strategies and cognitive processes employed by an individual. Generally, a task is, in and of itself insufficient for
successful learning. Cognitive processes such as attention, meaningful learning, elaboration, and self-monitoring comprehension must occur as people engage in a particular learning activity. Further, learners must think about what they are seeing, hearing and doing (Carroll, 1989; Tobin, 1986, Wittrock, 1983). Therefore, cognitive engagement is one of the benefits of a high level of motivation. Finally, intrinsic motivation is considered to be more central to producing meaningful learning than is extrinsic motivation.

Where Technology Comes In

The Internet and World Wide Web have great promise as they present new vehicles to enable educators to achieve their goals of promoting higher-order thinking skills while also enhancing learner motivation to promote the kind of cognitive processing necessary to produce meaningful learning.

In particular, an effectively designed WebQuest is an excellent vehicle to promote both higher-order thinking skills and motivation. A WebQuest furthers the technology integration initiative supported by educators across the country by offering an inquiry-oriented activity in which most or all of the information used by learners is obtained via the World Wide Web. Developed in 1995, by Bernie Dodge and Tom March, WebQuests are designed to maximize time on task by focusing learners' attention on using the information provided on the World Wide Web rather than searching for it. Effectively designed WebQuests encourage higher-order thinking skills such as analysis, synthesis and evaluation and are useful for integrating technology into the classroom while providing a safe way for students to research the Internet.

Part of developing a WebQuest involves researching appropriate World Wide Web links to be incorporated into a WebQuest. Anyone who has ever engaged in Internet searching has experienced the tremendous amount of time required to find meaningful and relevant sites while wading through a great deal of "garbage" to get to the good stuff.

In a recent paper, Herbert Simon and Richard King Mellon effectively summarize the dilemma faced by the technological revolution. They assert that it is not information that is the scarce factor today, it is a human being's ability to attend to the information and the time required to attend to it. "While the means of acquiring information have been expanding, there has been no expansion in the number of waking hours in the day available for attending to that information. Time and attention are scarce, and becoming scarcer every day. In particular, we have no time to process the new information that is being disgorged on us" (Simon & Mellon, 1996). According to Roblyer (1997), a predominant problem cited by teachers regarding Internet infusion is the amount of time required to adequately research and effectively integrate its use into K-12 classrooms.

Through the use of templates and other time-savings devices, WebQuests have the potential to give educators a concrete, quick-to-learn method of integrating technology into the curricula without requiring them to spend a prohibitive amount of time on the procedural aspects of learning new software. Further, it seems that it is just as important to motivate teachers to want to use technology in the classroom as it is to motivate students to want to learn.

WebQuests provide benefits to students in that they facilitate organization and management of on-line resources so that students are engaged in meaningful learning activities, thus reducing student time spent searching the Internet for sources and thus, promotes time on task. The Internet is a dynamic medium, full of information that is accompanied by visual and aural stimuli. If appropriately and effectively utilized via a WebQuest, these dynamic elements can help focus and maintain learner attention, promote student interest, and engender intrinsic motivation.

Methodology
The research undertaken is a multi-part project. The first part consists of "Linkey-Lou", a comprehensive educational Internet database developed using Microsoft FrontPage 98 and Microsoft Access. This web site is currently being developed to aid higher education faculty and pre-service educators in developing WebQuests to encourage technology integration while promoting higher-order thinking skills and motivation in elementary and secondary school students. The site, which is currently in development, consists of 4 main resource areas:

- Internet Ethics;
- Policies, & Security;
- Web Development;
- Professional Educational Organizations; and
- Software & Publishers, and Subject Web Resources.

Fig. 1 below represents an example of a resource page currently being developed.

Figure 1. Example from "Linkey-Lou" database.

EDIT 3318: Linkey-Lou Database
Applications of Technology in Elementary Education

</table>

A search mechanism is planned to enable educators to search the database by topic or keyword.

Another portion of the project involves the development of an evaluation rubric that will aid WebQuest developers to properly evaluate and select effective Web sites by assessing features such as aesthetics, cognitive effectiveness, cognitive task level technical sophistication, and resource quality and quantity. The evaluation rubric utilizes the foundations presented in the ISTE standards concerning planning and delivering instructional units for technology integration by incorporating guidelines for content comprehensiveness and clarity, screen design, motivational components based on Keller’s ARCS model (Keller, 1979), interactivity, and higher order thinking skills.

Data will be collected and analyzed as a result of a focus group study to evaluate the comprehensiveness and effectiveness of the WebQuest resource guide. A focus group collects data by way
of a semi-structured group session which is moderated by a group leader and held in an informal setting. The purpose of a focus group is to understand all the perspectives of the participants. A focus group was chosen because it saves times by allowing a researcher to interview several people at one time, it allows one to collect rich data at a reasonable cost, it can explore topics and generate hypotheses for quantitative research, and group interaction tends to bring out data that would not otherwise be obtainable through observation or via questionnaires or surveys. The sample selected for the focus group will consist of purposive sampling, which concentrates on those subjects that will provide the most meaningful information. In the case of this study, focus group participants consist of preservice K-12 teachers who are enrolled in EDIT 3318, Applications of Technology in Elementary Education, at Texas Tech University. Data collection is in progress to assess whether our resource model aided effectively in the development of student WebQuests.

Additionally, quantitative data collection will entail collecting information from university-level methods educators concerning the site's present and potential usefulness to their students. This information will be used to determine other possible needs that the Internet database resource might serve to further the College's aim of preparing pre-service educators in the State of Texas. The instruments being developed will utilize a Likert-type scale with comment choices ranging from None to High and a qualitative survey for more depth of comment to aid in the future development of the resource guide.

Data collection for this project is currently in progress. Preliminary data will have been collected for presentation at the SITE conference in February, 1999.

**Conclusion**

It is hoped that preservice educators, university methods educators and other education professionals may benefit from the findings of this research. Additionally, it is hoped that, in the future, this comprehensive Internet resource can be further expanded in to further educators' goals of infusing technology into elementary and secondary classrooms, to provide enhancement of the current curricular goals of educational systems, and to promote rich and meaningful learning experiences for elementary and secondary public school students.

Abstract: In the United States (U.S.) there is a shortage of new teachers possessing skills to integrate technology into the classroom. The U.S. Department of Education has recognized this problem and has funded projects targeted at pre-service teacher education. This paper focuses on a technology enhanced teacher education curriculum supported by a U.S. Office of Education Preparing Tomorrow’s Teachers to Use Technology (PT3) grant, which is designed to give pre-service educators the skills needed to integrate technology into their classrooms. Attitudinal measures, stages of adoption of technology and proficiency measures are addressed.

Introduction

Authorities estimate that 2,000,000 new teachers with technology integration abilities will be needed in the workforce of the United States over the next seven years, while the projected capacity of all the teacher education colleges in the nation is only half that amount (Green, 1999). Vast increases in the quantity of technology - infusing educators are needed, while the quality of good programs should continue to be improved, and greater progress toward equity in making the new teachers available to underprivileged students must be pursued as well. The Millennium Project: Pathways for Preparing Tomorrow’s Teachers to Infuse Technology, is one of more than 100 projects funded in the USA by the U.S. Department of Education in pursuit of these goals.

The curriculum on which this project is based has a credible foundation, in part due to strong alignment with state and national technology standards, and in part due to the use of reliable indicators capable of showing progress toward course and standard goals. For more than a decade the Computer Education and Cognitive Systems Program in the Department of Technology and Cognition at the University of North Texas has been offering a three-course sequence that leads to curriculum/technology integration skills for graduates. For the past two years data have been gathered to assess the attitudinal changes and student perceptions of their own technology integration abilities. This paper reports on the impact of this curricular sequence.

The Curriculum

Undergraduate courses at the University of North Texas are numbered in a four-digit sequence for which the first number indicates the approximate year-level of the content and the remaining three indicate the focus of the course. In keeping with this scheme, the first course in the UNT integration sequence is
considered a freshman-level computer applications course (1100) that is fairly standard throughout the campus, but the educational version utilizes educationally-relevant examples. The second course is a junior-level teacher productivity course (3440) while the third is a senior-level (4100) classroom/learner technology methods course. Approximately 20% of the students in the second and third course enroll in the two concurrently. Students completing the entire sequence typically enroll in the third course one or two semesters before student teaching. This three-course sequence has for more than a decade been approved for a Texas Education Agency Information Processing Technologies (IPT) endorsement which can be added to a teaching certificate. Beginning in 1997, in order to prepare future teachers for continuous K-12 technology integration as mandated by the new Texas Essential Knowledge and Skills (TEKS) curriculum, the third course was modified to include a major module on the TEKS. Students completing this sequence were encouraged to enroll in a graduate course (CECS 5500) focusing on locating and organizing materials related to the TEKS, during their last semester as an undergraduate. An undergraduate course focusing on technology integration was formulated during this time frame as well, and is scheduled to be offered for the first time during the spring semester of 2000. Funds awarded during the fall of 1999 from a U.S. Department of Education Preparing Tomorrow’s Teachers to Use Technology (PT3) grant are greatly expanding undergraduate offerings in this sequence during the 1999-2000 school year and beyond. The content of these courses is described in more detail in Table 1.

Table 1. Content for Computer Education & Cognitive Systems (CECS) Courses in Technology Applications Sequence

| CECS 1100: Computer Applications in Education | This is a tool-based course in which students learn to use an integrated word processing, spreadsheet and database package. |
| CECS 3440: Technology and the Teacher | This course includes the use of presentation software and theories as well as the instructional design of presentation materials. |
| CECS 4100: Computers in the Classroom | Students in this class learn to find appropriate instructional software for the classroom, develop a multimedia project, find Internet resources for classroom use, develop a technology infused lesson plan, and make a webpage to link to their instructional resources. |
| CECS 4XXX or equivalent from approved list or CECS 5500: Computer Applications for Curriculum and Instruction | Topics in this course include theories of teaching and learning, locating and organizing resources relevant to the TEKS, and developing a model curricular unit integrating technology, as a final project. |

Completion of this four-course sequence entitles undergraduates to a University of North Texas certificate in curriculum and technology integration. Although this certificate currently carries no official status other than recognition by the University of North Texas, it is consistent with the needs expressed by several Texas school districts and is closely aligned with the TEKS.

**Instrumentation**

**Attitude measures**

Instruments developed by the authors during 1995-97 (Christensen & Knezek, 1998; Knezek & Christensen, 1998) have been successfully used to assess pre-post changes in attitudes toward information technology in pre-service course participants for several semesters. The primary instruments used have been the Teachers Attitudes Toward Computers Questionnaire (Christensen, 1997), and the Teachers’ Attitudes Toward Information Technology Questionnaire (Knezek & Christensen, 1998). These two instruments collectively measure 15 constructs related to attitudes toward information technology. Subscale

---

1. Currently there are no teacher preparation standards adopted by the Texas State Board of Educator Certification, to be applied by the Texas Education Agency statewide, for the Technology Applications portion of the Texas Essential Knowledge and Skills.
reliabilities for sets of educators completing the instrument have ranged from .85 to .98. Changes in pre-service educators' attitudes on selected constructs will be featured in this paper.

**Stages of Adoption of Technology**

Christensen (1997) developed a direct self-report measure of educator stage of adoption of technology, based on the earlier work of Russell (1995). In this instrument, respondents select one of six stages that best represents where he/she currently lies in the continuum from Awareness (Stage 1) to Creative Application to new contexts (Stage 6). This instrument has proven itself to be useful tracking advances in in-service as well as pre-service educator development over time. A recent test-retest check on the reliability of this instrument for a sample of 98 teachers in the Dallas-Ft. Worth Metroplex, yielded a reliability estimate of .96. Stage of Adoption is a primary outcome measure reported in this paper. A copy of the instrument is provided in the Appendix.

**Skills Assessment**

The Technology Proficiency Skills Assessment Instrument (TPSA) (Ropp, 1998) was added to the battery of instruments completed by pre-service educators in the fall of 1999. This instrument assesses educator skills related to information technology in six areas: Electronic Mail, World Wide Web Utilization, Integrated Applications, Teaching with Technology, Multimedia Skills and Web Skills.

**Impact of Curricular Sequence**

**Stages of Adoption**

Data gathered to date indicates that the curricular sequence is reasonably well articulated and results in measurable advances in stages of adoption of technology, as reported by the course participants themselves. For example, during the fall semester of 1998, participants in the first course of the sequence (CECS 1100 – Computer Applications) began on the average at stage 3.1 and exited the course on the average at stage 3.9. Students in the second course in the sequence (CECS 3440 – Teacher Productivity Tools) began on the average at stage 4.1 (posttest data was not available), while students in the third course (CECS 4100) began on the average at stage 4.4 and exited from the course at stage 5.2. This can be compared to a typical teacher, as measured by a sample of more than 1000 from the same geographic area, during the same time frame. The average rating across practicing teachers was 4.13, a value lying near the center of the indices reported across the three-course technology integration sequence. These results are graphically displayed in Figure 1.

![Figure 1. Stages of adoption of technology for three classes of pre-service teachers versus in-service teachers (1998).](image-url)
Pre/Post Attitude Changes

Students in the third course of the sequence (CECS 4100) have in the past exhibited reduction in anxieties, the development of more positive attitudes toward technology for student learning, and more positive perceptions of technology as productivity tools. In addition, pretest data gathered from first course, second course, and third course students during the fall of 1999 indicate that the trends in attitudes for the three courses generally mirror the differences previously reported with respect to stages of adoption. Three of seven attitudinal constructs measured revealed significant differences between students in these three courses. As shown in Figure 2, students in the third of the three-course sequence were significantly higher (p < .05) than both other courses on F1 - Enthusiasm and F6 - Productivity.

![Figure 2. Fall 1999 pretest attitudinal measures for three UN T classes](image)

Technology Skills Assessment

Data were gathered from UNT pre-service teachers using the Technology Proficiency Skills Assessment (TPSA) for the first time during the fall of 1999. Initial findings, based on one CECS 4100 class of 21 students, are graphically displayed in Figure 3. Students enrolled in the Computers in the Classroom course reported large skill gains (p<.001) in six major areas measured by the TPSA. The effect sizes on these gains (post-test mean - pretest mean, divided by pretest standard deviation) ranged from 1.94 to 2.29. The average gain in level of technology proficiency was approximately two standard deviations.
Texas Essential Knowledge and Skills (TEKS) Proficiency

During the spring of 1998, students enrolled in CECS 4100 – Computers in the Classroom were given an additional form that enabled them to assess their level of knowledge of the K-12 Technology Applications curriculum and the resources provided by the state of Texas to support teachers in fostering student learning. As shown in Table 3, the effect size for self-reported improvement in knowledge of the TEKS ranged from .8 to 3.7. This can be compared to effect sizes ranging from .2 to .8 for the attitudes showing significant (p = .05) positive gains for the same group.

Table 3. Fall 1998 changes in attitudes and knowledge for computers in education (CECS 4100) students

Discussion

Texas adopted a new curriculum in 1997 that requires the integration of technology throughout the K-12 curriculum. However, Texas has not yet settled on a new set of teacher education standards for this new curriculum. In the absence of statewide guidelines, the University of North Texas, in consultation with area schools and educational service centers, has produced a Technology Applications Curriculum Integration sequence which consists of four courses at the undergraduate level. The technology infusion emphasis gives pre-service teachers the opportunity to learn how to structure lessons, student projects, and student activities that are motivational, involve active participation, permit collaboration, emphasize content mastery, and incorporate individualized instruction. As these teachers enter their profession, they will have a unique set of skills and technology-related experiences that empower them to be adept in their
classroom environment, plan the equitable use of technology resources, and build a dynamically networked learning community based on curricular goals.

References

Appendix

Stages of Adoption of Technology

Stage 1: Awareness
I am aware that technology exists but have not used it - perhaps I'm even avoiding it.

Stage 2: Learning the process
I am currently trying to learn the basics. I am often frustrated using computers. I lack confidence when using computers.

Stage 3: Understanding and application of the process
I am beginning to understand the process of using technology and can think of specific tasks in which it might be useful.

Stage 4: Familiarity and confidence
I am gaining a sense of confidence in using the computer for specific tasks. I am starting to feel comfortable using the computer.

Stage 5: Adaptation to other contexts
I think about the computer as a tool to help me and am no longer concerned about it as technology. I can use it in many applications and as an instructional aid.

Stage 6: Creative application to new contexts
I can apply what I know about technology in the classroom. I am able to use it as an instructional tool and integrate it into the curriculum.

Abstract: Today, elementary teachers often are required to integrate technology in their classrooms and to teach students to utilize technology. In Pennsylvania, preservice elementary teachers typically receive one course in technology instruction. There is little or no attempt to demonstrate to these preservice teachers ways to integrate technology into their classroom assignments in education or in methods courses. It is important to give preservice teachers the training and experiences they need to make valid decisions in the use of technology as a tool for instruction. In the program described in this paper, preservice teachers first master the use of technology for their personal needs. Second, students are taught ways to evaluate software packages. Next, they have opportunities to create lesson plans that integrate technology in appropriate ways. Finally, students are given opportunities to use technology in actual classroom situations with small groups of elementary students during methods classes.

Introduction

Although computers and technology are expanding in classrooms across the nation, a study conducted by Education Week and reported in The New York Times, (September 29, 1999) concludes that teachers remain abstrus about how exactly to incorporate the machines into their lesson plans. Often technology is used in the classroom simply to satisfy the demands of district officials or teacher review polices. According to a study conducted by the National Education Department and cited in The Pittsburgh Post Gazette (January 29, 1999) and in The New York Times (January 29, 1999), A78 percent of teachers reported training in technology, [but only] 20 percent felt very well prepared to use it in their classrooms. Weinman and Haag (1999) argue that in 1997 researchers found that only 15 percent of teacher candidates nationwide had received at least nine hours of technology training. This means that while new teachers are typically unprepared for 21st century technology, educational institutions need and expect new personnel to be able to provide leadership implementing technology throughout the curriculum and district.

Dr. Arthur Wise, president of the National Council for Accreditation of Teacher Education (NCATE), argues that most schools of education do not adequately train teachers to use and integrate technology into their teaching. By the year 2000, technology will have to be integrated throughout the coursework for a college to maintain NCATE accreditation. (Rosenthal, 1999). Rosenthal (1999) cites Lynn Silver, national strategic relations manager for Apple computer, who says that, Schools of Education must ensure that our future teachers can use technology to communicate, collaborate, and support critical thinking and problem solving.

According to the Milken Exchange, the federal government estimates that [the United States] will need 2.2 million new teachers over the next decade to accommodate both the increase in students and the public’s demand for smaller class size (Basinger, 1999). To establish baseline data on the status of technology use in teacher-training programs, the Milken Exchange surveyed 416 teacher-preparation programs representing approximately 90,000 graduates for the 1997-98 school year. The survey results indicate that over 70% of these teacher-training programs require at least some instruction in Instructional
Technology. The institutions that reported the highest levels of student technology skills and experiences, were those with no heavy computer course requirements, but those that made use of technology on a routine basis throughout the teacher training program" (Basinger, 1999).

The Milken-ISTE report cited above makes these conclusions:

1. Information-technology instruction should be integrated into all courses and SCDE activities, rather than being limited to stand-alone classes.
2. Institutions should engage in technology planning that focuses not only facilities but on the integration of information technology in teaching and learning.
3. Student teachers need more opportunities to apply information technology during field experiences under qualified supervision.
4. Faculty should be encouraged to model and integrate technology (Basinger, 1999).

Further research is needed to discover "the most effective models for learning how to integrate information technology into classroom practice" and "widespread dissemination of this new knowledge when available" (Basinger, 1999).

In a recent survey to elementary principals in Western Pennsylvania conducted by the Robert Morris College Education Department, 80% of the respondents stated that they would give special hiring preference to candidates with a professional expertise in technology. These administrators cited a need for new teachers to be proficient in evaluating and implementing technology software for computer, multimedia, and video use. For these reasons, Robert Morris College has developed an elementary education program that integrates technology into the basic education as well as the educational methods courses.

**The Program**

Given the opportunity by the State Department of Education to devise a new elementary education degree program, Robert Morris College (RMC) responded by incorporating technology not only through Instructional Technology courses, but by integrating technology into all education and methods courses throughout the curriculum. Table 1 lists the courses and course sequence for elementary education preservice teachers.

Table 1: Course sequence for elementary education preservice teachers.

Thus, at RMC pre-service elementary education majors are required to take 15 credits of technology courses: nine from the college technology core and six from the RMC core. With this background, students are prepared to effectively use technology to teach content in specific subject areas. These technology core requirements are not intended to make technology experts of elementary majors; rather, the goal is to produce competent, confident elementary teachers who are comfortable with the use of technology as a tool when implementing successful teaching strategies. To accomplish this goal, RMC faculty used the National Education Technology Standards published by the International Society for Technology in Education as a model for designing courses and assignments. Table 2 lists the standards for grade 5 and the courses in which these standards are met.

Table 2: Standards for grade 5 and the courses in which these standards are met. I represents the courses where the standard is included, and O represents courses where the standard is an objective of the course.

The integration of technology in course assignments illustrates to preservice teachers in a concrete manner ways in which technology can and should be used as a tool for educators instead of an Aby-product. Some examples of learning activities in various courses include:

- searching for appropriate Internet sites and creating hyperlinks for elementary students,
- corresponding via e-mail to elementary students,
- evaluating software packages in content areas such interactive readers,
- creating graphic organizers and data bases, using commercial packaged software such as PowerPoint™ and ClarisWorks for Teachers™,
- evaluating on line lesson plans and teacher materials,
- using scanners to integrate pictures of students' work into text and presentations,
- and evaluating video segments for use in the classroom.

Through these courses and activities, preservice teachers learn that technology is a natural extension of their lessons and can be incorporated in the classroom. More importantly, students learn the appropriateness of technology in classroom assignments. They learn when the use of technology is inappropriate as well as when the use of technology can enhance instruction.

In order to practice and present the ways they have integrated technology in their course assignments, all elementary education majors have access to presentation classrooms. These classrooms are equipped with computers, presentation rooms, video recorders and players, CD players, and camcorders. These students also have access to computer classrooms and labs. In addition to the presentation...
classrooms, these preservice teachers have access to a resource lab that is equipped with additional materials, both hardware and software. Here they are able to work on specific assignments, prepare lessons, and experiment with the technology. Elementary students, therefore, are able to demonstrate their individual use of technology in presentation situations in a variety of classes before they enter the methods classes.

Another unique feature to the RMC elementary education program is the use of area public schools and personnel to teach methods courses. Students spend part of the day in real schools with real elementary teachers and students. They are able to use the resources found in public schools to complete projects and assignments. School personnel teach method classes in the afternoons to the RMC students. Thus, RMC elementary majors benefit from instructors who are expert in translating theory into practice. They also benefit by having the opportunity to observe, for extended periods of time, real elementary classroom situations and instruction. Our public school partners benefit by having RMC elementary students who are competent in technology suggest ways that technology might be integrated into daily lessons.

Program Evaluation

Like all educational programs, evaluation of this new elementary education degree will be on going. The success of this program will be stringently evaluated in order that RMC can continue to deliver a high quality, technology-driven program that is demanded by the education community. RMC is dedicated to students, to colleagues in basic education, and to prospective elementary education students in classrooms today and in the future. RMC’s intent is to provide a program that strongly prepares elementary preservice teachers to help public school elementary students embrace the technology at the elementary level and prepare them to accept the technological challenges of the intermediate level. Thus, the success of this program will be evaluated by the following five measures:

1. An Elementary Education and Technology Steering Committee of colleagues from schools surrounding our campus will help guide the program. Most of the committee members work in schools where RMC students will be placed for field experiences. Receiving continual feedback from these individuals will be instrumental in assuring progress and improvement.
2. The cooperating teachers who supervise our students during student teaching will provide the second measure.
3. The faculty who developed and who will teach in the elementary education program will evaluate their courses. Students, in these courses, will also complete an evaluation form.
4. The Education Advisory Committee will provide feedback on up-to-date issues in education and how courses at RMC are meeting the requirements that these issues demand. Two of the new four members of the committee will be elementary technology specialists.
5. A formal evaluation request will be sent to the employers of graduates asking for feedback on the success of the graduate in the performance of classroom duties and how these graduates are integrating technology in their classrooms.

“Today’s students live in a global, knowledge-based age: They deserve teachers whose practice embraces the best that technology can bring to learning” (Education Digest Oct. 1999). It is the primary goal of the RMC faculty to prepare teachers who are intellectually prepared, professionally dedicated, and socially responsible and who strive to bring out these same qualities in their students. It is our philosophy that the teacher education program must enable prospective teachers to help their students grow in intellectual curiosity, self-confidence, knowledge, responsibility, and interpersonal relationships. It is our strong belief that prospective teachers must be prepared not only to capably teach in the educational programs of today, but also to build successful programs needed for the future. To achieve these objectives, it is important that students understand their roles as professional educators, to define life-long goals, and to accept the obligations associated with the achievement of professional status. In keeping with this basic philosophy, RMC has developed a technology-based elementary education degree program to fill the needs of the future.

Educational institutions at all levels are recognizing the importance of technology in the teaching-learning process. This growing awareness of the roles technology can play in the educational arena has spurred considerable research. This year’s SITE conference papers reflect a diversity of issues that are germane to the integration of technology in the educational setting. Thus, the researchers not only address the issues related to the use and integration of technology but also highlight the attitudes, beliefs and perceptions of stakeholders in using Instructional Technology, along with research on technology in practice.

The first portion of the research section is devoted to the perceptions and attitudes of the stakeholders in the educational arena. Fourteen papers reflect the diversity of the educational community. Each of these papers focus on teachers’, preservice teachers’, and/or students’ outlook pertaining to instructional technology. Ertmer, Ross and Gopalakrishnan look at the pedagogical beliefs and classroom practices of exemplary teachers finding that these are all rooted in student-centered classrooms where technology is only a means to an end. They suggest that finding ways to connect teachers with peers who have had successful experiences implementing technology is crucial.

Topper investigated how teachers’ assumptions and beliefs about teaching and learning influence their technology usage. Owens and Magoun look at teachers attitudes towards technology focusing on differences among school systems, teaching level, gender and teaching experience. Beers, Paquette & Warren describe how the use of technology is affected by school philosophy and the location of the technology in the building.

Greene and Zimmerman look at the effects of field experience in a technology rich environment on preservice teachers. This paper reports changes in students beliefs related to these experiences using a blend of quantitative and qualitative research tools. Prouty and McGrew-Zoubi describe attitudes and beliefs related to the developmental appropriateness of educational software that targets preschool children. Nanci researches the attitudes and beliefs of inservice teachers towards educational software evaluation criteria that they were asked to apply. Sammons and Strickland examine how teacher characteristics and attitudes relate to multimedia creation and conclude that confidence in their own ability inspired by proper training is most important. Gershner, Snider, Huestis and Foster describe a program implemented to integrate emerging technologies into the teacher preparation program. This program was multifaceted in its approach to reach preservice teachers, mentor teachers and instructors. Concerns about individual attitudes and perceptions focused this research project.

Yu-mei Wang has two papers, both are looking at student teachers’ perceptions. One paper focuses on the perceptions of teacher roles in the classroom with computers and the other focuses on computer use during Practicum experiences. Orit Hazzan describes the attitudes of preservice teachers on the use of instructional technology in the mathematics classroom. Akyurekoglu interviewed middle school teachers on their perceptions of computers and its use in the classroom. Coleman provides a rationale for using web pages linked with databases for field based teacher education programs. This paper addressed the perceptions of college faculty, K-8 teachers, and preservice teachers in regard to this type of instructional technology.

The second division in this section is devoted to the differential competence/use of technology in the classroom. This is also a large, diverse group of research documents with a common theme of Research on Technology in Practice. Pierson looks at the relationship between technology use and teaching ability. This paper uses graphics to illustrate excellence in teaching ability and technology integration. This combination requires content knowledge, pedagogical knowledge, and technological knowledge. Becker’s study discusses a model of addressing computer anxiety while increasing technology integration in the classroom. Drost and Abbott reported on the findings of a two part study determining how teacher education programs prepare preservice teachers to utilize technology. This study also looked to determine a relationship between the initial decade of certification and a willingness to use technology.
Leh, Meyers and Fisher present case studies that describe the computer literacy levels of school teachers and levels of computer use by a group of elementary school children. Zhang, Chen, Hartley and Fowler describe their ideas related to “CyberJive” which they operationalize as jargon used in information technology. Their study highlights the difference between high school students’ and preservice teachers’ understanding of CyberJive.

Serdiukov’s paper identifies the different technologies used in education based on the SITE Conference Proceedings. He also presents the most frequently used terms in Educational Technology. Chen conducted a content analysis of SITE annuals from 1990-1999. His research identified growth focusing on telecommunications, hardware/software tools and dissemination of annuals.

Rimor and Kozminsky discuss students reflections on their working in a database environment and propose a methodology for analyzing reflection data. Hartley and Bendixen discuss the influence of learner characteristics when using hypermedia: specifically learner’s epistemological beliefs and self-regulatory skills. These characteristics are known to influence learning in traditional environments, but have been overlooked in hypermedia research. Bao investigated the usage of a web based distance learning management system, TopClass, to enhance a traditional research course. This paper describes the experience and reflections associated with the incorporation of this new technology into the class. Molebash and Milman show gains in confidence with technology for preservice teachers who take an introductory educational technology course. Murphy provides a comparison of ICT competence and attitudes between two samples of student teachers.

Chih-Hsiung Tu redefines the social learning theory for an on-line learning environment. Three dimensions of social presence are discussed including social context, online communication and interactivity. Greene and Zimmerman summarized the results of a study conducted on preservice teachers utilizing the Fifth Dimension. Preservice teachers used their experiences with this program to respond to an open ended instrument determining what is teaching and learning. Topper’s second paper investigated the patterns of email use in established teacher inquiry groups focusing on individual teacher’s professional growth.

The final division in this section focuses on methodological issues related to the study of instructional technology and state standards for technology. Adamy’s paper identifies the potential benefits of using the computer in analyzing qualitative data. He specifically identifies software that are useful in content analysis and would enhance action research. Gunawardena, Lowe and Carabajal review the models and methods available for evaluating on-line learning.

Reehm used the technology standards implemented in the state of Kentucky as the backdrop for research. New standards put into place impact initial and continuing certification for teacher educators. This study will help determine future action by Colleges of Education to better prepare teachers to enter the field.

This body of research reflects the dynamic growth and movement in the use of Instructional Technology in today’s schools. Tomorrow’s teachers will benefit from the many hours of research conducted by this group of educators.
Technology-Using Teachers: How Powerful Visions and Student-Centered Beliefs Fuel Exemplary Practice

Abstract: This research examined the pedagogical beliefs and classroom practices of seventeen exemplary technology-using teachers. Open-ended questionnaire, interview, and observation data were collected and analyzed to identify the beliefs and practices that were common, as well as distinct, across teachers. Findings suggest that teachers' exemplary technology practices were guided by strong pedagogical visions which were rooted in their beliefs about student-centered classrooms. Teachers' primary reasons for using technology related, not to extrinsic rewards, but to the many ways in which students benefited.

Introduction

Previous research has examined the relationships among teachers' levels of technology use and a number of key factors including years of experience (Hadley & Sheingold 1993), degree of self-confidence (Marcinkiewicz 1994), and access to resources (Gilmore 1995). Although these factors are considered crucial in shaping teachers' use, Hadley and Sheingold noted that classroom integration may be more highly influenced by the particular context of the school, community, policies, purposes, and individuals involved. Thus, the same "key" factor (e.g., knowledgeable peers) may look and act differently in different situations; serving, perhaps, as an incentive in one context yet as a barrier in another. More specifically, although some teachers have limited access and support, they seek to incorporate technology in ways that put learners and ideas at the core of the educational process and that achieve consequential student outcomes (i.e., those that extend to real world applications). In other contexts, teachers with unlimited access and high levels of support may achieve negligible, or unintended, outcomes by using technology in carefully prescribed ways that focus primarily on students' acquisition of low-level skills (Harrington 1993).

Hadley and Sheingold (1993) suggested that technology's impact is a function of teachers' use, as well as their interpretations of that use. These interpretations depend on the value teachers assign to technology, which is embedded in the beliefs they hold about teaching and learning, in general, and about the use of technology, specifically. Based on the assumption that teachers behave in concert with their beliefs (Erickson 1986), it is important to identify the interpretations, meanings, and beliefs that foster exemplary technology practice (i.e., the use of technology to achieve consequential student outcomes, as described above) as well as additional incentives that motivate teachers to persist in their efforts.
Pedagogical beliefs provide a meaningful context for understanding what teachers are trying to accomplish in classrooms, as well as the methods and tools they choose for doing so. By identifying beliefs common to exemplary technology-using teachers, educators will be in a better position to situate technology training within a supportive pedagogical framework, thus increasing the chances that teachers will learn to use technology to implement new practice and achieve new goals.

This Study

Purpose

This research was designed to explicate the pedagogical beliefs of technology-using teachers in an effort to understand what leads to and supports integrated technology use. Specifically, the following questions guided data collection and analysis:

- What are the pedagogical beliefs of exemplary technology-using teachers?
- How do these beliefs facilitate and support meaningful uses of technology?
- What are teachers' perceptions regarding the incentives that foster meaningful use?

Methods

We used a qualitative case-study design to examine and describe the pedagogical beliefs of exemplary technology-using teachers. Case study methodology allowed us to examine the phenomena of technology integration in-depth and to describe it through our participants' eyes. Through a series of written responses, telephone and e-mail conversations, and extended face-to-face interviews and videotaped classroom observations, we examined how teachers' beliefs aligned with and supported their classroom technology use.

We initiated the participant selection process by soliciting self- and peer-nominations of exemplary technology-using teachers from k-12 school colleagues located within an hour's driving distance of the university. Twenty-two teachers, representing 17 different classrooms (8 teachers constituted 3 teacher-teams), completed an application form in which they described their beliefs and practices regarding classroom technology use. Seventeen of these 22 teachers were available for in-depth interviews and classroom observations (including all three teams). Teachers who were interviewed represented a range of subject areas, classroom contexts, and levels of access to technology and were not considered to be significantly different from those who were not interviewed.

Our interview sample included teachers from two high schools (grades 9-12), one 6th-12th cross-age private school, five middle schools (grades 6-8), one prek-8, and six elementary schools (grades 1-5). Five of the 17 teachers taught at private schools. The high school teachers (a 3-teacher team and a single teacher) taught science, four middle school teachers (a 3-teacher team and a single teacher) taught music, and 3 teachers (one elementary, one middle school, one prek-8) taught computer skills in a lab setting. The remaining teachers taught in self-contained elementary or cross-age (6th-12th grade) classrooms. The majority of each school's population was white; ethnic minority students accounted for 4% to 45% of each school's enrollment (Tab.1).

Teachers' applications comprised our initial data set. Specifically, 22 teachers (8 male, 14 female) completed the application form in which they described their instructional and professional uses of technology, their visions for an integrated classroom, and examples of successful classroom uses of technology. In respect to this last item, teachers were asked specifically "to include information about the roles you, your students, and the technology played, how students were grouped, the goal of the activity, its relevance to the curriculum, and the manner in which you assessed outcomes." By considering successful use from the teachers' point of view, we gained valuable insights into teachers' definitions of technology integration, as well as the kind of visions toward which they were oriented. Furthermore, the specific information that teachers included in their successful examples helped us identify similarities and differences among the relevant dimensions of teachers' pedagogical beliefs and classroom practices.

Based on teacher and researcher availability, 17 teachers were interviewed and observed in their classrooms during the 1998 Fall semester. Eight teachers were interviewed two times; nine teachers were interviewed one time. Four teachers were observed one time; all other teachers were observed two or more
times. Observations were conducted over a one or two hour time period; interviews lasted approximately an hour. Field notes were taken during each observation; interviews were audiotaped and transcribed. Interviews enabled us to examine, in more detail, teachers' beliefs about technology use and to identify the incentives that motivated them to integrate technology; observations enabled us to witness the manner, as well as the extent, to which teachers' beliefs were translated into practice.

Open-ended questionnaire, interview, and observation data were analyzed using both within- and cross-case analyses (Patton 1990). We began by searching for recurring words and themes that captured each teacher's beliefs about classroom practices as well as their technology use relevant to those practices. We also identified incentives that teachers perceived had impacted their use. Secondary data obtained through telephone and e-mail conversations, and teacher and student artifacts (lesson plans, technology projects) were used to support or negate tentative themes that emerged in early analysis stages. Finally, case profiles were created for each teacher and then compared across teachers to discern both common and unique patterns of beliefs and incentives related to exemplary technology use.

Table 1: Demographics of Interview Sample of Technology-Using Teachers (names are pseudonyms)

Findings
Teachers' technology integration stories are described using three overlapping themes: guiding visions, teaching pedagogy, and intrinsic incentives. Within each theme we highlight both the similarities and differences among teachers and their uses of technology.

Guiding Vision

Teachers' uses of technology were guided by what they believed was most important for their students to know and do, rather than by what could be done, given current technological capability. For example, one high school teacher stated, "To me the computer is not the coolest part of this. It is may be the weakest part. Learning happens when people are doing. The computer allows us simply to do more of that." Teachers were quick to recognize that technology enabled them to achieve educational visions that focused on learning, not technology. A few teachers took this a step further to emphasize, not specific content goals, but students' attainment of independent learning skills. As a fourth-grade teacher stated, "It's important not just to teach about carnivorous plants and that kind of thing, but to teach the skills of how you go about finding information on the Internet." A music teacher noted, "We feel more successful (when we use technology) motivating kids to like our subject area, but even more important, motivating them to like to learn."

While some teachers believed that technology had changed their educational visions, others simply saw technology as an enabler—a tool that allowed them to teach the way they have always wanted to teach. As one biology teacher noted, "I have always been devoted to the notion that you have to be active to learn. This computer technology has allowed me to pursue that. It hasn't really changed my philosophy; it has enabled my philosophy, allowed me to continue my philosophy that I have had for a long, long time."

Perhaps because these teachers had such strong visions of classroom technology use, they did not appear to be easily frustrated by common implementation barriers. In fact, many of these teachers had achieved high levels of use despite the lack of equipment, training, or time. Teachers tended to approach barriers with no-nonsense attitudes. It was quite common to hear a teacher state that a particular barrier was "no big deal—I'll just write a grant." Or "It's not a problem—I'll find resources in the community." All of the teachers we interviewed faced barriers, yet none of them permitted the barriers to halt their efforts. Their unwillingness to give up in the face of difficulty allowed them to overcome barriers that typically keep others from proceeding. It is important to note, however, that all of the teachers interviewed in this study felt strongly supported by their school administrations. By providing ongoing technical support, as well as multiple opportunities for continued professional development, the administrations demonstrated a strong commitment to technology integration, in general, and to these teachers, in particular. However, it is unclear from the results of this study which came first; were teachers' visions facilitated by this strong support or was support provided as a result of teachers having strong visions for use? Additional study is needed to determine the relationship among these factors.

Teaching Pedagogy

Teachers expressed similar beliefs about classroom practice, particularly as they related to four main categories: teacher, student, and technology roles; classroom organization and activities; curricular and social characteristics; and assessment practices. Specifically, teachers described learning environments that placed students in self-directive roles, themselves in facilitative roles, and technology in supportive, tool-oriented roles. In addition, classrooms tended to be flexibly organized and managed, with students moving easily among activities and groups. A great deal of students' work occurred in cooperative groups and revolved around the completion of project-based assignments.

Thematic instruction and interdisciplinary approaches were commonly noted among the teachers interviewed. For example, a music teacher noted how students' projects required knowledge of social studies and English, a math teacher described his use of process writing, and a middle school computer teacher noted how her students completed a project involving foreign languages, math, science, technology, language arts, and geography.

Almost all teachers interviewed described their classrooms as being student-centered; that is, they provided opportunities for students to set their own goals, make choices about learning methods and activities, and self-evaluate progress. Assessment practices were quite varied and included the use of...
rubrics, self-reflective journals, oral quizzes, group debriefings, product try-outs, peer evaluations, oral presentations, and web-based publishing. Although a few teachers still mentioned assigning grades, it appeared as though grades were based on multiple alternative assessment measures.

**Intrinsic Incentives**

There were many reasons why teachers persisted in their efforts to use technology. Not surprisingly, the incentives that inspired them were rarely related to external rewards. Rather, our participants indicated that their efforts were powered by their perceptions that technology leads to increased student motivation and achievement outcomes. As one teacher noted, "I use it because it allows the students to be active learners."

Although some teachers mentioned that they, themselves, enjoyed using technology, the majority of teachers were quick to point out that the primary reason for using technology related to the many ways in which students benefited. Student benefits were thought to go beyond preparing students to use technology for future jobs. Teachers noted how technology enabled all students, including students with attention deficit disorders, learning disabilities, and low self-esteem, to meet academic goals. In addition, students from culturally diverse backgrounds were thought to benefit from using technology. Teachers noted that students were more likely to own their learning when they created multimedia presentations or other technology-based products. As one music teacher noted, "When students create their own songs, it's their work. And they are so intent on it. They truly own their music when they are on computers."

When used well, teachers perceived that technology helped students make connections within and across subject areas, thus making content more meaningful and more authentic. As one teacher noted, "They use it as a tool for inference and other higher thinking skills, and have fun, too." Teachers also believed that the use of technology made classroom learning more dynamic and relevant, motivating students to actively engage in the learning process. "Students are engaged and excited about what they are doing."

Perhaps the incentives that inspired these teachers, and the successes that they have achieved, can be leveraged to help other teachers initiate the technology integration process. As we search for ways to motivate more teachers to begin the process, we might consider finding ways to connect them (via e-mail, classroom observations, or virtual field trips) with those who have already seen success in terms of increased student engagement and high levels of independent learning. According to Glenn and Knapp (1996), these types of successes can serve as powerful change agents: "What ignites the final fires of enthusiasm and commitment to change is when teachers see their colleagues integrating technology tools successfully, when they see students enthusiastically using them, and when they see the sophisticated products that these students create" (p. 221).

**Summary**

Although our participants described a variety of approaches to achieving technology integration, they shared a common vision of their students as self-regulated learners, capable of setting goals, making choices, monitoring progress, and evaluating learning outcomes. As noted by one high school biology teacher, "The least important of our goals is that they learn biology. We are much more concerned that they become independent learners and critical thinkers." Furthermore, this goal, although attainable without technology, was perceived as being more readily achieved when technology was used as one of many available learning tools.

**Educational Implications**

Achieving meaningful technology use is a slow process that is influenced by many factors. When educators and researchers look for ways to help teachers use technology effectively, it may be important to look at what they have (in terms of beliefs and practices) in addition to what they do not have (in terms of equipment). Understanding teachers' visions for technology use and their beliefs about teaching and
learning may be necessary if we are going to support their efforts to initiate and sustain the kind of systemic changes required for innovation to become practice.

The purpose of this study was to explicate the pedagogical beliefs that support integrated technology use as the first step in developing an effective approach to technology education for both pre- and in-service teachers. As with any professional development endeavor, it is critical that we know where we want to go first and then figure out how information technologies can help us get there. The results of this study suggest that it is important to address pedagogical issues during training efforts. Furthermore, it appears important to spend time fostering visions of technology use that focus on providing, increasing, improving and/or assessing student learning, as opposed to visions that focus on increasing technological capability (e.g., obtaining laptops for every student). It is hoped that by sharing these few teachers' stories, others who are just beginning their own technology integration journeys may benefit. By examining both the pedagogical beliefs and classroom practices of exemplary technology-using peers, we expect that teachers will gain a better understanding of how technology can be used (the practical considerations), as well as why it should be used (the supporting pedagogy). The visions and beliefs that have empowered our participants, as well as the strategies they have devised to overcome common obstacles, provide models for others who wish to change current classroom practice. It is our hope that the teacher case profiles generated from this study can serve as powerful reflection tools for others—visions on which to reflect and from which to grow new and even more powerful visions.

Acknowledgments

Portions of this work were supported by the Multimedia Instructional Development Center at Purdue University and the Herrick Foundation of Michigan. The authors wish to thank the participating teachers and their school principals for their hospitality and efforts during this project. In addition, we thankfully acknowledge the assistance of D. Scott Brandt, Dennis Dell, Valeria Moschetta, Suzy Steuben, and Olga Weiss during data collection and analysis.
Teachers' beliefs about teaching and learning shape their approach to planning and carrying out curricular activities in the classroom. These beliefs are filters through which teachers make sense of the curriculum and influence the instructional approach they use. Assumptions about the role of educational technology are an important influence on the plans and activities teachers make when they prepare to integrate technology into their teaching practices. This study examined individual teachers' beliefs and knowledge related to teaching and learning as articulated in a graduate-level course, looking closely at how these beliefs and knowledge shape plans for technology use in teaching. The results offer insights into the nature of teacher beliefs that shape technology use and help to clarify the interactions between knowledge and belief about teaching, learning, and technology. This line of research represents an important area for further study as more and more teachers view technology as a valuable pedagogical tool.

Introduction

Students in a Master's level educational technology course represent a place to investigate and better understand the relationships between teachers' beliefs about teaching, learning, and technology. Experienced teachers in an educational technology graduate program bring with them prior experiences, assumptions, and attitudes towards technology that are made public in class discussions. This provides a site for studying the interactions among individual teachers' beliefs and plans, influenced by the subject matter in the graduate course, by the instructors plans and activities, and by their peers.

Researchers have developed a variety of ways for thinking about teacher knowledge and beliefs that shape their classroom practices. Teacher beliefs -- encompassing suppositions, commitments, and ideologies -- have been studied in a variety of settings and contexts. It is generally assumed that beliefs are more often associated with affective and evaluative cognitive components than teacher knowledge, but that beliefs play an important role in teaching practices.

Calderhead (1996) identified five categories of teacher beliefs: (a) beliefs about learners and learning, (b) beliefs about teaching, (c) beliefs about subject areas, (d) beliefs about learning to teach, and (e) beliefs about self and the role of teachers in learning. Teacher beliefs about learners and learning often come from assumptions about student abilities, although beliefs about teaching usually reflect a teacher's overall beliefs about teaching and sustaining positive social relationships with their students.

Building on the work of Shulman (1986), Grossman (1990) offered a framework for thinking about teacher knowledge that includes: (a) general pedagogical knowledge, (b) subject matter knowledge, (c) pedagogical content knowledge, and (d) knowledge of context. General pedagogical knowledge describes a body of general knowledge, beliefs, and skills related to teaching and learning not specific to any particular content or domain. Subject matter knowledge includes not only factual knowledge of the domain, but also knowledge of the substantive and syntactic structures of the discipline. Pedagogical content knowledge incorporates beliefs about the purposes of teaching a specific subject area, knowledge of students' understandings of that subject area, curricular knowledge, and knowledge of instructional strategies and...
representations. Contextual knowledge refers to individual teachers' understandings of the school culture and setting in which they teach.

Teachers' knowledge and beliefs play an essential role in their practices and shape the learning that goes on inside and outside their classroom (Borko & Putnam, 1995). These beliefs and knowledge shape teachers' learning as they work to improve their teaching, acting as filters through which teachers view educational change. In order for teachers to adopt new educational innovations, such as technology, they will need to "think in new ways about students, subject matter, and the teaching-learning process" (p. 38).

While individual teachers can expand their knowledge and learn about technology, they need opportunities to develop and sustain professional relationships with their peers to effect changes in the larger school culture. These professional relationships, which I consider collegial, provide a supportive context for examination of teacher beliefs and teaching practices as well as a collective environment for changing aspects of the school culture necessary for successful technology adoption.

**Graduate Course Description**

EDG621: Topics in Educational Technology is a Masters' level course offered each term under the Advanced Studies in Education program at Grand Valley State University. In the past, this course has been taught in a traditional lecture format with some hands-on work in a computer lab. When I designed this course for the Fall 1999 term, which was my first time teaching it, I changed the format to include more discussion and less lecture while maintaining the hands-on experience in the lab. I also instituted a course research project in preparation for the Masters Thesis or Project students are required to complete before they graduate.

The published course goals were described as follows:

This course is intended to provide students with broad and deep exposure to a variety of educational technologies, drawing on their own interests and experiences in the classroom as well as research in the field. Using research on educational technology, where research takes a variety of different forms, we will examine how technology can support the goals and purposes of K-12 education. There will be a dual focus in this class on research related to the use of educational technologies, provided in traditional print publications (books, journals, etc.) and in electronic form, as well as the experiences of students in the context of their schools and districts.

A large part of my role in this class was facilitating conversations among students around the course readings, drawing on their experiences in the classroom. I wanted to create an intellectually stimulating environment for these students to make public their assumptions about teaching and learning in order to expose them to peer scrutiny. Another goal was to stimulate collegial interactions among students around technology learning in this class. I also wanted to encourage students in this class to connect what they were learning and the work on their projects with their classroom experiences, making this course more relevant to their everyday lives. As students in the class shared their views, their experiences, and their understandings of the course readings, I was given a glimpse into the ways they thought about using technology in their classrooms.

**Research Questions**

- How do teachers' assumptions and beliefs about teaching and learning influence their plans for technology use?
- How do teachers' uses of technology influence their teaching beliefs and practices?
- What is the relationship between teachers' beliefs, knowledge, and practices, and their use of technology for teaching and professional development?

**Methods of Inquiry**
After the term ended, I qualitatively analyzed the data I collected for this study to identify and track individual knowledge and beliefs related to teaching, learning and technology. Data collected includes field notes from my reflective journal (kept by me during the year), e-mail and Course Info conversations (Blackboard, Inc.) among graduate students (archived), surveys filled out by graduate students, and selected entries from graduate student journals (turned in as part of the class). Using triangulation, I analyzed student participation in the class and examined how their beliefs about teaching and learning -- as articulated in their journal entries and in their class correspondences -- shaped their planned uses for technology in their own classroom settings.

Procedures

During the fall 1999 and spring 2000 terms, I collected data from the participants as part of a Master's level courses I taught at GVSU. I analyzed the data looking closely at how students' beliefs and knowledge of teaching and learning -- as articulated in their class and on-line conversations, as described in their journal entries, and as described in surveys -- shaped their plans for use of technology in their teaching.

Department of Computer Science
The University of Louisiana at Monroe

Jan Anyan
Winn Parish School System

Introduction

Everyday, one sees or hears news about the latest advancements in educational technology and what these new technologies can do for our children and their learning environment. The focus of these studies concentrated on the effects of technology in the classroom and on the students. One major aspect, which is often overlooked in these investigations, is that of the teacher's attitude toward this technology and its utility as a learning tool. This study focuses on the often-overlooked teacher-link in the successful implementation of technology in the learning environment and investigates the attitudes towards technology of teachers from three school districts in Louisiana.

In this research, differences among school systems, teaching level, gender, and teaching experience are studied.

This study surveyed K-12 teachers representing three types of school systems - an urban system, a rural/urban system, and a rural system.

Survey Instruments

To assess the attitudes of the respondents in the study, the Teacher's Attitude Toward Information Technology (TAT) version 1.1 survey instrument was distributed to the faculties of the Monroe City Schools (an urban system), the Ouachita Parish Schools (an urban/rural system), and the Winn Parish Schools (a rural system). The TAT, which is composed of ten separate subscales, was developed and verified by the Texas Center for Educational Technology (TCET). TCET operates under the auspices of the University of North Texas and was developed by Christensen and Knezek (1998). Eight of the subscales are semantic differential subscales and were constructed using Zaichkowsky’s (1985) Modified Personal Involvement Inventory. These subscales focus on a person’s perceived relevance of the object based on inherent needs, values, and interests. The other two subscales uses Kay’s semantic perception of computers (Kay, 1993) and D’Souza’s (1992) classroom learning via electronic mail.

The Survey

The survey consisted of teachers from the Monroe City School System (MCSS), the Ouachita Parish School System (OPSS), and the Winn Parish School System (WPSS). Approximately five hundred (500) questionnaires were distributed to the faculty of these systems. Of these two hundred and forty-two (242) were returned for a return rate of 48 percent. The teaching level and system distributions are given in Table 1. In this study, there were 98 elementary school teachers, 42 middle school teachers, and 102 high school teachers. Furthermore, there were 101 teachers representing the urban school (MPSS), 68 teachers representing the urban/rural system (OPSS), and 73 teachers representing the rural system (WPSS), respectively. The study also consisted of by 42 males and 200 female teachers.

The survey results documented the various levels of teaching experience. The distributions of experience level by system are shown in Table 2. The survey consisted of 14 new or first year teachers, 38 teachers with 2 to 5 years experience, 46 teachers with 6 to 10 years of experience, 33 teachers with 11 to 15 years of experience, and 110 teachers with 15 or more years of experience.

* One of the teachers did not respond to the question pertaining to teaching experience.

In summary, the two hundred and forty-two respondents, who returned the questionnaire for this research, adequately represented the three systems in each of the categories of teaching level, gender, and teaching experience.

Research Hypotheses

The research hypotheses of interest are multifaceted and consist of comparing the teacher's attitude toward technology by school system, teaching level, gender, and teaching experience. Friedman's two-way analysis of variance (ANOVA) by ranks was chosen as the statistical procedure for evaluating these hypotheses. This non-parametric procedure was chosen over other statistical methods so that we may circumvent any problems with the assumptions of these methods. Friedman's two-way ANOVA by ranks makes no assumptions and uses the ranks of the data rather than the data itself. The hypotheses of interest are:

Hypothesis 1: Teacher attitudes toward technology are not dependent on the system.
Hypothesis 2: Teacher attitudes toward technology are not dependent on the teaching level.
Hypotheses 3: Teacher attitudes toward technology are not dependent on gender differences.
Hypotheses 4: Teacher attitudes toward technology are not dependent on teaching experience.

Descriptive Statistics

The TAT subscales used in the evaluation and testing of these hypotheses are given in Table 3. Subscales F1, F3, and F7 relate to the teacher's attitude about e-mail, multimedia, and the WWW. Subscale F5 relates to attitudes on how technology can improve the teacher's productivity. Subscales F2, F4, and F8, on the other hand, represent the teacher's perception of the student's attitude toward e-mail, multimedia, and the WWW. Subscale F6

relates to the teacher's perception of what technology can do for the productivity of their students, and subscales F9 and F10 relate to the teacher's attitude about e-mail in the classroom and to the teacher's general feelings about computers, respectively.

The data collected from this survey are summarized in Tables 4 through 7. Table 4 displays the average subscale values by school system; whereas, Tables 5, 6, and 7 display the average subscale values by grade level, gender, and teaching experience, respectively. The original data, quantified by the survey, ranged from 1 to 7.

where 1 was a least favorable or a negative attitude and 7 was a most favorable or a positive attitude about the subscale being measured. A response of 4 represented an "I Don't Know" or "Not Sure" response. These values were recorded for the subscales of F1 through F8 and F10. Unlike these subscales, F9 was measured using a Likert scale with values ranging from 1 to 5 with 3 as the "I Don't Know" or "Not Sure" response and 1 for "Strongly Disagree" and 5 for "Strongly Agree." For this investigation, the data values were scaled to be centered about zero. For subscales F1 through F8 and F10 the values were scaled to -3 to 3. For subscale F9 the values scaled to -2 to 2. The most negative number represents the strongly disagree or the most negative attitude about the subscale; whereas, the most positive represents the strongly agree or the most positive attitude about the subscale.

Results of the Study

The Friedman's nonparametric two-way analysis of variance by ranks test is used to evaluate the research hypotheses of this study. The two-way design developed by Friedman is the non-parametric extension to a two-way blocking design. The primary difference between the two designs lies in the fact that Friedman's analysis uses ranks; whereas, the block design uses quantitative or measured data. The blocks for the two-way ANOVA are represented by the TAT subscales F1 - F10 and the groups are represented by either school systems, teaching levels, gender, or teaching experience, depending of the hypothesis of interest. The data representing the cells of the two-way tables in this study are composed of TAT scores for each teacher in that category. In order to assess

average differences in the attitude of the teachers in our study, the data representing a cell in the two-way ANOVA were averaged prior to any analysis. The authors of this report felt that the average scaled values of the TAT subscales reflected the teacher's feelings about technology and as such these average feelings were used to evaluate the hypotheses of interest.

Systems. In this study, there were three types of systems - the urban system (MCSS), the urban/rural system (OPSS), and the rural system (WPSS). In this regard, the Friedman's anova by ranks indicated that a significant difference is present among the three types of school systems ($\chi^2 = 15.80$, p-value = 0.000). MCSS exhibited the largest average rank of 2.70; whereas, WPSS had the next largest rank of 2.30. OPSS had the smallest rank of 1.00. Tukey-Kramer's test indicated that MCSS's rank was significantly larger than OPSS's rank, and that the average rank of WPSS was not different for either MCSS or OPSS. Figure 1 depicts the average ranks by system.

Teaching Levels. When evaluating teaching levels, the data were divided into three mutually exclusive groups - elementary teachers, middle school teachers, and high school teachers. As with systems, the average TAT subscale score was used to represent the feelings about technology of the teachers in each of these three categories. The Friedman's two-way ANOVA indicated that a weak dependency on teaching levels is present ($\chi^2 = 4.974$, p-value = 0.083). Figure 2 depicts the average ranks by teaching level.

Gender. When evaluating gender differences, the data were divided into the two gender groups of Males and Females. The average TAT subscale was used to represent the feelings about technology of the male and female teachers. The two way anova by ranks indicated that the female teachers had a better attitude about technology than their male counterparts ($\chi^2 = 10.00$, p-value = 0.002). Figure 3 depicts the average ranks by gender.
Experience Levels. When evaluating differences in attitudes among the five teaching levels of 0-1 yrs, 2-5 yrs, 6-10 yrs, 11-15 yrs, and 15 or more years of experience, the average TAT score for each of the ten indices were used to represent the average feelings of teachers in each of these groups. The two-way ANOVA by ranks indicated that differences among the five groups are present ($\chi^2 = 27.280$, p-value = 0.000). Tukey-Kramer’s technique indicated that groups 1 and 4 had the best attitudes toward technology and that they were better than groups 2, 3 and 5 which exhibited similar attitudes. Figure 4 shows the average ranks by experience level.

In conclusion, this study found that the average feelings of the teachers representing the three school systems did show that attitudinal differences about technology were present among the teachers representing these systems. The urban system (MCSS) teachers exhibited a better attitude when compared to the urban/rural (OPSS) and the rural system (WPSS). The survey indicated that the MCSS teachers’ average attitude toward technology was 1.8 with a range of 0.53 (F2) to 2.46 (F5). WPSS averaged 1.6 with a range of 0.34 (F2) to 2.4 (F6); whereas, OPSS averaged 1.32 with a range of 0.16 (F2) to 2.08 (F5). Attitudes about e-mail were the lowest recorded values for the study. The teachers were not sure about what e-mail could do for their classroom or for their students. Overall the teachers representing the three systems felt optimist about technology; however, these feelings were not as positive as we hoped. The research showed that the female teacher had a better attitude about technology than their male colleagues. The average attitude of the male teacher was 1.21 with a range of 0.27 to 2.05; whereas, the average attitude of the female teacher was 1.67 with a range of 0.39 to 2.5. Consistently, the male teachers had smaller averages than the female teachers on each of the TAT subscales. The analysis further indicated that a weak dependency on the teaching level is present. Elementary teachers have the lowest average score (1.5) when compared to their middle (1.7) and high school (1.6) colleagues. The TAT subscales for all groups ranged from 0.36 (F2) TO 2.51 (F5). When considering the category of experience levels, we a priori felt that the attitudes of the teachers would be decreasing over time. However, this was not the case. The first year teacher had the highest average 2.03 with a range of 0.84 (F2) to 2.7 (F5). The 2-5 year teachers had the lowest average of 1.4 with a range of 0.18 (F2) to 2.03 (F7). The 6-10 year teachers displayed an average of 1.6 with a range of 0.34 (F2) to 2.4 (F6). The 11–15 year teachers had an average of 1.9 with a range of 0.37 (F2) to 2.7 (F6); and lastly, the 16 or more years of experience teachers had an average of 1.5 with a range of 0.37 (F2) to 2.2 (F5).

Abstract: Nine schools in a large suburban school district were selected to receive training on the use of information technology. Teachers were trained to use the World Wide Web, create their own web pages, use Microsoft PowerPoint, and HyperStudio. Both teachers and a random sample of students were surveyed and interviewed near the end of the year regarding the use of instructional technology in their classrooms. Students seemed to be very aware of the use of technology in their classes. Classroom use of technology varies with grade level grouping K-2, 3-5, and 6-12. Teacher and student perceptions of how technology is used in the classroom were quite different. The use of computers seems to be greatly affected by location within the school and philosophy of each school, which varied with grade level.

Introduction

The Department of Education and Human Development of the State University of New York at Brockport is in its fifth year of a Goals2000 funded project to prepare pre-service teachers to use technology and to increase in-service teacher knowledge and use of technology. The project has involved placing hardware in individual schools, training teachers to use the hardware, networking the schools, setting up a listserv for communication, and having periodic meetings and mini-conferences. SUNY Brockport has been involved in both the in-service teacher training and primarily in the pre-service training of future teachers.

Each year the number of schools involved has increased. The first year, 1995 – 1996 involved the placement of hardware and training of a core of teachers in four schools on the use of the hardware, e-mail, and listserv. The focus during the first year was for each school to develop an operational definition of professional practice school, as it would be implemented at their site. The technology was used as a support communication among schools and SUNY Brockport.

The second year of the project, 1996 – 1997, involved the addition of three more schools and a focus on multimedia applications in the classroom. Teachers in participating schools were trained in the use of HyperStudio and encouraged to use it in their classrooms and with their students. Each of the participating schools continued to use the provided technology both for communication with other members of the project as well as for the development of multimedia presentations. During this second year a core of teachers at participating schools were also introduced to the Internet, the World Wide Web, and Netscape as resources for their teaching. The focus of training on the World Wide Web was on searching and retrieving information to be used by students and teachers.

In an attempt to encourage more use of Internet resources in the K-12 classrooms, the third year of the project, 1997 – 1998, added four more schools, and focused on introducing teachers to a World Wide Web subscription service developed by American Cybercasting, called Educational Structures. Teachers at each of the eleven participating schools were trained on the use of this new tool and encouraged to use it in their
classrooms. Pre-service teachers at SUNY Brockport were also trained on the use of Educational Structures in their classes at the college, so that they could serve as a resource for teachers in the schools to which they were assigned.

The fourth year and fifth years of the project, 1998 - 1999 and 1999 - 2000 continued to focus on helping teachers help their students use presentation graphics, either HyperStudio or PowerPoint and to increase their use of the World Wide Web. Teacher workshops and training sessions centered on learning to use the presentation software, using the WWW as a research medium, and using Microsoft FrontPage to create classroom web pages.

Evaluation Plan

Teacher Surveys

In order to evaluate the effectiveness of training in-service and pre-service teachers in the use of Educational Structures, the first author developed a Likert-Type questionnaire for teachers, interviewed a sample of teachers, and analyzed training records. Survey questionnaires focused mainly on the knowledge and use of Educational Structures and the World Wide Web in general. Data from district Technology Integration Teachers indicates what types of training were provided and the number of teachers attending. The Technology Office has also provided information regarding special requests by teachers for help with projects.

In addition, those in attendance evaluated the annual Mini-Conference through the use of Likert-Type survey response forms. The overall conference was evaluated as well as individual sessions.

Student Surveys

The authors developed three different student surveys, one for grades K - 2, one for grades 3 - 5, and one for grades 6 - 12. These surveys focused on the student's perceptions of how information technology, in general, and the World Wide Web, in particular, had been incorporated into their classes. Ninety-five students from grades K - 12 participated in the survey.

Seven students selected from different grade levels were also interviewed. The interview questions were based on the surveys and allowed the researchers to validate or further expand on the findings. The interviews were conducted one-on-one with randomly chosen students and responses were recorded verbatim.

Surveys in grades K - 2 were administered by their teachers and then returned to the researchers. Surveys were read to the students and they were asked to respond by placing a mark on the "happy face" indicating a "yes" or the "sad face" indicating a 'no.' A total of 31 surveys were returned from the K - 2 level teachers to the researchers.

The researchers themselves administered the surveys to students in grades 3 - 5 and grades 6 - 12. Two of the researchers visited each high school, middle school and K - 5 school participating in the survey. Students were randomly chosen from each grade level and completed the surveys with the researchers out of the room.

The researchers randomly selected students to be interviewed from among those students who did not complete the survey. Each of the total of seven students was interviewed by one of the researchers in a one-on-one setting. The interviews lasted between ten and fifteen minutes. Responses were recorded verbatim and tape recorders were not used.

1609
General Results

The following results are from the teacher surveys, data regarding training supplied by the Technology Integration Teachers and data from SUNY Brockport:

- A total of 256 teachers received training on Educational Structures.
- Approximately 300 students were involved in the project activities.
- 4 Teachers have developed and implemented HyperStudio based projects in their classrooms.
- One high school class and a group of elementary students each produced a HyperStudio presentation.
- In-service training of teachers on the use of technology, especially Internet access and HyperStudio, has rapidly migrated to the students. Students in several schools access and use information and images from the Internet in projects they do for classes.
- Teachers at one high school implemented an interdisciplinary authentic assessment program after receiving training through Goals 2000. They have reported high student achievement.
- The Goals 2000 grant has allowed the establishment of an electronic network within the school district. Schools that would not have been connected for years are already on-line because of equipment provided by the grant.
- Each school in the Goals 2000 project has developed their own model for implementing a Professional Practice School at their site. This bottom-up approach will make success more likely.
- Teachers and students have been accessing information and images from the Internet for use in lessons and class projects. Digital images have become a big part of student projects.
- Teachers are no longer “textbook bound.” They are more confident in accessing current information from the Internet.
- All pre-service teachers learn to use e-mail and the listserv to facilitate communication with college faculty and teachers in the schools.
- A total of 195 pre-service elementary teachers received an average of 6 hours of training in the use of the World Wide Web and Educational Structures.
- Two schools in the project developed Student Teacher Manuals to be used with new student teachers.
- Student teachers at all project schools are included in all Goals 2000 activities creating more of a “community of learners.”
- There has been a conscious coordination of the training of pre-service teachers at SUNY Brockport with the directions taken by the Goals 2000 project. There is a real sense of cooperation and involvement of all parties. Planning and ideas from the Goals 2000 Steering Committee are used in planning pre-service teacher training activities at SUNY Brockport.

Teacher Use of the World Wide Web

The analysis of surveys returned by teachers involved with the Goals2000 project has indicated a substantial increase in the use of WWW resources in planning for instruction. Each of the teachers, working as part of the Goals2000 grant, has had at least one computer assigned to them. Due to location of rooms, telephone lines, network drops, and other infrastructure problems, not all of these have made it into the classrooms. In situations where the computers could not be located in the teacher’s classroom, they were placed in a location within the school that would be convenient for the project teacher. Often, the telephone lines come into the main office and the teacher’s room requiring computer placement at that location. As more and more schools are hooked up the wide area network in the district, more computers can be located in teacher classrooms.

Part of the problem in using Educational Structures and the World Wide Web as part of the classroom activities is that in many schools teachers only have a single computer in the classroom, if any. In several cases the computer is not in the classroom at all, but in the teachers room or the school office. The logistical
considerations severely limit full exploration of the power of the WWW and Educational Structures in the classroom.

Two of the most technologically advanced schools in the Greece Central School District are K-5 schools. These schools each have 4 or 5 computers in every classroom and the teachers are experienced in integrating the computer into their teaching. Another problem is that Educational Structures had only been designed with middle and high school students as the target population. American Cybercasting is presently expanding their materials to cover elementary students as well, but at the time the teachers were surveyed, the new materials were not available.

The middle and high schools tend to have a different philosophy regarding the use of technology and generally use a different configuration. The computers in these schools are located in media centers and computer labs and not in the classrooms. Students do use the WWW and Educational Structures in their work, but not in the classroom. As computer usage expands in the district, the middle and high schools will be equipped with at least one computer in each classroom making integration into teaching easier. Until that time, both teachers and students will continue to use computers as tools outside the classroom.

Teacher Perception of Instructional Technology Use

An analysis of the surveys returned by teachers involved with the Goals2000 project has indicated a substantial increase in the use of WWW resources in planning for instruction. Teachers indicated that they used computers mostly in their planning and preparing for classes. The surveys have provided the following information regarding teacher use of Educational Structures and the World Wide Web in general:

- Teachers responding to the survey used their computers between 1 and 5 hours per week with the World Wide Web.
- These teachers used the World Wide Web for class preparation and not for instruction or as part of work within the classroom.
- Teachers viewed World Wide Web use as a supplement to, not a replacement for, their usual teaching and preparation.

Student Perception of Instructional Technology Use

Analysis of student surveys and interviews indicated quite a different perception in the way instructional technology was used in their classrooms. It should be noted that student surveys focused on classroom use while teacher surveys focused on teacher use both in and out of the classroom. Differences in the use of technology were identified by grade level, with students in grades K – 2 having different perceptions from those in grades 3 – 5 and 6 – 12. The student surveys and interviews produced the following broad perceptions.

- Students in grades K – 2 use the computer anywhere from one to five days per week. They typically work alone at the computer and use it for practice, “games,” and “typing stories” they have written. Videos and filmstrips are used often in classrooms with this age group, as are overhead projectors.

- In grades 3 – 5 students use computers in their classrooms at least once per week. Students at these grade levels tend to work alone or with a partner. Some students use the computer for specialized purposes such as art. Students in this age group occasionally use the Internet. They also only occasionally watch videos or filmstrips. Interestingly students in grades 3 – 5 perceive their teachers as rarely using the overhead projector.

- At the grade 6 – 12 level it was apparent that the teachers used the computers in the classroom more than the students. When students have a chance to use computers they work individually to “research, play games, e-mail, and type labs or other homework assignments.” Most of the teachers and students used the
Internet in the classroom but it was usually the teacher who was in control. Filmstrips and videos were used occasionally and overhead projectors were used frequently. Teachers at these grade levels often give assignments that require the student to use a computer in some way, but that use must be outside the classroom.

Conclusions

The Goals2000 project has been successful in increasing the use of information technology both in and out of the classroom. Teachers are using the technology more than ever to prepare for their teaching. Teachers are also encouraging students to use the technology both for their own research and to prepare presentations for class. In a very short period of time teachers involved with the project have become very sophisticated computer users.

As a secondary outcome, teachers and technology integration teachers are looking at the placement of new computer equipment. The elementary classroom configuration with 4 to 5 computers in each classroom needs to be investigated for use at the middle and high schools. The location of computer labs, no matter how numerous, inhibits spontaneous use of information technology by students and prohibits its regular use as part of the instructional process by the teacher.

Students do indeed notice the technology being used in their classrooms regardless of their age and grade level. Many of the teachers actively use technology in their classes and some involve the students in such use. This occurs more frequently at the elementary grade levels than at the middle and high school levels. Students at the elementary level tend to use computers as part of their lesson while use at the middle and high school levels seems to have the teacher using it as a presentation device or model.

A final note. Over the 4 years of Goals2000 projects the Greece Central School District and the State University of New York College at Brockport have worked closely. The result of this affiliation has been the movement of more technology training into the college classroom and more use of pre-service teachers in the public school classrooms. Working closely with the school district has dramatically changed how we train and work with pre-service teachers.

Abstract: This research report summarizes the results of a study conducted on a group of undergraduates enrolled in an introductory preservice teacher education course. In this study participants were asked to respond to an open-ended instrument to determine their conceptions about teaching and learning before and after a field experience with public school children enrolled in the Fifth Dimension. Findings indicate the beliefs of preservice teachers change as a result of working in this technology rich environment.

Introduction

When preservice teachers enter teacher education programs they bring well established beliefs about teaching and learning. These preconceptions may be subject to change (Clark, 1988; Clark & Peterson, 1986; Florio-Ruane & Lensmire, 1990; Wilson, Konopak, & Readence, 1994) or may remain the same (Kagan, 1992; Weinstein, 1989, 1990). In several research reports, the findings indicate that teacher education programs have a limited impact on the beliefs of preservice teacher teachers (Finlayson & Cohen, 1967; Lortie, 1975; McDiarmid, 1990; Zeichner & Tabachnick, 1981). The influence of pretraining is more significant than formal training in pedagogy at the university level (Zeichner & Grant, 1981).

The degree to which teacher education programs impact preservice teachers is inconclusive. However, some research findings have revealed changes in preservice teachers' beliefs about teaching (Feiman-Nemser, McDiarmid, Melnick & Parker, 1989; Florio-Ruane & Lensmire, 1990; Tamir, 1991). Feiman-Nemser et al. (1989) investigated the preconceptions of preservice teachers and concluded that at entry-level, they defined teaching as telling whereas ending-level preservice teachers defined teaching as a more complex activity. Gibson (1972) found that the early part of the teacher education program seemed to significantly effect change in students' attitudes. Watter & Ginn (1995) concluded that college course work and student teaching may have some influence on teachers' sense of efficacy. The effects of field experiences on preservice teacher beliefs demands more research and analysis. What are the results when novices enroll in introductory level education courses that require a field component? How can we structure these experiences to ensure preservice teachers exit with more knowledge of the complexity of teaching and learning?

The Study

In this study we have drawn from the research of Gibson, Feiman-Nemser, and others to investigate the effects of an introductory course and its technology-rich field experience on the entry and ending level beliefs of preservice teachers. We utilized an open-ended instrument to determine students' conceptions about teaching and learning and to determine changes that might occur over time. Participants in the study consisted of 60 students enrolled in the introductory course CI – 2800 entitled Teachers, Schools, and Learners. These students were required to complete course work and a twelve week practicum in The Fifth Dimension which
operates in public school computer labs during the after school hours. Course content was closely linked to The Fifth Dimension through presentations, discussions, and reflections. The design of both CI – 2800 and The Fifth Dimension was based on the principles drawn from cultural-historical activity theory. Preservice teachers were expected to prepare weekly fieldnotes detailing their observations and interactions with children between the ages of five and twelve in this field experience. A website was designed for submitting, storing, and retrieving these reports.

Simple quantitative analysis was done to categorize the initial and final responses to two questions in this open-ended instrument – What is Teaching? and What is Learning? The belief survey was adapted from an instrument used at Michigan State University in their research on teacher education. It was modified for this study and has been used for three years with undergraduates at Appalachian. The value of this survey is based on the fact that it measures the attitudes of preservice teachers with regard to teaching and learning.

Qualitative analysis was used to examine the preservice teachers' fieldnotes submitted over a period of three months. These reflections gave insight into the daily events of The Fifth Dimension. Content of these fieldnotes included a description of the site, activities of the day, interactions with children, educational software selected for use, accomplishments in the lab, observations related to course content, reflections about their success with teaching, and documentation on the progress of the children.

We hypothesized that preservice teacher beliefs would be influenced by the course content and the connecting field experience.

Data Analysis

Data analysis included a comparison of the responses on the pretest and posttest on the belief survey consisting of two questions: What is teaching? and What is learning? The pretest was read to distinguish themes and to record the frequency of occurrence of these themes. The post test was read to determine whether or not identified themes on the pretest persisted and the frequency of these themes. The posttest was analyzed to determine any changes in the responses to these questions. Additionally, field notes submitted by the preservice teachers were read and analyzed to distinguish themes and to determine the extent and kinds of changes that occurred as a result of interactions with children enrolled in The Fifth Dimension.

Three researchers examined the responses to the pretest and the posttest administered to the preservice teachers. Responses to the two questions were discussed and categorized. The charts below indicate initial and final explanations of teaching and learning.

What is Learning?

A total of 56 preservice teachers responded to “What is Learning?” at the beginning of the semester. The range of responses fell into the categories of passive/receptive, active, active and passive. The large majority of students (N=36) defined learning as "being able to take in new information" or the "ability to receive information" or "absorbing information" which clearly fit the passive/receptive category. Several responders, N=13, defined learning as an active process and explained further by saying "learning is receiving, processing, and using data" or "learning is having different experiences" in their explanations. Only seven students perceived learning as a combination of active and passive characteristics. Learning was described by this population as “integrating data from ones lived experiences...and assimilating the new information given them as best as their cognitive abilities facilitates” and “when some new concept is placed in your thought pattern...interacting with others and observing the events and things around.”

A total of 58 preservice teachers responded to “What is Learning?” in the posttest. Following the CI-2800 course and its accompanying field experience in The Fifth Dimension, preservice teachers’ ideas regarding learning revealed changes and new categories emerged. Four new categories were identified by the researchers. They included active and social, active and passive (combination) and social, constructing knowledge, and social only. A large number of respondents (N=15) maintained that learning is an active and a passive activity. Also, fifteen stated that learning is a combination of active and passive and social. Examples of their responses included “Learning is the process of retaining useful knowledge for your own educational benefit. Children learn better if they can see and touch. Students also learn from their peers in communities of practice.” One defined learning as a process of constructing knowledge and said “children learn mostly by experiencing things—they like to work things out for themselves so that they can have a
Two saw learning as a social activity only and stated that “through the zone of proximal development, I can see how a competent guide can enrich the experience of the learner” and “I believe that for children to best retain their new knowledge, it has to be learned from a social context.”

Table 1: The responses to the pretest and posttest question “What is Learning?” are displayed in this table.

### What is Teaching?

A total of 53 preservice teachers submitted responses to the pretest question “What is Teaching?” and seven additional responses were submitted for the posttest. The range of responses for the pretest were categorized into the areas of telling/transmission (N=33), helping (N=18), and strategies (N=2). The majority of responses identified teaching as a task of telling or transmitting knowledge and explained by stating that teaching is “passing of knowledge,” “conveying information,” “transferring all that you know,” or “giving a person information.” Several students submitted the idea that teaching is helping and explained by saying “teaching is helping a student understand” or “teaching is being able to help students learn.” Two preservice teachers felt that teaching was “lecture and activities and experiments to get the students involved” and “methods ranging from field trips to guest speakers.”

A total of 60 preservice teachers submitted responses to the posttest question “What is Teaching?” Five new categories including sharing (N=4), collaboration (N=3), zone of proximal development (N=2), and creating an environment (N=1) emerged. The majority of students consistently regarded teaching as telling/transmitting or helping at the conclusion of the study. In the new categories, four students defined teaching as sharing or “sharing ideas, thoughts, and facts in a way that the learners understand.” Three students used collaboration as their definition and suggested that teaching is “collaborating in order to learn something and can occur between the teacher and the student, student to student, parent to student, or even parent to teacher.” Two students explained that teaching is “expanding the child’s zpd and getting the child to go beyond and do his best” and “teaching requires constructing zones of proximal development so children can reach their
potential and continue to grow and learn.” One student focused on the environment and defined teaching as “creating an environment in which learning is possible.”

Table 2: The responses to the pretest and posttest question “What is Teaching?” are displayed in this table.

Conclusions

In this study university students enrolled in an introductory level teacher education course completed open-ended questionnaires to assess existing beliefs about teaching and learning and to determine if these beliefs would change over time. With regard to the question “What is Learning?” students initially held strong convictions that learning is a passive/receptive activity. These responses are consistent with the literature on preservice teachers’ beliefs (Kagan, 1992; Holt-Reynolds, 1994). Although several students’ responses revealed on the pretest and posttest that learning was passive, several began to restructure their definitions and began to perceive learning as a process that included a combination of activity and social interaction. The majority of responses revealed new or broadened definitions of learning.

Initial and final responses to the question “What is Teaching?” reveal some changes in the beliefs of preservice teachers. Teaching was initially perceived as a very one-sided, teacher directed activity. Although several responders maintained this definition evidence supports a change in the definitions of many. Preservice teachers began to address the role of the teacher as one who provides assistance, assesses the zone of proximal development of the learner, provides social interaction and collaborates in learning tasks. This reconceptualization is correlated with the principles of cultural historical activity theory instantiated in the CI-2800 course.

Preschool Software: Developmentally Appropriate or Marketing Ploy?

Dr. Joan Livingston Prouty, Dept. of Language, Literacy and Special Populations, Sam Houston State University, USA  
edu_ilp@shsu.edu

Dr. Robin McGrew-Zoubi, Dept. of Curriculum and Instruction, Sam Houston State University, USA  
edu_rmz@shsu.edu

Abstract

This paper describes a study of software targeted to preschool children. Preservice teachers observed young children at work, reviewed the literature available on computers and young children, and interviewed early childhood and technology teachers, childcare providers, and parents regarding their beliefs about the appropriateness of computers with young children. Analysis is still in progress regarding specific software packages and their alignment with developmental benchmarks. Observations and interviews also focused on emerging gender stereotypes among young children.

Introduction

For a technology project in an elementary teacher education program at a mid-size university in the southwest preservice teachers investigated young children, three years old through Kindergarten age, and their use of the computer. Those working towards an early childhood endorsement or a reading/language arts specialization gathered data over two semesters for the teacher research project. The research question follow:

Questions:

The teacher researchers asked three questions for this project:

1. What are considered the major benchmarks of early childhood development according to teachers, childcare providers, parents, and experts in early childhood education?
2. Does computer software offer young children developmentally appropriate interactions?
3. What behaviors can be documented as young children interact with the computer? Are gender-based stereotypes evident at this age relevant to computer use?

Methodology/Investigation

Interviews with certified and non-certified teachers and specialists in early childhood, math, and science, was well as interviews with parents offered a large body of anecdotal information. Areas of inquiry included developmental benchmarks in young children, developmentally appropriate activities, gender preferences, time at the computer, and opinions and views about the software marketed for use with young children. In addition, preservice teacher researchers conducted a review of the literature on young children and computer usage and reviewed the NAEYC position statement entitled, Technology and Young Children—Ages Three through Eight. They also gathered over 120 hours of observational data of young children at the computer in a variety of educational settings, public and private.
Analyzing the anecdotal data from observations and interviews as well as data from the literature review, the preservice teachers constructed a rubric that included the constructs found in their collected data—age appropriate activities and abilities, preferences or interactions that appeared gender based, computer time, language interactions at the computer, and software characteristics. In addition, the commonalities among interview respondents were examined and summarized, noting similarities or discrepant information with the literature review.

Findings

Benchmarks for Early Childhood Development

Particular agreement among all respondents and the literature emphasized children's need for physical movement in daily activities. Respondents and the literature information emphasized that in physical actions, young children move through age appropriate skill development of fine motor, gross motor, social, and language abilities (Haugland 1996). Also, the development of self-identity and self-esteem at this young age were deemed important.

The characteristics by age in the development of young children have been well-documented and discussed in the literature. The chart on the following page illustrates some of the most common descriptors by age (NAEYC 1996).

The literature review and the degreed specialists had similar views about the benefits of monitored computer use for young children. Computer use should extend the child's learning and offer potential for growth in self-esteem, self-understanding, and problem solving (Samaras 1996). The common view in the literature, however, suggests a much shorter time frame for daily computer use than that discussed among the interviewees—20 minutes in the literature to 30-60 minutes by the interviewees.

Software and Developmentally Appropriate Interactions

Computer use in early childhood settings is both innovative and controversial. The two most common concerns are that computers are not developmentally appropriate for young children and that children working alone at a computer can become isolated and fail to develop social skills. At the same time there is agreement in the literature and among interviewees that computers offer important growth experiences for young children.

Dr. S, a technology specialist, states that “computers develop hand-eye coordination, abstract and cognitive thinking, problems solving, and exposure to vast information.”

According to daycare provider, Ms. L, “Very young children have shown comfort and confidence using software. No longer do we need to ask whether the use of technology is developmentally appropriate.”

“Computers should not take the place of experience, adult supervision is required, children should balance computer use with activities that use their five senses,

Behaviors of Children Working with Computers

Observations of young children at the computer show a variety of interactions. In many situations, children worked amiably. At other times, the observed children worked at the computer in harmonious partnerships. At other times, observations showed conflict between partners, mostly stemming

</table>
mouse. In one observation, a five year old girl sat quietly in tolerance of the short-term partnership formed for a computer task until completion and then both boy and girl quickly dispersed to their gender groups. In boy/girl partnerships, observers noted cordial and conflicting partnerships. In some situations, the girl would defer to the boys leadership throughout the computer activity.

**Emerging Gender Stereotypes**

The existence of gender preferences in young children generated the most discrepant positions among the interviewees. Some see few if any differences between young girls and boys in behavior, play, or choices. Some see differences attributed to societal influences. And, some respondents describe brain differences.

While working in a threesome (two boys and a girl) on a computer lesson, the boys stated, "Boys should be in charge because they work faster." Towards the end of the program being used there was a game format that the boys were interested in. After some patient waiting, the girl insisted that it was her turn at the keyboard. She went carefully through the remainder of the program and the teacher called the students back to a group activity with the group never getting to the game at the end. The girl walked away with a big grin.

The literature supports the view that in early childhood, there are few differences between genders in overall mental and motor development or specific areas of ability (Woolfolk 1998). Most research findings also agree that both boys and girls share an equal interest in computers at an early age. There does appear to be agreement that after approximately six years old, girls do not choose the computer as often as boys ( ).

Factors that appear to give boys the advantage when it comes to computer technology include 1) the software is often developed by males for males, 2) the boys' use of computer games outside of the classroom, 3) girls' deference to the boys during technology based collaborative learning situations, 4) and the message girls receive that computer sciences and related fields are for boys (Aldridge 1999 ).

In one review, 36 software titles were reported for girls out of the thousands on the market, and none of those offered any appropriate math or science instruction (Aldridge 1999).

To promote girls' involvement in technology, Aldridge (1999) suggests nine areas of focus.
- provide girls the opportunities for play and open-ended exploration on the computer,
- set rules for coed groups to ensure girls get equal opportunities to perform the higher status computer based tasks,
- expose students to female role models,
- give girls responsibilities for technology related situations,
- make sure that technology integrated lessons meet girls' social learning preferences,
- educate parents about the need to keep girls involved in technology,
- design lessons that challenge girls to think beyond the traditional language arts and into the domains of math and science,
- evaluate software and websites for appeal to girls, and
- involve girls in technology while they are still young.

INSTRUCTIONAL SOFTWARE EVALUATION CRITERIA
USED BY THE TEACHERS:
IMPLICATIONS FROM THEORY TO PRACTICE

M ge N ANC I
Basic Education Program Coordination Council
Ministry of National Education
Milli E itim Bakanl K at1 Blok:B
Bakanl klar, Ankara, TURKEY
mnisanci@meb.gov.tr

Abstract: This study examines the perception of basic education school teachers on the theoretically developed educational software evaluation criteria from the viewpoint of actual users. Data was collected through structured interviews, group discussions and participant observation. The findings indicate that instructional adequacy is the most important criterion both from the theoretical and from the practical perspective.

Background

The age of technology carries with itself several requirements for all educational institutions to respond in order to keep up with it. On the other hand, evaluation of educational technology programs has its place as a particularly hard task among others. As there is an increase in the number of countries making efficient use of technology and developing technology plans and strategies to the aim of improving the quality of education and learning achievement, there rises the need for understanding the impact of technology on improving the student achievement.

The Ministry of National Education of the Republic of Turkey (MONE), like all other educational institutions, face the necessity of preparing students for the 21st century. Towards this objective, the Ministry has initiated a reform program, first step of which has been to extend the period of basic education from five to eight years. This reform program was legalized through the passage of the Basic Education Law No.4306 in 1997, which also enacted several additional revenues to finance the Government's Basic Education Program.

The Basic Education Program is the Government's action program to apply its new basic education strategy, the objectives of which are (a) to achieve universal coverage in an expanded eight-year basic education cycle, (b) to improve the quality of basic education, and (c) to make basic education schools a learning source for the community. The Program aims to achieve these objectives through (a) expanding the capacity of basic education schools throughout the country, (b) facilitating school attendance of children who are least likely to attend school, (c) reducing classroom overcrowding and double shifting, (d) improving training and incentives for teachers, (e) improving the supply of educational materials to basic education schools, (f) introducing computer-aided learning, and (g) increasing parental and community involvement in schools (World Bank, 1998).

Total estimated cost of this program is USD 11.2 billion for a total of three years. The aforementioned revenues would finance approximately 90% of the Program, and to respond to the remaining, a partnership has been established with the World Bank, which has mainly focused on the qualitative part of the Program. USD 300 million loan was received from the World Bank to finance the first phase of the whole Basic Education Program, which consists of renovation, rehabilitation and construction of additional facilities for 340 basic education schools in rural and slum areas, provision of instructional materials, textbooks, and stationary to those students in rural schools, and to provision of 2828 IT Rooms in 2451 basic education schools throughout the country. These 2451 schools have been selected from all provinces on the basis of at least two schools from each sub-province. The scope of the IT Component of the Basic Education Program will be expanded in the second and third phases to cover approximately 15,000 basic education schools located in Turkey.

To the aim of improving the quality of education, the Ministry of National Education has intended to provide all basic education schools with IT Rooms where children will become computer literate and work with computers to support their education (MONE, 1999). Since the objective is to put the technology into the use in all basic education schools, the IT Rooms have been designed to have, besides computers, overhead projectors
and some other technologies. In order to enable an efficient and full use of these technological equipment by the students and teachers, the Ministry has also aimed at providing all instructional materials to these schools, ranging from transparencies, educational video tapes, handbooks for teachers, and multimedia instructional software.

Amongst the Ministry’s endeavor to create an effective learning environment for teachers and students, the provision of multimedia instructional software has had a very important place, since acquisition of software needs a very detailed examination and evaluation of the software submitted. The Ministry, as for the procurement of computer hardware and other technological equipment, has held an international competitive bidding for the procurement of multimedia instructional software. The preparation of the bidding documents, particularly of the technical specifications, has been done through a hard process, on the basis of a thorough literature review. The technical specifications, prepared in coordination with the specialists, have consisted of a detailed evaluation criteria based on national and international literature and applications, to be used for the procurement of educational software including multimedia instructional software in several subject areas between 1st-8th grades (English, German, French, Turkish, Science, Social Sciences, and Mathematics), electronic references, and educational games.

The criteria prepared by the MONE is based on four main areas; namely, (1) curriculum adequacy, (2) instructional adequacy, (3) programming adequacy, and (4) cosmetic adequacy. There are several items under each title, which are clearly defined and scored accordingly. The essential items within the criteria have consisted of consistency with the curriculum, adequacy to the pedagogical level of the students, ease of use, use of colors, etc., among which the consistency with the curriculum has been the primary one: Any software which could not respond to this item would not be taken to further evaluation.

Following the bid opening, the Ministry of National Education has established committees for technical evaluation of the multimedia instructional software submitted to the bidding. The committees consisted of subject area teachers who were currently working in the basic educational schools, subject area teachers who were currently working for the Board of Education of the MONE (a Board responsible for evaluating and approving any kind of instructional material to be utilized in primary and secondary education level), computer teachers, Turkish language teachers, and pedagogues. The committees have reviewed, evaluated, and scored accordingly a total of 230 instructional software within 6-month period. This period has also covered a fifteen-day basic training on multimedia instructional software evaluation. Those teachers participated in the technical evaluation committees were, then, asked for evaluating the criteria on which the technical evaluation has been based, and for providing recommendations from the perspective of practicing teachers.

The Study

The purpose of this study is to explore the applicability of the instructional software evaluation criteria developed for the acquisition of Multimedia Instructional Software by the Turkish Ministry of National Education. The study focuses on what teachers who have actively participated in the evaluation process have found most practical/feasible/applicable and what have found unnecessary or to-be-modified among those criteria developed on the basis of literature and theory.

For instructional software evaluation, there has been a crescent need for qualified human resources required, towards the provision of an efficient learning environment and the improvement of learning quality and achievement. This is also the case for Turkey. Besides, Turkey do not have a specific research institution specialized on software development or evaluation process. However, it is possible to obtain information from various researches on in-class use of technology (U.S. Department of Education, 1988) and other studies conducted by private software evaluation companies (Children Software Review, 1995). Among the features of a good instructional software, articles, dominantly, speaks of motivation, user control, Internet access, timely and efficient feedback, pedagogical adequacy, interactivity and instructional content (Hannefin & Pack, 1988; Alessi & Trollip, 1991; Comer & Geissler, 1998; Baumgartner & Payr, 1996; Persichitte, 1995; Caftori & Paprzcki, 1997; Abramson, 1998). Notwithstanding, the researches in this field, also forewarn the researchers about the application of a social science approach to the evaluation of multimedia products (Baumgartner & Payr, 1996; Reeves, 1993). Thus, it is essential to know how the literature-based educational software evaluation criteria differ from any other software evaluation criteria developed considering teaching experience and application of utmost importance and what the impact of such criteria on output is.

Instructional software evaluation criteria observed during the literature review have focused on the importance of instructional quality, which is one of the most significant among the Ministry’s evaluation criteria.
The criteria observed have foreseen to support the instruction process through the use of several instructional strategies where computer use has the central role, via following such basic steps as stimuli, guidance, drill and practice, and assessment (Abramson, 1998).

Other essential issues emphasized in the literature, besides instructional content, have consisted of efficient and proper use of computers through the aim of related instructional objectives, being free of technical errors, and use of accurate engineering processes (Persichitte, 1995).

Some researches conducted as to the instructional software evaluation have been based on applying a supervision mechanism to some extent for the use of instructional software. Another relevant issue has been that some instructional software labeled as instructional or educational may not be instructional or educational at all, and those software may not serve to instructional or educational objectives. Hence, these researches point out the problem of evaluation and supervision, two important criteria in the use of instructional software. This brings another question: the necessity for taking into consideration some other criteria to enable the teacher to evaluate and supervise student use and achievement, along with student control (Caftori & Paprzcki, 1997).

Another problem taken into consideration in the researches concerned has been that the instructional software evaluation processes have not included professionals specialized on pedagogy. Similarly, those researches, which have revealed the problems encountered as to the instructional software evaluation methods, have recommended a social sciences approach to software evaluation process in order to overcome these problems (Baumgartner & Payr, 1996).

In view of these studies and researches, this study lays open to view the instructional software evaluation criteria prepared and utilized by the Ministry of National Education for the acquisition of off-the-shelf instructional software, through making use of qualitative research method. Information has been obtained from a group of those teachers participated in software evaluation process through interviews and open-ended questions. The study has also employed a variety of data collection methods ranging from documentary evidences to interpretation of the comments of the senior staff of the Ministry who are a part of the Ministry’s education policy. Data analysis method used in this study consists of data examination, data reduction, data display, and finally conclusion drawing from specific to a more generalized (Miles & Huberman, 1994).

Results

As stated before, participants of this study are those teachers participated in the Ministry’s multimedia instructional software procurement evaluation process. 10 volunteer participants were observed from the beginning of the evaluation process. Besides these observations, 10 participant teachers were asked to respond, in written, to four open-ended questions at the end of the evaluation. Responses to these questions have shown certain emphasis on certain issues as to the instructional software evaluation.

Responses to the first question, which is for determining the conditions, as a teacher, under which instructional software may be used, have pointed out that necessary physical conditions and hardware. Three of the participants have stated that it is essential to provide a computer per student for an efficient implementation of technology assisted instruction. Merely two of the participants have emphasized a re-arrangement of the curriculum, and an effective time management for technology assisted instruction. Quality of the instructional software, amount and variety of the instructional software to be used, and provision of in-service training to teachers on the use of instructional software to support educational activities are the factors disregarded by the participants.

The second question is related to criteria, to which instructional software has to respond, to be utilized for educational purposes. Participants responses to this question have concentrated on the criterion of being consistent with and supportive of the curriculum. The second factor mentioned has been that an effective instructional software should include examples from real life and simulations of abstract concepts in real life to allow the students these concepts with their actual lives. The criteria considered as having secondary importance have been the variety and number of exercises, aspect of developing students creativity and critical thinking capacity, presentation of accurate information, being free from scientific errors, individualizing learning, being in accordance with the pedagogical level of students, and being enriched through the use of a variety of sound effects, images, videos and animations. Content-related richness, motivation and technical features have only been emphasized by two participants.

The shortcomings observed in the evaluation process of the instructional software submitted for the Ministry’s procurement process have included, primarily, consistency with the curriculum, being supportive to
the curriculum, proper use of Turkish language, proper use of audio-visual effects in required amount, and consistency with the pedagogical level of users. It has been stated that software's being free of technical errors shall prevent students' disappointment and losing their motivation. It has also been emphasized that informing students of the objectives before the lesson shall have a positive impact on learning. In view of the fact that the participants have not mentioned about the provision of examples from real life and the use of effective simulations, which have been emphasized for the second question, it has been considered that the software submitted to the Ministry have responded well to these criteria.

The last question asked was related to the issues to be taken into consideration in the future phases of instructional software procurement and technology assisted instruction. Two answers to this question were emphasized much. The criterion of consistency with the pedagogical level of students has also been of utmost importance for this question. Another significant issue underlined by the participants has been the formal measures to be taken at the senior level and circulation or regulations to be issued by the Ministry. These participants have stated that the central Ministry should take necessary measures to ensure the efficient use of IT Rooms. Three of the participants have pointed out the necessity of strengthening local software production sector, supporting an increase in the number of software companies, and accordingly the number of software in the market, and ensuring competition among the software market. Issues having secondary importance have been stated as taking into consideration national conditions for software production, and as preparing the technical specification in more detail. Some participants have recommended as essential as having modern and contemporary content, ensuring interactivity with the student, and providing teacher training on the use of instructional software. Only one participant has emphasized the importance of having students' views and comments during the software production and development process, since they are the actual users of the software. Another participant underlined the necessity of having a pilot application for efficient use of such a large-scale project.

Taking into consideration the socio-economic status of the participants and the schools where they were working, it has been observed that these participant teachers have been working in those schools attended by lower-middle-class children, and that, accordingly, they have not been familiar with technological applications. Hence, while participant teachers have been responding well to the efforts for technology assisted instruction, according to them, the provision of physical conditions and necessary hardware are the primary criteria for using technology in educational activities since they have had no opportunity for application. In parallel, participant teachers have stated that responsibility of expansion and of efficient implementation of computer literacy and technology assisted instruction has been of the Ministry, and emphasized the importance of teacher training and necessary formal measures for effective use of technology in education.

When we look at the Ministry's part, we see that the most essential criterion of an instructional software from the perspective of the senior staff of the Ministry has been the instructional content. Consistency with the curriculum, and at least being supportive of the curriculum, is of utmost importance for the central Ministry. The second important factor for the Ministry is the consistency with the national values of Turkish culture and presenting no deviation from the constitution of the Republic of Turkey. The written content and all other images, pictures and animation should also be respectful to these criteria. From the interviews, it has been seen that the senior Ministry staff considers teachers as the most essential factors and, believes in the importance of teacher training for an efficient implementation of technology assisted education. The provision of physical facilities and necessary hardware is of secondary importance to the Ministry because the Ministry assures that all physical conditions can be provided with no problem.

Conclusion

Those issues, received by the participant teachers both through observations and interviews, show no major deviation either from the literature or from the criteria prepared by the Ministry based on the literature. As stated in the literature, the participant teachers have emphasized most the importance of preventing the instructional and educational nature of the instructional software, of being supportive to the curriculum, of ensuring interactivity with the student, of motivating students, of reinforcing the students through the use of drills and exercises, and of having simulations to present abstract concepts to students.

Acknowledgements

I would like to express my sincere gratitude to Assist. Prof. Soner Yildirim of the Middle East Technical University who supported and guided me during this study. I am also thankful to the participant teachers in the evaluation committees, and the senior staff of the Turkish Ministry of National Education, for all their help and support.
Correlations between Teacher Characteristics and Teacher Attitudes toward Multimedia Development among Teachers Utilizing the Multimedia Authoring Program, HyperStudio

Dorothy Sammons, College of Education, Idaho State University, USA, sammdott@isu.edu

A.W. Strickland, College of Education, Idaho State University, USA, strialbe@isu.edu

Abstract: This study examined possible correlations between certain teacher characteristics and teacher attitudes toward multimedia development among teacher creating multimedia projects in teacher-teams and with students, using HyperStudio. Information on personality type, age, gender, grade level, years of teaching, computer experience, and self-reported skill levels was collected from 123 teachers participating in a federally funded teacher training grant. This information was correlated with four separate constructs concerning teacher perceptions of the multimedia development process for both teacher-created and student-created projects. Analysis found few significant correlations between the attitude constructs and teacher characteristics. Only self-reported skill levels were consistently and positively correlated with teacher attitudes toward multimedia development. The conclusion is drawn that confidence in one's ability to utilize the software and hardware necessary to create self-authored multimedia projects is the primary factor in predicting attitudes and perceptions of multimedia development. It is suggested that such confidence can be fostered by proper training.

Introduction

This study (Sammons, 1999) proposed to examine the possible correlation between teacher characteristics – including personality type, demographics, self-reported computer skills, and computer experience in the classroom – with teacher attitudes and perceptions of self-authored multimedia. It has been suggested that integration of self-authored multimedia into the classroom will affect both student attitudes and student achievement, as students engage a subject by writing, recording, and illustrating in multimedia computer formats (Turner and Dipinto, 1992; Ayersman, 1996; Lachs and William, 1998). At least one study also suggests that the introduction of self-authored multimedia will influence teaching methods, with teachers working collaboratively as facilitators and mediators, with the students (Berg et al., 1998).

Subjects for this study were a group of more than 240 teachers who were participating in a federally funded Technology Innovation Challenge Grant obtained by the Blackfoot, Idaho, School District. The Challenge Grant has, as one of its goals, the training of teachers in the creation and integration of self-authored multimedia. The initial group of teachers represented teams from nearly 40 school districts within Idaho. Each team attended an intensive four-day training session in multimedia development in the summer of 1998. This training included sessions on flowcharting, storyboarding, authoring using HyperStudio software, as well as on using digital cameras, scanners, and image manipulation software.

Four attitude constructs were identified for this study; each of the four constructs were measured by means of an attitude survey distributed to the teams in the spring of 1999. These four constructs were (1) teachers’ perceptions of the individual stages of multimedia development, based upon their development of multimedia projects within their teams; (2) teachers’ perceptions of the individual stages of multimedia development, based on their integration of self-authored multimedia into their classrooms for student-created projects; (3) teachers’ attitudes toward the cooperative activities required by the grant; and (4) teachers’ attitudes toward integrating self-authored multimedia into their curricula. Additional information was gathered on teachers’ gender, age, the number of years they have taught, the grade level they teach or area of responsibility within the school district, their previous computer and multimedia technology experience, and their self-reported skill level with the hardware and software provided by the grant. The
Myers-Briggs Personality Type Indicator (MBTI) was used to determine a personality type for each respondent. Each of the four attitude constructs were correlated with each of the demographic and computer experience variables.

Previous studies (Clark and Wheeler, 1994; Katch & Francis, 1995; Katz, 1992; Smith et al., 1995) have examined possible relationships between personality types and computer aptitude. Although none of these studies indicated that a certain personality type could be predicted to adopt computer technology more readily than others, Smith (et al., 1995) noted a tendency for Introverted/Sensing types to have more positive attitudes toward computer technology than other types. Clark and Wheeler (1994) noted a tendency, which was not statistically significant, for Judging types to achieve higher grades than Perceiving types on computer programming. They also noted that Sensing types had higher programming scores than did Intuiting types. The results of these studies encouraged us to examine whether personality types, as indicated by the MBTI, might be a factor in teacher attitudes toward self-authored multimedia programs, such as HyperStudio, and the development of multimedia projects.

Limitations of the Study

Because the study population was not selected at random, the results of this study cannot be taken as representative of the general teaching population nor even of teachers in Idaho. The study is also limited in that it does not account for every possible variable which might affect teacher attitudes toward multimedia development. Other factors which are not measured here might include support (or lack of support) for multimedia development from administrators and colleagues, personal and professional time available to development multimedia skills, individual cognitive styles, individual teaching styles, and the teachers' interactions with students.

However, by using grant participants as the study population, some external factors have been controlled. For example, the uniform nature and timing of the training provided by the grant lessens possible differences in basic skill levels or available technology among the participants. Each grant trainee was given the same suite of hardware and software, and each participated in one of six identical, week-long training sessions. Some participants may have greater skills levels, of course, but questionnaires during the first day of each session indicated that a majority of grant participants were completely novice to multimedia development and to HyperStudio in particular.

Another limitation of this study stems from the delivery and administration of the instruments. Because both the MBTI and the grant-created questionnaire were self-administered in the field, grant staff had little control over the timing, sequence, or environment of administration. A final limitation concerns the response rate. Although 244 MBTIs and surveys were sent to grant participants, only 117 MBTIs and 123 inventories were returned, a response rate of slightly less than 50%. The respondents are in some sense self-selecting and may not accurately represent the attitudes, perceptions, and experiences of the group as a whole. Thus, the conclusions of this research are confined to the respondents themselves. These conclusions are consistent with findings in previous research, however, (as summarized in Dupagne and Krendl, 1992, for example) and suggest possibilities for future research.

Method

Two instruments were distributed to the 244 teachers who participated in the grant's 1998 training sessions. The MBTI (Form G) and a grant-created inventory were sent to team leaders in the spring of 1999 with the request that the team leader oversee their completion and return. An equal number (123) of MBTIs and inventories were returned, but six of the MBTI forms were unsigned and could not be correlated with the inventory.

The grant-created inventory had six parts. The first part gathered demographic information from the participants: age, gender, years of teaching, primary responsibility in the school district, and grade level/subjects taught. Part II asked respondents to rate their skill level on each of the six computer skills relevant to multimedia development. Rating their skill level from Low to Advanced, participants were asked
to assess their capabilities with (1) their operating system, (2) Inspiration flowcharting software, (3) image manipulation software such as PhotoShop or PhotoStudio, (4) HyperStudio multimedia authoring software, (5) the digital camera, and (6) the scanner. All the software, the camera, and the scanner, as well as training in their use, were provided to the participants by the grant.

In Part III of the inventory, participants reported their experience with computer technology in their classroom (how many computers in the classroom, how many years had computers been used in their classrooms, how much time did students spend on computers at school) and their experience with multimedia authoring software. More than two-thirds of the respondents indicated that the grant training was their first experience with HyperStudio. In Part IV of the inventory, respondents were asked to assess the four stages of multimedia development as modeled for them during the summer training. First they were asked to rate brainstorming, flowcharting, storyboarding, and authoring (HyperStudio) as either simple/complex, easy/difficult/ and understandable/confusing based upon their development of multimedia projects within the teacher teams. Then they were asked to rate these four steps in terms of usefulness, effectiveness, and efficiency, based upon their integration of multimedia development into their classrooms for students projects. Part V of the inventory asked respondents to assess the cooperative nature of the teams’ activities as determined by their perception of the team’s collaboration on four team projects assigned by the grant. The final part of the inventory (Part VI) gathered information on the teachers’ attitudes toward the importance of integrating self-authored multimedia programs into their classroom curricula.

Following receipt of the MBTIs and inventories, all forms were hand-scored and entered into spreadsheets by grant staff. MBTI categories were determined following scoring procedures provided by Consulting Psychologist Press, the publishers by the MBTI. Scores for the inventory were combined by constructs. In some cases, scores were grouped or averaged so that meaningful categories of responses could be obtained which would be suitable for chi-square analysis. For example, teacher ages ranged from 26 to 58. These data were grouped as 20-29, 30-39, 40-49, and 50-59 so that only four age groupings would be used for correlational analysis. Similarly, scores for the perceptions of the four stages of multimedia (a possible range of 1-4 on each construct for each stage for an overall possible range of 12-48) were also averaged and categorized as values 1 through 4. This grouping of data assured that there would be sufficient cases in each possible cell to warrant chi-square analysis.

Results

Descriptive Statistics

Results of the MBTI show that all sixteen personality types are represented among the grant respondents. The personality type that is most frequent, the ISFJ type, is over-represented in the grant population when that population is compared to normed general population samples as reported by Myers and McCaulley (1985). The ISFJ type is characterized as organized, dependable, and responsible. “ISFJs often choose careers where they can combine their careful observation and their caring for people,” such as health professions or teaching (Myers and McCaulley, 1985, p. 27). Their tendency to be accurate and organized often places these individuals in supervisory roles. Previous studies (Smith et al., 1995; Clark and Wheeler, 1994) indicate that Introverted/Sensing and Judging types all display positive attitudes and aptitude for computer applications.

Demographic information from the respondents indicates that the typical respondent is between 40 and 49 years of age and is female. Most teachers in the group had ten or more years of teaching experience. While many of the respondents are elementary teachers (37.2%), most teachers among the respondents have middle or secondary schools responsibilities (48.9%, grades 6-12).

Descriptive statistics for each question, construct, and part of the grant inventory suggests that the teachers in this sample have a predominantly positive attitude toward the stages of multimedia development and toward integrating self-authored multimedia projects into their curricula. The respondents also had a strongly positive attitude toward the cooperative activities required by the grant and report that they too
would utilize a cooperative learning model in teaching or utilizing multimedia development in their classroom.

**Inferential Statistics**

Of all the correlations between the four attitude and perceptions constructs and the demographic and computer experience variables, most proved to be insignificant. There were, however, some very suggestive correlations which were found to be significant.

Teachers’ perceptions of multimedia development, based on their team projects, did not demonstrate any significant relationship with personality type, gender, age, number of years teaching or grade level taught. The Sensing/Intuition preference scale, which is one of four scales along which the MBTI types are defined, shows a slight but definite positive correlation with this construct. Teachers’ perception of multimedia development, based on their team projects, also correlated positively with self-reported levels of computer skills and with general computer technology experience.

Teachers’ perceptions of multimedia development, based on their team projects, did not demonstrate any significant relationship with personality type, gender, age, number of years teaching or grade level taught. Teachers’ perception of multimedia development, based on their team projects, also correlated positively with self-reported levels of computer skills and with general computer technology experience.

No relationship was found between any of the independent variables and the questions concerning attitudes toward the cooperative activities required by the grant.

Attitude toward integrating self-authored multimedia into classroom curricula did correlate slightly with number of years teaching and with general computer technology experience. Respondents who had taught ten years or less tended to demonstrate mixed responses to questions concerning multimedia integration. Respondents with 11 or more years of teaching tended to be more positive in their attitude. Respondents who had more experience integrating technology into their classrooms or who had more computers in their classrooms also tended to have more positive attitudes toward integration of self-authored multimedia. This construct also correlated positively with self-reported computer skill levels.

**Conclusions**

This study has provided evidence of positive correlations between teachers’ attitudes toward the stages of multimedia development and toward multimedia integration, and teacher characteristics such as years of teaching, grade level taught, general computer technology experience, and self-reported computer skill levels. Of these variables, only the last correlates strongly with all three measures of teacher attitudes toward multimedia development.

Dupagne and Krendl (1992), in a summary of literature, found that most studies reported a positive correlation between attitude and experience. They also found that factors which negatively influence attitude include inadequate training. Cate and McNaull (1993) also found that level of training significantly affects attitude toward computer technology. Marcinkiewicz (1994, 1996) went beyond a simple correlation between training and attitude to infer that training fostered feelings of self-efficacy, and it was the sense of self-efficacy that improved attitude and performance. The results published here (also see Sammons 1999) support these previous studies. The strongest correlations occur between self-reported computer skills and attitudes toward multimedia development and integration. A majority of teachers rated their skill level as High or Advanced in all designated computer skills, except flowcharting software (Sammons 1999, Table 11). A majority of teachers also reported that they had less than a year’s experience with HyperStudio and that they had learned multimedia development primarily through the grant training. How then did these teachers come to feel so comfortable with the different hardware and software necessary to author multimedia projects on their own and with students? It seems obvious that the answer to this question is: the training provided by the grant. Therefore, a logical inference is that positive attitudes toward
multimedia development and integration can be fostered by increasing practitioners' confidence in their ability to use the necessary programs and equipment. This confidence is increased by appropriate training.

Abstract: According to Shaw (1998) in his Report to the President on the Use of Technology to Strengthen K-12 Education in the United States, "a large scale program of rigorous, systematic research on . . . educational technology . . . will ultimately prove necessary to ensure both the efficacy and cost-effectiveness of technology use within our nation's K-12 ."

Introduction

The Teacher Education Reform Movement has been at the forefront of debate in colleges of education for many years, and questions about how best to integrate technology into teacher education programs are often at the center of this debate. Recommendations range from efforts to convince student teachers to use e-mail to programs designed to infuse
technology into every aspect of the teacher education curriculum. E-mail, listservs, and electronic dialogue journals are a few of the recent innovations tried by teacher education faculty in attempts to combat the isolation that preservice teachers often feel. Virtual workshops, out-of-field certification programs, and add-on technology courses have all been implemented with varying degrees of success. Finally, plans to integrate technology throughout the teacher education curriculum have been reported in increasing numbers over the past few years (Drazdowski, 1998; Parker, 1994; Shrum, 1998).

The efficacy of many of these efforts has been called into question. According to Shaw (1998) in his Report to the President on the Use of Technology to Strengthen K-12 Education in the United States, “a large scale program of rigorous, systematic research on . . . educational technology . . . will ultimately prove necessary to ensure both the efficacy and cost-effectiveness of technology use within our nation’s K-12 schools” (p. 115). In spite of these reservations, Shaw warns that “limitations in our current knowledge must not be used as an excuse to allow our schools to fall further behind other information-based institutions” (p. 125). Dusick (1998) and Roblyer (1998), among others, agree. While Dusick provides an egalitarian perspective arguing that computers must be placed in schools so that all students will have access (p. 12), Roblyer basically asserts that technology is here to stay whether or not we are prepared for it: “We have a multimedia future, the task at hand is to become fluent in our new native tongue” (p. 53).

An equally important task, as Shaw suggests, is the rigorous evaluation of the programs that we create in order to insure that our students achieve this fluency. However, it is difficult to assess and evaluate when there is no time to reflect, and as Blanchard (1999) claims, “try as we might, technology will not stand still long enough so it can be viewed and reviewed objectively” (p. 1). Since information technology is in constant flux, it becomes imperative to evaluate the use of educational technology as a process of change. A successful technology program is an adaptive one--one that adapts to individual as well as group differences in attitudes, skills, and availability, and one that can quickly accommodate emerging technologies.

This paper provides a brief overview of a technology program designed to integrate emerging technologies into the teacher preparation curriculum at Texas Woman's University and then details the associated research (evaluation) endeavor. The program described below, as well as the accompanying research, is supported by a U. S. Department of Education implementation grant entitled Preparing Tomorrow’s Teacher to Use Technology (http://www.pt3.org).

The LINKS Program (Overview)

The Learning and Integrating New Knowledge and Skills (LINKS) program is designed to support the use of emerging technologies by pre-service teachers within an integrated context of meaningful learning. This context is the field-based teacher education program administered by the PDC, and the technology indicators are tied to specific requirements within that program. The five learner-centered proficiencies tested by the Examination for the Certification of Teachers (ExCET), the Texas Essential Knowledge and Skills (TEKS), and the Professional Development Appraisal System (PDAS) provide the framework for the field-based teacher education curriculum as well as the associated
technology requirement indicators. Competencies related to technology foundations, accessibility, productivity, and integration are documented through course portfolios, classroom logs, desktop conferencing, and professor validation. Students are introduced to specific technology indicators via whole group orientation to the TechTrek Website completing much of their coursework online, and these technology indicators are summarized in the Technology Passport. The Technology Passport assists students, as well as their professors and mentors, in determining and documenting progress toward and mastery of the required technology proficiencies.

The three strands of the LINKS program address the technology needs of future teachers by supporting their development as well as the associated development of mentor teachers and university faculty. Students in professional coursework receive specific instruction on campus as Interns I, II, and Residents as well as extended experience in the field. In field settings, LINKS personnel train technology resource personnel and mentor teachers how best to assist Interns and Residents with technology competencies. Professors of courses leading to certification are provided with technology support and training in the LINKS Center technology lab on the TWU campus. Students may use both university and school technology resources and training opportunities to advance their technology competencies.

The Research (Purpose and Instruments)

The LINKS Program research effort provides for the assessment of individual attitudes and competencies of pre-service teachers, mentor teachers, and instructors. These assessments, in turn, help program developers to refine the four cornerstones of the TechTrek program--foundations, connectivity, productivity, and integration.

Six instruments will be used during the course of this research in order to gather quantitative and qualitative data. These six instruments are (a) the Basic Technology Competencies for Educators (BTCE), (b) the Self-Evaluation Rubrics for Basic and Advanced Teacher Computer Use, (c) the Technology Needs Assessment Survey, (d) the Stages of Concern Questionnaire (SoCQ), (e) the Levels of Use Interview (LoU), and (f) the Open-Ended Statements of Concern.

As previously suggested, a successful technology program is a flexible one; therefore, studying the process of change becomes imperative as pre-service teachers adopt and adapt to the use of educational technology to meet the needs of their 21st century students. Three of the instruments listed above address this need.

The SoCQ, the LoU, and the Open-Ended Statements of Concern are all products of the Concerns-Based Adoption Model (CBAM) Project of the Research and Development Center for Teacher Education, University of Texas at Austin, and have been heavily used in the change literature (Fullan & Stiegelbauer, 1991; Fullan, 1993a; Fullan, 1993b, Hord et al, 1987). The CBAM accepts that change is a process and that the successful adoption of any innovation (in this case educational technology) depends on the attitudes, preceptions, and efforts of the individuals who are expected to use the innovation.

All of the instruments used in this study except the Levels of Use Interview will be administered electronically. Quantitative data will be imported into SPSS for analysis, and NUDIST will be used to facilitate the analysis of qualitative data.

The Basic Technology Competencies for Educators (BTCE)
The BTCE is a self-report summated rating scale which is divided into nine competency domains: (a) basic computer operations skills; (b) setup, maintenance, and troubleshooting of equipment; (c) word processing; (d) spreadsheets; (e) database; (f) networking; (g) telecommunication; (h) media communication; and (i) social, legal, and ethical issues (Flowers, 1997). Within each domain five items are given. The fifth item is a summary for that dimension. This instrument measures basic technology competencies (foundations) and will be used as a repeated measure to evaluate participant and group progress.

Self-Evaluation Rubrics for Basic and Advanced Teacher Computer Use

The Self-Evaluation Rubrics for Basic and Advanced Teacher Computer Use involves seven dimensions that address basic computer use and ten dimensions that address Internet use. Each dimension includes four levels of performance. These dimensions variously represent basic teacher computer use (productivity), Internet use (connectivity), and advanced teacher computer use (integration). These rubrics will be repeated and used to assess progress. They can be found in An Educator's Guide to Evaluating the Use of Technology in Schools and Classrooms (USDE, OERI, 1998), and permission to freely copy and use these rubrics is given.

The Technology Needs Assessment Survey

The Technology Needs Assessment Survey is also available from An Educator’s Guide to Evaluating the Use of Technology in Schools and Classrooms. It encompasses one hundred items divided into four areas: (a) personal technology background, (b) staff centered technology, (c) student centered technology, and (d) staff development activities. This measure will be administered only once with each group of participants.

The Stages of Concern Questionnaire (SoCQ)

The Stages of Concern Questionnaire (SoCQ) consists of 35 items that use a seven point Likert response form. Analysis of the data results in a profile of the subject’s varying intensity of concern at seven distinct stages: (0) Awareness, (1) Informational, (2) Personal, (3) Management, (4) Consequence, (5) Collaboration, and (6) Refocusing (Hall, Wallace, & Gossett, 1973). These seven stages of concern reflect broader categories of self, task, and impact concerns, and the typical progression for the adoption of any innovation is from more intense informational and personal concerns (self), to more intense management concerns (task), and finally, to more intense consequence and collaboration concerns (impact). The individual is most vulnerable, and thus the innovation at greatest risk of failing, when personal concerns are intense. This questionnaire will be administered repeatedly in order to create individual and group profiles and evaluate progress toward innovation adoption.

The Levels of Use (LoU)
The Level of Use (LoU) data are collected by individual focused interviews. Analysis of the interview data results in the assignment of a Level of Use rating for each subject. These ratings are closely related to the seven stages of concern. There are three levels of non-use—Level 0 (Non-Use), Level I (Orientation), and Level II (Preparation)—and five levels of use—Level III (Mechanical Use), Level IVA (Routine), Level IVB (Refinement), Level V (Integration), and Level VI (Renewal). Again, the typical progression for most individuals who are non-users at the introduction of an innovation is from less sophisticated behaviors focused on learning how to use the innovation and/or how to more efficiently manage the innovation to more sophisticated behaviors that reflect a concern for the effects of the innovation on one's students. This interview will be conducted twice in order to describe any behavioral changes.

The Open-Ended Statements of Concern

The Open-Ended Statements of Concern is essentially a writing prompt that provides participants with the opportunity to describe their concerns. They are requested to respond to the following question: When you think about educational technology in the classroom, what are your concerns? Since the SoCQ provides information on the intensity of certain concerns but not on the nature of those concerns, this qualitative procedure is used to increase the investigators' depth of understanding about participants' concerns and will be administered along with the Stages of Concern Questionnaire.

Participants and Procedures

Participants will be the pre-service teachers enrolled in the normal curriculum of TWU's PDC as Interns or Residents, their mentor teachers in the field, and their University instructors (professors, graduate teaching assistants, adjuncts, and liaisons). All pre-service teachers will be expected to participate since self-evaluation and course evaluation are course requirements. Instructors from all parts of the campus who teach courses in the interdisciplinary program or in the education specialties and professional development sequence and all mentor teachers in the PDC’s 11 consortium school districts will be invited to participate in this research.

30-40 mentor teachers and 15-20 instructors will be recruited each semester beginning in Spring 2000. Over the 5-semester course of the Preparing Tomorrow's Teachers to Use Technology implementation grant, 150-200 mentor teachers and 75-100 instructors will be involved. Participants will receive whole group, small group, and one-on-one assistance with their technology needs. In addition to advancing their own technology skills, both mentors and instructors will acquire an increased awareness of state-mandated teacher competencies.

Pre-service Teachers
Pre-service teachers will complete four measures: (a) the Basic Technology Proficiencies for Pre-Service Teachers; (b) the Self-Evaluation Rubrics for Basic Teacher Computer Use, for Advanced Computer Use, and for Internet Use; (c) the Stages of Concern Questionnaire; and (d) the Open-Ended Statements of Concern. Students will complete all of these measures at the beginning of each semester as they progress through the field-based teacher education program (three semesters). They will also complete all measures at the end of their final semester, resulting in a total of four repeated measures for each student. Profiles will be developed and evaluated each semester, and those students with high anxiety profiles (i.e., intense Stage 2 Personal concerns) will be contacted and offered appropriate one-on-one interventions. The overall program will be adjusted based on the aggregated results of these analyses. At the end of the three-semester program, ANOVA will be used to assess the overall effectiveness of the program.

University Faculty

Instructors will complete the SoCQ and the Open-Ended Statements of Concern, and they will be interviewed concerning their LoU. The SoCQ and the Open-Ended Statements of Concern will be administered during whole group training sessions once at the beginning and once at the end of the semester, and the Levels of Use interviews will be scheduled during these whole group session.

Involved instructors will participate in five whole-group professional development sessions, and if they choose, additional one-on-one sessions which meet their individual needs can be scheduled. The initial whole-group session will consist of an introduction to the LINKS Program and thus to the high levels of technology proficiency expected of pre-service teachers. The second session will be an exploration of the Internet in general, and the final three sessions will cover the use of BLACKBOARD—the University’s Web-based course delivery template.

After initial data collection is complete, SoCQ profiles, LoU ratings, and Statements of Concern will all be reviewed in order to determine whether or not planned interventions are appropriate. After final data collection is complete, Wilcoxon Signed Ranks Tests will be run on the SoCQ and the LoU data in order to assess the practical and statistical significance of any changes. In addition, to the extent possible, these instructors will be followed for an additional semester to determine the scope of their use of the targetted innovation.

Mentor Teachers

Mentor teachers will complete all six measures. The procedures for collection and analysis of SoCQ, Open-Ended Statements of Concern, and LoU data will mirror those used with the instructors. In addition, mentors will complete both the Technology Needs Assessment (once) and The Self-Evaluation Rubrics (twice—once at the beginning and once at the end of the semester).

Mentor teachers will participate in six whole-group professional development sessions in which they will experience the four cornerstones of the LINKS Program—foundations, productivity, connectivity, and integration—via a WebQuest. Individual needs
identified by Stages of Concern profiles and Open-Ended Statements of Concern will be addressed as needed.

The data from the Technology Needs Assessment will be analyzed along with the initial data from the SoCQ profiles, the LoU interviews, and the Open-Ended Statements of Concern in order to determine whether or not planned interventions are appropriate. If necessary, the overall program will be adjusted based on the aggregated results of these analyses. After final data collection is complete, Wilcoxon Signed Ranks Tests will be run on the SoCQ data, the LoU data, and the Self-Evaluation Rubrics in order to assess the practical and statistical significance of any changes.

Significance

Concerns about individual attitudes and perceptions have been the focus of many recent research efforts. Medcalf-Davenport (1999) contends that pre-service teachers question the emphasis on technology integration instruction in their teacher preparation courses because they are often times not "exposed to the uses of any technology in the school classrooms as they observe and do field experience" (p. 1424). Medcalf-Davenport further contends that because of a lack of technology-trained faculty, many pre-service teachers do not have an opportunity to have teaching with technology modeled.

Pre-service teachers, in-service teachers, professors, instructors, and liaisons are busy people, and insufficient time is often cited as the reason for the slow integration of technology into the classroom or curriculum. When time is such a crucial element, interventions that do not address specific needs for specific groups of individuals fail. Each participant’s concerns and needs must be assessed and promptly addressed in order to make the change process successful. According to Hall and Hord (1987), “the first step...is to develop a picture of how each staff member, as an individual, experiences the change process. Only then is it appropriate to aggregate the individuals and plan the change process for all involved staff” (p. 10). This research endeavor attempts to insure that the changes proposed by the LINKS Project are successful.

Preservice Teachers' Perception of the Teachers' Role in the Classroom with Computers

Yu-mei Wang
College of Education
University of Guam, USA
ymwang@uog9.uog.edu

Abstract: This study investigated preservice teachers' perceptions of the teachers' role in the classroom with computers. The teachers' role was measured as teacher-centeredness and student-centeredness. The findings of the study showed that there was no significant difference between preservice teachers' perceptions of teacher-centered roles and their perceptions of student-centered roles in the classroom with computers. The preservice teachers perceived that they would likely to engage in teacher-centered activities and student-centered activities on an equal basis while teaching in classrooms with computers. Nevertheless, there was a significant difference between the preservice teachers' perceived teacher-centered computer use and the student-centered computer use. The preservice teachers would more likely to use the computer as a teacher-centered tool than as a student-centered tool.

Literature Review

In response to the challenge of the introduction of computers in educational settings, teacher education started to offer computer training courses to prepare preservice teachers for the successful use of technology in their future teaching practice. "College of education must have program requirements to insure adequate preparation for students to use the computer as a tool in their teaching" (Bitter, 1989; p. 34).

The successful use of technology in teaching practice, however, involves more than mastering computer skills. "Equally important are the beliefs and perceptions about computers in education that these future teachers take from their training" (Byrum & Cashman, 1993; p. 260).

Preservice teachers' beliefs and perceptions play a crucial role in shaping their teaching styles. Therefore, "understanding the belief structures of teachers and teacher candidates is essential to improving their professional preparation and teaching practices" (Pajares, 1992; p. 307). With computers becoming a part of the learning process in classroom settings, it is imperative to investigate preservice teachers' beliefs and perceptions of the teachers' role while teaching in the classroom with computers.

'The teachers' role' has been the major focus of the on-going discussion whether the computer could have an impact upon schools. Numerous reports recounted the failure for technology to bring changes to our educational system. "Computers by themselves did not lead to the restructuring of education" (Riel, 1980; p. 180). There has been an increasing awareness that "teachers' use of technology often forces it into traditional teaching paradigms that have
existed for decades" (Sprague, 1995; p. 52). To fulfill the potential of technology, there is a need to redefine the teachers' role and change existing teaching practice. "For computers to make a difference in how students experience schooling will require teachers and administrators to modify their concepts of appropriate and inappropriate teaching behaviors, to reprioritize the value of different types of instructional content, and to change habits and assumptions that guide their classroom and school management strategies (Becker, 1991; p. 8).

Teaching with computers requires a shift from the traditional teaching style. Computers changed the arrangement of classrooms (Chin & Hortin, 1993-94), social organization of student learning (Becker, 1985), and interactive patterns between teachers and students (Riel, 1989). Classrooms need to be arranged in a way so that students and teachers could move around for individual and group work. Computers facilitated more independent learning. Students assisted each other completing the learning task and solving problems collaboratively often with their teachers as partners. Students participated in the evaluation process and frequently evaluated each other's work. Teachers worked with individual students and small groups rather than directing the attention to the whole class. (Becker, 1985; Keirns, 1990; Riel, 1989; Sandholtz, 1990). "The direction of their change was toward child-centered rather than curriculum-centered instruction" (Dwyer, 1991; p. 50). The concurrent agreement is that the teachers' role has been shifted from an "information dispenser" to a "coach" (Sheingold & Hadley, 1990); from a "centralized authority" to a "decentralized facilitator" (Chin & Hortin, 1993-94), from a "sage on the stage" to a "guide at the side" (Cifuentes, 1997). "Technology forced a re-evaluation of the authoritative teacher role" (Chin & Hortin, 1993-94; p. 83).

This shift of the teachers' role has been a daunting task on the part of the teacher, which involves frustration and uneasiness at times. "In large part, teachers' uncertainty is based on lack of knowledge, but more significantly, on the fact that using computers will require some changes in the ways they've been teaching" (Preskill, 1988; p. 25). The shift of the teachers' role "brought deeply held beliefs about real schools into conflict with emergent awareness about instruction and learning" (Dwyer, Ringstaff, & Sandholtz, 1991; p. 50). Teachers had to confront their traditional beliefs about teaching and learning. As one teacher acknowledged: "As you work into using the computer in the classroom, you start questioning everything you have done in the past and wonder how you can adapt it to the computer. Then, you start questioning the whole concept of what you originally did" (Dwyer, Ringstaff, & Sandholtz, 1991; p. 50). Even with teachers who are willing to experiment with innovative technology. The change is slow, and sometimes includes temporary regression (Sandholtz, 1990; p. 35).

The discussion of the teachers' role shift has significant implication to teacher education. "The way that teachers teach is a product of their own schooling, training, and experiences as teachers" (Becker, 1991; p.8). It raises a key issue on how teacher education shall prepare preservice teachers for their future role teaching in the classroom with computers. "To realize any vision of smarter schooling by using technology, ...college of education must prepare teachers to use the technology...adequate teacher preparation is probably the most important determinant of success. (Hancock & Betts, 1994; p. 29). The challenge that faces
teacher education is to provide effective instructional technology (IT) training to preservice teachers so that they will develop appropriate teaching styles to function well while teaching with computers.

Up to date, research on preservice teachers in the field of educational computing primarily focused on their computer attitudes and computer competence (Beaver, 1990; Liu, 1990; Overbaugh & Reed, 1992; Reed & Overbaugh, 1993; Reed, Ervin, & Oughton, 1995; Savenye, 1993; Savenye, Davidson & Orr 1992). Nevertheless, it is imperative to investigate the beliefs and perceptions of preservice teachers in terms of the teacher's role in the classroom with computers. "There are good reasons why attempting to understand the beliefs of preservice teachers is essential to teacher education" (Pajares, 1992; p. 328). This study was designed to investigate preservice teachers' perceptions of the teachers' role in the classroom with computers.

The Purpose of the Study

This study investigated the following questions: (1) What are the preservice teachers' perceptions of the teachers' role in the classroom with computers? The preservice teachers' perception of the teachers' role is to be measured as teacher-centeredness and student-centeredness. (2) What are the preservice teachers' perceived computer use once placed in the classroom with computers? The preservice teachers' perceived computer use is to be measured as the teacher-centered computer use and the student-centered computer use. (3) Do the preservice teachers' perceptions of the teachers' role in classrooms with computers differ from their perceptions of the computer use in terms of teacher-centeredness and student-centeredness?

Method

Sample

This study was conducted at a public university in a territory of the United States in the Pacific Rim. The sample for this study was all the preservice teachers (N=78) who had completed all their course work and were ready for student teaching in the Fall 1999. All the 78 students participated in the survey. Out of 78 questionnaires, four were deemed not usable because of missing items.

Instrument

The data collection instrument for this study was a survey questionnaire adapted from the one originally developed by Bichelmeyer, Reinhart and Monson at the Indiana University to measure teachers' beliefs about the teachers' role teaching with technology (1997). The survey questionnaire contains three sections; (1) demographic information; (2) preservice teachers' perception of the teachers' role in the classroom with computers; (3) preservice teachers' perceived teacher-centered computer use and student-centered computer use.
Section 1 contained six items collecting subjects' personal information: (1) gender; (2) major; (3) birth date; (4) number of years at the university; (5) years of computer experience; (6) grade levels likely to teach.

Section 2 included 12 items on a likert scale (1-5) measuring preservice teachers' perception of the teachers' role in the classroom with computers. Six items dealt with teacher-centeredness while the other six items student-centeredness. Teacher-centeredness defined the teachers' role primarily as (1) planning instructional activities for the whole class; (2) being the main directing force in conducting the class; (3) keeping order and quiet in the classroom; (4) presenting lectures; (5) attending the class as a whole; (6) being the main resource in the student learning process. Student-centeredness defined the teachers' role primarily as (1) collaborating with students in planning lesson; (2) providing individualized learning objectives; (3) using authentic assessment methods; (4) evaluating students on individual basis; (5) including students in the evaluation process; (6) creating student subgroups for class projects.

Section 3 collected data on preservice teachers' perception on how they will use computers specifically if once placed in the classroom with computers. Six items in this section were the teacher-centered computer use and six items were the student-centered computer use. The teacher-centered computer use was defined as teachers using computers to: (1) create instructional materials; (2) find resources; (3) communicate with others; (4) keep track of students' grades; (5) present information to the whole class; (6) provide computer enrichment activity. The student-centered computer use was defined as students using computers to (1) create learning resources; (2) find resources for learning activities; (3) communicate with others; (4) present information; (5) complete class projects; (6) engage in computer hands-on learning activities.

Data Analysis and Results

Data was analyzed by using SPSS (Statistical Package for Social Sciences).

(1) What are preservice teachers' perceptions of the teachers' role in the classroom with computers? Paired-sampled ttest was used to compare the means of preservice teachers' perceptions of the teacher-centered role and the student-centered role in the classroom with computers. The comparison showed that there was no significant difference (t=.48 p>.05) between preservice teachers' perceptions of the teacher-centered role (M=4.1227 S.D.=.598) and their perceptions of the student-centered role (M=4.0926 S.D.=.672).

(2) What are the preservice teachers' perceived computer uses? Means for the preservice teachers' perceived teacher-centered computer use and the student-centered computer use were compared. The comparison showed that there was a significant difference (t=9.7 p<.05) between preservice teachers' perceived teacher-centered computer uses (M=4.0137 S.D.=.677) and their perceived student-centered computer uses (M=3.3659 S.D.=.718).
Do preservice teachers' perception of the teachers' role in the classroom with computers differ from their perceptions of the specific computer use? Paired-sampled t test was used to compare the means of preservice teachers' perception of teachers' role in classrooms with computers and their perceived computer uses. The test showed that preservice teachers' perception of the teacher-centered role did not differ significantly from their perceived teacher-centered computer use (t=1.05 p>.05). Preservice teachers' perception of the student-centered role differed significantly from their perceived student-centered computer use (t=6.5 p=.000).

Discussion

There was no significant difference on preservice teachers' perceptions between the teacher-centered role and the student-centered role in the classroom with computers, which indicated that these future teachers would likely engage in teacher-centered activities and student-centered activities on an equal basis while teaching in the classroom with computers. The preservice teachers did not take an exclusive stance on the teachers' role in the classroom with computers leaning towards the teacher-centered role or the student-centered role. It appeared that the preservice teachers considered that both roles were important and the two roles were complementary rather than exclusive to each other.

However, when tested on their perceived computer use, these preservice teachers shifted to the teacher-centered computer use. The data indicated that these preservice teachers would more likely to use the computer as a teacher-centered tool than a student-centered tool, thus creating a discrepancy between the perception and the practice. This discrepancy might be due to the fact that these preservice teachers became uncertain of the teachers' role in terms of the specific computer use. "Since classroom use of computers ... is still a relatively new idea, preservice teachers do not have many models from which to base their ideas on how to use computers and other technologies in their own classrooms" (Poole & Simonson, 1996; p. 145).

The preservice teachers' perception of the computer use might reflect the IT training they have received in teacher education. Although these preservice teachers have completed university IT courses, their IT training courses might expose them to more teacher-centered computer uses than student-centered computer uses. The student-centered computer use requires different strategies including scheduling the computer use, utilizing different classroom management skills, designing curriculum-related activities, and developing evaluation methods accordingly. These preservice teachers might not be feeling comfortable using the computer as a student-centered tool since it required strategies they had not yet developed.

The findings of this study touched a fundamental issue on IT training in teacher education. For years, teacher education has been wrestling with the issue of what counts for an effective IT training. "The issue now is how to structure the computer experience to prepare teachers to use computers most effectively" (Dugdale, 1994; p. 250). Teacher education have since adopted a variety of IT training models from offering the computer core course to integrating
the computer training into methods courses. Each model contributes to the preparation of preservice teachers' use of technology (Wang, in press).

Nevertheless, "Few courses relate teachers' delivery styles to what types of materials and activities they select and it is even more difficult to find courses that are addressing teaching styles and how they impact the use and misuse of technology" (Flake & Molina, 1995; p. 337). Teaching styles is an neglected component in IT training. IT training courses should explore and foster appropriate teaching styles involving the use of technology and present examples and models of the student-centered computer use. It is helpful to make it explicit the distinction between the teacher-centered computer use and the student-centered computer use. Preservice teachers' perception of the teachers role can be shaped and changed via intervention. Stuhlmann, Taylor, & LaHaye (1995) found that preservice teachers changed their traditional perception of the teachers' role by participating an innovative technology project. One participating student observed: "I have never had a teacher, in all of my grammar and high school, who did not stand up in the front and talk. Ms. LaHaye (the school teacher involved with the project) is the only teacher I have seen that didn't do that. It's wonderful the way she just stands in the back or on the side and watches us work" (p. 275).

Preservice teachers' IT training should be grounded in practice. There is a sizable gap between the university classroom and the real world. Teacher education should make efforts to seek connections with the real world. "Most schools of education offer coursework intended to prepare their graduates for using information technologies. While these courses are having a positive impact on later classroom practice, seeing technology used in a few university courses is insufficient for preparing knowledgeable consumers of technology. Students must have many models of effective technology use" (Hunt, 1995).

Field experience offers such a connection and should be an integrated component of IT training courses. Parkinson (1998) suggested that IT training courses should be taught through university-based component and the school-based component. "It needs to be borne in mind that the influence and importance of the school-based component is beyond dispute..." (p. 69). Students perceived that observation and participation in technology use in real classroom settings played a strong role in preparing them for the computer use in teaching practice (Handler, 1993). Opportunities should be created for students to visit school computer labs, observe computer use in real classroom situations and collaborate with classroom teachers to implement ideas of integrating the computer into the curriculum. Dugdale (1994) described a successful computer course incorporating field experiences. Students were required to design curriculum unit integrating the computer and implement their projects in the real classroom setting. Both students and practicing teachers considered the experience worthwhile and valuable.

Conclusion

This research provides baseline data on preservice teachers' perception of the teachers' role in the classroom in the Information Age. Teachers often teach the way they were taught. The goal of teacher education is not simply to produce graduates to fill up the pool of the teaching profession, but to produce qualified graduates who can make an impact on the extant educational system. Teacher education needs to restructure IT courses, exposing preservice teachers to innovative models of using technology and grounding IT training in practice so that the future teachers can be equipped with appropriate teaching styles to function effectively in the classroom with computers. "Our challenge is to provide a clear vision of how computers and technology can transform classroom instruction" (Wetzel, 1993; p. 335).

Student Teachers' Perception and Practice of the Computer Use during the Practicum

Yu-mei Wang
College of Education
University of Guam
ymwang@uog9.uog.edu

Abstract: This study investigated the student teachers perception and practice regarding the computer use during the practicum in terms of their teaching styles. The student teachers' teaching styles were measured as teacher-centeredness and student-centeredness. The result of the study showed that there was no significant difference between student teachers' perceptions of teacher-centered roles and their perceptions of student-centered roles teaching in the classroom with computers. The student teachers indicated that they would engage teacher-centered activities and student-centered activities on an equal basis while teaching in classrooms with computers. Nevertheless, the test showed that there was a significant difference between the student teachers' teacher-centered computer use and their student-centered computer use during the practicum. The student teachers used the computer significantly more as a teacher-centered tool than a student-centered tool.

Literature Review

It is a long and complicated process to prepare prospective teachers using technology in their future teaching practice. For more than a decade, teacher education has been offering computer training courses in the hope that the newly graduates would be confident and competent computer users once they are on job. "To realize any vision of smarter schooling by using technology, college of education must prepare teachers to use the technology. Adequate teacher preparation is probably the most important determinant of success" (Hancock & Betts, 1994; p. 29). Nevertheless, research indicates that the computer use of the newly graduates was low. When the newly graduates did use computers, their use fell into the traditional teaching practice and related to low level of instructional activities (Novak & Knowles, 1991; Olive, 1994).

It is far from an adequate training by simply teaching prospective teachers computer skills. The study by Diem (1989) found that the prospective teachers seemed to have mastered the necessary technical skills, however, they had difficulties incorporating computers in instructional activities. "They could identify parts of the computer...However, they could not delineate how the computer fit into their subject matter content areas" (p. 35). Dunn and Ridgway's studies (1991a, 1991b) yielded the same result. They found that prospective teachers could not embrace the wide range of instructional uses of computers although the majority of them reported that they did not experience problems technically while using the computer.

In order to successfully integrate computers in the teaching practice, it is imperative that prospective teachers develop appropriate teaching styles where computers can fit in to impact
student learning. Researchers were concerned about the prospective teachers' perception of the role of the computer in the learning process. The prospective teachers during the practicum (Dunn & Ridgway, 1991a, 1991b) did not consider the computer's role as a one to develop students' higher order thinking skills as much as a one to develop students' computer skills and they adopted the Noah's Ark teaching style and would send students in pairs to get their "weekly dose of the computing" which were not related to their learning task.

Teaching with computers requires a shift from the traditional teaching style. Computers changed the arrangement of classrooms (Chin & Hortin, 1993-94), social organization of student learning (Becker, 1985), and interactive patterns between teachers and students (Riel, 1989). Classrooms need to be arranged in a way so that students and teachers could move around for individual and group work. Computers facilitated more independent learning. Students assisted each other completing the learning task and solving problems collaboratively often with their teachers as partners. Students participated in the evaluation process and frequently evaluated each other's work. Teachers worked with individual students and small groups rather than directing the attention to the whole class. (Becker, 1985; Keirns, 1990; Riel, 1989; Sandholtz, 1990). "The direction of their change was toward child-centered rather than curriculum-centered instruction" (Dwyer, 1991; p. 50).

Educators are aware that there is a need to redefine the teachers' role and revise extant teaching practice in order for computers to have an impact upon school curriculum. "Technology forced a re-evaluation of the authoritative teacher role" (Chin & Hortin, 1993-94; p. 83). Research found that technology-enriched classrooms tend to be more student-centered rather than teacher-centered. The concurrent agreement is that the teachers' role has been shifted from an "information dispenser" to a "coach" (Sheingold & Hadley, 1990); from a "centralized authority" to a "decentralized facilitator" (Chin & Hortin, 1993-94), and from a "sage on the stage" to a "guide at the side" (Cifuentes, 1997).

The discussion of the teachers' role shift has significant implication to teacher education. The instructional technology (IT) training in teacher education should reflect and lead the trend and edge in the field of educational computing. What are prospective teachers' perceptions of the teachers' role in the classroom with computers? How will they use computers when they are placed in the classroom with computers? The answers to these questions will help teacher education to adjust and improve their IT training courses accordingly.

Student teaching is a crucial period for education majors. Their experiences in this period help prepare their future teaching style. "It is in these experiences that education majors become acquainted with the realities of life in elementary and secondary classrooms, look for real-world connections to content presented in their university foundations and teaching methods classes, and develop their instructional and managerial skills" (Hunt, 1995; p. 37).

Research is scarce on student teachers in the field of educational computing. A few studies were conducted to examine this crucial period (Diem, 1989; Dunn & Ridgway, 1991a; 1991b; Downes, 1994; Wang & Holthaus, 1998-99). These studies mainly focused on student teachers' computer training adequacy and the frequency of their computer use during the practicum. While these research did attempt to investigate the pattern of the student teachers' computer use, the pattern was more often than not described by the types of software involved.
"Questions remain unanswered on the nature of student teachers' computer use" (Wang, 1999-2000). Up to date, no study has ever been conducted to evaluate the student teachers' perception of the teachers' role in the classroom with computers and their computer use in terms of teacher-centeredness and student-centeredness. This study was conducted to gain insight into student teachers' teaching style and their computer use during the practicum in terms of teacher-centeredness and student-centeredness.

The Purpose of the Study

This study investigated the following questions: (1) What are the student teachers' perceptions of the teachers' role in the classroom with computers? The student teachers' perception of the teachers' role is to be measured as teacher-centeredness and student-centeredness. (2) How did the student teachers use the computer during their practicum? The student teachers' computer use is to be measured as the teacher-centered computer use and the student-centered computer use. (3) Are there any differences between the student teachers' perception of the teachers' role and their practice of the computer use during the practicum?

Method

Sample

This setting for the study was at a public university in a territory of the United States in the Pacific Rim. The sample for this study was all the student teachers (N=48) who have completed student teaching in May 1999. A survey questionnaire was the data collection instrument for this study. The survey was adapted from the one originally developed by Bichelmeyer, Reinhart and Monson at the Indiana University to measure teachers' perceptions of the teachers' role in the classroom in the information age (1997). It contains three sections: (1) demographic information; (2) student teachers' perception of the teachers' role in the classroom with computers; (3) student teachers' computer use during the practicum.

Instrument

The data collection instrument for this study was a survey questionnaire adapted from the one originally developed by Bichelmeyer, Reinhart and Monson at the Indiana University to measure teachers' beliefs about the teachers' role teaching with technology. The survey questionnaire contains three sections; (1) Demographic Information; (2) Student Teachers' Perception of the Teachers' Role in the Classroom with Computers; (3) Student teachers' perceived teacher-centered computer use and student-centered computer use.

Section 1 contained six items collecting subjects' personal information (1) gender; (2) major; (3) birth date; (4) number of years at the university; (5) years of computer experience; (6) grade levels likely to teach.
Section 2 included 12 items on a likert scale (1-5 points) measuring student teachers' perceptions of the teachers' role in the classroom with computers. Six items dealt with teacher-centeredness while the other six items student-centeredness. Teacher-centeredness defined the teachers' role primarily as (1) planning instructional activities for the whole class; (2) being the main directing force in conducting the class; (3) keeping order and quiet in the classroom, (4) presenting lectures; (5) attending the class as a whole; (6) being the main resource in the student learning process. Student-centeredness defined teachers' role as (1) collaborating with students in planning lessons; (2) providing individualized learning objectives; (3) using authentic assessment methods; (4) evaluating students on individual basis; (5) including students in the evaluation process; and (6) creating student sub-groups for class projects.

Section 3 collected data on the student teachers' computer use during the practicum. Six items in this section were teacher-centered computer use and six items were student-centered computer use. The teacher-centered computer use was defined as teachers using computers to (1) create instructional materials; (2) find resources; (3) communicate with others; (4) keep track of students' grades; (5) present information to the class; and (6) provide computer enrichment activity. The student-centered computer use was defined as students using computers to (1) create learning resources; (2) find resources for learning activities; (3) communicate with others; (4) present information; (5) complete class projects; and (6) engage in computer hands-on learning activities.

Data Analysis and Results

Data was analyzed by using SPSS (Statistical Package for Social Sciences).

(1) What are student teachers' perceptions of the teachers' role in the classroom with computers? Paired-sampled t test was used to compare the means of student teachers' perceptions of the teacher-centered role and the student-centered role in the classroom with computers. The comparison showed that there was no significant difference (t=.48 p>.05) between student teachers' perceptions of teacher-centered roles (M=3.8704 S.D.=.856) and their perceptions of student-centered roles (M=3.8407 S.D.=.864) in the classroom with computers.

(2) What was the student teachers' computer use during the practicum in terms of teacher-centeredness and student-centeredness? Paired-sampled t test was used to compare means for the student teachers' teacher-centered computer use and the student-centered computer use. The comparison showed that there was a significant difference (t=7.48 p=.000) between the student teachers' teacher-centered computer use (M=3.2037 S.D.=1.113) and the student-centered computer use (M=2.1905 S.D.=1.096).

(3) Do the student teachers' perception of the teachers' role in the classroom with computers differ from their practice of the computer use during the practicum? Paired-sampled t test was used to compare the means of the student teachers' perception of the teachers' role and their computer use during the practicum. The comparison showed that there was a
significant difference between student teachers' perceptions of the teacher-centered role in classrooms with computers and their teacher-centered computer use (t= 3.62 p=.001). There was a significant difference between student-teachers' perceptions of the student-centered role in classrooms with computers and their student-centered computer use during the practicum (t= 8.78 p=.000).

Discussion

The student teachers in this study perceived no significant difference between the teacher-centered role and the student-centered role in classrooms with computers. The data indicated that they would likely to engage teacher-centered activities as well as student-centered activities in classrooms with computers. These student teachers seemed to prefer a combined teaching-style which balanced teacher-centered activities and student-centered activities rather than a dichotomous teaching style leaning towards teacher-centeredness or student-centeredness. They considered the two types of teaching styles are complimentary rather than exclusive to each other.

This result was confirmed by Bichelmeyer's study (1997). Bichelmeyer's study measured the practicing teachers' perception of the teacher' role in the classroom with computers. Her study showed that teachers perceived no significant difference between the teacher-centered role and the student-centered role in the classroom with computers. The participants in both studies did not appear to share the popular belief that the availability of technology in the classroom changes the teacher-centered teaching style completely to the student-centered teaching style.

Although the student teachers perceived no significant difference between the teacher-centered role and the student-centered role in the classroom with computers, their computer use during the practicum revealed quite a different picture. There was a huge gap between the teacher-centered computer use and the student-centered computer use. These student teachers used the computer significantly more as a teacher-centered tool than a student-centered tool. There are several possibilities that might explain this discrepancy.

One possibility was that these student teachers lacked strategies to use the computer as a student-centered tool. Although these student teachers had completed university IT courses, their IT courses might get them to the level of using computers as a teacher-centered tool, but not a student-centered tool. The student-centered computer use requires different strategies including scheduling the computer use, using different classroom management skills, designing curriculum-related activities, and developing evaluation methods accordingly. Their computer use might reflect their IT training orientation which exposed them adequately to the teacher-centered computer use, but not the student-centered computer use. 'Few courses relate teachers' delivery styles to what types of materials and activities they select and it is even more difficult to find courses that are addressing teaching styles and how they impact the use and misuse of technology" (Flake & Molina, 1995; p. 337).
The student-centered computer use develops through practice. Downes (1993) observed the student teachers' computer use throughout three practicums and noticed there were shifts in the way student teachers' using computers with students. Student teachers' computer use with students progressed from Practicum 1 to Practicum 3. University IT training courses should be grounded in practice. Parkinson (1998) suggested that IT training courses should be taught through university-based component and the school-based component. "It needs to be borne in mind that the influence and importance of the school-based component is beyond dispute - certainly with student teachers" (p. 69). Field experience should be an integrated component of IT courses. Prospective teachers should be offered opportunities to observe how classrooms teachers use computers with students and be able to practice computer uses in real classroom settings.

Practicum school environments play a central role influencing student teachers' computer use (Downes, 1994; Pakinson, 1998; Wang & Holthaus, 1998-99). Student teachers need a supportive practicum environment to be able to use computers with students. "Practicing teachers are role models for student teachers. Student teachers learn from their cooperating teachers as well as other practicing teachers they observe" (Wang & Holthaus, 1998-99). Student teachers are facing many challenges as they are trying to cope with their first experience in the real classroom setting. Often they are mentored into the culture of the practicum school. "Pressure existed on student teachers to conform to the instructional patterns of their cooperating teachers. If the cooperating teachers did not use the computer as part of their instruction, the student teachers did not have models to follow" (Diem, 1989; p. 35).

Hardware and software resources in practicum might be another reason why the student-centered computer use was low in this study. Although the abundance of hardware and software does not necessarily determine the student teacher' computer use, using computers with students is demanding on the availability and convenient access to computer hardware and software. Most practicum schools in this study have limited computer resources. On one hand, limited resources present difficulties that hinder the student teachers' computer use. On the other hand, it is a challenge to teacher education to prepare prospective teachers how to utilize limited IT resources in schools to its maximum to enhance the quality of teaching and learning.

There was a discrepancy between the student teachers' perception of their teaching styles and the practice of their teaching styles. This discrepancy might also be an indication that student teachers would take a balanced approach in terms of the teacher-centered computer and the student-centered computer use if they were not constrained by external circumstances. On the other hand, it might indicate that student teachers would always perform lower than they themselves expect due to "external circumstances or those over which they have no control unless they are extraordinarily motivated" (Marcinkiewicz, 1994-95; p. 194).

Conclusion

This research is the first attempt to investigate the student teachers' perception and practice of the computer use during the practicum in terms of their teaching styles. The findings of this study have important implications to teacher education IT programs. IT courses at the university should lead the trend and edge of IT practices in the classroom instead of lagging behind it. Teacher education needs to offer IT courses that emphasize the appropriate teaching styles regarding the computer use and expose prospective teachers to strategies and models
of student-centered computer use. It would be a nightmare if our graduates have to undo what they have been trained in teacher education programs once placed in classrooms with technology.

Introduction

Hundreds of papers are published nowadays arguing that computers have become an integral part of our lives and, as such, should be integrated into educational systems as well (Cf. Eden, Eisenberg, Fischer and Repenning, 1996; Edelson, Pea and Gomez, 1996; Flake, 1996). Since such integration requires a change in teaching methods, teachers play a central role in such a transition. Of course, this is also true in regard to teaching of mathematics.

There are many benefits in using computers in our math classes (Cf. Sfard and Leron, 1996). However, as it turns out, the number of high school mathematics teachers who integrate computers into their math classes remains relatively low.

This paper tries to explain why this is so, by analyzing the attitudes of prospective high school mathematics teachers towards integration of computers in their future math classes.

Background

Data presented in this paper have been collected during these past three years (1996-1998). During that time, I have been teaching courses about integrating computers in the teaching of mathematics for prospective high school mathematics teachers. In the course, the prospective teachers work with, and experience, both general computational environments (such as the Web), and mathematical software tools (such as dynamic geometry environments). Since no one can guaranty that the specific computational environments that the prospective teachers meet in the course will be used in the future, emphasis is placed on general principles and ideas of integrating computers in math learning and teaching.
The course takes place in a computer lab. Most of the time, the prospective teachers work on activities in pairs in one of the computational environments, guided by worksheets I prepared in advance. Each class session ends with a class discussion and reflection of what was learnt during the lesson. On the one hand these discussions address mathematical topics, and on the other hand, they address pedagogical issues (mainly, cognitive and social ones). Assignments in the course include planning of activities for high-school pupils in the various computational environments, reading papers and submitting theoretical discussions.

Data presented in this paper was gathered from four classes of prospective high school mathematics teachers (total of ninety-four prospective teachers). The issue of pros and cons the integration of computers into mathematics classes was the subject of written questionnaires and of class discussions.

**Results**

The analysis of the prospective teachers’ pro and con arguments about integrating computer activities in their future teaching of mathematics, revealed the following two-dimensional theoretical framework:

<table>
<thead>
<tr>
<th></th>
<th>learner</th>
<th>teacher</th>
<th>mathematical content</th>
<th>learning environment</th>
<th>class atmosphere</th>
</tr>
</thead>
<tbody>
<tr>
<td>cognitive factors</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>affective factors</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>social factors</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In what follows I present the arguments according to the five categories which represents the class’s components, that is: the learners, the teacher, the learning material, the class atmosphere and the learning environment. I briefly explain what each category means and present pro and con arguments in each category, in relation to most of the psychological aspects, as presented by the prospective teachers. For reasons of space limitation, I only present a sample of the arguments here. Additional arguments will be presented in the talk.
Arguments focused on the learner: In this category there are arguments the subject of which are: pupils’ ways of thinking, pupils’ system of learning-values, and students’ attitudes and behaviors.

<table>
<thead>
<tr>
<th>SAMPLE OF PRO ARGUMENTS</th>
<th>SAMPLE OF CON ARGUMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cognitive aspect:</strong> Learners can conjecture, check their conjectures, improve their solution without being embarrassed when making a mistake, work in teams conducting a “mathematical conversation”, and explore mathematical ideas guided by the extent of their curiosity. All this is done when learners know that the teacher is in the class if additional help is required.</td>
<td><strong>Cognitive aspect:</strong> Some of the may progress without understanding previous stages. <strong>Affective aspect:</strong> Some students may feel they have too much freedom.</td>
</tr>
</tbody>
</table>

Arguments focused on the teacher: Interestingly, in this category most of the prospective teachers’ arguments were con arguments. A plausible explanation for this fact is that the prospective teachers do not feel secure in this mode of teaching. Indeed, in the table below we can see that most of their worries deal with the teacher’s role in a class that learns with computers. In my opinion, the imbalance between the pro and con arguments presented in this category is significant, and may partially explain avoidance of the part of some teachers of integrating computers in schools in general and in mathematics classes in particular.

<table>
<thead>
<tr>
<th>SAMPLE OF PRO ARGUMENTS</th>
<th>SAMPLE OF CON ARGUMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cognitive aspect:</strong> The teacher becomes a guide and is not the focus of the lesson anymore. Moreover, being released from his or her traditional centered role, the teacher can follow the work of the students by looking at the computer screens.</td>
<td><strong>Cognitive aspect:</strong> The computer becomes the class’s “brain”. The teacher’s role is simply to navigate, guide, and connect students’ knowledge with official mathematical knowledge. <strong>Affective aspect:</strong> The computer is conceived as being more clever than the teacher because of its numerous abilities and the fact that it does not make mistakes. <strong>Social aspect:</strong> Lessons in computer labs are not carried out in the traditional manner and traditional obedience is replaced with some noise. As a result, teacher control and authority are lost.</td>
</tr>
</tbody>
</table>

Arguments focused on mathematical content: In this category there are arguments whose focus is on mathematics. The fact that the prospective teachers present mathematics as the subject of their arguments is important since such arguments deal with abstract ideas and topics.

<table>

on the computer stimulates the pupils' thinking, leads them to connect among mathematical topics and enables them to think broadly without being distracted by technical problems. Moreover, the fact that computers may serve as cognitive partners influences the kind of activities suggested to pupils, such as multi-solution problems. Such problems encourage pupils' creativity, motivation and inventiveness and improve their mathematical thinking. Since learning with computers emphasizes learning processes over final results, it is much more difficult to assess pupils' knowledge.

**Arguments focused on the learning environment:** Arguments in this category deal with the nature of learning with computers and with the barriers and opportunities one encounters when learning with computers.

<table>
<thead>
<tr>

</thead>
</table>
| **Social aspect:** Computers provide:  
- A possibility to communicate with pupils around the world.  
- An opportunity for classmates to work in teams and to collaborate. | **Social aspect:** Since computers are expensive, not all pupils may be able to afford them. Thus, those pupils who have computers at home may progress faster than pupils who do not, and therefore will have an advantage over those who do not own PCs. |

**Discussion**

The above analysis describes prospective teachers' attitudes towards the integration of computers in their future teaching of mathematics. From the prospective teachers' answers we can learn that they refer to the main participants of the lesson: Learners, teachers and the learning material, and to the interaction among them: the learning environment and the class atmosphere. Moreover, we can see that the presented arguments deal both with cognitive, social and affective aspects. It is interesting to
note that in many of the written responses, after specifying the pro arguments and the con arguments, many of the prospective teachers have added a remark in the following spirit: *It is worth integrating learning with computers together with learning and teaching without computers.* Such a statement indicates that the prospective teachers do not take it for granted that computers would solve all problems embodied in the complexity of learning and teaching processes, but rather that, the integration should be given serious thought in each individual case. In regard to this, one of the prospective teachers wrote: *The computer can supply information, but we may lose its potential if we do not educate our pupils to use that information. Many databases are accessible now but our target should be the analysis of this data and not just getting it.*

Another interesting observation is that both in the teacher and in the learning environment categories, the number of pro arguments is significantly lower than the number of con arguments. Moreover, the situation is reversed in the learner and the mathematical content categories (that is, the number of pro arguments is significantly higher than the number of con arguments). This can be explained by the prospective teachers’ lack of teaching experience. Thus, it is reasonable to assume that in addition to their anxieties as new teachers, they express concerns which stem from the integration of computers. These concerns are especially expressed in the teachers and the learning environment categories. The question to be asked now is: Why do they see the benefits when they think about the learners and the mathematical content? Based on the class discussions, in which the prospective teachers’ arguments were elaborated, we can learn that prospective teachers are faced with a conflict. On the one hand, they believe that teaching and learning with computers may improve the learning of mathematics. This belief is reflected in the number of pro arguments in the learner and the learning material categories. On the other hand, they feel that such integration may change the traditional teachers’ role, a role which they are familiar with from their experience as school pupils. These concerns are reflected in the number of con arguments in the teacher and the learning environment categories.

It is known that motivated employees introduce positive changes into their organization, while unmotivated employees are satisfied with existing situations in their organization (Inamori, 1985 in Senge, 1997, p. 147). Looking at schools as organizations, we should ask ourselves questions such as: How to motivate the
prospective teachers towards integrating computers into their classes (in those cases in which it is appropriate to do so), regardless of anticipated difficulties? How to help them cope with their worries from the expected change in their role in the class and in the class atmosphere?

One of the outcomes of the research is a set of activities currently under development. The aim of the activities is, on the one hand, to help the prospective teachers cope with their concerns, and, on the other hand, to encourage them to be guided by their beliefs when they feel that the integration of computers in mathematics classes may improve the learning of mathematics on the part of their pupils. One activity is based on simulation games, i.e., playing situations that may occur in classes learning mathematics in computer labs. The idea is to let the prospective teachers play unfamiliar situations, and thus let them get a sense of such situations in a supportive environment.

Perceptions of Teachers at Miami Shores / Barry University (MSBU) Charter School of Using Computers in their Classrooms for Teaching

Hasan Akyurekoglu
Education Computing and Technology Department
Barry University
United States
hakyur@ibm.net

Abstract: This study is about the perceptions of middle school teachers of using computers in a classroom environment for teaching. A purposive sampling technique is used to select the school and the teachers involved in this study. A constructivist approach is used to understand the perceptions of the teachers about computers and computer related applications in their classrooms. All participants were interviewed about their perceptions of computers and observed about how they use them in their classrooms. Kvale's six steps of analysis method was used for the interview analysis. The data analysis revealed an overlying theme of using computers as tools for different purposes. Computers are perceived as teaching tools, classroom management tools, and communicative tools.

Introduction

"I see them [computers] as excellent tools that is very necessary in conveying the main math concepts. In a society in which everything is computerized, I feel it is very necessary to have them in the education unit, in your classroom, exposing students to what is around them. They’re in their homes, therefore they should be in the classroom as well to emphasize and further explore all the advantages of using a computer” said Ms. Smith, one of the math teachers at the Miami Shores/Barry University Charter School, during her interview. With almost 12 years of experience, she was one of those teachers who dedicated herself to her profession and students. During our interview, she showed me her classroom, her computers and some of the projects her students done in the past. It was obvious that she was able to integrate computers into her teaching activities very successfully and she was using them as “excellent teaching tools” in her classroom. Then, I wondered how many teachers perceived computers as she did, and how many are able to integrate them into their curricula successfully.

Purpose of This Study

The main purpose of this study is to understand and explore the perceptions of middle-school teachers about computers and computer applications in a classroom setting. The study focused on the following research question: “What is the perception of middle-school teachers of using computers and computer applications in their classrooms for teaching?”

For the purpose of this study, teachers at the Miami Shores/Barry University (MSBU) Charter School have been selected. MSBU Charter School, established in 1996, is a middle-school in Miami Shores, FL.

Background

The promise of today’s government for the future of our schools is that “every classroom in America must be connected to the information superhighway with computers and good software and well-trained teachers” (President Clinton, State of the Union, January 23, 1996). Since 1996, schools all around the nation have been
actively trying to connect to the information superhighway with computers. In their book, *Fostering the Use of Educational Technology*, Glennan and Melmed (1996) indicate that the growth in use of technology by schools is strong; schools are adding equipment and developing connections to the national information infrastructure at a high rate. The expended penetration of computers in schools is projected to continue, they say.

A nationwide survey, conducted by the National Center for Education Statistics in 1994, shows that there was about one computer for each 125 students in the nation’s public schools in 1983. By 1995, there was a computer for each nine students. In the same year, schools spent $3 billion on computer and network-based technology. There is no doubt that computer and computer related applications would be part of classroom teaching activities. As the backbone of our school system (Fullan, 1991), teachers will be the most influential people in using computers in classrooms and connecting their classroom with the information superhighway. However, studies show that there have not been many studies about teachers’ perceptions of using computers. Without a clear understanding of teachers’ perceptions of these new technologies, it is very difficult how to place them in a classroom. Some studies show that computers have not been used effectively because of the teacher-related issues.

Despite the rapid growth of computers in schools, surveys suggest that the average school make limited use of computers (Glennan & Melmed, 1996). The limited usage of computers in the classrooms may be related to several factors. A study on teacher perceptions and attitudes toward computers and computer-related teaching skills showed that level of experience and educational level of teachers are among the most important factors that shapes and affects perceptions of computers in teaching (Green, Kluever, Lam, Staples, & Hoffman, 1997). This study concluded that the teachers with the knowledge of computers and computer applications have a positive attitude toward computers in classroom teaching. Teachers with knowledge are able to see what computers can be used for and how to integrate it into classroom activities.

Perceptions of teachers of computers and computer related applications might be different form school to school and from state to state. A nationwide survey showed that 97% of the Florida’s teachers see computers as powerful motivators to improve learning in comparison to 67% of teachers said the same thing in California. The same study indicates that computers are perceived as teaching tools and powerful motivators in schools. The level of knowledge, experience, and educational level of teachers are important factors that affect teachers’ perceptions of computers.

**Method**

A constructivist approach is used to understand the perceptions of the teachers about computers and computer related applications in a classroom setting. The purpose of a constructivist inquiry is “understanding and reconstruction of the constructions that people initially hold, aiming toward consensus but still open to new interpretations as information and sophistication improve” (Denzin & Lincoln, 1998). Computers and computer related applications have been invading classrooms during 1990s and this invasion, as Glennan and Melmed indicate (1996), will increase in the future. Teachers have to find ways of integrating these new technologies in their classroom activities. Computers will bring new ways of teaching and learning activities. Teachers will have to understand and reconsider the way they teach and administer their classroom activities. They will have to reconstruct their teaching methods including these new technologies. From this perspective, to use a constructivist approach seemed appropriate for this study.

A purposive sampling technique is used to select the school and the teachers involved in this study. Miami Shores Barry University Charter School and teachers at this school are selected for this study. The school is established in 1996 with 60 sixth grade students. The student-computer ratio is 3.5 and this is a high ratio comparing to other schools in Florida. Three teachers were selected based on their use of computers in their classrooms from among the 12 teachers. The first participant was a female math teacher with 12 years of experience. The second participant was a male social studies teacher with two years of teaching experience. The third participant was a science teacher with six years of teaching experience.

Initially, the participants were asked verbally if they would volunteer in the study. Once they said yes, the researcher prepared a consent form to inform them about the purpose, process and conditions of the study. The interviews were conducted during their teacher planning time in their classrooms. There were not students and other school personnel in the classrooms during interviews. Each interview took approximately 45 minutes. During this time, the researcher focused on the following question: What is your perception of using computers and computer related applications in your classroom for teaching? The interviews were tape-recorded and transcribed verbatim, and then the tapes were erased.
Data Analysis

Kvale's *six steps of analysis* method was used for the interview analysis. In the first step, the participants described how they perceived using computers in their classrooms. They talked about their feeling and experiences. In the second step, the researcher condensed and interpreted the meaning of what the interviewee described. For example, when one of the participants said she made her students to use a computer program to demonstrate their research findings, the researcher interpreted these comments as using computers as a visual tool to communicate the data. The interviewee agreed and said that was exactly what she meant. In the third step, the participants realized they have been using computers for several purposes in their classrooms. One of them mentioned that he never thought about computers as being classroom management tools, but he has been using them to keep track of his students' grade, attendance and other records. In the fourth step, the researcher interpreted the transcribed data alone. During this process, the researcher categorized data under different concepts and then looked relationships among these concepts. The fifth step (re-interview) and the sixth step (action) were not applied to this study because of the time limitations.

Results

The data analysis revealed an overlying theme of using computers as tools for different purposes. Computers are perceived as teaching tools, classroom management tools, and communicative tools.

Computers as teaching tools

It was obvious that computers have been perceived as teaching tools more than anything else by the teachers in this study. When asked, they gave detailed descriptions of how they used them as teaching tools. “I see them as an asset...as a teaching tool...as a method of research for students” said one of the participants. “I find that in my particular class, I am a math teacher, I find that without computers, it is hard to convey some visual concepts that computers allow you to do” said another participant.

The math teacher showed me some of the software she had downloaded on the workstations in her classroom. She was using Math Blaster as a “practice tool”, as she described it. After she teaches main subject concepts, she asks her students to open the program and do the practice questions. “That makes my class more...”

Another participant describes how he uses tutorials for teaching: “We have tutorial programs that the students can use them to better their skills in grammar, spelling and punctuation...The computer has a lot to offer and the students can learn from the computer by using it as often as possible”. His perception of computers as a teaching tool was based on using them as tools, which guide and help students to learn by themselves. He believes that computers can help students to learn by themselves with little help from teacher.

Computers as classroom management tools

While computers have been perceived as teaching tools, they also have been perceived as classroom management tools. The participants seemed fully aware of the potential that computers can bring them in managing their classroom activities. “It [computer] lets you to keep records of grades, lets you keep track of the students’ work” said one of the participants. She had her own workstation by her desk and students were not allowed to use her computer. On that computer, she kept works of her students in different folders. She called these folders “electronic portfolios”.

At Miami Shores/Barry University Charter School, teachers are required to contact parents periodically to report the progress of their child. One of the participants mentioned that she used electronic mail to inform parents who had electronic-mails at their homes about their child’s progress. However, she calls parents and lets them know that she sent e-mail. It was a nice way of combining two media to report the progress of the students.

Computers as communicative tools

Each classroom had an Internet connection to the World Wide Web (WWW) at MSBU Charter School. Teachers are encouraged to use them as much as they can to integrate classroom activities with materials on the
World Wide Web. The school administration especially emphasizes the importance of communicating with other students around the nation and world via Internet. Teachers seemed to understand the potentials of using the Internet for classroom activities. “Nowadays, with the Internet, the students can access various areas and do research for projects that they are working on...that opens a wide range of doors for them as far as interacting with a lot of information” said one of the participants. He was requiring his students to go on the Internet and do some search for their research projects.

With the doors opened to schools via World Wide Web, it was not surprising to see them being used as communicative tools in the classrooms. They can let students and teachers interact across the miles and share information. It seemed that social science teachers have more opportunities for their students to communicate over the Internet with other students around the nation.

Computers are also perceived as a means of communication tool between the teacher and students in the same classroom. One participant expressed his future vision of using computers as follows: “You can probably use them as a means of communications. For instance, if you have them [students] to write a term paper, you can ask them to e-mail it to you instead of having a hard copy. You can have them to communicate with you using the Internet if they have questions. You can do all of it by giving them access to an e-mail account”.

Although the MSBU Charter School did not have a Local Area Network (LAN) yet, the perceptions of teachers about using computers as a communication tool were very obvious and clear.

Discussion

According to the Teachers and Technology Survey, conducted on behalf of the Tenth Planet Explorations, Inc., by Field Research Corporation, an independent market and opinion research organization located in San Francisco, California, 97% of Florida teachers say that they see computers as “powerful motivators to DiCamillo, 1998). Kluever, Lam, Staples and Hoffman (1995) indicate that computers are perceived as instructional tools and used in many different ways for this purpose, from drill and practice activity to simulation of events.

This study found out that teachers perceived computers as teaching, classroom management and communication tools. When put together, these three findings are tools to improve learning of the students. Computers have a direct impact on teaching activities of teachers and their teaching methods. They have to find new ways of integrating these technologies into their curriculum. That forces them to develop new instructional methods, combining their knowledge with the power of these technologies. This way, computers will be used as instructional tools to improve learning.

The findings of this study may help teachers and school administrators to see computers as powerful tools of teaching. When properly used, computers are powerful tools to motivate students to learn. As classroom management tools, computers make it easier for teachers to keep track of their students’ work by creating electronic portfolios. As communication tools, computers have the potential of allowing teachers, students and parents to communicate with each other over the Internet.

To conclude, I would like to mention that the teachers at MSBU Charter School have strong support from their school administrators. School administration provides all the equipment, hardware and software, for teachers to use in their classrooms for teaching. That may have an affect on the perceptions of the participants of this study. During the interviews, participants mentioned how their administrators supported and encouraged them in using computers. That brings us to another research question: What are the factors that affect the perceptions of teachers of using computers in the classroom for teaching? That is a subject to be investigated in the future.

Databases Linked to the Web: Facilitating Collaborative Inquiry in Teacher Education

Scott D. Coleman
Education Division
Lewis-Clark State College
United States
scoleman@lcsc.edu

Abstract: This paper describes the rationale for using a web page linked with a database to share perceptions among diverse stakeholders in a field-based teacher education setting. The efficiency of the web as an inquiry tool can make applied and empowering research possible despite severe time constraints. The second section of the paper and gives an example of how this idea was tested in practice. The perceptions of college faculty members, K-8 teachers, and teacher education students in a new field-based program were shared, analyzed, and commented on using easily constructed web-pages linked with a database.

Introduction

The difficulties inherent in establishing comprehensive teacher education partnerships involving K-12 teachers and faculty from colleges of education are daunting. Whether these difficulties can be overcome in a specific setting is largely a function of communication. This point is made clearly in a recent article by several faculty members at Brigham Young University which describes, in candid detail, the challenges, successes and failures that accompany the building of long term partnerships with schools. “Even with a stable university faculty and low turnover, communication was poor. Too many schools, too many students, too many cooperating teachers created this problem. Disappointment followed. One teacher educator posed the dilemma this way: ‘There are more opportunities to communicate and build relationships than ever before, but you don’t have time to pursue and develop them, you only end up with hurt feelings and miscommunication’” (Bullough, 1999, p. 381).

The Need for Communication

The rationale for partnerships between K-12 schools and colleges of education for the purpose of simultaneously improving education has been convincingly made (Goodlad, 1994). Building and sustaining these partnerships requires meaningful and sustained communication. Informal and formal meetings, telephone and e-mail conversations and memos are all essential elements of communication, and each serves well in meeting specific types of communicative needs.

Bringing the spirit of effective and ongoing inquiry into the school environment is perhaps the most essential contribution the college partner brings to the table. Effective inquiry holds promise not only for improving teacher education, but also for helping teachers and schools improve the practice of K-12 education. Recognizing that the inquiry aspect of the partnership may be the one most at risk when the school and college cultures clash, it is particularly important to ensure that communication mechanisms are in place for inquiry-related activities.

Inquiry models that treat school personnel as subjects rather than co-researchers, can be efficient in terms of time, but are not likely to serve well in a partnership (Lincoln & Guba, 1995). However, communication intensive collaborative research is very demanding of time, which is very likely to be a rare commodity among teachers and faculty involved in school partnerships.
Potential of the Web-Database

Recent software advances allow relatively non-technically oriented users to create databases that are linked to web pages. This offers a powerful means to efficient and collaborative inquiry. A web site linked with a database allows information to be collected, analyzed, and reported with an ease unimaginable a few years ago. The simplicity and speed of collecting, analyzing, and reporting data thus has the potential to greatly facilitate collaborative inquiry.

One way to make use of the web-database combination is in gathering, summarizing, and sharing perceptions using a survey or questionnaire. Thoughtfully used technology can overcome some of the drawbacks traditionally encountered in survey research. Low response rates, due to the time and expense involved in sending out, completing and returning forms can be avoided. Lack of follow up communication can similarly be avoided as the cost and time involved in sharing results with all respondents becomes minimal. Using a web-based survey, respondents can easily submit their perspectives and participate fully in receiving and interpreting the overall results. With the technology of a database linked to the World Wide Web (WWW), the implementation of a well-designed survey as a means to gather and share the collective perceptions of a diverse group of individuals becomes possible and efficient.

Theory into Practice

In the early Fall of 1999 an opportunity to explore the methodology and effectiveness of inquiry using a database linked to the web presented itself at Lewis-Clark State College in Lewiston, Idaho. For nine years, the Lewis-Clark State College teacher education programs had worked very closely with partner schools. However, beginning with partial implementation in the 1998-1999 school year, and with full implementation in the 1999-2000 school year, year-long internships placed students in one school site for their final two semesters, intensifying the college/K-12 partnership. This new program required supervising faculty members to work on a daily basis with a small number K-12 teachers. Exploring the perceptions of teachers, students, and college faculty regarding this work in progress was of significant interest to those involved.

Getting Started

A formal study was initiated six weeks into the full-scale implementation of the year long internship. It began with the general question: do the cooperating teachers, college faculty, and student interns share common perceptions about the early benefits and problems of the year-long elementary (K-8) internship program? To develop specific survey items, members of the college faculty were consulted by phone and e-mail, asking them which issues they would most like to know about. The result was a 20 item survey, plus four biographical questions (school site, number of semesters involved in new program, affiliation, e-mail address).

The Questions

All 20 questions were multiple choice items which asked the respondents to share their perceptions on specific issues related to the year-long internship. The exact wording of the response choices varied, but in general they were: none, low, medium, or high. The topics addressed in the survey were:

1. Does the presence of the intern students benefit the K-8 students?
2. Does it appear that the internship experience is likely to be superior to the more traditional student teaching experience?
3. Is the amount of time spent in the schools properly balanced with time on campus?
4. How critical is the need for instruction on campus in each of these areas: classroom management, lesson planning, methods instruction?
5. How prepared are the internship students to teach each of these: special needs students, reading, math, writing, speaking and listening, science, art, music, PE, health
6. How prepared are students to develop lessons requiring integration of subject areas?
7. How prepared are students to use computer technologies in the classroom?
8. How aware are you of the new standards the teacher education program has adopted?
9. How important is your voice in guiding the direction of the teacher preparation program?
1. Based on what you have directly observed, is the presence of LCSC students in the classroom benefiting K-8 students?
   A. not that I can tell
   B. possibly, to a limited extent
   C. definitely yes, there is some benefit
   D. there is clearly a very significant benefit

2. Based on your experience so far, does (or will) participation in the internship year make LCSC students more ready to work as full time teachers when they complete their program?
   A. not that I can tell
   B. possibly, to a limited extent
   C. definitely yes, there will be somewhat more ready
   D. they will clearly be more ready

Figure 1: Two sample survey items (of 20) shown in a web browser.

Preparing the WebPage and Database

From a methodological perspective, the key question of this study was how much time and effort will it take to prepare the survey and analyze the results? The process of developing the individual questions was similar to that of developing a paper and pencil survey: drafts of the proposed questions were shared with all faculty members involved in the internship and feedback was invited and received (this process was done primarily by e-mail). Once developed, the questions were placed into a Claris Homepage document (see Figure 1), a process which took less than an hour. The major development work involved creating a FileMaker Pro database to store and analyze the survey data. Creating fields needed to input the data was relatively simple: 24 fields were created for that purpose, which took the author less than 30 minutes to complete. The next task was to create fields that would calculate the percentages for each response. This involved creating approximately 200 additional fields, a somewhat tedious process that took about 3 hours. Each question required four fields in order to determine whether the response was a, b, c, or d. For each of these 80 fields, a summary field was created to add up the total number of responses for that field. Finally, a calculation field was created for each of the 80 basic fields to calculate the percentage of responses for each item (see Figure 2).
Round 1

Once the survey was placed on the Education Division's web server, faculty members were contacted and asked to fill out the survey as well as to request that they ask their K-8 colleagues and students to also fill out the survey. The initial request was to fill out the survey within one week. After 4 days it became apparent that more time for responding and an additional appeal would be necessary. For that reason, requests were e-mailed to 2-4 cooperating teachers in each of the nine internship sites and the faculty were reminded to ask their students to fill out the questionnaire. The deadline for completing the survey was extended an additional week.

At the two week deadline, 40 surveys were received, 20 (of 30) from K-8 teachers, 15 (of 30) from interns, and 5 (of 6) from the faculty. It appeared that the relatively low response rate from interns was a matter of communication—many of them were rarely on campus and used individual (home) e-mail accounts other than their college accounts (which is why they were not contacted by e-mail directly). As the surveys were submitted via the web the results were automatically summarized in the database. These results were not immediately made available via the web (although they could have been).

Round 2

After two weeks the results were made available on a results web page, which replaced the original web survey at the same site (see Figure 3). It would have been simple to display the overall results for each question by calling those results directly from the database. However, since a major purpose of this particular survey was to look for discrepant perceptions among the three groups (faculty, teachers, and interns), results for each of those groups were calculated by doing simple searches for each group's results and then entering those results manually into the web page. In a similar way, the results were analyzed in terms of the number of semesters (1, 2, or 3) the respondent had been involved with the year long internship program. The entire summarizing process took approximately 3 hours for the author to complete.

Each respondent was then sent an e-mail message, telling them that the results were available for their viewing, and encouraging them to comment on the results within the next week. As comments were received they were added to the results page to be shared.

Somewhat surprisingly, very few comments were received. Comments were made via e-mail immediately after the survey was completed (before the group results were available) and other comments were made verbally after individuals had viewed the group results, but for the most part, respondents did not choose to share their comments and interpretations via e-mail. Two reasons for this were readily apparent in hindsight.

1. It would have been preferable for the respondents to be able to add comments right on the web site as they were reviewing the results (which could have been easily done). Instead, they had to e-mail their responses separately, a less convenient option.
2. A shorter survey and/or less analysis for respondents to react to would have been better. With 20 questions each analyzed along two different dimensions, the amount of data appeared to be somewhat overwhelming.
3. Overall, how well is the need to spend time on the LCSC campus balanced with the need to spend time in K-8 classrooms?

A. Too little time is spent in the college classroom
B. Just about the right amount of time is spent in the college classroom
C. Too much time is spent in the college classroom

Figure 3: Excerpt from a web browser showing results from one of the 20 items, including a follow-up comment from one of the respondents.

Lessons Learned

First, it is very clear that using a web-based survey with a database is time efficient. The amount of time needed to create, disseminate, analyze, and receive comments was very low compared to any other option. The database-web vehicle does enable people to easily share their points of view and to comment on the points of view of others -- a great need in collaborative inquiry. Improvements that should be made to the process and cited in this example are consistent with the principles of good survey research: keep the number of questions to a minimum, and make it as easy as possible for respondents to participate.

An area to be explored further is finding ways to balance the need to openly share data with all respondents with the need to keep the results from being too detailed. For example, all the results were shared with the respondents. If, instead, only results that showed a somewhat significant difference of opinion between the three groups had been shared, a useful collaborative discussion would have occurred more easily. Further trials with this strategy are needed to determine whether limiting data in this manner maintains the integrity of the group's reactions while eliminating the need to wade through redundant data.

References

Abstract: This paper reports on a study that investigated the relationships between technology-use and teaching ability in the practice of elementary teachers. Case study data from exemplary technology integrators, representing various levels of teaching and technology-use ability, led to the formulation of assertions about ways these teachers taught with technology. Differences observed among technology-use practices were associated with individual levels of teaching expertise. The paper concludes by proposing a theoretical definition of technology integration, along with specific recommendations for the professional development of both preservice and inservice teachers.

Introduction

As computer technology reinvents the ways in which we create, find, exchange, and even think about information, school districts are forced to bow to societal pressure to fund technology. Unfortunately, purchases are often approved before implementation plans are in place, a lack of foresight which leaves disparity between teachers who are attempting innovative integration and other users and non-users. The existence of success in isolated pockets prompted this study of how teachers at various levels of technology-use and teaching abilities used technology and how technology-use practice related to general teaching practice.

The history of studying experts in various disciplines has repeatedly identified a series of expert characteristics, (e.g., Glaser, 1990) that include having a highly structured and accessible knowledge base and efficient domain-related routines. It has been shown that pedagogical expertise develops with comparable characteristics. Expert teachers set goals during planning based on their previous knowledge about students and past teaching events (Berliner, 1994). They make a greater number of contingency decisions and consider management and instructional strategies ahead of time (Livingston & Borko, 1989; Westerman, 1991). With an organized store of knowledge, experts employ a set of routines to automate recurring teaching practices (Berliner, 1986; Leinhardt & Greeno, 1986). Past experience supplies insight into student learning needs, confidence to incorporate student input to tailor lessons, and the ability to critically analyze classroom situations to propose solutions (Gonzalez & Carter, 1996; Sabers, Cushing & Berliner, 1991).

Integrating technology into the curriculum is becoming an inseparable part of good teaching. Research on exemplary technology-using teachers has revealed that these individuals spent a good deal of personal time working with computers, had more extensive computer training and teaching experience (Becker, 1994), and had high levels of innovativeness and confidence (Marcinkiewicz, 1993). They were surrounded by colleagues who used computers for meaningful activities, enjoyed school and district level support for technology use (Becker, 1994; Hadley & Sheingold, 1993), and had sufficient staff development opportunity (Office of Technology Assessment, 1995; Richie & Wiburg, 1994). Common teaching practices included planning for regular computer use, consistently using technology as a tool in a variety of instructional projects (Evans-Andris, 1995), maintaining higher expectations for student learning, and shifting the focus toward activities that were student-centered (Hadley & Sheingold, 1993) with less whole-group instruction and more independent work (Waxman & Huang, 1996). Finally, these
teachers made conscious decisions to alter established curriculum, allowing student choice in learning activities and promoting varied grouping schemes (Becker, 1994).

The review of literature on expert teaching and exemplary technology use led to a series of research questions: What role do exemplary technology-using teachers perceive for the computer technology in their classrooms for themselves and their students? In what ways do they plan for computer use, and what routines do they establish to facilitate and manage the use of computers in instruction? What strategies do they use to teach with and about computers, and how is learning assessed? And finally, in what ways are the practices of exemplary technology-using teachers comparable to indicators of pedagogical expertise?

Methods

The initial research questions indicated qualitative case study methods. Sixteen elementary teachers from a school district known for a commitment to technology were identified as exemplary technology-users by the Director of Technology, two Teachers on Assignment for technology, school media specialists, and principals, and were observed for a half-day screening interview. It soon became clear that although these teachers had all been recommended as exemplary technology-users, the group was not homogeneous, representing instead a range of combinations of levels of teaching abilities and technology-use abilities. The goal of the study therefore changed from examining only those teachers who were exemplary technology users to comparing individuals at different levels of technology use and teaching abilities. A framework loosely intersecting composite levels of teaching expertise (Berliner, 1994) and stages of teacher technology adoption (Dwyer, et al., 1991) proved an effective way to investigate the variety in the this sampling pool and at the same time gain a richer insight into the relationship between teaching abilities and technology-use abilities. One teacher was finally selected as the best representative of each category. Data from two in-depth interviews, classroom observations, planning “think-alouds”, computer-use logs, and technology-related documents were collected during approximately one month per case study classroom over the course of one school year. Through repeated readings of the entire data record, potential themes of teaching and technology-use practice were informally noted and then grouped into larger, related categories.

Interpretation of Findings

This study was designed to understand how teachers at various levels of technology-use and teaching abilities used technology, as well as how technology-use practice related to general teaching practice. Through interpretive analysis, emerging patterns in the data led to the formulation of five assertions that illustrated the ways these teachers taught with technology:

- **Assertion 1**: The ways technology was used determined the teachers’ personal definitions of technology integration.
- **Assertion 2**: Teachers at the lower levels of either technology use or teaching ability altered their planning habits when planning for technology inclusion.
- **Assertion 3**: Teachers taught with and about technology according to their own personal learning strategies.
- **Assertion 4**: Teachers’ individual definitions of technology integration directed their management of student computer use
- **Assertion 5**: Teachers at the lower levels of either technology-use or teaching ability altered their perspective on assessment when assessing student use of technology.

The comparisons drawn among the strategies these three teachers employed when teaching with technology versus teaching without technology proved most interesting. Evidence presented in this study suggests that these variations in technology use were closely linked to the teachers’ respective levels of general teaching expertise.

1673
Exemplary Technology-Use/Adequate Teaching Ability: Steve

Steve’s reliance on textbook planning, his teacher-centered approach, and his lack of motivation to modify teaching practices demonstrate his settling into a state of “experienced non-expertise” (Bereiter & Scardamalia, 1993) in which experience is not capitalized on to continue developing knowledge or a fluid level of expertise. In some respects, teaching with technology prompted positive change in Steve’s teaching. He gave more thought to lesson planning and taught with enthusiasm. His plans and teaching demonstrated, however, how his technical expertise did not automatically result in quality teacher performance. Many experts in a particular domain are not able to instruct others effectively because they cannot articulate how they do what they do (Berliner, 1994; Bransford, Brown, & Cocking, 1999). Steve’s advanced technology skills were developed prior to his teaching skills, and as his teaching had remained somewhat stagnant past his initial pedagogical learning, he had thus far been unable to link his technology expertise to his teaching. Consequently, technology remained a separate activity with regards to planning, management, and assessment, and it furthermore was not connected in a pedagogically sound way to other learning opportunities. Future progression along this line would not likely result in Steve using technology in any concerted or meaningful way to improve the learning of his students.

Exemplary Teaching/Adequate Technology-Use Ability: Jill

Jill had in place established routines and highly organized mental schema for what she considered to be “teaching.” She was able to recognize patterns across different subjects and was able to use such knowledge to present fluid, flexible lessons. However, in spite of her interest in learning about technology, she did not recognize technology as being similar to other tools she typically used in her teaching. Expert knowledge has been shown to be contextual and domain specific (Berliner, 1994). Perhaps Jill needed to recognize the place of technology use as related to her general teaching practices before it could become an integral component of her teaching repertoire. By perceiving technology use as a practice distinct from her teaching practices, Jill essentially slipped back into novice teaching habits when teaching with technology. Her plans for technology use remained conscious, deliberate thoughts that were largely separate from other subject matter plans. Others have suggested that expertise is not directly transferable to other situations (Berliner, 1994; Huberman, 1985) and, in fact, must be “reinvented or adapted” (Huberman, 1985, p. 256). The adaptation process for Jill involved seeking ways to utilize technology within the framework of her prior knowledge about teaching.

Exemplary Teaching/Exemplary Technology-Use Ability: Sheila

Because technology was used so pervasively in Sheila’s classroom, there were few notable distinctions between the ways she viewed planning, management, and assessment of technology use and her comparable strategies for more traditional learning activities. She made conscious decisions, based on her knowledge of both the content and her students, to use or not use technology tools under certain circumstances. Routines facilitated much of the student computer use, making Sheila available for novel circumstances requiring her attention. On the whole, Sheila’s uses of technology were not only the most prolific of the three teachers, but such teaching practices were also the most closely aligned with the content-area curriculum. Using technology so that it is truly a part of what is practiced by an expert teacher with curriculum, rather than as an activity that has its own set of rules, was the meaning of integration to this teacher.

Discussion

Findings from the present study demonstrate how the term technology integration can connote very different concepts for different teachers. Perhaps schools are so eager to have teachers begin using
technology that they use the term too freely, mistaking simply having and turning on a computer as integration. While it may not be possible to arrive at one indisputable definition of a term so dependent on educational beliefs, technological availability, and even community expectations, the use of research and national standards could help such a concept to be locally defined so that it can be planned for, implemented, assessed, and generally understood by all stakeholders. To aid this understanding, I propose a theoretical definition of technology integration derived from the literature on expertise in teaching. Researchers (Berliner, 1986; Leinhardt & Greeno, 1986; Shulman, 1986; Wilson, Shulman, & Richert, 1987) agree that expert teachers possess both content knowledge and pedagogical knowledge, the intersection of which is described as pedagogical-content knowledge, or knowledge about specific learners and useful ways to represent specific curriculum. The findings of this study suggest adding to the model technological-knowledge, which would include not only basic technology competency, but also an understanding of the unique characteristics of technology that would lend themselves to particular aspects of the teaching and learning processes. A teacher who effectively integrates technology would be able to draw on extensive content knowledge and pedagogical knowledge, in combination with technological knowledge. The intersection of the three knowledge areas, or technological-pedagogical-content knowledge, would define effective technology integration. Figure 1 illustrates the possible relationships between the types of teacher knowledge.

![Figure 1: Relationship among content, pedagogical, and technological knowledge. Section (a) represents knowledge of content-related technology resources. Section (b) represents such knowledge as the methods to manage and organize technology use. Section (c) represents the intersection, or technological-pedagogical-content knowledge, which is technology integration.](image)

**Recommendations**

This study raises important issues for preservice teacher education and school districts professional development programs.

**Recommendations for Preservice Teacher Education**

1. If the use of technology is seen as an additional skill that teachers need to acquire once they begin their first teaching assignment, the time necessary to integrate technology into their teaching repertoire will be delayed. Preservice teacher education programs must address this need by designing appropriate program sequences that involve future teachers in using technology for meaningful purposes throughout all subject methods instruction.

2. The relationship between teaching ability and technology-use ability must be made explicit early in a new teacher’s education. Rather than have each subject methods component taught separately, college
of education faculty must work together in interdisciplinary teams to coordinate efforts of teaching in general and teaching with technology tools.

3. Attention should be given to the methods that teachers at different levels of teaching ability and technology-use ability employ. Specific communication routes need to be established among preservice students, expert technology-integrating teachers, and teachers who are novices at using technology for instruction.

4. Beginning teachers need valid models of technology integration from the outset, rather than learning to teach and then tackling the challenge of integrating technology later and out of context.

Recommendations for School Districts

1. "One-shot" inservice trainings do not explicitly demonstrate technology connections to other teaching methods that would allow teachers to situate technology use within their rich content and pedagogy knowledge structures. Experienced teachers need time for reflection and collaboration in order to envision technology use in relation to established practices and in multiple contexts.

2. In addition to technology professional development, ongoing efforts must address issues of general teaching improvement. Inservice trainings should not be solely applications-based, such as how to use a particular piece of software, but instead should be problem-based to assist teachers in identifying all of the ways to solve particular teaching problems using a range of tools that include technology.

3. Professional development must view teachers as individual learners, and therefore must be varied and focused on what the learners know, what the content demands, and how assessment and community needs impact learning.

4. If the definition of technology integration is not clear, teachers may believe that any use of a computer is acceptable as technology integration. The devising of a district framework or rubric that outlines the range of ways in which different ability-level teachers might use technology could make professional development efforts more focused and meaningful.

5. Teachers would benefit from release time to witness exemplary technology integration practices from teachers in their own district, with similar student populations and available technology. They might also benefit from videotaped case examples that could be viewed, studied, and repeatedly discussed.

Conclusion

More important than teachers who know how to use computers are teachers who know how to effectively use all of the tools at their disposal for the learning benefit of students. The proposed definition of technology integration suggests that technology in the hands of a merely adequate teacher will lack the experienced and thoughtful motivation necessary to embed it within a context of sound teaching practice. Conversely, technology in the hands of an exemplary teacher will not necessarily result in integrated and meaningful use. Unless a teacher views technology use as an integral part of the learning process, it will remain a peripheral ancillary to his or her teaching. True integration can only be understood as the intersection of multiple types of teacher knowledge and therefore is likely as rare as expertise. Educational leaders would be well served to focus efforts on creating environments that are conducive to continued growth in pedagogy as well as in technology use.

Faculty Development Model: Addressing the Disparity between Pre-service and In-service Educators in Technology Integration of the Public School Classroom

Melissa Roberts Becker
College of Education
Northeastern State University
United States of America
beckermr@nsuok.edu

Abstract: Northeastern State University requires all education majors to enroll in EDUC 4823, Technology in Education. Pre-service teachers are introduced to the use of technology in the classroom. However, graduates report a vast disparity as they enter public schools because in-service teachers have limited training in technology integration. A faculty development model was created to address this need.

EDUC 4823 students secured a public school in-service teacher for participation. Students meet two hours with the instructor and one hour with in-service teachers weekly. Students taught in-service teachers technology integration techniques learned in the college classroom. These in-service teachers' posttest scores were compared with posttest scores of a school district participating in traditional in-service training. Both groups of in-service teachers increased posttest scores. In order to determine if the faculty development model increased scores significantly more that traditional in-service training, an analysis of covariance must be performed.

Research Background

"[These instruments are] not uncommon, but are little resorted to by the teacher...the teacher knows almost as little how to use it as his pupils." (as quoted by Dockterman, 1998, p.10). While similar statements have been made addressing computer technology in this decade that was not the reference of this quote. Neither did this quote reference overhead projectors, television or moving pictures. This statement was made in 1840 and therefore predates all common technologies of this century. The technology of reference was the chalkboard!

In 1980, Dr. Seymour Papert of Massachusetts Institute of Technology stated in his influential book, Mindstorms, "I believe that the computer presence will enable us to so modify the learning environment outside the classroom that much if not all the knowledge schools presently try to teach with such pain and expense and such limited success will be learned, as the child learns to talk, painlessly, successfully and without organized instruction." (Papert, 1980, p.9). The current challenge computer technology presents to educators of this century is similar to the challenge of the chalkboard in 1840. Integrating technology, whether computer or chalkboard, into the teaching and learning activities of the classroom requires training and the reduction of anxiety on the part of the educator.
In a recent analysis of current uses of technology in public schools (kindergarten through twelfth grade), only a small proportion of teachers were evaluated as major computer users (Becker, 1994). In a similar study, teachers reported a reason for this lack of computer use is the absence of hands on training and time needed to incorporate the use of computers into the curriculum (Honey, Henriquez, 1993). Furthermore, research indicates that computer anxious individuals learn less about computers when instructed and use computers less than non-anxious individuals.

Obviously, pre-service teacher education institutions are the logical place to begin reducing computer anxiety and training educators in the appropriate use of technology in the classroom environment (Office of Technology and Assessment, 1995). Currently, Northeastern State University located in Tahlequah, Oklahoma requires all education majors to enroll in EDUC 4823, Technology in Education. During this three credit hour class, pre-service teachers are introduced to the use of technology in the classroom. The students demonstrate the use of technology as a tool for presentations, learning, assessment and personal productivity.

As the Northeastern State University graduates enter the public school classroom, a vast disparity becomes apparent. While public schools across the state of Oklahoma conduct annual in-service training for faculty, the topic of this training is not always technology integration. As a result, many in-service teachers have limited training in this area. Even traditional in-service instruction addressing technology integration is not adequate to keep educators current with the application of technology in their specific classroom setting. In general, in-service educators have limited training and experience opportunities in the use of technology integration (Simonsen & Thompson, 1997, p. 12-13). The results of a case study conducted in 1996 reported the most effective way to assist educators in using technology in course content is one-on-one mentoring where individual needs and anxieties can be addressed (Thompson, Hansen & Reinhart, 1996).

Reflecting on these studies, and as the instructor of the Technology in Education course, this researcher developed the following faculty development model to address this expressed need of both the pre-service and in-service education communities during the fall semester, 1999.

The purpose of this study was to determine if the newly created faculty development model would reduce computer anxiety of in-service teachers as reflected by the Computer Anxiety Index. Furthermore, could the faculty development model reduce anxiety more efficiently than traditional in-service training provided by school districts?

Operational Definitions

Technology integration is using computers effectively in content areas allowing students to apply computer skills as a means of learning, assessment and communication. The curriculum content drives the use of technology (Wentz, C. & Wentz, P., 1995). This process organizes the goals of curriculum and technology skills into a coordinated learning experience for students (MacAuthur & Pilato, 1995).

Computer Anxiety is defined as the fear or apprehension felt by an individual when using a computer or when considering the possibility of computer utilization (Simonson, Montag, Maurer, Oviatt & Whitaker, 1992, p. 12).

CAIN is an abbreviation for the Computer Anxiety Index, entitled the Computer Opinion Survey to minimize the possibility of answer bias. The CAIN can be used at the beginning and the end of a computer learning experience to identify the changes produced in anxiety as a consequence of the learning
experience. This is a norm-referenced instrument published by the Iowa State University Research Foundation, Inc (Simonson et al., 1992).

In-service teachers are educators currently certified by the Oklahoma State Department of Education. The participating teachers are currently employed by an Oklahoma public school and have computer access on their local school campus. The schools are located in the northeastern portion of Oklahoma.

Pre-service teachers are Northeastern State University students who have been admitted to the teacher education program and currently enrolled in EDUC 4823, Technology in Education during the fall semester, 1999.

Methodology

The in-service teachers are not randomly assigned, therefore, this is a quasi-experimental study (nonequivalent control group design). The researcher enlisted the control group and the EDUC 4823 students recruited the experimental in-service participants. Participation requirements were established in an effort to equate the control and experimental groups (employed, certified educators in the northeastern portion of Oklahoma with access to computers on respective campuses). Seventeen in-service participants comprised the control group. 46 participants comprised the experimental group. Both groups of in-service teachers were given a pretest, administered a treatment and given a posttest. The posttest was given to each group twelve weeks after the pretest was administered in order to control the time-lapse variable. The quasi-experimental design was as follows:

- O X(1) O
- O X(2) O

Control Group Treatment

The Northeastern State University instructor (researcher) conducted a traditional in-service training for a public school district in the northeastern portion of Oklahoma. The faculty completed the CAIN as a pretest, thus establishing a baseline for the control group. The instructor then conducted the traditional three-hour in-service session addressing the effective use of technology in the classroom (treatment one). Twelve weeks after the treatment, the faculty completed the CAIN as a posttest.

Experimental Group

Each pre-service teacher secured a public school in-service teacher for participation. In-service teachers met the established requirements for participation to insure equivalent groups. The in-service teachers completed the CAIN as a pretest, thus establishing a baseline for the group. The pre-service teachers met with the Northeastern State University instructor (researcher) two hours each week for instruction and thirty minutes each week with an in-service teacher. This model continued for twelve weeks. However, six of these weeks were spent collecting information about computer operating systems, interviewing in-service teachers, reviewing/practicing new computer skills and fall breaks. Actual time spent instructing the in-service teachers was three hours. During these three hours, the pre-service teachers taught the in-service teachers technology integration techniques they learned in the college classroom (treatment two). At the end of the twelve-week program, the in-service teacher completed the CAIN as a posttest measuring the faculty development progress.

Statistical Analysis

There were no identifying codes used, so participants were guaranteed complete anonymity. The mean gain/difference was computed for each group. The Control Group scored an average of 11.411 on the...
CAIN pretest and 13.666 on the CAIN posttest. This reflects an average gain of 2.254 points. The Experimental Group scored an average of 14.5 on the CAIN pretest and 15.631 on the CAIN posttest. This reflects an average gain of 1.1315 points.

Before the two groups' posttest scores can be analyzed correctly, the performance of the two groups on the pretest must be examined. Because both groups were not relatively equal on the pretest, the posttest scores cannot be directly compared using a t test. As a result of this difference, an analysis of covariance must be performed. This will adjust posttest scores for initial differences on the pretest related to performance on the dependent variable as reflected by the CAIN posttest.

**Preliminary Results**

The initial result of this study indicates that technology training reduces computer anxiety. Both the Control Group and the Experimental Group showed reduction in anxiety levels as reflected in the score increase on the CAIN posttest. These results answer the research question affirmatively. The faculty development model reduced computer anxiety of in-service teachers as reflected by the CAIN.

There is a difference in the CAIN posttest scores between in-service teachers who participate in the faculty development model and in-service teachers who participate in traditional faculty technology integration training. Further statistical analysis must be completed to determine if there is a significant difference.

This paper was submitted to the Society for Information Technology and Teacher Education conference for inclusion in the Proceeding Papers. The previously mentioned statistical analysis was formally presented at the SITE 2000 conference. If unable to attend the presentation, contact the researcher for final statistical analysis.

Abstract: This paper is a report on the findings of a two-part study undertaken to determine how teacher education programs prepare pre service teachers to use technology in their instruction, and to determine the influence of decade of initial teaching degree on a teacher's willingness to use technology. The teacher education faculty from four institutions with teacher education programs were surveyed to determine the method of technology introduction currently being used. In the second part of the study, teachers from a small Pennsylvania school district were surveyed to determine the decade of initial teaching degree and the technology that these teachers were using in the classroom. According to the results of this study, decade of initial teaching degree is not a sound indicator of a teacher's willingness to use technology.

Introduction

Throughout the country, teacher education programs have been undergoing a restructuring process that is, in part, aimed at preparing students to teach in the twenty-first century (Barker, Helm & Taylor, 1995). Efforts are being made to provide future teachers with the expertise that they will need to use the technological resources that have become available in recent years. Among these new technologies are audio, video, computers, telecommunications, distance learning, and multimedia. As additional research is presented citing the benefits of technology on teaching and learning, it has become increasingly important for teachers to have exposure and experiences that will lead to their competence in these areas.

Review of Research

Recent research has shown that many areas of education can benefit from new technologies. Johnston (1997) completed a study of the changes in verbal abilities of kindergarten students when exposed to interactive CD ROM storybooks. He demonstrated that when these storybooks were used with students for as little as 50 minutes per week, their verbal abilities improved. In 1989, Reed was able to show how composing process software could improve the quality a student writer's creative writing. Later, in "The Effect of HyperCard Authoring on Knowledge Acquisition and Assimilation", Reed and Rosenbluth (1992) determined that students creating HyperCard programs showed dramatic increases in their ability to interrelate knowledge. In a later study, Higgins (1996) determined that the use of hypermedia study guides was an important factor in the retention of factual and inferential information presented to remedial students. Research into specific technologies, such as speech recognition computers, has shown promise when used with learning disabled students (Wetzel, 1996) and programs such as KidPix and Writing Center have been effective in helping even very young children with the task of creative writing (Wetzel & McLean, 1995). The area of mathematics has benefited from selected hypermedia programs that have been used successfully to improve mathematical problem-solving skills (Babbitt & Miller, 1996).

Beyond the findings of recent research, additional incentives to add technology to teaching programs have come about as a result of the National Council for Accreditation of Teacher Education (NCATE) concern for the state of technology programs being offered to the nation's teachers. NCATE, a national organization that accredits teacher preparation programs, suggests that "education schools should be required to incorporate technology into their programs in order to be accredited" (Bradley, 1997). As a result, more college and teacher education programs now include some form of computer training in their programs to satisfy this requirement for certification. Most teachers now exit the teaching programs with some knowledge of computers and technology and their various applications.

Generally, pre-service teacher education training programs are approaching this technology training in one of two ways. One approach, the competency model, offers students technology training in a core computer
literacy course. Instructors with specific skills and computer knowledge teach these classes, and they have the advantage of being planned so those students will exit the class with predictable general technology skills. The other approach, the integration model, introduces the core course competencies within the methods and content courses. The integration of the technology is theoretically introduced in meaningful ways and is applied to the methods being taught. It is assumed that the instructors of these methods courses are competent users of the available technology (Wetzel, 1993).

Purpose of Survey

To determine how local teacher education institutions are introducing technology training, an informal e-mail survey was sent to teacher education faculty of four colleges and universities located in Pennsylvania and West Virginia. These institutions were chosen because they offer known teacher education programs and because the faculty e-mail addresses were readily accessible from the institution’s WEB sites. When choosing the institutions to be included, an attempt was made to include schools with both large and small teacher education programs. This determination of size was made after comparing the number of faculty associated with each program. The larger programs were designated University #1 and University #2. The smaller programs were from College #3 and College #4.

In this survey, instructors were asked to respond to four questions. Question one asked the instructor to identify the classes he/she was currently teaching. The second question asked if a core computer course was required within the teacher education program. The third question asked the respondent if he/she included any technology training within the classes being taught, and the final question asked for an explanation of how technology was being integrated into the courses to make it a meaningful presentation.

Results

Responses to the survey were received from each institution. College #3 sent one reply that was initiated from the Dean and was meant to be a statement of college policy regarding computer and technology. The other three all gave detailed and individual information about their teacher education programs and how technology was being integrated into their classrooms. Eleven individual replies were received from University #2, two were received from College #4, and eleven were received from University #1.

From these survey returns, the following information was gathered: University #2, College #3 and College #4 each presents technology directly through the use of required courses. They rely on the competency model of computer and technology training for their instruction in these areas. Though they represent different regions and are of varying sizes, they have chosen the same model for this instruction.

University #1 is the only one of the four surveyed institutions using the integration model of computer and technology training within the teacher education program. This university is the largest of the surveyed institutions with an undergraduate enrollment of approximately 15,000 students. At University #1 technology is introduced within the education classes being taught, following the integration model. Instructors introduce and present technology applications from within the methods and content courses. Most, but not all of these classes have some requirements that students use word processors, and many of the instructors use e-mail with students on a regular basis. However, while this integration of technology is a mandatory inclusion in the program, not all faculty are at ease with computers and the requirement to include computer technologies into the curriculum is apparently often ignored.

TECHNOLOGY AND THE PUBLIC SCHOOL

Some of the nation’s school districts, recognizing the need to train computer literate students, have spent millions of dollars to bring technology to the classroom (Toroian, 1998). However, this massive expenditure on hardware may be ill spent if it is not used correctly or to its full capacity. Education Week (Coley, 1997) reported that currently the use of computers in classrooms is meager, and that many students in American public schools spend less than an hour a week (or 2%-3% of instructional time) at the keyboard. This article continued by pointing out that the computer applications commonly used are unimaginative and often inappropriate, and are usually limited to word processing and remediation activities. Even among the schools that have adequate multimedia capability, it is unusual to find schools that are using technology for much more than “drill and practice” exercises. Wetzel (1993) claims that at least from a holistic view, “drill and practice” is actually an inappropriate use of computer technology. Yet, this is usually the primary emphasis of many
computer programs and is the main purpose for Title I programs that supply computer technology for remediation (Coley, 1997).

The Minnesota Department of Education addressed the question of computer competency of public school teachers after conducting a statewide survey of teachers that pointed out that few teachers had any more than the "most rudimentary computer skills" and were unable to pass on any computer knowledge to their students (West, 1990). Despite their lack of computer skills, the survey also showed that these teachers were curious about how to use technology in more effective ways. The survey also indicated that short term training programs for teachers were ineffective and that teachers needed five or more years of experience with computers before they began to use them for more than the most basic instructional applications (West, 1990).

The inability to use the technology creatively is often blamed on the lack of teacher training and the hesitancy of the classroom teacher to use the hardware and software available to them in appropriate ways. Possibly, older teachers who never received technology training lack the skills necessary for creative integration. Currently, new teachers are being taught many of these skills within their teacher education programs (Fulton, 1998). These programs now recognize the need for technology training and are making efforts to include this knowledge, but many new teachers still exit the programs unwilling to use technology for any but the most basic uses. Wetzel (1997) suggested that teacher education programs are at fault and that the method of instruction should be a combined form of the integration and the competency models rather than the current trend of using only one model. He believes that the core classes are needed to teach students basic skills but that the integration model is necessary for prepare students to integrate technology into their classrooms.

The Study

The second part of this study was undertaken to determine how teacher descriptions of their use of technology in the classroom vary according to the decade in which they were certified to teach. In an attempt to answer this question, a survey was developed to explore attitudes related to computer use of teachers in a small school district in Pennsylvania. Following administrative approval the survey was distributed to teachers in a small Western Pennsylvania school district. This district is comprised of eight schools. Five of the schools are located in rural areas and the remaining three are within the city limits.

The questions in the survey pertained to the use of technology in the classroom, personal feelings about computer technology, and how technology is being integrated into the instruction. Specifically, the survey was designed to determine the year of original teaching degree, the teacher’s familiarity with computers and other technology, the instruction they had received from college or university courses into the uses of technology, and ways in which they were able to apply technology within their own teaching situations. The results were tabulated to provide information in two ways. District totals for all teachers were counted to determine overall technology usage and then these counts were separated according to the decade of the teacher’s original teaching degree.

Data Collection and Analysis

The survey and a stamped, self addressed, return envelope were distributed to 235 teachers in the district. One hundred twenty-three (52%) of the surveys were returned by the cut off date indicated. All were usable for tally purposes and 84 (68%) included comments that were useful in determining actual computer and technology usage within the classroom.

Teachers who had graduated within the past 8 years comprised the most recent graduate group and it was determined that this group would be the most helpful in determining how teaching programs currently train students. Therefore, all questions were divided into groups representing information from teachers graduating within ten-year time frames. Also, the year of original teaching degree was used as an indicator of the age of the teacher. Dates of original degrees ranged from 1962 to 1997, and were divided into decade groups for comparisons. Interestingly, fifty percent (N=62) of the respondents received their degrees between 1970 and 1979 and only eleven percent (N=14) had graduated within the past eight years. Responses to remaining survey items were tallied and percentages were calculated.

Results

Fifty-five percent of the surveyed teachers indicated that they had used computer applications or instructional technology in their classroom in the 1998-99 school year. There was little difference between those who had graduated in the 1960s and those who were recent graduates in this specific area. Fifty-nine percent of the 1962-1969 graduates had used computers or instructional technology, and fifty-seven percent of those graduating between 1990 and 1997 reported using it. For the most part, the actual technology used was the TV/VCR, (62%) but thirty-seven percent indicated that they included word processors, twenty-five percent used instructional software, twenty-two percent used drill and practice software, and twenty-one percent reported using video presentations. Almost exclusively, the technologies used could be considered passive learning experiences, meaning those experiences that required no construction of knowledge by the student.

When teachers were asked about their personal computer use, sixty-nine percent indicated that they have a computer in the home. When broken down into decade of original teaching degree, there was very little difference in percentages between those graduating in the 1960s and those more recent graduates about which group was more likely to own a computer. When asked about how they rated their proficiency with computers, sixty-one percent rated themselves as beginner or novice users, twenty-nine percent indicated that they were intermediate users, and the remaining nine percent rated themselves as advanced or expert users. One failed to respond. When these numbers were broken down by decade of original degree, the percentages were much the same, with no one age group rating themselves as more proficient than the overall average. There was however, a noticeable difference between decades when answering this question about attitudes towards technology. Twelve percent of the teachers admitted to hating or barely tolerating computers, thirty-six percent rated them as OK, and fifty percent stated that they liked or loved using computers. The 1962-1969 graduates reported that forty-six percent of them liked or loved computers, but the 1990-1997 graduates reported that sixty-four percent had the same attitude. Those more recent graduates were more likely to like or love computers, when compared to those who had graduated in the 1960s or 1970s.

The questions about computer classes taken and feelings about preparation for using computers and technology in the classroom may be related to why teachers are not using these technologies in the most appropriate ways. These questions showed that the percentage of those taking a college level computer class has risen from thirty-eight percent of the 1962-1969 graduates, to ninety-two percent for the 1990-1997 graduates. It also points out that only 50% of those 1990-1997 graduates rate their college or university experience as having prepared them to integrate technology into their classrooms.

Discussion

This survey indicated that eighty percent of the teachers in this district received their initial teaching degrees between 1962 and 1979 and only twelve percent of them have graduated within the past seven years. If initial degree can be used as an indicator of approximate age, over all, the teachers in this district are between the ages of 40 and 55. Therefore, most received their teacher training before computers and other current technologies were included in the teacher training programs. Only thirty-three percent of those 99 who graduated between the years 1962 and 1979 reported having ever taken a college level technology or computer class. Surprisingly, though few had any college level classes in computers, there was very little difference in their reports of technology use within their classrooms when compared to the more recent graduates.

The possible conclusion drawn from this survey is that age of the teacher, as determined by date of college graduation, may have little to do with how likely the teacher is to use technology within the classroom. Also, age seems to have little bearing on how users rate themselves in computer proficiency, or how likely they are to have a computer in the home. Age does appear to be related to rating personal interest in computers. Age may also be related to how individuals feel about their college training in preparing them to integrate technology into their instruction. Of those graduating in the 1960s, only eight percent stated that they have been adequately prepared, while fifty percent of the most recent graduates feel prepared. Those more recent graduates are also far more likely than their older colleagues to indicate that they enjoy using computers. If the results from these surveys can be taken as an indicator, it appears that teacher education programs may have little effect on a teacher's willingness to use computers and other technologies within the classroom.
Interestingly, those teachers graduating in the 1960s were more likely to rate themselves as using computers in meaningful ways in their instruction than those who had graduated within the past ten years. (59% vs. 36%)

The most meaningful and insightful parts of this survey were gathered from the handwritten notes that many respondents attached. From examining these notes it was determined that many teachers attributed the inaccessibility of computers and other technology for their failure to use them in meaningful ways. Many responded that the technology was not available to them or was not available in sufficient numbers to be useful. Two teachers actually reported that they had computers in their rooms but that they were still in the box. One explained that only ‘certain people’ were permitted to remove and set up the computers and that those persons were not yet available to them. Teachers also wrote about inadequate training in the use of available technologies, lack of priority for computers and other equipment being included in the budget, lack of time within the school day for including computer usage, and a lack of priority by the school district in recognizing the importance of the role of technology in education. Another complaint reflected in the handwritten notes was that technical help was not available for keeping the equipment maintained and in operating order. The overall feeling gathered from these surveys was that budget constraints largely determined the minimal integration of technology for other than remedial and passive learning situations.

Abstract: The paper reports two case studies conducted at three schools in California. The first case study investigated computer literacy levels of thirty-five teachers at two schools. Findings indicate that teachers do not fully use software available to them and that they need technology training, especially small group or one-on-one training. The second case study examined the levels of twenty 5th grade students at a school. Results indicate that students do not have sufficient computer skills and more training needs to be provided. The case studies reveal that computer skills of both teachers and students need to be enhanced.

Introduction

Technology has become an ever-increasing factor in today's classrooms, and computer usage in the classroom is on the rise. Along the trend, we have been seeing President Clinton and Vice president Gore promoting technology use in education, business sectors donating money to institutions, schools receiving federal or state grants for upgrading technology on sites, and decision makers investing a tremendous amount of money into computer technology. While all of these are happening simultaneously, training our teachers and students to be technology literate to improve the quality of education is the ultimate goal.

The literature indicates a close relationship between the training a user has on technology and his/her comfort level of using the technology. Chiero (1997), in her study of teacher computer users, noted that the more training the teachers received, the more likely they were to be comfortable users of the technology. Walters and Necessary (1996) studied business school students and found strong correlation between the number of computer classes a student had taken and the positive attitudes those students had about computer usage in general. These studies indicated that if users have more
training, they feel more comfortable of using technology. Do our teachers have adequate computer experience and training to be comfortable users of computers in classrooms?

Mowrer-Popiel, Pollard, and Pollard (1994) found that many preservice teachers did not have much computer experience upon entering the classroom and concluded that districts should invest heavily in teacher technology inservice training. The preferred method of learning new technologies in their study was in the following order: a tutor, a class, own experimenting, and instruction manuals. Marcinkiewicz (1994 & 1995) found that preservice teachers had much more experience with computers than did their inservice teaching counterparts. This indicated that although schools are investing in computer technology, either not enough is invested into training or that the training is not being utilized to its fullest.

The following two case studies examined levels of computer literacy of school teachers and students. Research methods and results are reported. Suggestions are provided to educators.

The Case Studies

Computer Literacy of School Teachers

The study is intended to discover whether teachers at two schools, that are well equipped with modern computers, are as computer literate as one would expect. The focus was on one elementary school and one middle school in a school district in Southern California. Both schools have fast access to the Internet, and each classroom has at least one computer hooked up to the Internet. Teachers have received extensive training in a variety of software applications, and each school has had a technology mentor residing at the school for the past two and one half years. Has the training that the teachers have received over the past couple of years benefited them? The goal of this study was to examine the current use of computers among teachers at these two technologically advanced schools.

The instrument used for this study was a survey. Thirty-five teachers at the two schools responded to the survey on their use of technology. The survey asked specifically about the teachers' use of computers, related software, and the Internet. Surveys were to remain anonymous to aid in the truthfulness of respondents. The survey was meant to discover teacher knowledge of their own computers, to ascertain the software usage and frequency of use, and to discover what type of training they would like to see in the future.

Results indicated that teachers had several programs available to them. The two schools belong to the San Bernardino County Open Mail (Omail) system. Both schools rely heavily on email for communication, and it is understandable that this percentage of use is high. Of the 88.57% of the teachers who said they had access to the Omail software, 93.55% of the respondents said they used it at least once a week. In a related question, it was found that actually 100% of the teachers used Omail at least once per week. Some teachers were just not aware that they used the Omail software as their e-mail system.

Three word processing programs were available to the teachers. Of the teachers that had access to various word processing programs, the usage dropped to only 50 percent of the teachers using them at least once a week. As to the use of a grading program, sixty percent of the teachers had a grading program at their disposal and yet only 57 percent of those teachers utilized this program on a regular basis. Many teachers had software available to them but did not seem to utilize it as much as they could.
A vast majority of teachers said they were comfortable using a computer. Sixty three percent of the respondents stated that they had moderate computer experience and 20 percent of them expressed that they had a lot of computer experience. The teachers who stated that they had a lot of computer experience utilized software more often and to a higher degree than did others who rated themselves with moderate computer usage or little computer usage. These high-end users also tended to use a larger variety of programs than did other users.

Respondents overwhelmingly (91 percent) wanted to see more technology inservices within the district. Eighty six percent felt that small group or one-on-one instruction would be the most beneficial way of having future inservices. One teacher stated, "I find I am particularly slow in the large group training sessions. Most others are way ahead of me and if I make a mistake the leader sometimes will not get around to help me for 20 minutes, and I am lost." Several teachers felt the smaller group setting would be more advantageous for teachers to build up their self-confidence especially when coupled with follow-up training within 3 to 5 weeks after the initial training.

Overall, the results indicated that the teachers, who felt they were moderate computer users, did not have the confidence that this could instill in them. Teachers did not use the available software in great numbers with the exception of the high-end users. The findings validated Chiero's study (1997), which found that a small group of high-end users utilized most of the programs available to them and were considered to be "exemplary computer users", while lower-end users got by with the basics. Marcinkiewicz (1994 & 1995) found that districts often invested in computer training inservices, but often that training, which was done in large group settings, seemed to benefit the high-end users the most. Since high-end users made up the smallest group of computer users within the district, the money for these training inservices did not seem to be utilized the best way possible. Teachers of this study also stated they would like to see more inservices, but at a smaller scale. It is recommended that school districts provide small group inservices training. In this inservices training, teachers may get one-on-one help without feeling intimidated by high-end users who are often moving at a more rapid pace. Since the preferred method of learning new technologies, according to Mower-Popiel, Pollard, and Pollard (1994), was via tutor, it would make most sense to provide this type of one-on-one instruction. Teachers would get what they wanted, and districts would probably get more long term technology users for the money they spent on inservices.

Computer Literacy of Students

The study was intended to examine whether there was a discrepancy between what students perceived to know and what they actually could do with the computers. The study was conducted in a 5th grade class at an elementary school. In January of 1999, the 5th grade class was given 5 computers. These computers were going to be wired to the Internet later this year. The school district was studying whether students would do better on writing prompts that the district used if they used computers. The school district had made the assumption that the 5th grade students could use computers and could understand how computers worked. The researchers attempted to examine the assumptions—students’ computer literacy levels.

Subjects of the study were a convenient sample of ten boys and ten girls in a 5th grade class at the school. Students were mostly Limited English Proficient students (LEP). The school has been designated an underachieving school by the school district. The school scored in the 19% in the Stanford-9 and had been ranked as the lowest school out of 23 elementary schools. The social economic status of the student population was low; Eighty seven percent of all of the students received free lunch based on the criteria set up by the state.

The survey consisted of 15 simple yes or no questions to gauge the students’ computer skills. The questions ranged in level of difficulty from basic to more complex, like whether they knew how to turn on a computer, print a document, or change font in Microsoft Word. The students completed the survey in class. They were not given a time limit for completing the survey. One of the students was given assistance in translating some of the questions from English to Spanish.
A few days later, the students' practical performance was tested based on the same survey. The students were called over to the computers two at a time. They demonstrated the skills addressed in the survey and were graded. The researchers tabulated and compared the scores of the students' perceptions and the scores of their demonstrations.

The results indicated that although the students had often been exposed to the computers and had five computers in the class, the students did not have the skills needed to comfortably use the computers. The students tested higher than perceived with questions such as "Do you know what a monitor is?" "Do you know how to eject a CD from the computer?" and "Do you know how to use HyperStudio?" They tested lower than perceived with questions such as "Do you know how to turn on a computer?" or "Do you know how to save your file to a disk?" Many students had also problems navigating through Microsoft Word.

The results also showed that the boys had higher confidence on using computers than girls. All of the boys perceived that they could draw a picture using the paint tool from HyperStudio. When tested, 100% of the boys succeeded drawing the picture. The girls on the other hand were more conservative on their perceptions. Forty percent of the girls perceived that they could eject a CD from the computer. However, when tested, 100% of the girls were able to complete the task. Both groups tested lower than they perceived on the use of the spell check while typing something. Seventy percent of the girls perceived that they could use the spell check. Only 40% of the girls knew how to use it. The boys on the other hand perceived that 100% of them knew how to use the spell check. When tested, 60% of the boys could use it. It was noted that the girls tested higher than the boys on only one item out of 15. On the question about changing the font using Microsoft Word or Works, the girls tested 80% while the boys tested 70%.

The results showed that the students needed to enhance their skills of how to operate computers. Before meaningful instruction via computer can be achieved for these students, the students will have to feel comfortable with the basics covered in the survey. Teachers will have to be aware of the difficulties which the students have in using computers, and will have to be aware that the students will not be able to judge their own abilities quite correctly. Extra time for teaching these basics was necessary.

Conclusion

The results of the studies revealed that computer literary levels of teachers and students need to be enhanced and that technology training must be provided. In addition to large scale training sessions, teachers, especially teachers who do not have advanced computer skills, prefer small group training or one-on-one instruction. As to students, there might be a discrepancy between what they think they know about computers and what they really know. When evaluating students' computer knowledge, it is helpful to have students demonstrate their skills using computers. In the Information Age, computer skills are becoming necessary skills for every citizen. Training teachers to be computer literate to enhance education quality and helping students to be computer literate to face their future challenges are one of the important missions of our nation. We can only imagine the positive impact of the training on our society.

Abstract: Preliminary surveys conducted by the authors suggest that students at the secondary school level are likely to feel much more at ease with the vocabulary of information technology than the pre-service teachers who will soon be expected to integrate technology into their teaching. We present a discussion of our survey instruments and first results and we explain why we feel teachers should understand the sources of technology jargon, which we call "CyberJive."

The Special Nature of Technological Jargon

Although software designers have long promised intuitive interfaces and "transparent," easy-to-use devices and software agents, we have good reasons to believe that technology is getting more, not less complex (Fowler and Zhang, 1994). We also doubt the claim that a new generation of pre-service teachers will be technologically sophisticated, as part of a "Nintendo" or otherwise-labeled generation. Although we would like to concentrate on the applications and curricular integration of instructional technology, we find preservice teachers don't understand the tools well enough to apply them to instruction.

We have evidence that preservice teachers are hampered by the terminology related to the tools we want them to use. Lacking the necessary vocabulary, novice users simply don't know what is going on. Not only do most preservice teachers not possess the requisite terms and expression, most of them do not want to know the terms.

Unlike the jargon of many other areas, for example the terms of physiology or traditional mathematics, where the terms have a certain linguistic consistency, based on Latin and Greek roots, the jargon of instructional technology is a hodgepodge of expressions of different sources. For example, we have acronyms, marketing terms, and desktop metaphors often mixed into the same sentences as part of an overarching explanation.

As Fellenz, Parkkinen and Shubin (1998) point out,
"Metaphors can help users achieve their goals in using a system. The desktop metaphor has been very successful in making computer systems accessible to the general public. On the other hand, metaphors can lead users astray, especially when they are mixed together in one user interface. Users find it difficult to determine which controls apply to which part of the application. This has created confusing environments for users. Advances in technology, such as frames and dynamic HTML have further added to the complexity of the situation, creating potential pitfalls for designers and ultimately usability problems for users."

We assert that most terms used in instructional technology come from one of the following sources:
1. Fundamental technologies, such as development of computer operating systems and low-level languages;
2. Variations on the "desktop" metaphor
3. Variations on the "Web" metaphor
4. Marketing labels and slogans derived from the above and from science fiction sources.

Most readers are familiar with the distinction between declarative and procedural knowledge. A simple example often given describes procedural knowledge as knowing how to carry out a task—for example how to ride a bicycle—without being able to explicitly describe what is necessary to carry out the procedure. There may be no special disadvantage to the ordinary task of riding a bicycle without knowing the names of any of the parts of the machine. On the other hand, to repair a bicycle, or more emphatically to teach someone to repair a bicycle, one needs to know the names of the components. Therefore to establish a foundation for a smooth communication.

Although we once thought that by now our various instructional technologies would be "seamlessly" integrated, and the use of computers would be as simple as riding a bicycle—without knowing any special terms, other than a few obvious "desktop" metaphors—this has not happened.

The increasing complexity is reflected in the terminology of instructional technology, not just in the increasing size of the vocabulary, but in the strange mixture of terms that have come together from various sources to comprise the strange language we call CyberJive.

We have appropriated the term "jive" in the dictionary definition: "a special language of difficult or slang terms." We feel that this term, used with this sense, comes closest to describing the way we speak when we try to convey the complexity of technology to our preservice teachers. We conjoin the terms "cyber" and "jive" because cyber is one of, perhaps the central, term from which our present-day array of neologisms develops.

A Preliminary Assessment

We presented the following survey to two groups. The first group was a set of high school juniors enrolled in a summer course in computers and business management. The second group was a set of preservice teachers enrolled in a course in instructional technology.

Our purpose was to establish a preliminary comparison of preservice teachers and secondary school students by asking them to make a self-appraisal in terms of their understanding of terminology commonly encountered in the use of computer technology. Participants were asked to rate their understanding of the list of terms by circling the appropriate number:

1- Understand this term  2- "Sort of" understand this term  3- Don't understand this term

We selected twenty terms in each of four categories:
- Technical vocabulary: asynchronous, bit, byte, CD-ROM, ...
- Desktop metaphor: copy, cut, paste, window, ...
- WWW vocabulary: browser, link, search engine, home page, ...
- Science fiction and marketing: Cosmo, Cyberspace, Cyberstudio, Firewire, ...

The survey results have been analyzed using a t-test for paired samples. We set the level of significance at \( \alpha = .01 \) for two tail t-test. The self-perception survey included 80 terms. The result shows preservice teachers' average understanding as 45.03% and high school students' averaged as 78.84%. In comparing
the means of the two groups, the data produced a t statistic of $t = -15.41$. The difference is significant because in the t distribution table for df=79 and $a=.01$ for two-tailed test, we find a critical value $+2.660$. Thus, a t statistic more extreme than $-2.660$ would be significant.

The mean scores for the two groups show a significant difference, and encourage us to explore more sophisticated instruments for measuring content knowledge. Even allowing for over-estimation of knowledge by the younger participants, the results imply that this group has a much higher comfort level with the vocabulary.

We believe that it would be useful to present our pre-service teachers with background information on the sources of technical terms, as outlined in the following description.

**From Steersman To Mirror Shades**

The term "cybernetics" was coined by the mathematician Norbert Wiener, as an over-arching term to describe the work of a group of mathematicians, physiologists, engineers and scientists working on related problems in control and communication theory. The intersection of various research paths connecting theories of automatic gun control with studies of nervous system disorders are described in the introduction to Wiener's book, *Cybernetics, or Control and Communication in the Animal and the Machine* (Wiener, 1961). A central theme in these studies was the concept of feedback. The notions of steering, piloting, or control were ideally described by a Greek term for one who steers a vessel. As Wiener describes it:

"After much consideration, we have come to the conclusion that all the existing terminology has too heavy a bias to one side or another to serve the future development of the field as well as it should; and as happens so often to scientists, we have been forced to coin at least one artificial neo-Greek expression to fill the gap. We have decided to call the entire field of control and communication theory, whether in the machine or in the animal, by the name Cybernetics, which we form from the Greek cybernetes, or steersman." (page 11).

Few neologisms have proliferated to such a degree. Perhaps only Buckminster Fuller's term "synergy" has been so enthusiastically appropriated. Wiener and company were closely associated with the development of computing machinery, which in the late 1940's was still implemented in vacuum-tube-based hardware. Even then, the computer had captured the imagination of the public as well as scientists. The notion of a "thinking machine" fit naturally with the notion of "robots," a term coined by Karl Capek in 1923. Although "artificial intelligence" was not officially designated until 1956, when John McCarthy, Herbert Simon, Marvin Minsky and Allen Newell used the term in a conference at Dartmouth, Groff Conklin had already assembled an anthology of short stories speculating on the possibilities of machinery with cognitive capabilities (Conklin, 1954). In a preface to one of the stories, Conklin wrote: "The idea of the less inhibited cyberneticists [emphasis added] is that every function of a repetitive nature that man now has to perform should eventually be taken over by machines." Thus "cybernetics," and increasingly, the root cyber became associated with computers, especially computers with higher-level cognitive abilities.

Wiener would probably have been fascinated to see the collision of neologisms with the resulting designation "cyberpunk" for a genre of science fiction that developed during the 1980s, characterized by integration of visionary stretches of technology combined with street gangs, mega-corporations and international alliances of hustlers. The style itself is accurately described in Bruce Sterling's anthology, *Mirrorshades*. (Sterling, 1986). In the center of the cyberpunk movement, characterized by Sterling as the author of the "prototypical cyberpunk novel," is William Gibson. In his novel, *Neuromancer*, Gibson (1984) imagined an international network of scientific, governmental and commercial computer systems loosely connected into a system called The Matrix. The Matrix may originate in various forms of hardware, but somewhere along the line The Matrix becomes something else:

"Cyberspace. A consensual hallucination experienced daily by billions of legitimate operators, in every nation, by children being taught mathematical concepts...A graphic representation of data abstracted from the banks of every computer in the human system. Unthinkable complexity. Lines of light ranged in the nonspace of the mind, clusters and constellations of data. Like city lights, receding..." (Gibson 1984, 51).
From Academic Concept To Amazon.Com

Cyberspace provided the background for a series of novels and stories in which "cowboys" accessed the matrix through direct neural connections and engaged in illegal and dangerous attempts to extract information from proprietary computer systems. By 1991, Michael Benedikt, a professor of architecture at the University of Texas at Austin had published a collection of essays on the implications of Gibson's concept, extrapolating the writer's ideas into the domains of architecture, film and video entertainment, sociology and "virtual reality" (Benedikt, 1991). Ted Nelson's term "hypertext," taken from his notes on Vannevar Bush's "Memex" concept, was well-established by this time, and several authors in Benedikt's collection envision some means for constructing an actual cyberspace by using hypertext links.

As we all are aware today, the practical means for constructing the system was invented by Tim Berners-Lee, who decided to call the system a world-wide web. This system seemed close enough to Gibson's cyberspace to deserve the name. Once the National Science Foundation left the Internet free for commercial development, the equivalence between "The Web" and "The Matrix" was established in most peoples' minds. There may, after all, be a thin line between shared metaphor and "consensual hallucination."

Descriptions of the technical structure of Berners-Lee's system contain references to computer "protocols," "URLs," graphics file specifications, and "HTML," the subset of the generalized mark-up language that is used for description of a web "page" The metaphor of a web, with its associated images of spiders, spinning and strands, underlies some of the product names now used for creating web documents, such as Spider Writer. (http://www.spiderwriter.com/scriptwiz.html.) Other components of the Web, for example the web page generate their own names, e.g., "PageMill." We also have marketing terms such as "Web Whacker," or the unlovely "DogPile" that provide practically no functional description. Such terms add to the confusion of the novice user.

We note that fiction, if not always science fiction, continues to provide terms as metaphors for technology. A popular graphics program running on the LINUX operating system is called GIMP, an association with the mysterious figure in Tarantino's film Pulp Fiction. The graphics add-on called Shockwave, traces its name to a science fiction novel by John Bruner. Neal Stephenson's novel Snowcrash has helped popularize the use of "avatar" in reference to web agents acting in virtual environments.

Why Kids Get It So Quickly...And Preservice Teachers Don't

We would like to suggest three conjectures concerning the technology gap between students and preservice teachers:

Perhaps one of he advantages that younger users of technology possess is their lack of concern with the mixing of metaphor. The older user of technology, trying to find a consistent pattern through the acronyms, information-processing jargon, desktop and web metaphors and outlandish marketing terms gets hopelessly boggled, while the young users simply keep track of the names and labels they need and enjoy the process of using the system.

Perhaps the younger users are living in a significantly different culture than those a few years older. Certainly popular fashions change quickly - couple this with the 18-month technology development cycle, and it is possible that we are living in a time when an insoluble culture inequality exists between students and teachers.

Perhaps the students who want to become teachers are motivated by an interest in the human service side of teaching, and see computer technology as an antisocial force. In fact, web-based communication gives us great potential for human interaction, once we understand the uses of the system. Pre-service teachers who are not immersed in the internet have not experienced this. Hence, they reject the tools.

Conclusion

Learning to use instructional technology means confronting a confusing, even contradictory collection of metaphors. Understanding the history of technology helps us sort out the different metaphoric strands. A good start for instructional technology teachers would be to include a video series such as The Machine that Changed the World, and the accompanying text (Palfreman and Swade, 1991).
Finally, we note that most instructional technology conferences, whether regional, state, or national, include at least one "futurist," to tell us where technology is headed. Perhaps the field is reaching a state of maturity where we can begin to profit from the thoughtful analysis of the origins of our present technology and the language we have inherited with these tools.

Terminology of Educational Technology: A Quantitative Study Based on SITE Conference Proceedings

Peter Serdiukov
Reading Center
University of Utah
Serdiu_pe@gae.utah.edu

Abstract: This paper is a report on the findings of a quantitative study of the Educational Technology (ET) terminology conducted on the materials of SITE 99 Conference. These findings allowed us to single out different technologies used in education, give a formal definition of ET, and identify its areas. A model of ET area is developed. The list of the most frequent terms is presented.

Introduction

Terminology of a specialty field or an area is like a human body's vital signs: its parameters can reflect its current status and help derive interesting and useful conclusions relating to the field itself. Our quantitative analysis of Educational Technology (ET) terminology is based on the Proceedings of the SITE 99 10th International Conference that took place in San Antonio on February 28 - March 4, 1999 (3). In all we processed 986,619 word forms that yielded 26,972 different words. Some of the findings are presented in this paper.

Technologies in ET

What is ET of today? It is a rapidly developing field embracing a wide range of areas. It covers a number of topics from General Education, Pedagogy, Methodology of Teaching and Learning, Psychology, Social Constructivism, and Information Technologies. Educators now participate in the development of new forms of technology-assisted/supported/mediated/based or related teaching, training, instruction and learning (e.g. Computer-Assisted Learning – CAL, Computer-Assisted Instruction - CAI, Computer-Based Instruction – CBI, Web-based Instruction (WBI), Distance Learning (DL), Asynchronous Learning (AL), Teleteaching, Webtraining and so on).

Technology of today can be simply Educational (ET) or even Advanced-Educational (AET), Teaching, Training, Instructional, plain face-to-face Learning and Distance Learning, Computer (CT), Microcomputer, Supercomputer or just Computerized, Electronic, Digital, Informational (IT), Delivery, Communications and Telecommunications (TT), Active, Interactive, Media, Multimedia and Hypermedia. New terms were coined in Europe for the ET areas: Educational Informatics – the Science of Education based on Informational Technologies, and Telematics – Telecommunications-Based Education.

It is natural that due to the ET rapid development there is some confusion in the use of its terminology: thus, in the general term “technology” different authors include various technologies, devices, their parts, and techniques, e.g.: telecommunications technologies, wireless technologies, telephone communications, teletext, video, computers, CD-ROM, CD-players and even multimedia applications.

At the SITE 99 Conference, 85 various technologies were named (Appendix 1). It is doubtful that all the "technologies" presented by the speakers could be actually called technologies, for instance, "audio tape", "chat", "discussion list", "hand-held", "preservice", "spreadsheet-based", "text-based" and other technologies. I suggest that we differentiate between technologies, like Information, Computer, Telecommunication, Educational Technologies, and techniques, for instance, how to use ET in training preservice teachers, or how to apply spreadsheet in teaching accounting. Here we agree with R. Heinich...
who wrote: "a teaching technique is not technology... some prestigious reports represented seating chart as technology in the classroom. This trivializes technology" [1].

It is necessary to cut a dividing line between technologies, tools, applications and methods. Thus, there is Communication, Instructional and similar technologies, and tools, such as hardware tools: CD-ROM, laser disk, audio tape; software tools: word processor, database, teletext, etc., and educational tools: courseware, computer courses and tests, educational computer games, teleconferencing, etc. Then come applications of these tools and techniques, and methods of their use in teaching and learning.

Definition of Educational Technology

What, actually, is ET? It is a set of specific educational tools and their applications in teaching and learning. (NB: It is remarkable that Pedagogy is differentiating between non-machine and machine didactic tools and corresponding technologies.) What tools does ET deal with? – Today in the inventory of pedagogic tools we include technical (hardware), programming (software), didactic (courseware, textbooks and other materials), and methodological (methods and techniques) tools. These tools are used by the people (teachers) and for the people (students) to deliver new information and provide the building and development of a general and particular professional knowledge and skills. Application of ET has for the goal an increase of efficiency of teaching/learning processes, of educational research and of the administration of educational institutions of all levels.

ET can be defined as a system of technical, programming and didactic tools that are used in education together with human and informational resources to construct individual and group general and specific professional knowledge, to provide meaningful interaction between students, teachers and teaching/learning materials, to mediate communication and collaboration among people involved in the educational process, and to develop particular competencies and skills on the basis of related sciences, technologies and techniques with the goal of improving the efficiency and quality of teaching, training and learning, of pedagogical research and school management [2].

Areas of ET

To single out the areas of ET, we analyzed the structure of the SITE 99 Conference and found out that there were 24 separate sections at the Conference with 414 papers presented and published in the Proceedings. The most active sections were: Distance Education - 44, Research - 38, Graduate and Inservice - 34. Three telecommunications sections pulled together 35 papers. So, it was clear that the primary topic of the last conference was Telecommunications Technology in education and Distance Learning as a specific form of education based on this particular technology.

Our study allowed us to define 3 major ET areas: Computer, Telecommunications and Non-Computer Technologies, the latter embracing audio, video, audio-visual, TV, projection and other technologies. An important part of ET terminology field is the area of General Educational terminology that relates to all other areas and includes major educational terms associated with ET.

Table 1. Structure of the ET Terminology Field

<table>
<thead>
<tr>
<th>Terminology Areas</th>
<th>General Education</th>
<th>Computer</th>
<th>Telecommunication</th>
<th>Other Technologies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Terms</td>
<td>536</td>
<td>598</td>
<td>628</td>
<td>160</td>

<tr>
<td>Total Frequency of Usage</td>
<td>25067</td>
<td>16788</td>
<td>17238</td>
<td>1973</td>
</tr>
</tbody>
</table>
The majority of different terms, as follows from Table 1, are related to the Telecommunications Technology area, though the General Educational terms make up the largest part of the field.

Model of ET Area

We developed a model to describe an ET area that consists of 10 components:

<table>
<thead>
<tr>
<th>1. Technology Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>2. Hardware</td>

</table>

The Most Frequent Terms

Very significant is the list of 47 most frequent words (with the frequency ≥1000) (Appendix 2). These terms fall into 5 distinct subject groups (some words fall into two groups - e.g. program, information, communication):

1. Technology: Technology, computer, software, Web, Internet, online, support, tool, site, system, (computer) program, environment, e-mail, information, communication;
2. Education: Education, learning, instruction, teaching, training, course, class, curriculum, process, activities, development, knowledge, skills, information, resource, design, system, level, (course) program, material, communication;
3. School: School, university, classroom;
4. Research: Research, project, study, data, experience, need;
5. People: Student, teacher, faculty, professional, group.

These words allow us to determine the general focus of the conference reports.

Compound Terms

There is a tendency to create new compound terms that denote the level and character of technology use in education. They typically combine an extension with one of the four major terms - technology, computer, Internet and Web. The extensions are varied: accessible, administered, aided, assisted, based, controlled, connected, delivered, driven, enhanced, equipped, enriched, facilitated, focused, generated, infused, integrated, intensive, mediated, networked, oriented, related, rich, supported, and using. The table below shows current preferences in the use of compound words. We used the extensions the frequency of which is 10 or higher.
Table 2. Compound Terms

<td></td>
<td></td>
</tr>
</tbody>
</table>

It is clear that the most frequently used compound words are formed with the terms 'Web', then 'based' that points out to the tendency in today's application of technology: if only a few years ago we often used the compound terms CAL, CAI, etc. that demonstrated the supportive role of technology in education, now we mean education based on technology. This shift in our perception of technology is very remarkable.

Reduction of Compound Terms

The research also showed that there is a tendency to eliminate a dash in a number of compound words thus reducing them to one word: on-line - online (833-1021), pre-service - preservice (316-847), in-service - inservice (193-323), web-page - webpage (11-34), web-site - website (18-154), though in two words the most use is traditional with the same tendency: e-mail - email (726-357), cd-rom - cdrom (147-14). "Off-line" was found to be used only in one form.

Neologisms

We recorded quite a few neologisms which is natural for our fast developing field. To mention just a few, we will present a list of terms based on the stem 'tech': techlearning, technofear, technophobia, technophobe, technophile, techno-poetry, techoutcome, techreform, techtrend, techuse, and so on.

Conclusions

Terminology of a science or a special field like ET is a set of laws that regulates the correct use and comprehension of its notions, units, relationships, and reflects its structure. So, the function of terminology is not only to mirror the status quo in the field, but also to organize it, structure, differentiate between its areas and units, standardize and make it exact and, so, efficient. Incorrect terms or their improper use may lead to the misunderstanding or misinterpretation of the real situation in the field.

The First Decade of the SITE: 1990-1999

Linlin Irene Chen, Ed. D
Assistant Professor
Department of Urban Education
University of Houston Downtown
Cheni@zeus.dt.uh.edu
713-221-8038

Abstract: The SITE annuals have grown from a couple of hundred pages in early 1990s to two big volumes of almost two thousand pages in total in 1999. The advancement of the SITE conferences and annuals reflects the maturity of the field of Instructional Technology itself. The paper plans to conduct a content analysis of the SITE annuals published during its first decade. Main focuses of the discussion will be the development of the telecommunications, the advance of the hardware/software tools, and finally the dissemination of the Annuals and related information. The Annuals represent a significant increase in quality as well as quantity. As the SITE begins its second decade, it is worthwhile to look back at the past.

Introduction

During each spring for the past ten years, the Society of Information Technology and Teacher Education (the SITE, was called the Society for Technology and Teacher Education, the STATE, from 1990 through 1994) conferences have offered faculty, graduate students and staff around the world in the field of educational technology a series of events designed to prompt discussion around issues of information technology and teacher education. These events have been as varied as papers, tutorials & workshops, posters & demonstrations, panels, and corporate showcases. The topics covered in the events serve as major sources indicating the current state of teacher education and information technology.

The author has been involved with the SITE conferences and the annuals since the first Instructional Technology course she took at the College of Education, University of Houston as a doctoral student. It was back in 1994, when Dr. Jerry Willis was the instructor of the course mentioned above and also the presiding president of the SITE. The different roles she has played include: associate editor, author, presenter, paper reviewer, and proceeding CD developer.

The paper plans to conduct a content analysis of the SITE annuals published during its first decade. By analyzing the volumes, total numbers of contributors each year, numbers of contributors for each section, the categorizations of papers into sections, the topics of the papers, the quality of the papers, and the projects described in the papers, we may get a big picture of the emergent trends in the IT field.

The Growth of the Telecommunications Sections

It is not surprising that telecommunications is one of the fastest growing areas in technology and teacher education. The topic of telecommunications has grown from one section of 11 papers in 1991 to two sections (Telecommunications: Pre-service and Telecommunications: Graduate, In-service, & Faculty Use) of approximately 35 papers in the 1995 annual when the World Wide Web was in its infancy stage, to three sections (Telecommunications: Graduate and In-service, Telecommunications: Pre-service Applications, and Telecommunications: Systems and Services) of over 40 papers in the 1999 version. Not to mention those many telecommunications related papers that have been re-categorized in other sections to avoid overflowing.

The projects described in the papers within the telecommunications section(s) also flag the general trends in this field. In the 1990s the SITE had included several papers that outlined large-scaled projects designed to provide initial Internet access for teachers via the networks. These early papers have a mission of serving as a model for other schools and universities that were planning to jump on the Internet bandwagon. For example, in the 1991 version, the majority of the papers (6 out of 11 papers) are devoted to describe initiatives such as PEN (the Virginia Public Education Network), GC EduNET (Georgia...
College Educators’ Network), WCTLN (Wyoming Centers for Teaching and Learning Network), GTE Electronic Pages at Sam Houston University, and FrED (the Free Educational Electronic Mail Network). Some of the described networks may have already been phased out and replaced with newer technology.

The contents of the papers in the telecommunications sections also documented contributing authors’ change of interests from ‘how to start’ to ‘how to improve the practice’. As examples of the early ‘how to’ papers, in SITE 1993, several papers spent pages introducing Internet jargons such as FTP, BBS, telnet, WAIS, Gopher, Archie, Veronica, and listserv. Although listserv is still being used in today’s education, the rest of the terms have been made obsolete by newer technology. The initial projects were exploratory in nature, providing teachers with the opportunity to exchange information and teaching ideas. The explosive growth of the Internet has made it a classroom reality. The latter ‘how to’ papers started to appear in the 1995 version of the annuals with titles such as ‘Teacher Education and the Internet: Where Do We Go from Here?’ (1995), and ‘Look at Communication Patterns on the MariMuse’ (1995). The annuals published in the following years have included more of this reflective type of papers on the topic of telecommunications.

An interesting observation about World Wide Web is that, although many resources indicate that World Wide Web first came into being in 1991 (Geyer, p. 585), the first mentioning of the term was found by the author the section editor’s remark in 1994 by Glen L. Bull and Frank Becker. ‘Although Internet gophers are evolving rapidly,’ Bull and Becker noted in the Preface to the Telecommunications I section, ‘other graphical client-server tools are also maturing. The Mosaic interface is one of the more promising of these tools’ (Bull & Becker, p. 629). While Bull and Becker have not mentioned the term World Wide Web, the first paper on the topic of World Wide Web was found in 1995 Annual, “The Teacher’s Ultimate Classroom Resources: Mosaic and the World Wide Web” written by Roger W. Geyer. This introductory paper first gives a short history of World Wide Web and then provides some demonstration of Mosaic browser.

Ten years have passed since teachers gained initial access to electronic mail and electronic conferencing utilities housed at colleges, and schools. The expanding Internet exceeds any other academic network by an order of magnitude. Beginning from 1991, in the early versions, the names of ‘senator’ Albert Gole, National Research and Education Network (NREN), and the act Gole has sponsored, ‘the High Performance Computing and Communications Act’ have been brought up times and again. NCSA (National Center for Supercomputing Applications) and National Science Foundation are two other names that several other early papers have contributed for the Internet’s rapid growth in schools all across the US.

The Advance of Hardware/Software Tools

The Annual is also a spectator of the advance of hardware/software tools for the preparation of teacher educators. For example, the section name for hypermedia/multimedia/new media has undergone several changes -- from hypermedia in the early 90s, to multimedia/hypermedia in the mid 90s, to new media in the late 90s. This phenomena reflects the development of the computer hardware and software technologies. In the early 90s, the term hypermedia had recently become popular for describing the use of multimedia technology combined with some type of program that will allow for far more interactivity than has been previously possible.

Several authors who had more resource at their disposal than other teachers have also developed their own video-discs to utilize their programs. The application courseware described in the early Annuals was varied and innovative, but limited by hardware such as computer memory space, and scarcity of CD writer, and software features such as media formats, the products are not as diverse as the products widely discussed in the late 90s. Many of the earlier packages have been used to teach classroom methods to preservice teachers. Integrated learning systems (ILS), interactive videodisc technology (IVD), interactive video instruction (IVI), video tape players (VTP), computer-assisted interactive video (CAIV) were the major tools in the early 90s.

Newly added to the contents and tools of the papers published in the late 90s are Zip drives, VRML, WWW, laptops, digital overhead projectors, document cameras, smart whiteboards, CD recorders, and digital cameras, DVDs, computers with TV output, and high definition scanners.

Many of the innovative, cutting edge projects described in the early papers have become routine, expected activities in the late 90s. On the other hands, a new level of interactive multimedia is on the forefront of web and multimedia authoring and is now available for educators to access and create as supportive information to their curriculum. Software names such as HyperCard and HyperStudio for the
Macintosh and LinkWay for IBM were the topics of the majority of the early papers. Online course tools were not heard of in the earlier years. Today, the names and capabilities of electronic publishing software are too various to list here. During this decade, technology -using educators have also brought information technology out of isolation in the educational computing course and integrate it into the entire range of teacher education. The reclassification of the sections and additions of new sections are indications of the attraction of various audience to the society and the progress of the field itself.

The Dissemination of the Annual-related Information

The SITE annuals are the product of both the time and the hard work of many teacher educators who were selected because of their knowledge and expertise in the field. Each conference is accompanied by a printed proceeding, the Annual. The SITE annuals have grown from a couple of hundred pages in early 1990s to one volume of approximately one thousand pages in 1995, and to two big volumes of almost two thousand pages in total in 1999.

By 1992, the founding organizers of the STATE had elected to move under the umbrella organization of Association for the Advancement of Computing in Education (AACE) (Willis, D. 1999, Preface). And in 1995, when founding organizers the started thinking in more international terms, the society has a new name, the Society of Information Technology and Teacher Education (the SITTE, or the SITE).

To enhance the exchange of information, the Society for Technology and Teacher Education (STATE) Internet server was announced at the 1993 STATE conference in San Diego (Bull & Becker, p. 629). Directions for accessing the National Teacher Education Internet Server established under the auspices of STATE are provided in the article 'The Teacher Education Internet Server – A New Information Technology Resource' Diego (Bull & Becker, p. 629).

The first Annual CD was disseminated in the 1995 SITE conference in San Antonio. The author is proud to participate in developing the CD and HTML version of the 95 Annual. The process was documented in the paper 'Producing Electronic Books: Creating and Using the CD-ROM Version of the Annual' (Chen & Willis, p. 575). As described in the paper, FolioViews has been picked as the interface for the 1995 CD because of its powerful searching and indexing engines. The drawback of the FolioViews interface is that the editors have to spend the same amount of time to convert articles into the HTML format for the Internet archive. Because of this reason and other considerations, from 1996 till this year, Acrobat PDF (portable document format) has been chosen and the dissemination of the Annuals has become easier and more systematic.

To expand the potential audience, the proceedings accompanying the SITE (or STATE) conferences (Technology and Teacher Education Annuals, or the Annuals) are now distributed as printed Annuals, on ERIC microfiche, on searchable electronic books on CD-ROMs, and through the Society's Internet server. Currently, the society has converted its 1994-99 Annuals into PDF version and made available through CD-ROMs and the AACE web site. The HTML version 1995-99 of the Annuals is also available through CD-ROMs and the AACE web site.

Conclusion

From the transition of contents discussed in the papers published in the Annuals, readers have witnessed the replacement of the computer operating systems, computer hardware, and software. The VMS and MS DOS operating systems described in the early papers have been replaced by the more current Unix, Windows, and MAC operating systems. As for computer hardware, VAX, Apple computers, IBM XT, Commodore, MS DOS clones in the early 90s have been phased out by the Windows computers, workstations, and more powerful models of the Macintosh computers. E-mails have been consolidated from various proprietary e-mailing systems such as cc:Mail, FIRNMAIL, and GTE's Electronic Page to e-mail as we see it today. The Internet itself has also stood out to be 'The Internet', instead of being just one of the 'Internets' like BITNET, NFSNet, and FidoNet, etc. as it was in the Annual's early history. There are also validated models, methods, and instructional packages.

The SITE Annuals have chronicled the pioneering efforts of several hundred technology leaders in teacher education. Collectively the papers tell us that teacher education, as a technology-using field, is thriving.

Abstract: In the study reported here 24 ninth-grade students investigated several issues related to modern Israeli society. In their investigation students were engaged in activities such as data search, data sorting, and inquiries, project writing and construction of a new computerized data-base related to the subjects of their investigations. Students were encouraged to write personal reflection notes after each session throughout the five months period of their work. Studying these reflections allows us to improve our understanding of the way students think about themselves as learners, about the task's demands and about strategies that are needed to deal with the demands. We propose a tool for analyzing the reflections based on Flavell's metacognitive components. Replicas are analyzed according to eighteen dimensions. This tool enables us to compare different patterns of reflections among students, as well as to detect dominant dimensions within the student's own protocols of reflection.

Theoretical Background

The aim of this study is to investigate the metacognitive process of students who reflect verbally on their learning experience in a data-base environment, and to introduce a tool for analyzing their reflections. The relationship between learning in information technology environments, such as databases, and metacognitive processes has not been documented enough yet. However it seems that learning in these environments entails metacognitive activities, such as reflecting on data search strategies and on their efficiency, as well as monitoring their impact (Butler & Winne, 1995).

The ability of individuals to reflect upon their own thinking is one of their unique characteristics as human beings. This capacity was termed by Flavell (1976) as Metacognition. Theoreticians have approached metacognition in different ways, but all of them relate the contribution of metacognitive processes to the enhancement of thinking and learning (Gange & Briggs 1974, Brown 1978, Brown, Bransford, Ferrara & Campione 1983, McCrindle &Christensen, 1995). The consent among researchers (e.g., Paris & Winograd, 1990) is that successful learners apply specific strategies while being aware to their own learning and thinking processes and that they practice it more efficiently and more frequently than less successful learners. Another consent among researchers in the field of metacognitive processes relates to their contribution to Self-Regulated Learning (Butler & Winne, 1995). Self-Regulated Learning (SRL) does not rely only on the development of regulation and monitoring skills, but also involves beliefs in one’s competence as well as a self-conviction that learning is a tool to achieve personal goals.

In order to succeed in constructing knowledge in a technological environment that is flooded with information, one has to know how to select the most essential data. Students learning in a data base environment practice different strategies that bear on SRL, such as determining their path of data search, selecting and sorting relevant data, making inquiries and constructing their own data-base. However, learners differ in the extent of which they are capable of accepting responsibility for their own learning and by the extent of which they wish to be independent learners.
Recently, educators have come to realize that the educational system did not adequately enhance students' conception of self-responsibility and sense of autonomy, which are essential for SRL. The teacher's role has changed from being an infallible expert responsible for a final product, to being a guide who is more responsive to the context in which the learning is occurring. The new context that the educators are currently trying to promote stems from the Constructivist approach. This approach encourages learners to control their learning processes, reflect upon them and evaluate their results and progress in an open debugging procedure, which entails self reflection and peer dialogue.

Researchers have promoted the usage of reflections through writing and talking aloud techniques for learners in different learning environments (Cohen 1991, Di pardo 1990, Flower 1989, Graswohl 1989, Weiner 1986, Sarig & Folman 1990). Some interesting works were done about fostering reflections of students working with computers during science studies class (Beretier & Scardamalia, 1987, Taback et al. 1998). However, not enough effort has been invested yet in analyzing and characterizing reflections of students working with databases, as part of their social science studies. The importance of inducing a reflection process in data base environment should be emphasized since this environment is considered as ill defined learning environment. In this environment the learners need to select the desired data and organize it according to their own concepts of the investigated issue. The assumption here is that learning in less structured environment increases the need for reflection as a self-scaffolding and consequently improves learning.

**Method**

In the study reported here 24 ninth-grade students investigated during History classes several issues related to modern Israeli society. In their investigation they all started with a search for data using different resources such as books, fixed databases and dynamic data-base like the Internet. After the search students were engaged in construction of new databases, using Edubase software, and concluded with writing projects based on their investigation. In addition, students were engaged in activities such as data search, data sorting and categorization, data-base inquires and construction of an appropriate data-base related to the subjects of their investigations. They performed their task in pairs over a five months period, two hours a weekly session. Students were encouraged to write personal reflection notes after each session throughout the whole period of the study. The reflection notes included insights about the topic of their study, difficulties in achieving their plan, ways of solving the problem, new ideas, etc. They avoided writing when they felt that they did not have something to reflect upon. Their reflections were not graded, yet they expressed a keen motivation and a need to reflect upon their work. Students wrote between 1-14 reflections throughout the period of their investigations. The present analysis includes 24 students who wrote at least five reflections.

We attempt to answer two questions regarding students' reflections:
1. How do we evaluate reflections in a data-base environment?
2. What are the characteristics of learners' reflections?

In order to answer these questions we analyzed the reflections through the method of content analysis. We used Flavell's (1976). In their reflections students relate to the content of the task, to the activity involved, describing personal preferences and difficulties concerning the task, criticizing the task's demands, insights about the solution and more.

**A Tool for Evaluating Metacognitive Components of Students Reflections (MCSR)**

Students' written reflections were analyzed and classified according to components of metacognition: one's own knowledge about: his/her personal characteristics (P), the task requirements (T), strategies needed for accomplishing the task (S). Material within these three main categories was reread to identify subcategories. On the whole we identified 18 subcategories which became the tool dimensions. These dimensions represent students' notions and reflections about their actions during their work with the data-base. The dimensions of the metacognitive tool were coded and are identified in Table 1. Two independent judges performed the coding procedure. After the coding was completed differences were resolved in a conference.

In order to provide examples of the various dimensions, we quoted replicas from three students' reflections:

**Personal traits (Pt)**
D: Deadlines are difficult for me. I feel pressured and I don't read the text profoundly and then forget what I have read (30/10/98)

**Learning styles (Ps)**
D: I realize that sometimes I can understand better from a picture or a caricature than from regular text (30/10/98)

**Task relevance (Tr)**
L: Today I searched for information in the library...I found some relevant pieces of information that I needed for my work (3/1/99)
Task feasibility (Tf)
M: The same problem – Imbalance between the amount of data relating to the different women... We don't have enough material to start writing (26/3/99)

Problems and difficulties (Tp)
D: We could not connect to the Internet (8/1/99)

Characteristics of data-base (Ts)
L: The headings in the Tekuma data-base are misleading because the documents we found did not match our search (16/10/99)
N: we have learned how to connect between the data-base fields and to create quires (22/1/99)

Planning strategies (Sp)
M: We think it is clever to write the introduction at the end (19/2/99)
M: We decided to focus on specific topic (10/4/99)

Selecting and applying strategies (Ss)
M: we sorted the women list into categories (as: Politics, literature, poetry etc.)

Drawing conclusions and generalizations (Sg)
D: I learned that the difference between a great leader and an ordinary person is the ability to look forward and to vision future (31/10/99)
N: The most important thing is that I have learned to look at things from different perspectives and this is more important and more interesting (31/10/98)

Asking for help (Sh)
D: First we did not know how to import data from the Internet to our data-base. We had to ask Zehava for help and she demonstrated it for us (1/1/99).

Studying these reflections will allow us to improve our understanding of how and what students think about themselves as learners, about the task’s demands and about strategies that are needed to deal with the demands. A comprehensive research can benefit from this kind of analysis by comparing different patterns of reflections among students, as well as analyzing dominant dimensions within the student own protocols of reflection. The following case example demonstrates the proposed method of reflections’ analysis.

A Case Example

The following is an example of dimensions’ analysis of reflections. The reflections were written by two 15 years old students: Michelle(f) and Lior(m). In order to demonstrate their reflections’ pattern and to compare between them we selected two dimensions of the Strategy components: 1. Evaluating results (Se) 2. Articulating explanations (Sa). Analysis of these dimensions’ frequencies (Table 2) yield a unique pattern for each student and allows a comparison between their reflections.

Table 2: Total Frequencies of Michelle’s and Lior’s strategy’s dimensions

<table>
<thead>
<tr>
<th>Student</th>
<th>Number of Reflections</th>
<th>Se</th>
<th>Sa</th>
</tr>
</thead>
<tbody>
<tr>
<td>Michelle</td>
<td>14</td>
<td>6</td>
<td>13</td>
</tr>
<tr>
<td>Lior</td>
<td>10</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

Comparing the two dimensions within each student reveals that Michelle is engaged much more in articulating explanations than in evaluating results (6:13). Lior’s reflections pattern is clearly dominated by evaluating results than by articulated explanations (2:8).

Comparison between the two students reveals that Michelle has a clear advantage (4.64 to 1, controlling for the total number of reflections) in accompany her descriptions with articulated explanations whereas Lior tends to evaluate his results more than Michelle does (1.87 to 1).
Another aspect of analyzing the reflections is to evaluate the various dimensions in a qualitative approach. This approach is aimed at evaluating the richness of the dimension rather than its frequency. The following replicas are used to demonstrate a qualitative analysis of the strategy dimension of Articulating explanation (Sa):

Michelle: we think it was a smart idea to write the introduction at the end of our project since we have already resumed the work and we had conclusions and a general view, so it was easier to explain our research question.

Lior: We agreed to split the work between us. Yotam who understands better Edubase was responsible on creating the data-base's fields.Lior: ...today we were supposed to finish the project and to submit it, but because of technical problems with Edubase we needed to...

Analysis of the three replicas above suggest that Michelle's explanations are better articulated, detailed and explicit than Lior's. His first explanation is implicit and rather short and the second replica is missing any information to identify the technical problems he claimed. Michelle's replica has also an argumentative structure that includes a claim and proofs and a conclusion, which Lior's replicas are missing. Based on this analysis we can claim that her articulation is qualitatively richer than Lior's.

Conclusions

It seems evident that by encouraging students to practice reflections we may increase and foster their ability and practice to do it. The contributions of reflection to learning in general and to learning in data-base environment specifically, were discussed earlier in this paper. Analysis of learners' reflections can serve teachers as a prism to get a real time view of their teaching process and as an authentic tool for evaluation of their students learning. Further analyses are performed in order to study gender differences, as well as to examine changes in dominance of various dimensions, along the time course of the intervention.

Abstract: This paper discusses the use of hypermedia as a mainstream instructional tool and what this use means for the success of all learners. Hypermedia research has not provided evidence of superiority to other instructional media. This research has, however, indicated that learner characteristics play a significant role in achievement in these new environments. Epistemological beliefs and self-regulatory skills have been demonstrated to be essential determiners of success in traditional learning environments. These beliefs and skills may be especially crucial to learning in cyberspace. This paper reviews relevant research from the educational psychology and hypermedia literature and discusses implications for the delivery of hypermedia instruction. Future research opportunities are described.

Introduction

More than half of the nation's classrooms are now connected to the Internet (Fatemi, 1999). Online high schools and computer laptops replacing books are just two of the numerous movements that will result in students accessing content knowledge in a hypermedia format. Original conceptions of the World Wide Web described a very interactive medium in which users had a great deal of control over how material was presented. In fact, Tim Berners-Lee, one of the people credited with the advent of the World Wide Web, originally envisioned web browsers as readers and editors of text (Berners-Lee, 1999). Unfortunately, hopes of an inherently interactive medium have not materialized. Research with instructional hypermedia has failed to demonstrate superiority over the traditional text (Dillon & Gabbard, 1998). However, when we look at specific learner characteristics, differences are often noted.

The increasing use of hypermedia for instructional purposes demands that we better understand how it affects all learners. Much of the research involving hypermedia in instruction has focused on characteristics of the medium and their impact on learning. Learner characteristics are equally important to success in any instructional setting. What are the characteristics of learners that will impact their success in these new environments? This paper reviews research from the instructional technology and educational psychology literature that demonstrates the importance of epistemological beliefs and self-regulation in learning. The implications for hypermedia-based instruction are presented.

This paper will begin with a brief review of the hypermedia research landscape. We will then describe two concepts that we believe hold a good deal of promise in understanding how all learners react to hypermedia instruction, epistemological beliefs and self-regulation. For each concept we will discuss potential implications for hypermedia learning. Finally, we will describe what type of research is necessary to provide us with a better understanding of the relationships between epistemological beliefs, self-regulation and learning with hypermedia.
Hyperm\begin{document}edia Research\end{document}

Credit for the discovery of the hypertext concept (but not the term) is given to Vannevar Bush who in 1945 described a system (the Memex) that allowed the retrieval of information based on association rather than traditional indexing (Landow, 1997). Theodore Nelson is credited with the first use of the term “hypertext” to describe this method of linking documents. The term “hypermedia” is simply an extension of the original term to incorporate the linking of other media such as images, videos and sound. These and other pioneers in the field originally envisioned hypermedia as a superior learning tool in part because it closely mimics the workings of the human mind (Tergan, 1997).

A recent review by Dillon and Gabbard (1998) explored the hypermedia literature concerning learning comprehension, learner control, and style (i.e. learner characteristics). They concluded that the benefits of hypermedia over other methods of instruction are limited. There is, however, evidence that individual characteristics play a role in success in hypermedia environments (Dillon & Gabbard, 1998). The preponderance of existing hypermedia research literature has investigated differences in user interfaces or instructional methods. Less research has been conducted that explores learner characteristics and their impact on learning in a hypermedia environment. Some of the attributes that have been studied in a hypermedia environment include ability (Repman, Willer & Lan, 1993), passive/active learners (Lee & Lehman, 1993), field independence/dependence (Jonassen & Wang, 1993), and deep vs. shallow processors (Shute, 1993). Dillon and Gabbard’s review of each of these areas concluded that these characteristics might offer “the beginning of an explanation for the generally conflicting results in the literature comparing hypermedia and non-hypermedia learning environments” (p. 344). In another review of hypermedia research, Tergan (1997) concludes: “A major result of these studies is that individual learning prerequisites like differences in learning goals may override structural parameters of hypertext/hypermedia documents in affecting performance” (p. 263). We concur with these authors in the need for a better conceptualization of the impact of learner attributes in these new surroundings.

Two learner attributes that are almost completely unexplored in empirical studies of hypermedia are epistemological beliefs and self-regulatory skills. These characteristics hold promise in that they are related to each of the characteristics mentioned above that interact with achievement in hypermedia environments. For example, if one holds the epistemological belief that knowledge consists of discrete facts (see complete description below), they are less likely to deeply process instructional material (Hofer & Pintrich, 1997). In hypermedia environments, this takes on added import as we consider the decisions that the learner must make in terms of sequence of instruction and accessing supplementary materials.

Epistemological Beliefs

Epistemology refers to the study of the nature of knowledge. Researchers have shown that the epistemological beliefs held by students may have important influences on thinking and problem solving. Expanding on the work of Perry (1970) and King and Kitchener (1994), Schommer (1990) has proposed five separate epistemological dimensions corresponding to beliefs about knowledge. Each dimension is based on a continuum. The following lists the “naive” end of the continuum for each dimension:

1. Certain Knowledge (i.e. absolute knowledge exists and will eventually be known)
2. Simple Knowledge (i.e. knowledge consists of discrete facts)
3. Omniscient Authority (i.e. authorities have access to otherwise inaccessible knowledge)
4. Quick Learning (i.e. learning occurs in a quick or not-at-all fashion)
5. Fixed Ability (i.e. ability to acquire knowledge is innate)

Research conducted with traditional instructional materials indicates that certain epistemological beliefs correlate with achievement. Schoenmer, Crouse, and Rhodes (1992) reported that beliefs in Simple Knowledge negatively affected complex problem solving. Schoenfeld (1983) investigated some of the consequences of a belief in Quick Learning. He reported that even experienced students who were asked to solve math problems gave up after five to ten minutes on the assumption that if they failed to solve the problem during this time, the problem could not be solved.
Implications of Epistemological Beliefs for Hypermedia

A study by Jacobson and Spiro (1995) that examined their cognitive flexibility theory briefly addressed epistemological beliefs in a hypermedia environment. They found students with simple epistemological beliefs had difficulty with the non-linear and multidimensional nature of an ill-defined hypertext system. However, the measurements used in this study were exploratory in nature and epistemological beliefs were not the focus of the study. As indicated by Jacobson and Spiro in their paper (1995), more research is necessary, but this study represents an important beginning to the application of what is known about epistemological beliefs to hypermedia learning.

Why would these differences exist? As discussed above, certain epistemological beliefs coincide with a less adequate approach to learning. The belief in Fixed Ability as a primary determinant of success leads students to believe that more effort does not coincide with more learning. As a consequence, the additional hypermedia tools available, such as links to definitions, diagrams, self check materials, objectives and advanced organizers, may have little positive impact. The effort required to use the hypermedia tools is less than in traditional settings (e.g. clicking on a term for a definition is easier than looking it up in the glossary). However, it still requires mental effort and thus one would expect the belief in Fixed Ability to be negatively correlated with use of hypermedia tools. Similarly, a student who takes a Quick Learning approach to hypermedia instruction will be less likely to take advantage of some of the useful tools available in hypermedia environments.

Self-regulation

Like epistemological beliefs, students' self-regulatory skills will also significantly mediate success in most learning environments (Schraw, 1998). Self-regulatory skills include, but are not limited to, the learner's ability to monitor their understanding as they read a text passage and their ability/willingness to set goals. Students who lack skills such as monitoring for understanding and goal setting tend to struggle in many learning environments (Zimmerman, 1990). Short-term instructional goals help students focus on relevant instruction and its relationship to current knowledge. Evidence suggests that students will exert more mental effort on tasks they see as attainable and when they can perceive progress towards a goal (Schunk, 1990).

Self-regulation also depends on students understanding of their own cognition. For example, skilled learners understand how much information they can retain in memory before they need to engage in an alternative approach to storing information (e.g. take notes). These learners have a wide repertoire of learning strategies from which to choose and a good understanding of when to use each.

Implications of Self-regulation for Hypermedia

Most studies that investigate self-regulation and hypermedia are concerned with teaching self-regulatory strategies within the hypermedia environment (e.g. Puntambekar & du Boulay 1997). Other studies investigate strategies used with hypermedia (Hill & Hannafin, 1997). No studies that we are aware of have investigated the relationship between these self-regulatory skills and learning with hypermedia. The learner's self-regulatory capacity is vital to their success in any learning environment, including hypermedia. The learner's repertoire of reading strategies like summarization and their willingness to invoke such strategies when appropriate, have a dramatic effect on their understanding. Highly self-regulated students are better equipped to take advantage of the hypermedia environment. Links to objectives and the opportunity to take a self-test will be of little value to students who do not take advantage of them.

One specific characteristic of hypermedia instructional materials that may cause differences in student success is the web-like organizational structure. It is clear that the learner's ability to develop new, or modify existing, schemata is an important determinant of understanding. The more complicated organizational structure of hypermedia documents (as compared to the largely linear structure of a traditional text) may hinder the success of students who have difficulty organizing topics in their mind.
Future Research

It is important to begin to research the relationships between epistemological beliefs, self-regulatory skills and achievement in a hypermedia instructional environment. These relationships should be measured with tools that have a proven record of reliability. One such measure is the Epistemological Beliefs Inventory, a well-researched measurement tool based on Schommer’s (1990) five dimensions of epistemological beliefs. Students’ self-regulatory skills should be measured with tools such as the Metacognitive Awareness Inventory (Schraw & Dennison, 1994), a self-report tool that determines the extent with which the learner uses strategies such as rereading (an indication of monitoring for understanding).

The hypermedia instructional materials used in such research should simulate instructional materials now commonly used. Specifically, the materials should include tools such as links to definitions, advanced organizers, objectives and self-tests. How does the use of tools such as objectives and self-check questions relate to students’ epistemological beliefs and self-regulation skills? In addition, how does the choice of paths through the content relate to these beliefs and skills? For example, are students with better self-regulation skills likely to progress through the content in a more systematic fashion? These approaches can be easily collected and analyzed using computer log files.

We believe that students who hold more sophisticated epistemological beliefs and greater self-regulatory skills will perform better than their peers in the hypermedia environment. This would have useful and important implications for the delivery of instruction via hypermedia. As online-high-schools, laptops-as-textbooks, and distance learning become commonplace in our system of education, these relationships become increasingly vital.

Using *TopClass* to Facilitate Regular Educational Research Course

Julie Bao  
Teacher Education  
Shippensburg University  
U.S.A.  
Jqbao1@ark.ship.edu

**Abstract:** *TopClass* is a web-based distance learning management software. The instructor incorporated it in her regular Educational Research course. The integration enabled her to enhance teaching objectives, promote communication with students, increase individualized instruction and manage time more efficiently. Concerns emanating from the experience included time constraint and her struggle between focusing on research curriculum requirements and facilitating students' technology skills. This paper describes the integration experience and her reflections.

**Introduction**

*TopClass* is a distance learning management software developed by the WBT System to facilitate a web-based learning environment. It can help instructors deliver content over the Internet and create tests with automatic correction. It supports embedded Java Applets and is compatible with HTML and Microsoft Word. During the course of the study, students may access coursework, communicate with each other and instructors can monitor students' learning by tracking their progress status individually.

First released in 1995, *TopClass* has been used in distant learning programs at over 600 sites around the world (WBT, 1999). In the last three year, much research has been done to study on-line delivery software and evaluate their effectiveness for classroom instruction. Driscoll studied the advantages and disadvantages of web-based training (Driscoll, 1998). Harrison illustrated how to design self-directed distance learning programs (Harrison, 1999).

In collaborating with three technology committees of British Columbia, Bruce Landon conducted comparative analyses of *TopClass* and other viable applications according to their technical specifications, instructional designs, media capabilities, tools, ease of use, potential for collaboration and contact information (Landon, 1999).

*TopClass* was used at the education programs of University of Waikato in 1996 and was found that it allowed for more efficient use of lecturers' time. It in turn lead to a higher quality of teaching (Moodie, 1999).

Sharon Gray contributed an extensive web-based instructional resource page which listed *TopClass* and many other course development tools. She compared TopClass, WebCT and other eight distance learning tools based on Course Design, Collaboration Tools, Course Management features and Administrative Convenience. More specifically, these features included Platform Requirements, Set-up Wizards, Communication Convenience, Student Progress Tracking, Contextual Help, and Testing Capability (Gray, 1998).

With its great popularity and continued improvement, *TopClass* was selected as one of the three (with WebCT and Course Info) State System sponsored web-based instructional software for the Pennsylvania State System of Higher Education. Its Center for Distance Learning offered multiple workshops to train SSHE faculty to use these software for instruction.

In spite of the fact that every SSHE faculty member was provided with an access code, there were very limited distance learning courses being taught. During the academic year of 1998 – 1999, there were only three distance learning courses offered at Shippensburg University. While there was a need to encourage professors to develop more distance learning programs, it was also important to encourage faculty to make maximum use of web-based software in their regular instructions. To this end, the instructor tried *TopClass* in her regular Educational Research course.
The purpose of the paper was to share the instructor's experience of using TopClass in her regular graduate level Educational Research course. The instructor described her software-integrated lesson planning, illustrated different ways TopClass was used in the course, analyzed advantages and disadvantages of the software in a regular classroom, and shared her reflections.

### Integrated Planning

Whereas any teaching requires good planning, integrating software in instruction certainly demands more preparations. A primary requirement for an instructor was to be able to deliver curriculum content in a very short period. Adding an unfamiliar software would undoubtedly take some time away from the regular instruction. Therefore, how to incorporate the software without sacrificing the curriculum objectives became the first concern of the instructor. The purpose of the educational research was to help students learn basic elements of research, which included analyzing research categories, conducting electronic research, writing up research components, mastering functional knowledge of descriptive and inferential statistics and applying their knowledge to design and complete a research project.

Because TopClass was such a powerful software, using it for instruction could be a course by itself. If the instructor spent too much time on technology, the research curriculum requirements could be undermined. Consequently, the instructor had to weigh carefully the time spent on technology and its effectiveness on students' learning of elements of research. Therefore, it was clearly stated that the purpose of using TopClass was to enhance research skills. Any features that were too time consuming or did not directly facilitate research skills would not be used.

The instructor decided to start with the communication tools that included Message, Discussions and Class Announcements. Almost all students had e-mail accounts before coming to the course; it was easier for them to adapt to a new communication tool that had added features such as Attached URL, Discussion List and Class Announcements. Most of students felt comfortable starting with communication tools and proceeding to others choices.

After making it clear that the purpose of using TopClass was to enhance research skills, the instructor planned a list of tasks as optional items, among which were Research Design submissions and test tryouts. Students were exposed to these items, but no requirements were made. As part of the planning, the instructor made a class list, uploaded the major course materials on the web and assigned each student a temporary password. She tested these passwords and assignments online three times on different days for system reliability purposes before passing these codes to students.

Incompatibility of platforms and equipment was another concern the instructor had in planning, because it was one the major issues that had affected earlier web-based instructions on campus. The minimum platform requirement of TopClass was Version 3.0 of Mac, Os 7.1 or Window NT 4.0/Windows 95. It used to be a problem for many students, especially if they wanted to open large graphic files. With upgrading of operation systems and limited use of TopClass functions, it didn’t pose any problem for this course.

### Using TopClass in the Classroom

**Introducing the Software** Students were first exposed to these features of TopClass in a team-teaching setting at the Library Technology Room. It was planned to incorporate the skills of Library staff and use time most efficiently. The Librarian introduced students to electronic resources and the Keystone Library System of PA. The instructor demonstrated the most useful features of TopClass for this course, such as Message, Discussions, Class Announcement, Student Course Work, and Utilities. Features like Create/Edit a Course, Export/Import and Administrative Control, which were mainly used by instructors, were only mentioned in passing. It was a hands-on session. Each student could try out these features. Students had plenty of time to ask questions and conduct individualized resource search after the class.

**Curriculum Focus** Because TopClass had so many fascinating features, it was very hard for the instructor to put aside students' curious questions. Nevertheless, too many inquisitive technology questions could distract them from the focused elements of research. Therefore, the instructor had to be very conscientious of the teaching objectives of the course. She strictly followed the curriculum requirements to teach research skills and
resisted much temptation to further improve students' technology skills.

Course Requirements: For any learning activities, it was easy to get some early explorers to participate. In order to get the whole class involved, it was important to make requirements. The requirements for the course were divided into two parts: Preliminary Requirements and the Optional Tasks. The former consisted of: 1. Locate the course materials on the web; 2. Send the instructor a message with attached URL; 3. Read the Overview of the TopClass (Access to the Learning Environment, Communication Tools, Web Course Materials, Discussion List and Tests); and 4. Communicate with peers. Examples of Optional Tasks were using TopClass to submit their homework (Problem Statement, Review of Literature, Hypotheses, Research Designs and Article Critique) and trying out web-based tests.

Effectiveness of the Integrated Instruction

Teaching Objectives The effectiveness of the TopClass-integrated teaching approach was mainly demonstrated in the following four areas: Enhanced teaching objectives, improved communication, individualized focus and better use of time in class. Compared with Educational Research courses the instructor taught earlier, these students submitted more versions of drafts and hence received more individual feedback. Though there were no data to actually make a quantitative statement, the completed research proposals and projects demonstrated stronger evidences of enhanced research skills and resources.

Improved Communication The software enabled students to read and send messages in an asynchronous way, conduct peer discussions to cooperate, read course work on line if they preferred to do so and submit Research Designs electronically for feedback. When some students were frustrated at the beginning of the semester, which was a typical reaction to the course, the Peer Discussion feature of TopClass released much of their anxiety and greatly promoted interactions among students.

Individualized Attention In a regular classroom, individual students usually did not have enough time to ask questions. By allowing them to submit write-ups step by step, student could get much more individualized attention from the instructor and more detailed feedback for their written work.

Time Efficiency Communicate through web-based software could even allow students to cut some of the classroom attendance. In a small town setting, it was not uncommon for some graduates to drive an hour and a half to come to class. Some of the driving time could be better spent on learning course work at home by using TopClass. A combination of the in-class and distance learning formats could greatly enhance learning efficiency.

Discussions

Time Constraint One of the biggest challenges for the instructor to incorporate technology in teaching was to use it without sacrificing curriculum requirements. Any technology tools added to the course had to be weighed very carefully in respect to how much time it would take for students to master, and how effective it would be to enhance productivity of the course. Each student had a different need and technology background, facilitating students individually was very time consuming. There was simply not enough time to explore features such as TopClass Player, Assistant, Creator and Analyzer.

Uneven Development of Technology Skills Lack of technology training for some graduate students also contributed to the limited use of the software. There was a big discrepancy between students who thrived on technology and those who were not willing to try anything beyond reading and sending email messages. For beginners, trying out the software once was not enough to encourage them to use the software to enhance learning. Many education students typically came to the Educational Research course with great anxiety and limited knowledge on web-based software. Therefore, the instructor had to spend a lot more time to facilitate their technology skills. Consequently, this became an added burden to the instructor.

Feedback of students Students generally welcomed familiar communication tools with added features such as Discussion and Class Announcements. The improved message system in TopClass made their communication easier and more enjoyable. They liked the Attached URL in their messages, but they generally stayed at the Plain Text realm in stead of using the function of Multimedia messages. They were a little disappointed that the email messages in TopClass could not be automatically forwarded to their other email addresses. They were
afraid that if they did not check their emails separately, they might miss important messages. A few students tried out some sample tests on the web. Due to students’ anxiety over tests online and also because of the instructor’s concern over the reliability and the format of those tests, online testing was not a required item for the course. Upload and Download functions never intrigued them. When time factor became more acute toward the end of the semester, students didn’t want to hear about the sophisticated functions such as TopClass Player, TopClass Assistant, TopClass Creator and TopClass Analyzer.

Summary

Using TopClass to facilitate a regular Educational Research course was a great learning experience for both students and the instructor. It enhanced teaching objectives, promoted communication in and after class, increased individualized instruction and managed time more efficiently. The greatest concerns emanating from the experience were the instructor’s perpetual struggle to balance curriculum coverage and facilitate students’ computer skills. Uneven development of computer skills prevented some students from full benefit of the software. Both students and faculty need to improve their technology skills in learning. Despite these limitations, The Integration of TopClass in the regular Educational Research course has demonstrated a positive effect and suggested potential applicability of distance learning tools in more regular courses.

Technology in Teaching: Just How Confident are Preservice Teachers?

Philip Molebash and Natalie Milman
University of Virginia
United States
pmolebash@virginia.edu, mnilman@virginia.edu

Abstract: This paper examines the effectiveness of increasing confidence of preservice teachers in using technology for personal and instructional purposes as a result of participating in an introductory educational technology course offered at the University of Virginia’s Curry School of Education. Course participants attend sections designed for specific content areas – Elementary/P.E., secondary Humanities, and secondary Math/Science. Pre- and post-survey instruments are given to course participants, measuring personal confidence (22 items) and instructional confidence (21 items) using technology. A modified version of Dawson’s (1998) instrument was used to gather data. Factor analyses were performed to group items into like factors, followed by repeated measure analysis of variance to test for significant differences. Results indicate that students’ confidence levels significantly increased, across all factors, as a result of taking the course. Difference in content areas was found only for one factor of personal confidence – using spreadsheets and databases.

Introduction/Purpose

The National Council for Accreditation of Teacher Education (NCATE, 1997) and the International Society for Technology in Education (ISTE, 1999) have reported that schools of education are not adequately preparing its preservice teacher education students to effectively integrate technology in their future classrooms. Despite the educational technology standards that have been developed for teachers by international, national, and state organizations, Willis and Mehlinger (1996) suggest that part of the problem is a lack of universal agreement regarding what teachers should know or how teachers should be prepared. NCATE describes the problem as “deficiencies” (p. 7), which are a lack of hardware and software, limited faculty knowledge and skill in using technology, and scarce resources (money to invest in technology). To genuinely integrate technology into preservice teacher education programs requires system-wide change, initiative, and time. Cooper and Bull (1997) contend that teacher educators supporting change need “to be realistic about the time frame that will be required to accomplish this [integration of technology] in the depth that may be eventually desired” (pg. 101).

Many schools of education are in the process of restructuring their programs to better meet the needs of its preservice teacher education students. For example, the University of Virginia’s Curry School of Education, recognized for its leadership in integrating technology for over a decade, has been participating in a number of endeavors to more effectively infuse technology into its instructional program. One of its efforts was the establishment of the Center for Technology and Teacher Education (CTTE) in 1997; a goal of the CTTE is to prepare preservice teacher education students to be educational technology leaders. To cultivate these leaders, the CTTE promotes the integration of technology into methods courses and requires all of its preservice teacher education students to complete a two-credit introductory technology course, EDLF 345, Introduction to Educational Technology. Unlike most stand-alone technology courses, EDLF 345 incorporates content-specific instruction in utilizing technology. Grouping students into three different areas of emphasis – Elementary, secondary Humanities, and secondary Math/Science – allows instructors to design classes that move beyond mastery of basic technology skills to instruction that encourages students to think of how technology can be used in instructional practice.

A trend witnessed throughout the Curry School has been the increased technological competence of incoming students in recent years. However, students possess a wide repertoire of technological skills and experiences varying from novices, advanced users, and a myriad of others somewhere in between.

Adapting to the needs of the expanding range of students is recognized by the CTTE as pivotal in its efforts to continue to be a leader in integrating technology into preservice teacher education. In order to assess
these needs, a pilot study instrument was administered to the students of EDLF 345 in the fall semester of 1998 to gauge prior technology training, usage, attitudes, and confidence towards using technology, both personally and for instruction. By quantifying these attributes, the Curry School expects to provide a better learning experience as well as determine if students are meeting state and NCATE technology standards.

**Purpose**

Due to length of paper considerations, this paper primarily explores the results of the confidence portions of the pre- and post-survey instrument given to the participants of an introductory educational technology course. The confidence portions of the instrument contain one portion measuring confidence in instructional use of technology while another portion measures confidence in personal use of technology. The confidence portion of the instruments serves as the basis for this paper because developing confidence in preservice teachers is the first step in preparing them to use technology in their teaching (Mager, 1992; Olivier & Shapiro, 1993). The purpose of the study was to:

- Pilot an instrument aligned with the Virginia Technology Standards for Instructional Personnel (Virginia Department of Education, 1998),
- Gather baseline data about students' backgrounds and attitudes about using technology,
- Determine whether the course affected students' personal and instructional confidence in using technology, and
- Determine whether different content areas tended to display different levels of confidence.

**Design and Methodology**

After consulting with program faculty and researching other existing instruments (Atkins & Vasu, 1998; Becker, 1994; Dawson, 1997; Delcourt & Kinzie, 1993; Trushell, 1994; Moersch, 1999), the authors chose to utilize a modified version of Dawson's (1998) survey. It was chosen because it specifically addressed the Virginia Technology Standards for Instructional Personnel (Virginia Department of Education, 1998). By 2002, all preservice teacher education students in the state of Virginia will need to demonstrate proficiency in these standards. Using such an instrument would provide information that could be used in demonstrating such proficiency. In addition, two tested instruments (Delcourt & Kinzie, 1993; Becker, 1994) were used in its development. Participants were undergraduate and graduate students enrolled in EDLF 345 at the University of Virginia's Curry School of Education during the fall semester of 1998. The pre- and post-survey instruments, examined the following areas as outlined in Table 1:

<table>
<thead>
<tr>
<th>Pre-Survey</th>
<th>Post-Survey</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Student demographics</td>
<td>7.</td>
</tr>
<tr>
<td>2. Previous computer instruction (8 items)</td>
<td>8.</td>
</tr>
<tr>
<td>3. Current use of technology (10 items)</td>

<tr>
<td>5. Confidence in instructional use of technology (21 items)</td>
<td>11.</td>
</tr>
<tr>
<td>6. Confidence in personal use of technology (22 items)</td>
<td>12.</td>
</tr>
</tbody>
</table>

Most of the pre- and post-survey items required answers in a 4-point Likert scale format, with responses ranging from Strongly Disagree (1) to Strongly Agree (4). The items being explored in this paper, numbers five and six, used the 4-point Likert scale format.
The design for the study was the one-group pretest-posttest design (Campbell & Stanley, 1963). The pre- and post-surveys were administered to 95 undergraduate and graduate students enrolled in four different sections of EDLF 345. Data reported here reflect pre- and post-surveys from 81 students who completed both instruments (pre and post) and signed informed consent forms allowing the researchers to report their data. The demographic information collected in the survey included gender, year in the Curry School (the Curry School has a five-year teacher education program), major, and area of concentration in the Curry School. Participants were also asked about any prior technology courses or experiences. Data were entered into and analyzed using the statistical software program, SPSS.

Principal axis factor analyses were performed to summarize data related to the post-survey items for both confidence portions of the instrument (see Table 1, numbers 5 and 6). After items were grouped into factors, reliability analyses were performed on the items in each factor.

A one-within, one-between repeated measures analysis of variance design was used to test for significant changes in confidence among course participants. Questions of interests were:

1) Does personal and instructional confidence using technology increase as a result of taking EDLF 345?
2) Is there a difference in personal and instructional confidence using technology between content areas?

From these questions, several Null Hypotheses were made:

Null Hypothesis 1: There will be no significant change in instructional confidence using technology across all factors.
Null Hypothesis 2: There will be no significant change in personal confidence using technology across all factors.
Null Hypothesis 3: There will be no significant difference in instructional confidence using technology between different content areas across all factors.
Null Hypothesis 4: There will be no significant difference in personal confidence using technology between different content areas across all factors.

A repeated measure analysis of variance design was used to test for significant changes in confidence among course participants.

Results

Factor Analyses/Reliability

For the Confidence in Instructional Use of Technology items (21 items), four factors were obtained from the factor analysis. Reliability coefficients were calculated for the items in each factor. The results of these analyses are found in Table 2.

Repeated Measure ANOVA

In instructional confidence, significant main effect differences were found for all factors ( < .01), allowing for the rejection of Null Hypothesis 1. However, no significant differences in confidence were found between content areas ( > .05) preventing the rejection of Null Hypothesis 3. Table 4 presents the results of the analysis of variance tests for instructional confidence:

Table 4

Confidence in Instructional Use ANOVA (Main Effects and Interaction)

</tr>
</tbody>
</table>

In personal confidence, significant differences were found for all factors ( < .01), allowing for the rejection of Null Hypotheses 2. Slightly different from the instructional confidence interactions, a significant difference in personal confidence between content areas was found for Factor 1: Using Mindtools (Spreadsheets, Databases) ( < .05), allowing for the rejection of Null Hypothesis 4 for Factor 1 only. The following table presents the results of the analysis of variance tests for personal confidence:

Table 3 – Personal Confidence ANOVA

Discussion of Results
As expected, the participants of EDLF 345 experienced significant increases in personal confidence in using technology. Typically, if someone is shown how to do something and also given the opportunity to practice doing it, they will feel more confident when they must do that thing in the future. While it was the desire of the authors to see a significant increase in instructional confidence in using technology, expectations were not as high as with personal use. Since the instrument was not given to the participants of EDLF 345 until after the class was divided into content-specific sections, it is not known whether this had an impact on the significant increase in instructional confidence witnessed in the data. However, it is of the opinion of the authors that offering content-specific sections of the course did indeed play a role in increasing instructional confidence. Giving preservice teachers the opportunity to work independently and collaboratively on technically oriented content-specific projects early in the teacher education program, provides them with a lens to view technology as an instructional tool for several years before they become inservice teachers.

In looking at the graphs of interaction that existed between content areas for Factor 1, several things were noticed. The Math/Science preservice teachers tended to score higher at the pretest level for items in this factor — using mindtools (spreadsheets, databases) — than other content areas. This is to be expected considering the more frequent use of spreadsheets and databases in mathematics and science. This suggests that spreadsheets and databases can be introduced at a more advanced level to the math/science section of EDLF 345 than with the other sections. Interestingly, Elementary preservice teachers scored higher at the posttest level for items in Factor 1 than other content areas. It is speculated that, while students in the elementary sections of the course typically knew less about spreadsheets and databases at the time of the posttest than other content areas, they learned more relative to their starting point than the other content areas. They therefore felt a higher sense of accomplishment with these tools, ultimately increasing their level of confidence of using these technologies.

The Next Step

The instrument has also been administered to the 1999-2000 participants of EDLF 345 and will be administered at least through the 2000-2001 academic year. Pretest results will be compared from each year to determine whether previous technology training, usage, attitudes, and confidence towards using technology is increasing each year for each incoming class as hypothesized. Closely examining this trend will play a major role in the evolution of EDLF 345.

More importantly is the need to track the relationship between confidence and genuine implementation into the teaching arena. It is possible that preservice teachers experience a “technological high” after completing an introductory technology course, but as they proceed through their methods courses, student teaching, and teaching career experiences their confidence dissipates. Several studies have shown results similar to the results found in this study (Gunter et al, 1998; McInerney et al, 1990; Okinaka, 1992; Von Holzen et al, 1990), but few if any studies have continued to track these preservice teachers into the teaching field. It is planned to have this instrument administered to last year’s EDLF 345 course participants again after they have completed their fourth-year methods courses, and once again after student teaching (in their fifth year). In addition, it is hoped that qualitative data, in the form of interviews and teaching observations will provide added insight to the most important question as to how well preservice teachers are incorporating technology into their future classrooms.

Educational Significance

This study is significant to the field of teacher education in several ways. It provides baseline data about preservice teacher education students’ confidence towards using technology. ISTE (1999) recommends that further research be conducted on where and how preservice teacher education students are acquiring their technology skills. In addition, ISTE’s study surveyed deans and faculty of schools, colleges, and departments of education rather than the students in those programs. The results of this study can be used to assist the Curry School of Education in determining whether students have met state technology standards. As the study is carried out during the 1999-2000 and 2001-2001 academic years, by extrapolating current usage trends into future years, the Curry School will be able to forecast the future
technological needs of its preservice teachers. Finally, this study offers research that relates how effective the technology course was in increasing students' technology skills and confidence, key factors that will influence whether they use technology in their future classrooms.

Effective Use of ICT by Student Teachers – Is It Improving?

Colette Murphy
Graduate School of Education
Queen’s University, Belfast
United Kingdom
c.a.murphy@qub.ac.uk

Abstract: Effective use of ICT by student teachers is vital if these technologies are going to be successfully used in the education of children in schools. An earlier study by this author identified three main obstacles that could have limited ICT uptake by student teachers in 1996/7: student access to computers, the ICT policy adopted by initial teacher training providers and the lack of encouragement for students to use ICT on teaching practice. This paper presents a comparative study of the ICT competence and attitudes of a similar cohort of student teachers in the current academic year (1999/2000). It argues that whilst the overall sample of current student teachers appeared to be more competent and confident in the use of ICT than in 1996/7, female and younger students lagged behind their male and older peers. This issue needs to be addressed in the ICT policy adopted by initial teacher training providers.

Introduction

The purpose of this study is to investigate the changing use of ICT by student teachers. Data from the academic year 1999/0 is presented, together with data previously reported for the academic year 1996/7 (Murphy and Greenwood, 1998). The implications for ICT training provision within initial teacher training courses are considered in the light of these findings. The paper will therefore present an empirical study of ICT competence and attitudes in two cohorts of student teachers in a UK university, and contribute to the international debate concerning the low uptake of ICT by student and beginning teachers.

Research findings suggest that ICT is significantly under-used by student and beginning teachers. The problem is world-wide and many explanations are offered. Lack of resources or lack of access to resources in schools/initial teacher training (ITT) institutions has been suggested in the United States by Yopp (1993), Fisher (1996) and Topp, Mortenson and Grandgenett (1996); in Australia by Wild (1996), and in the United Kingdom by Byard (1995), Dearing (1997), Taylor (1997) and Murphy and Greenwood (1998). Lack of ICT experience and training at pre-service level (Oliver, 1994a and Wild, 1995 [Australian studies]) and of confidence in computing skills of both students teachers and teacher trainers (for example, Chen 1997 [China]) have also been implicated as factors leading to low student ICT uptake. Lack of opportunity (Dunn and Ridgway, 1994 [UK]), and lack of encouragement to use computers during school placement (Collison and Murray 1994 and Murphy and Greenwood 1998 [both UK]) and the predominance of other classroom pressures (Wild, 1996 [Australia]) may explain the low level of ICT use by students during school experience.

The importance of gender influences on ICT usage is in dispute. Reports from Summers (1990 [UK]) and McMahon and Gardner (1995 [UK]) suggest that male students are less anxious about and make more frequent use of ICT. Several other studies have reported that female students are less confident or knowledgeable than males about using computers (Blackmore et al 1992 [UK]; Oliver 1993 [Australia]; and Marshall 1997 [US]). In contrast, there are also many reports from the United States and Canada which indicate that there are no significant differences between the attitudes of male and female students, for example: Koochung (1989), Kay (1989); Hunt and Bohlin (1993), Marshall and Bannon (1986) and Woodrow (1991).

Conflicting reports have argued whether or not age is a significant factor in determining the extent of low student teacher ICT uptake (Woodrow 1991 [Canada], Blackmore 1992 and Liénard 1995, [both UK]). The age phase for which students are being trained to teach may also be significant in that Blackmore (1992)
and Oliver (1994a) demonstrated respectively that primary-trained students were more anxious and used computers less than secondary-trained students, both findings later confirmed by Murphy and Greenwood (1998). Finally, results from Summers and Easdown (1996) indicate that the subject specialism of student teachers may influence the extent of ICT use. They reported that student teachers attending a UK university specialising in geography tended to use computers more in their teaching when compared with main subject history students.

The Study

For the present study, two cohorts of students attending a one-year Postgraduate Certificate in Education (PGCE) course to teach in UK secondary level schools were compared. The extent that PGCE students used various ICT facilities in the year 1996/7 was compared with the use of similar facilities in the current academic year (1999/2000). The attitudes of the two groups of students towards ICT were also examined. Student groups completed questionnaires (see Murphy and Greenwood [1998] for the research instrument). The first part of the questionnaire consisted of questions designed to collect data concerning access to, training in and use of ICT, and the second part consisted of a set of items designed to measure attitudes towards ICT. Three pilot studies were carried out to test for reliability, validity and selection of items for the main questionnaire. Reliability was tested using an internal consistency method (Cronbach’s Alpha coefficient [Cronbach 1990]), which yielded reliability coefficients with values higher that the 0.8 criterion which is regarded as internally viable (Bryman and Carter 1997). Estimates of concurrent validity were measured using Pearson’s product moment correlation coefficient. Highly significant positive correlations were observed between positive attitudes and the frequent use of ICT.

Findings

Changes in the Sample Characteristics between 1996/7 and 1999/0

The sample characteristics of the 1999/2000 PGCE cohort of student teachers indicate that there has been a dramatic overall increase in many aspects of their ICT use since 1996/7 (See Tab. 1).

<table>

</tbody>
</table>

* these figures refer to teaching carried out PRIOR to starting the PGCE course – it is anticipated that the percentage use of ICT during school experience in 1999/0 will be much higher due to the current emphasis on ICT in the PGCE course.

Table 1: ICT use by PGCE students in 1996/7 and 1999/0

The percentage of students in these cognate samples who have access to a home computer has more than quadrupled in less than three years and a similar increase is observed for home e-mail access. The use of e-mail, the Internet and discussion lists have all shown highly significant increases – note the almost 10-fold
increase in e-mail users among student teachers since 1997. Differences in the mean response of PGCE groups from 1996/7 and 1999/0 regarding the extent they used word processing and how often they used ICT in lesson preparation and teaching were not significant. It would be expected that the percentage of the 1999/0 cohort of PGCE students often using ICT for teaching will be higher after their school experience.

Despite the fact that more students starting the PGCE course in 1999 were using ICT than in previous years, there remains the problem that significant numbers of current students entered the course with very little or no ICT experience (Tab. 2). In this sample, 1 in 5 students entering the PGCE course in 1999 had never used e-mail.

Table 2: Lack of ICT experience in PGCE students 1996/7 and 1999/0 (%)

The vast range in ICT competence of incoming students to the PGCE course is difficult to accommodate during the short period of time PGCE students spend in the initial teacher training institution. The students sampled in the current study attend the University for 10 weeks of their one-year course. A further 22 weeks are school-based. The problem is exacerbated by the relatively small amount of ICT being used by teachers and pupils in the schools. Mansell (1999) discusses a recent UK Office for Standards in Education analysis of the secondary curriculum based on inspections in 1997-98 which found that more than half of English secondary schools do not comply with national curriculum requirements in ICT. Teachers' lack of expertise in ICT is blamed for this shortfall. If ICT is to be effectively used in schools, then it is vital that the current student teachers receive sufficient ICT training to enable them to take the lead in this process. ICT is the one area of teaching in which the student teachers could generally be considered more competent than many class teachers.

In 1996/7 the percentage of male PGCE students often using e-mail, the Internet and discussion lists was markedly higher than female students (Murphy 1997). This is not the case in 1999/0 when it can be observed that there was little gender difference in the extent of use of these ICT facilities (Tab. 3). Since teaching is a female-dominated profession and the majority of PGCE students are females (approximately 75% female in this study), it is important that women student teachers use ICT as extensively as their male counterparts.

Table 3: Gender and ICT use by PGCE students in 1996/7 and 1999/0

The reverse situation appears to be the case when comparing the effect of age on ICT use by PGCE students in 1996/7 and 1999/0 (Tab. 4). Whereas there was little effect of age in 1996/7 there now seems to be a difference, with the younger students making more use of e-mail, Internet and discussion lists.

Table 4: Age and ICT use by PGCE students in 1996/7 and 1999/0 (%)
It appears, therefore, that the students entering the teaching profession in 1999/0 are more computer literate
than those of three years ago. Whether this higher level of technical competence will translate into the more
effective use of ICT in the classroom is less clear and partly depends on the attitudes of student teachers
towards ICT.

Changes in Student Teacher Attitudes towards ICT between 1996/7 and 1999/0

The attitudes towards ICT held student teachers also appear to have changed over the past three
years. A summary of these changes is presented in Table 5. Overall, as expected, the 1999/0 PGCE students
indicated more positive ICT attitudes than those in 1996/7. However the desire for more ICT training was
higher in 1999/0 than in 1996/7. This suggests that student teachers still feel that they are not well equipped
to use ICT in their teaching.

</tr>
</tbody>
</table>

Table 5: Summary of Attitude Results (Mean Responses)

Regarding gender, there was a significant increase in the relative confidence of female to male
students in using ICT between 1996/7 and 1999/0, although female students still appear to be less confident
than males. Women students in 1999/0 also indicated an increased liking for computers and were more
positive about the value of computers in education. The attitudes of male students in the sub-scales of liking,
confidence and value of ICT in education did not show any significant change between 1996/7 and 1999/0.
The implications of these results are that ICT training for student teachers must be concentrated more on the
educational uses of ICT and should be made more female-friendly. Morgall (1993) draws a distinction
between a context-oriented (feminine) approach to technology assessment and a technology-oriented
(masculine) approach. Feminist approaches to systems design are centrally concerned with developing
systems that allow women to enhance their competences and their confidence in the use of systems that are
appropriate to the reality of their working lives (Webster 1996). In a teacher-training context, therefore, the
emphasis should be changed from the current requirement to using ICT in the classroom to a demonstration of
ways in which ICT can be used to enhance teaching and learning.

The relationship between age and attitudes to computers in 1999/0 was similar to that in 1996/7.
Older students, despite making less use of e-mail and the Internet (see Tab. 4) displayed a greater liking for
computers, more confidence in their use of ICT and more appreciation of the value of ICT in education than
the under 25 group. It is possible that the context(s) in which the under 25 students were using e-mail and Internet may have been totally unrelated to work involving teaching and therefore did not have any effect on their confidence in using ICT in a classroom situation. The implication of this finding is that teacher trainers must be made aware that younger students may be more apprehensive about using ICT during their school-based work and may require more practical assistance during their time in the initial teacher training institution.

Conclusions

The overall level of ICT competence of incoming students to the PGCE course appears to be significantly higher in 1999/0 than in 1996/7. However, there is still an extremely wide range of competence that is difficult to accommodate during the short period of time PGCE students spend in the initial teacher training institution. Female and younger students indicate lower levels of confidence in using ICT. This problem should be addressed in the ICT policy of the institution, perhaps by a stronger concentration on the educational uses of ICT (including demonstration of good use by specialists and practical application by students).

Strategies To Increase Interaction In Online Social Learning Environments

Chih-Hsiung Tu
Educational Media & Computers
Arizona State University, USA
chih@asu.edu

Abstract: Social presence is one of the most critical factors in technology-based learning. To increase the level of interaction, the degree of social presence must be increased. Social presence was defined as the degree of person-to-person awareness in previous studies. This does not provide a clear definition of social presence. This study was designed to redefine the social learning theory for the online learning environment. Three dimensions of social presence and the privacy factor were examined in this study to redefine the social presence theory. It was concluded that three dimensions of social presence, social context, online communication and interactivity, emerged and the privacy factor correlated to the social presence theory.

Introduction

The importance of examining social factors that impact communication and learning in telecommunications-based systems has been emphasized in recent studies (Feenberg, 1989; Hackman & Walker, 1990; Lea, 1992; Sanders & Wiseman, 1990; Walther, 1992, 1995, 1996). Virtual classrooms with multicultural students are pervasive. McIsaac and Gunawardena (1996) have suggested that future research should explore the relationship between media and the socio-cultural construction of knowledge, and examine the cultural effects of technology and courseware transfer in distance education. Social presence is the degree of person-to-person awareness, which occurs in the computer environment. Social presence, the most important concept in social context, is an important key to understanding person-to-person telecommunication (Short, Williams, & Christie, 1976). Recent studies (Dillon & Walsh, 1992; Rice, 1984, 1993; Spears & Lea, 1992) have emphasized that social presence possesses potential for future study. Gunawardena (1995) argues that social presence is necessary to enhance and improve effective instruction in both traditional and technology-based classrooms. When the level of social presence is low, interaction is also low (Garramone, Harris, & Anderson, 1986). The lack of social presence will lead to a high level of frustration, an attitude critical of the instructor's effectiveness, and a lower level of affective learning (Rifkind, 1992).

Most text-based users transfer their traditional written style to the computer-mediated communication (CMC) environment without considering the receiver's local social context and/or the characteristics of CMC systems. The degree of social presence has not been considered in instructional design. Two groups of researchers (Connolly, Jessup, & Valacich, 1990; Hiltz, Johnson, & Turoff, 1986) concluded that CMC was unable to provide social context cues and was, therefore, considered to possess limited social presence because it was perceived as an impersonal medium (Walther & Burgoon, 1992). For instance, e-mail is considered to be casual written conversation, unlike traditional correspondence. CMC users often compose e-mail in a very formal written style, such as “Dear Mr. Tu,” “Sincerely,” etc.; some users are unable to apply “emoticons” to express non-verbal cues, producing an impersonal feeling; and, others resort to using all capital letters to express emphasis, which is considered as “shouting” by the receiver. These examples
demonstrate the problems of delivering low social presence, or an inappropriate degree of social presence, online.

The social presence theory was not originally designed to explain CMC; in fact, it was initially studied in face-to-face, audio and closed-circuit television encounters. Unlike traditional media, CMC provides very different characteristics, such as multiple identities, anonymity, etc. What is the social presence theory for CMC systems? Is it the same as or different from the original social presence theory that was studied in face-to-face, closed-circuit television and audio conferencing formats? If it is different, what is the difference? How will social presence affect online learning? How will the online learner perceive and respond to this new medium as a communication tool? To provide discipline for the instructional design of distance education, these questions must be examined and answered.

The current CMC application of social presence has not been clearly defined (Rafaeli, 1988; Svenning & Ruchinskis, 1984; Walther, 1992). The universal application of CMC as an educational communication tool requires that social presence be redefined. A clear understanding of social presence is necessary to direct research and to provide practitioners with clear guidelines for instructional design for distance education.

**Literature Review**

**Summary of Social Presence**

Recent studies have shown that social presence is a significant factor in improving instructional effectiveness; therefore, it is one of the most significant factors in distance education. Hackman and Walker (1990) investigated the effects of conveyance system design and social presence, in the form of teacher immediacy behavior on perceived student learning and satisfaction in the televised classroom. They conclude that system design and teacher immediacy behavior strongly impact student learning and satisfaction. Gunawardena and Zittle (1997) report similar findings in a CMC system. Social presence is a strong predictor of satisfaction within a CMC environment. Also, it is considered to be an element of interpersonal communication in an online learning environment. Perse, Burton, Kovner, Lears, & Sen (1992) studied college students' utilization of e-mail, and concluded that students used CMC more when they felt that e-mail conveyed more interpersonal presence.

The user judges the degree of social presence (Perse et al., 1992; Walther, 1992). Lack of non-verbal cues in CMC causes an impersonal feeling, doubted to be inherent to the system (Walther & Burgoon, 1992; Walther, 1996). Online users have perceived CMC as a high social presence medium (Gunawardena, 1995; Gunawardena & Zittle, 1997; Perse et al., 1992). Social presence can be cultured by teleconference users and leaders or encouraged by initial learning sessions (Johansen, Vallee, & Spangler, 1988). Gunawardena (1995) suggested that by successfully “inculturating” themselves within CMC, learners promote their levels of social presence, and allow themselves an opportunity for greater participation. In spite of the characteristics of the medium, students’ perceptions of the social and human qualities of CMC will depend on the social presence created by the instructors/moderators and the online community (Gunawardena, 1995; Gunawardena & Zittle, 1997). Therefore the instructor or the moderator must utilize their interaction skills and techniques, rather than those of the medium; this will enhance students' perceptions of social presence on CMC.

**Purpose of the Study**

The social presence theory is not clearly defined for CMC because low levels, and inappropriate levels, of social presence are usually found in the CMC environment. The purpose of this study is to examine social presence, determine how it relates to online interaction; and, to provide an operational definition.
Research Questions

By examining the learner's perception of social presence in three CMC systems, e-mail, bulletin board, and real-time chat, the following questions are answered:
1. Is there a relationship between social presence and online interaction?
2. Do issues of privacy influence online social interaction?
3. Do social relationships affect online interaction?
4. Does task orientation impact online interaction?
5. How does online communication literacy impact interaction on CMC?
6. Does the use of CMC intensify social interaction among online learners?

Method

Both quantitative and qualitative methods were used to gain a better understanding of the student's perception of social presence for redefinition of the social presence theory for CMC. Fifty students enrolled in EMC 598 Internet for Teachers, a graduate level course offered by the College of Education at Arizona State University.

Participant observation method with a dramaturgy perspective was used to understand the issues of privacy, social relationships, task orientation, online communication, and social interaction on CMC from the student's point of view.

Quantitative methods was used to examine the relationship between social presence and online interaction; and, whether social context, online communication, and interactivity, the three dimensions proposed in this study, and privacy, will significantly contribute to the degree of social presence.

Fifty participants were asked to answer the Social Presence and Privacy Questionnaire (Tu, DiGangi, Jannasch, & Yu, in preparation). This questionnaire, evaluating e-mail, bulletin board, and real-time chat, contains seventeen social presence items, and thirteen privacy items each with a 5-point Likert scale, and twelve demographic identifiers. Bartlett's test of sphericity (Bartlett, 1973) was applied to increase the validity because of the small number of participants. Confirmatory factor analysis was utilized to examine the three dimensions of social presence.

Triangulation

Triangulation was not a validation process in this study. Rather, it was considered a means to a better understanding about the perception of social presence. Triangulation allows the consideration of analyses from a novel standpoint, additional data are available for study, but, further, these additional data may alter the researcher's perception of the initial data (Bloor, 1997).

Results

Quantitative Results

A confirmatory factor analysis was performed on 30 questionnaire items on social presence, risky behaviors, and computer privacy. Five factors analyses from a previous study (Tu, 1999) were computed. These five factors accounted for 76.7 percent of the variance. The five factors were extracted using varimax rotation. With a cutoff of .45, three items were removed from the loading. These five factors were social context, online communication, interactivity, system privacy, and feeling of privacy yielding a
Cronbach's coefficient alpha of 0.82, 0.88, 0.73, 0.75, and 0.71, respectively. Correlations were computed between social presence and privacy, and among five factors. The result was $r = 0.311$ with significance at the 0.05 level.

A Pearson correlation between mean social presence rating and frequency produced a correlation of $r = -0.004$, and this correlation was not significant at $\alpha = 0.05$ ($r = 41) = -0.004$, $p > .05$). It was concluded that the level of social presence did not vary with frequency.

**Qualitative Results**

Social context dimension included the recipient, task, social relationship, social skills, message topics, locations, psychological issues, and flaming messages. The level of social presence decreased when a group member typed too fast, was too talkative, didn't listen to others, and dominated the conversation. Those participants have a negative impact on other’s participation because of their communication behavior. One’s fast typing could have a negative impact on the other’s level of social presence because the other could not keep up with the typing speed and could easily generate pressure on the slower typist. This situation occurred when one talked a lot, many of these communications were nonsensical.

Online communication is the exchange of thoughts, messages, or information that occurs online. Online immediacy includes expressiveness, stimulation, and the conveying of feelings and emotions through online language. The language used in an online communication expressed meanings and thoughts with difficulty and was easily misunderstood. Many messages were perceived and interpreted as not stimulating while some were perceived as stimulating. To convey feeling and emotions, emoticons and paralanguage were used to compensate for the absence of non-verbal cues. Female students tended to use emoticons and paralanguage more frequently to convey their feeling and emotions. Both genders agreed that the use of emoticons and paralanguage made the message more stimulating, sensitive, and expressive.

In the interactivity dimension, immediate response, communication style, multi-thread communication, and physical distance between users contributed to the level of social presence. Personal communication style had a great impact on the level of social presence, such as formal/informal style, short/long messages, stylistic communication style, task-oriented style, use of humor, inviting tone, slang, and using of you versus we. E-mail communication has been considered to be a casual written communication. However, many e-mail messages are formal communications that increased the psychological distance. Long messages were identified as inappropriate for e-mail and real time chat.

Private/public issues on CMC have an impact on the level of social presence. When students perceived a medium as more public, the level of social presence is lower, and vice versa on a medium that is perceived as more private. Students perceived e-mail communication as more private than bulletin board while real time chat varied with the numbers of participants. It was found that very private and personal e-mail messages were sent to multiple recipients and group discussion folders without notifying the original senders. Although e-mail was conducted mostly as a one-to-one communication, whether the recipient read the message or not is unknown. Students could share an e-mail account with their spouse, family members, or others. E-mail messages with a long recipient list that preceded the body of the message were perceived as impolite because e-mail is supposed to be a more personal communication medium. The long recipient list made the individual recipient less important. Although both bulletin board and real time chat can be considered as one-to-many communications, bulletin board is perceived as a more public communication because the bulletin board messages were available online most of the time, unlike real time chat messages which disappeared at the end of the chat, an erroneous impression. However, students considered private real time chat could be public as well because one could just observe and not participate. This could have a negative impact on the chat participants.

PATTERNS OF E-MAIL USE IN A CONVERSATION-BASED TEACHER DEVELOPMENT GROUP

Andrew G. Topper
GVSU School of Education
U.S.A.
Toppera@GVSU.EDU

Abstract

Telecommunications has been proposed as a way to address the problem of teacher isolation and provide opportunities for teacher professional development. The literature on teachers' use of telecommunication suggests that the medium may be ideal for supporting teacher learning and growth when collegiality in a school is insufficient or unavailable. This study investigated the nature of e-mail use in an established teacher inquiry group focusing on patterns of use and support for individual teacher growth. The results suggest that while telecommunications provides opportunities for teachers to engage in substantive discussions and collaborations with peers who are distant but share interests and curricular work, the actual uses of e-mail and other forms of electronic communication are constrained by a number of factors. These include access, time, shared goals, and interdependence. The results also suggest that even groups that meet the criteria suggested by researchers as essential for success do not guarantee successful use of e-mail for professional development.

Introduction

Proponents of educational technology often point to the value of telecommunications and the Internet as a tool for teacher professional development. By providing classroom teachers with access to conversations and collaborations with their peers through virtual communities, it is argued, participants can benefit from collegial interactions that they rarely have access to within their own school culture. While it is probably true that existing school structures may prohibit or restrict sustainable collegial relationships, there are questions about the extent to which telecommunications can offer a viable form of teacher professional development.

A popular view suggests that by providing teachers with access to telecommunications they will discuss their beliefs with their peers, reflect on their own teaching methods, and adopt educational innovations (Bos, Krajcik, & Patrick, 1995; Lieberman & McLaughlin, 1992). While this may be true for some teachers, especially those pre-disposed to using technology, what is needed is a better understanding of how telecommunications can be used by more teachers to accomplish their own goals and reflect on their beliefs about teaching. An important question is: how do teachers come to use technology, especially telecommunications, for their own purposes to shape their own learning and development?

In order to understand how this question might be answered in the context of practicing teachers, we need to examine the literature on the use of e-mail and its potential to support substantive conversations about teaching and learning.

Teachers Use of Telecommunications

Studies of e-mail use suggest that members of electronic discussion groups tend to participate more equally than members of face-to-face groups (Sproull & Kiesler, 1991; Kiesler et al, 1984). Students may also be more efficient and uninhibited while using e-mail (Dubrovsky, Kiesler, & Sethna, 1988). Some researchers
have found a lack of inhibition among experienced and novice users of e-mail (Kiesler et al., 1984) while others found that e-mail groups produced a greater variety of opinions (Hiltz et al., 1986).

A study of beginning teachers' use of a computer network (Merseth, 1989) found that it was most effective in providing moral support and least effective in providing technical support for curricular planning. The factors found to enhance the network included its convenience, its ability to reduce feelings of isolation, and the safe non-evaluative environment it created for teachers.

These and other studies suggest that e-mail may represent an ideal medium for fostering and examining critical reflective conversations among professionally isolated teachers. The growing availability and use of e-mail in colleges and K-12 schools makes it a good choice for further study. In addition, e-mail conversations may be more topic-centered than person- or task-centered, and, as such, may represent a forum for discussion where the explicit focus is on ideas rather than on individual status.

While telecommunications might provide teachers with access to ideas and innovations, teachers need to consider how these innovations can be transformed to fit into their local conditions and supported as they experiment with adapting these ideas into their regular classroom activities. Technology, then, is necessary, but insufficient, to support the kind of reform described in the literature. Teachers also need a supportive school context in which they can experiment with new ideas and try out new teaching practices as they grow professionally.

In a recent review of research related to characteristics of successful networks, Riel & Levin (1990) described differences between networks that succeeded -- that is, that accomplished their goals through the interactions and meaningful conversations through technology -- and those that failed -- that is, they never "got off the ground" or they were unable to sustain their efforts. The five characteristics needed for success were: (a) the group already exists, (b) it has need for telecommunication, (c) it has a shared goal with specific outcomes, (d) it has a person who facilitates group planning and work, and (e) all members have easy, efficient access to technology.

An existing conversation-based teacher development group (Florio-Ruane, 1991; Florio-Ruane, 1990; Raphael et al., 1994; Raphael & McMahon, 1994) provides a site for studying how an existing group, with a specific inquiry focus, might benefit from access to asynchronous communication. Using the characteristics described by Riel & Levin, we examined how e-mail was supportive of teacher learning over the first year of this project. This study investigated how e-mail was used in a teacher development group during a 12-month period and how member use of e-mail may or may not have been supportive of their individual growth and development.

Research Questions

We began this study with a series of guiding research questions:

1. How will e-mail be used by members of an existing teacher inquiry group?
2. Will e-mail be used as a tool in the pre-existing activity setting?
3. Will e-mail change the nature of that activity setting and/or the learning opportunities within it?
4. Does e-mail help participants cross borders or does it help reify existing patterns of interaction?
5. If you start with an inquiry premise (this is not a course nor is it a support group; it is an existing group with an explicit focus on inquiry), will you get discourse that is more tolerant of conjecture and skepticism -- even though there is an inclination in these kinds of groups not to challenge each other directly?
6. If we do see evidence of critical conversations, will we see challenges in the form of indirect questioning of one another, or of self, or of the emergent explanations?

Data sources for this study include participant surveys, archived e-mail messages, and a yearly events timeline. Analyzing these data, we examine how the use of e-mail as a medium for communication and collaboration shapes the regular patterns of interactions among the members of this teacher inquiry group.
The results show that even when specified conditions for success are met, teachers may be inclined to use electronic communication in subtly different ways and for different purposes.

**Methods of Inquiry**

Using the archived e-mail messages posted to a list server, along with private e-mail messages exchanged between a small number of group participants, we analyzed the nature of the electronic conversations using discourse analysis. We also asked participants to return a questionnaire that focused on their use of e-mail within the group as well as a timeframe for major events that occurred within the group and corresponding exchanges over e-mail. Using triangulation, we identified key themes or patterns that emerged from these data and also used modified viewing sessions with participants looking at the data to verify our interpretations and conclusions.

**Procedures**

For the first year of the group's participation in an on-line e-mail list server, we examined the nature of these interactions with an eye towards the characteristics of successful electronic networks identified by Riel & Levin. We attempted to verify which of these characteristics existed in the teacher development group and how these factors did or did not contribute to the use of e-mail as a medium for communications and collaboration during the data collection period. We also investigated the nature of the electronic conversations paying special attention to the relationships between the community, its' established but changing practice, and the media's role on both.

Using Computers to Enhance Action Research

Peter Adamy
School of Education
University of Rhode Island
United States
adamy@uri.edu

Abstract: This paper outlines the potential benefits of using computers to enhance the action research process for classroom teachers. An argument is made for classifying action research as a type of qualitative methodology. This argument is then used to apply the literature on computer use in qualitative research to its use in action research. Specific applications of various types of software are discussed in terms of their potential for supporting and strengthening action research efforts.

Introduction

Action research is hailed by its proponents as an effective way for teachers and other classroom practitioners to actively and rigorously examine aspects of an educational environment in order to inform efforts to change current practice or routine (e.g., McKernan, 1991; McNiff, 1997; Stringer, 1999). In form, the action research process is made up of several components that are traditionally seen as hallmarks of qualitative research:

- It is focused on the meanings of participants within an environment, and thus reflects the *emic* perspective adopted in qualitative studies. This is evidenced by the fact that action research efforts are geared towards change and development for those who are members of the researched community; such an effort is deemed successful when subsequent changes (if any) positively impact the educational experience of those involved (Stringer, 1999).
- The researcher serves as the main measurement instrument. It is the teacher/practitioner who collects, analyzes, and interprets the data, and who ultimately acts on his or her findings.
- The research takes place in a naturalistic setting. For the purposes of this paper, that is presumed to be the classroom.
- In action research, the teacher/practitioner takes on the role of the qualitative researcher and acts as the primary investigator for the study. Typical duties for both types of researcher include collecting, analyzing, and organizing data, as well as making decisions on sampling issues of depth versus breadth (McNiff, 1988).

Because of these similarities in design and method, it is reasonable to classify action research as a qualitative research endeavor. While some professionals balk at any attempt to label action research as “real” research, its structure and methodology do provide an adequate basis for consideration as one variant of the educational research process.

The increased general use of computers during the last several decades has resulted in increased application of their functions and capabilities in the research process. Many qualitative researchers make use of the organization, storage, and retrieval functions of various computer software applications to aid their efforts in making sense of the data they collect (see: Fielding & Lee, 1998; Kelle, 1995; Weitzman & Miles, 1995). Given the argument presented above for classifying action research as a form of qualitative methodology, it is reasonable to assume that similar applications of computer technology will benefit the action research process as well.

The purpose of this paper is to explore the possible uses of computer applications for teachers and practitioners who are conducting, or are interested in conducting, action research projects in their own schools or classrooms. As with the use of computers in qualitative research, computers should be used in action research only in those cases in which their applications can enhance and not replace the research...
process. Accordingly, it is important for those conducting action research to have a clear understanding of how various computer software programs can add rigor to sampling, coding, and hypothesis refinement.

Definition

The action research process is applicable to many areas in which participants in a context or members of a community wish to analyze their practice and the ways in which members mutually influence the action of others. At the most basic level, the main goal of such analysis is to inform efforts to effect positive change in an organization or community. Stringer (1999) and Zeichner & Gore (1995) demonstrate the application of action research principles in both community and educational settings. However, their approach is focused on its potential as a social reconstructionist process aimed at empowerment and social justice. For the purposes of this paper, action research is defined as a method of educational, qualitative research in which teachers and practitioners rigorously examine their own practice in an effort to improve their teaching and communicate their findings to colleagues.

Computers and Qualitative Research

The application of computers to qualitative research efforts can be seen as a merging of incompatibilities. Bogdan & Biklen (1998) state that qualitative research deals with "soft" data that is primarily composed of "description of people, places, and conversations, and not easily handled by statistical procedures" (p. 2). Computers on the other hand, are generally classified according to their numerical nature and ability to process quantitative data rapidly. When the two are joined in the research process, a contradiction can arise in which some fear the loss of the inherent artfulness and humanity of qualitative methodology, while others fear the loss of rigor in the analysis process (Hesse-Biber, 1995). While this contradiction is far from trivial, it is not prohibitive to productive use of the computer's potential for enhancing research efforts. There are some specific, useful features of computer software that can aid the action researcher in some of the more basic functions of qualitative research.

Data collection and Analysis

The lack of regular, systematic tests and measurement instruments in qualitative research places the focus of data collection and analysis on the researcher. He or she is responsible for ensuring the collection of adequate amounts of data that most accurately represent what is happening in the context of a study. They are simultaneously charged with analyzing that data in a way that most clearly and accurately represents the meanings of phenomena and contexts for participants.

This notion of the researcher as instrument in qualitative methodology is particularly applicable to action research, as it is the researcher's own environment and practices that are analyzed. This places particular emphasis on the context of any action research study. Tesch (1990) describes the process of de-contextualizing and re-contextualizing data that is inherent in all qualitative data analysis, and which can be aided by the use of computer software. The first step in this process is the segmentation of relevant chunks of data that are coded and subsequently separated out of the data corpus. This is done in such a way as to ensure that the chunks retain meaning once they are separated. It is then the task of the researcher to reassemble these pieces into meaningful categories in "data documents". Connections are then made between these documents that represent and support a theory of the phenomenon under study. Tesch argues that Computer Assisted Qualitative Data Analysis Software (CAQDAS) can aid this process through its increased capacity for archiving and organizing data. In essence, CAQDAS is much more efficient at the traditional tasks of cutting, pasting, organizing, and retrieving data as it is de-contextualized and subsequently re-contextualized according to the design of the researcher. Since the average teacher as action researcher is not rigorously trained in research methodology, this particular functionality of CAQDAS programs can help them more efficiently organize what might otherwise be an intimidating amount of data in a way that is not necessarily familiar to them.
Validity

In their ability to aid the researcher in processing larger amounts of data more efficiently, computers and CAQDAS programs help address common criticisms leveled at the validity of qualitative research findings. The complaints that qualitative research is subjective, not rigorous, not systematic, and narrow in its sampling can be countered to a certain extent with the use of computers for the research process. CAQDAS makes it possible to collect, organize, and manage much larger amounts of data from a greater number of subjects than was previously possible for human researchers. It is also possible to be more systematic and accurate when coding using the search and retrieval capabilities of many CAQDAS programs.

In action research, validity is tied to three key elements (McNiff, 1997): Self-validation, peer-validation, and learner validation. In essence, the action research process can be considered valid if it adequately enhances the learning process and environment for teachers, their colleagues, and their students. Triangulation of these three perspectives strengthens the validity claims of any action research study (McKernan, 1991). As discussed below, advances in computer technology have greatly enhanced the ability to record and communicate multiple perspectives among participants, thus increasing an action researcher’s ability to achieve this type of triangulation.

At the same time, Seidel (1991) warns of the danger of becoming too enamored of the ability to process large amounts of qualitative data with computers. He argues that is possible for qualitative researchers to fall victim to the illusion that their research is more scientific in nature simply because they are using larger sample sizes. He points out that in some cases, single subjects and/or single occurrences of phenomena are more significant than occurrences across large groups. Ultimately, he argues, while it is advantageous to be skilled in the use of computers for qualitative research, it is equally important to be aware of what the applications can and cannot do, as well as how they can be misapplied to the research process (see also: Hesse-Biber, 1995; Kelle & Laurie, 1995). In the following sections, appropriate applications of computers and CAQDAS programs for action research are discussed.

Productivity Tools

For most teachers time is precious. While the concept of examining one’s practice, reflecting on that examination, and taking action to improve the learning process is attractive to those who are committed to education, it is also a time-consuming practice. As a result, action research involves a significant commitment of time and effort. When computers, and especially CAQDAS programs, are added to the mix, the amount of time required can increase dramatically due to the learning curve that is inherent in many computer applications.

It is therefore important for action researchers to consider those computer resources that already exist in their environment, and how they might be applied to the research process. In most cases, those resources will include some basic productivity software tools that are standard issue with most computers purchased in today’s market.

Databases and spreadsheets are non-specialized programs that can be used to efficiently store, organize, and present data. They have the advantage of being two of the most commonly used software applications, which increases the likelihood that experienced users can readily be located locally to assist researchers who are not familiar with their capabilities. Spreadsheets are particularly advantageous because of their ability to save and import data as delimited text. This facilitates the transfer of certain data configurations between several types of computer software applications (e.g., spreadsheets, word processors, SPSS, QSR NUD*IST, etc.).

While there are specialized programs such as Inspiration that are designed to facilitate the visual display of qualitative data (see: Miles & Huberman, 1994), standard draw and paint programs can be used to achieve similar types of display. This eliminates the need for action researchers to learn an entirely new software package, and allows them to use an application that they are most likely using with their students already.
CAQDAS Software

If an action researcher is committed to using software that is specific to qualitative research, there are a number of specialized packages that can enhance and facilitate the basic tasks they must accomplish in the analysis process (e.g., QSR NUD*IST, Atlas/ti, FolioViews, HyperQual, HyperResearch, The Ethnograph). In most cases, these programs require a significant investment of time to become familiar and comfortable with their basic functionality. However, they have the advantage of providing some very powerful tools for data analysis.

Coding

A basic function of all CAQDAS programs is the ability to assign codes to chunks of data. An advantage to doing this on the computer is the ability to create, assign, and keep track of a greater number of codes than would be humanly possible using pencil and paper. At the same time, when dealing with fewer codes and more manageable amounts of data, the organizational functionality of CAQDAS programs can still outperform human ability, thus freeing the researcher to concentrate more on analysis and less on organization. In most packages, the creation, naming conventions, and organizational scheme for coding is flexible. This allows the researcher to have increased ownership of the analysis process, and to proceed in a manner that is most intuitive to them. For action researchers, this alleviates the need to stick to formal classification and hierarchical organization schemes that may not be familiar to them, and allows them to structure the coding process to fit their needs and abilities.

Search and Retrieval

A second basic function of CAQDAS programs is the ability to search for specified strings or patterns, and to retrieve and display the results of such searches. As the analysis begins to take shape within the software program, the individual researcher becomes intimately grounded in his or her original data, the coding schemes they have identified and used, and patterns that begin to emerge as the process moves forward. The ability to search for occurrences of single or multiple codes helps the researcher to explore relationships between concepts and phenomena, and to then reorganize those patterns and relationships into an explanation of what they have found.

The action researcher who chooses to use such CAQDAS programs for data analysis can take advantage of this functionality to formulate and examine hypotheses about their practice. One of the key elements of action research is the ability to gain a new perspective on personal practice. The rigorous organization and analysis of data within this type of software can help the action researcher to explore their practice more deeply, to formulate hypotheses that are grounded in their data, and, ideally, to gain new insights into how they can improve what they are doing in the classroom.

Communication

At the most basic level, action research is a social process (McNiff, 1997; Stringer, 1999). In opposition to traditional scientific research, action research is concerned less with an objective, primary investigator and more with a practitioner who is invested in the inquiry into his or her own practices. The successful action research study moves forward only as the researcher gains insight into and understanding of his or her practice (McNiff, 1997). It is a process that is validated through the exploration of different perspectives, and built upon successful communication between all the members within a community or context (Stringer, 1999).

In recent years, developments in technology have greatly increased the potential for easy, inexpensive communication over long or short distances. For the action researcher, this provides an excellent avenue for the sharing and comparison of different opinions, perspectives, and findings. Tools such as electronic mail, electronic mailing lists, online newsgroups, web sites, and video conferencing can
all be used to communicate with colleagues during the research process. This type of technology is particularly valuable for communication across distances and in an asynchronous mode. Given the restrictive daily schedule required of most teachers, it is not always possible to find common times for meeting and sharing ideas or findings. The ability to post and retrieve information online at any time permits communication on a more flexible basis.

Conclusion

At a basic level, action research is designed to benefit practitioners who are not professional researchers. In the process of conducting action research, teachers have the opportunity to take an in-depth look into their educational practices in a way that is illuminating and, ideally, transforming for themselves and the members of their communities of practice. Computers, and specifically CAQDAS programs, can serve as tools for the action researcher that can simultaneously simplify and enhance the research process. As teachers approach action research with a plate that is already overflowing, CAQDAS offers a way to support them in their new role as researchers, and to lend credibility to their efforts, which can ultimately help ensure their continued participation in this type of critical, self-evaluation.

Abstract:
This paper critically reflects upon the questions we have asked and the models and methods we have employed to evaluate online learning in several studies. The paper examines the methodologies used to answer the following evaluation research questions:
1. How can we describe online participation, interaction patterns, and group dynamics? 2. Were students satisfied with the experience of participating in the conference? 3. Did participants learn? 4. Was knowledge constructed?

One of the critical challenges facing educators as we move into the twenty-first century is the development of appropriate methodologies and tools for evaluating online learning networks. The open-ended nature of online learning projects, the multiple threads of conversation, and the fluid participation patterns pose new challenges to evaluators. Online learning designs are often based on constructivist, learner-centered principles which provide more learner control, facilitate the sharing of multiple perspectives, and places emphasis on individual learners creating their own meaning. Behavioral objectives with a stated outcome for all learners, is not the goal of many online learning projects. Traditional evaluation methods used to evaluate learning within the four walls of a classroom do not transfer well to the online context. Evaluators therefore, are challenged to understand the unique characteristics of the online medium and its social and ecological structure in order to develop new principles for evaluating learning.

The purpose of this paper is to critically reflect upon the questions we have asked and the models and methods we have employed to evaluate online learning in several studies we have conducted. These online studies range from setting up online networks for social
interaction, facilitating collaborative learning experiences among graduate students in several universities, to moderating worldwide online professional development activities.

This paper will be organized according to the evaluation questions we have asked and attempted to answer:
1. How can we describe online participation, interaction patterns, and group dynamics?
2. Were students satisfied with the experience of participating in the conference? Did they feel that it had been a worthwhile use of their time, and one that they would be willing to repeat?

These questions were answered using a variety of techniques; both quantitative and qualitative. However, while these questions have value in understanding the nature of a computer conference (CC), they do not yield useful information on the quality of the learning that took place.

One significant question which has yet to be satisfactorily answered is: How do you assess the quality of the learning experience in a computer-mediated conference (CMC)?

Questions we need to ask are:
3. Did participants learn?
4. Was knowledge constructed?

Currently, the question that has intrigued us, is: How is knowledge constructed in online learning networks through the process of social negotiation? In order to address this challenging question, content analysis or interaction analysis of computer transcripts using qualitative research techniques is essential. We have relied on interaction analysis in our attempts to develop an interaction analysis model for examining social construction of knowledge in online learning networks (Gunawardena, Lowe, and Anderson, 1997) which we will describe in this paper.

How Can We Describe Online Participation, Interaction Patterns, and Group Dynamics?

Participation analysis techniques examine the capacity of a conference to engage members and reveal comparative patterns of participation among learners from varying backgrounds. An evaluation tool we have employed to address these questions is the model developed by Levin, Kim and Riel (1990) for analyzing instructional interactions on electronic message networks. This model has four dimensions of analysis: 1) Participant Structures Analysis, 2) Intermessage Reference Analysis, 3) Message Act Analysis, and 4) Message Flow analysis. We used this model to evaluate a peer support network for medical students at the University of New Mexico (UNM), set up to maintain the social and psychological support network during the period of time that they worked with preceptors in isolated rural communities in New Mexico (Gunawardena, Gittinger, and Dvorak, 1991).

In reflecting on the use of the Levin, et al. (1990) model, we found that while it is a good starting point for obtaining an overall picture of the network group, activities, and interaction, it did not fit neatly with the purpose of our project. The Intermessage Reference Analysis was difficult to apply since our application of CMC was primarily
social in nature. All participants on-line were peers; no instructor activity existed. The purpose of these communications was not academic and tasks were not performed on-line. As a result, information such as whose messages were referenced most, what topics were referenced most, did not stand out in any particular way. Levin, et al. do not address content analysis within Message Act Analysis. We found our research was enriched by a careful analysis of the content of the interaction. We have found other data such as unsolicited participant reactions online, solicited participant reactions, both instructor and student perspectives on interaction and the analysis of computer transcripts to be more useful in forming a picture of events that occurred in the online community (Gunawardena, 1993).

Were Learners Satisfied with Their Online Learning Experiences?

The methods we have used most often to solicit learner reactions to and satisfaction with online learning experiences include online surveys, paper and pencil surveys, and participant reactions to the conference posted online in a conference area designed for this purpose. Another important source of data are the unsolicited comments on participant satisfaction or dissatisfaction with the learning experience that occur throughout the transcript.

Structured survey questions are useful in obtaining an overall view of student reactions to the conference and their satisfaction. It is also possible to obtain more in-depth data on selected open-ended questions. The survey is an easy vehicle to obtain data when students are scattered across geographic distance. Analysis of survey data has taken many forms depending on the questions we have asked related to various studies we have conducted.

Hiltz (1990) discussed an approach to determining learner satisfaction by examining the social psychological (characteristics of the users); human relations (characteristics of the groups and organizations within which systems are implemented); and technological determinist (characteristics of the system); factors that impact student satisfaction with, and subsequent use of computer conferencing. Using her theoretical framework we examined a computer conference in which a group of graduate students from the University of New Mexico joined 13 academic experts from 7 countries to discuss "cooperative learning" within the context of a global electronic pre-conference for the international TeleTeaching '93 conference held in Norway (Gunawardena and Heeren, 1993). The analysis was based on a questionnaire that addressed Hiltz's dimensions. One of the major problems associated with our study and with quantitative analysis when applied to the CMC context was sample size and sample selection. While multiple regression and analysis of variance were conducted to examine these variables, the statistical significant differences are not convincing because of the small number of participants in our study.

A recent quantitative study we conducted to answer the question: What are the variables that can predict student satisfaction in online learning networks? yielded more positive
outcomes (Gunawardena & Zittle, 1997). The purpose of this research was to examine which process variables such as proficiency in technical skills, learner support, and "social presence" or the degree to which a person is perceived as "real" in mediated communication (Short, Williams, and Christie, 1976), could predict learner satisfaction within a CMC environment. The process and satisfaction variables were measured by a 61-item questionnaire consisting of predominantly five-point Likert scale items specially designed for this study.

The subjects were fifty graduate students from five universities: San Diego State (N=8), Texas A & M (N=11), University of New Mexico (N=14), University of Wisconsin-Madison (N=7), and University of Wyoming (N=10), who participated in the Fall 1993 Globaled inter-university virtual conference. The Globaled conference was an academic exercise that was a class requirement at each participating university (Gunawardena, et al. 1994).

In this analysis (Gunawardena and Zittle, 1997), eight process variables were used to predict overall satisfaction with the Globaled conference. The stepwise regression analysis converged on a three-predictor model revealing that social presence, student perception of having equal opportunity to participate in the conference, and proficiency in technical skills accounted for about 68% of the explained variance. Social presence alone contributed about 60% of this variance, suggesting that it may be a very strong predictor of satisfaction. Although care must be taken in generalizing these results due to sample selection and size, the results suggest that social presence alone is a strong predictor of satisfaction in a text-based computer conference.

When reflecting on the quantitative analyses we have done using surveys, we feel that the strengths of these analyses lie their ability to point out salient differences in process variables as they relate to learner satisfaction. One of the shortcomings of quantitative analysis however, is the inability to explain the reasons for the significant differences observed. This is where qualitative analysis of open-ended questions or interviews is of value. A related problem with quantitative analysis when applied to the CMC context, is the small sample size in many conferences, and problems related to sample selection as random sampling is difficult in the distance education context. Quantitative analyses should be performed only when there is an adequate sample size to study the variables of interest. Qualitative data used in conjunction with quantitative data can usually explain the significant differences found. Therefore, we would advocate a mixed methodology approach (Tashakkori & Teddlie, 1998) combining quantitative and qualitative data to overcome some of the problems related to quantitative data alone.

Did participants learn?

How did the individual learner make sense of the computer conference? What did he or she learn? These questions are more difficult to answer if we subscribe to a constructivist view of learning where the individual learner is expected to take away a unique perspective from the learning experience. Traditional methods of measuring learning
using pre and post tests will not work well in this context as learning occurs in many different forms and is not limited to learning the content or subject under study. We have been interested in examining questions related to learning from two perspectives: What did participants learn about the subject/topic/content that was discussed? and What did they learn about the medium of computer conferencing and it’s influence on the learning process?

One method is to analyze the computer transcript as it affords an unobtrusive, and fairly accurate means of gauging whether participants learned during the conference. If one looks carefully at the transcript, we can decipher several unsolicited comments or “thinking aloud” comments that refer to individual learning such as the following in a debate that discussed the importance of ‘interaction’ to distance education: “In the past two days, you who are participating in this conversation have made me stop and think about ‘interaction.’ I guess you’d call that ‘learning.’ Without your thoughts this would not have happened. I think this demonstrates the importance of ‘interaction’ to learning.” (Gunawardena, Lowe, and Anderson, 1995, p. 202).

Another technique is to ask participants directly what they learned, either through open-ended questions in questionnaires, or individual interviews, or, asking them to discuss their learning in a separate conference space specially designed for this purpose. In a study where we used open-ended questions in a questionnaire to find out what students learned about “cooperative learning,” the topic of the conference, we found that students learned about: 1. cooperative learning as an educational concept, 2. how to participate in a conference that generated diverse opinions, 3. what makes a good and a bad conference, and 4. how to use the technology to participate in a computer conference (Gunawardena and Heeren, 1993).

Evaluation data on student learning can also be collected online by asking very general questions such as: What did you think about this computer conferencing experience?

In order to understand the myriad forms of learning that occurs in a computer conference, we have often asked students to keep weekly journals documenting all aspects of learning. These journals have given us a unique perspective of each individual’s learning process. Other techniques we have used are to ask students to critique their online learning experiences and to apply and transfer what they have learned from the computer conference to developing a computer conferencing design.

In reflecting on the various evaluation techniques we have used to understand student learning, we have found that qualitative approaches work better than quantitative methods in being able to understand the unique ways in which individual students learn.

Was Knowledge Constructed?

Perhaps the most challenging and the most exciting question one can ask in evaluating online learning is: Was knowledge constructed within the group by means of the
exchanges among participants? We will discuss two interaction analysis models we have used to answer this question. Initially, we began to use Henri's (1992) model to analyze the transcripts of a global online debate we had conducted as an adult professional development experience. However, it became clear that three aspects of Henri's model; its basis in a teacher-centered instructional paradigm, its distinction between the cognitive and the metacognitive dimensions, and its treatment of the concept of interaction, were unsuited for application to the debate. We felt that we needed to develop a new definition of interaction for the CMC context if we are to examine the process of social negotiation (Gunawardena, Lowe, and Anderson, 1997).

We believe that the metaphor of a patchwork quilt better describes the process of shared construction of knowledge that occurs in a constructivist learning environment. A quilt block is built up by the application, one after another, of small pieces of cloth, which when assembled form a bright and colorful pattern. The pieces, according to this analogy, are the contributions of individual participants. Each participant contributes to the whole his or her own texture and color of thought, just as every scrap of fabric forms a distinctive element in the overall pattern. The pattern may not be complete during a single conference, but individual responses can contribute toward the formation of a pattern. The process by which the contributions are fitted together is interaction, broadly understood, and the pattern which emerges at the end, when the entire gestalt of accumulated interaction is viewed, is the newly-created knowledge or meaning. Interaction is the essential process of putting together the pieces in the co-creation of knowledge.

Based on this new definition of interaction, and grounded theory principles, we developed an outline of the process of negotiation which appears to occur in the co-construction of knowledge. The outline led to the development of the interaction analysis model which has five phases, reflecting the complete process of negotiation which must occur when there are substantial areas of inconsistency or disagreement to be resolved. The phases of learning outlined in this model occur at both the individual and social level and can be described as:
Phase I: Sharing/Comparing,
Phase II: Dissonance,
Phase III: Negotiation/Co-construction,
Phase IV: Testing Tentative Constructions, and
Phase V: Statement/Application of Newly-Constructed Knowledge.
A detailed discussion of this model and its underlying theoretical framework is found in Gunawardena, Lowe, and Anderson (1997).

Two major themes were observed related to knowledge construction. One was the progress of certain strands of argument from Phase I to Phase V which can be described as an exercise in the co-construction of knowledge, moving from lower to higher mental functions. The other was the evidence of more than one and sometimes three phases within a single message posted by one participant, which usually progressed in sequence through the phases, showing progress from lower to higher mental functions, showing how individuals contributed toward the co-construction.
Conclusion

The adoption of a single technique for analyzing the quality of the learning experience in online learning networks has not yielded satisfactory answers. The complex nature of online learning calls for the use of multiple methods and multiple sources of data to understand group as well as individual learning. While quantitative analysis of interaction patterns and learner satisfaction has yielded useful information on the overall nature of online learning and the variables that influence its success, several problems exist in the application of the quantitative paradigm to evaluating learning in the online context. Two problems relate to sample size and selection. While quantitative data can point out a significant difference, it cannot adequately explain the reasons for the observed difference. The naturalistic paradigm employing qualitative data from in-depth interviews, observations, and computer transcript analysis, can often explain the observed differences. When used in conjunction with quantitative data, qualitative data can overcome some of the shortcomings of utilizing quantitative data alone. Therefore, it is recommended that a mixed methodology approach be used to study the complex nature of online learning networks.

Abstract: This paper is a report on findings of a study conducted with the purpose of assessing the level of technology skills of graduate and undergraduate students enrolled in the teacher education program at Eastern Kentucky University. The study revealed both strengths and weaknesses in relation to a new technology standard for teachers recently adopted by the state of Kentucky. Marked differences were found among three groups of undergraduate students. These differences were analyzed and used as a basis for recommended changes in the teacher education program.

Introduction

The state of Kentucky has been engaged in a wide-ranging reform of elementary and secondary education since the Kentucky Educational Reform Act (KERA) of 1990. As part of that reform, the state has adopted New Teacher Standards (NTS) and Experienced Teacher Standards (ETS) for initial and continued certification for teachers. Although technology was an emphasis in KERA, no standard for technology was included in either the New or Experienced Teacher Standards. In early 1999, the Kentucky Education Professional Standards Board proposed that a new standard for technology be added to both the New and Experienced Teacher Standards. As a part of preparation to meet such a standard, the authors conducted a survey in the College of Education at Eastern Kentucky University to assess technology needs of undergraduate and graduate teacher education students and to compare the needs with those of a selected sample of faculty members. The new technology standard was adopted by the Kentucky Department of Education in October 1999.

Project Description

Eastern Kentucky University is one of the eight state supported universities in the state of Kentucky and has the largest teacher preparation program in the state. A computer literacy requirement has been in place for pre-service teachers for several years. Approximately five years ago, all course syllabi for teacher preparation programs were re-examined and revised to include a technology component. It seems important to ascertain the level of skills attained by teacher education students who have been in this program before deciding whether additional provisions are needed to meet the change in Kentucky Teacher Standards.

Kentucky's technology standard for teachers is similar to guidelines established by the International Society for Technology in Education (ISTE) as the Recommended Foundations in Technology for All Teacher. (ISTE, 1997). Kentucky's introductory standard statement is: "The teacher uses technology to support instruction; access and manipulate data; enhance professional growth and productivity; communicate and collaborate with..."
colleagues, parents, and the community; and conduct research” (Kentucky Department of Education, 1999). This statement is followed by 16 performance criteria that relate to how the teacher uses technology in the preparation and delivery of instruction and for professional growth and productivity. Findings from the survey described in this paper were analyzed in relation to these performance criteria, and recommendations for changes in the teacher preparation program were made based on the analysis.

Several constraints exist for proposed changes in the teacher preparation program designed to meet the new standard. First, there is an immediate need for addressing the new standard. The state has developed an implementation time line such that teachers beginning their teaching career in the fall of 2000 will be held accountable for the standard. Second, any new course proposal would be highly unlikely to be approved due to the university’s desire to limit the number of credit hours to 128 for all teacher preparation programs. Even if approved, students currently in the program could not be required to complete an additional course. Third, the university climate would make it extremely difficult to get approval for a course designed to focus on technology for teachers. Taken together these constraints require accelerated but thorough planning for assessing strengths and weaknesses in the current program, integrating instruction for use of technology into existing required classes, and designing means for helping faculty members utilize technology more efficiently and productively in their classes and as part of course requirements.

A survey focusing on computer skills needed by adult users of computer hardware and software was administered to three cohorts of undergraduate students during the fall semester of 1999. The three groups included (1) all students enrolled in the first course in the language arts sequence for elementary and middle grade majors (juniors), (2) all students enrolled in the elementary blocked methods classes, and (3) all students enrolled in middle grades methods classes. These students were all either junior or senior level students who were enrolled in teacher education programs. The survey was also administered to two groups of graduate students enrolled in education classes, and to faculty members in the Department of Curriculum and Instruction.

**Findings from the Project**

All the undergraduate students had taken at least one 3-semester hour credit class related to computer literacy and/or usage. Approximately 86% reported that they have a computer at home, yet only 45% responded that they felt very confident about using them. Another 39% stated that they felt somewhat confident in their use of computers. A few students reported being timid about using computers and avoided them when possible.

A majority of the graduate students had taken a minimum of one course plus additional in-service computer training. They represented a wide variety of teaching levels and experience. Approximately 70% reported having their own computers at home. Length of use and frequency of use varied for this group. Some had used computers less than two years, others reported two to four years with many reporting more than five years use for instructional purposes. However, most had used them for word processing and electronic mail only.

Very few of the faculty members surveyed had any college credit hours in computers, but most had taken some in-service computer training. Eighty-two percent reported having computers at home and all have computers in their offices as well as access to related peripheral devices (e.g. scanners, video and digital cameras). The majority reported using computers for more than five years and most said they used them on a daily basis. However, like the graduate students, most faculty members used them for word processing and electronic mail only.

All the groups reported good skills in using computer technology to access electronic mail and use the Internet. Most of the respondents reported using electronic mail for communication. A similar majority responded that they use the Internet for research to support instruction. All three groups also reported feeling comfortable with operating a computer and some types of software. The major software used was a word processing program. These findings indicate areas of strength in all groups.

In a question on using database programs, 2% of the juniors, 14% of the elementary methods students, 21% of the middle grades methods students, and 27% of the graduate students reported using databases regularly while only one faculty member did so. Forty-two percent of the elementary methods students, 46% of the middle
grades. students, 34% of the juniors, 33% of the graduate students and 15% of the faculty reported using spreadsheets regularly. All these percentages represent less than half of any group. Since a part of the new technology standard is that everyone will be able to use productivity tools for database management and spreadsheet applications, these results are an indication of a major need area for all groups surveyed.

Several questions in the survey were related to the skill level of the teacher in operating a multimedia computer and peripherals and in doing simple connections and installations of the computer and peripherals. All groups reported being somewhat unsure about installation and troubleshooting minor problems with both hardware and software. All groups rated themselves low on being able to evaluate the type of hardware needed for use in the classroom for instruction. They also rated themselves low on being able to use a computer manual and other technology reference materials. This indicates additional areas of need for all groups surveyed.

In some skill areas there was a marked difference in the response of the various groups. The students enrolled in the middle grades methods courses rated themselves higher on five areas of technology use for instructional purposes. These areas were 1) creating multimedia presentations and using presentation software in the teaching of lessons, 2) using the scanner and video and digital equipment in preparation of lessons and for professional productivity. 3) choosing appropriate software for use in the classroom, 4) developing lesson plans that include using the computer as a part of the instruction, and 5) planning pre- and post-computer interaction activities.

One area in which the graduate students rated themselves more skilled than the other groups was in the use of computer software to individualize instruction. Sixty percent of the graduate students, 45% of the middle grades methods students, 35% of the elementary methods students, 16% of the juniors and 40% of the faculty members rated themselves high in this area.

Discussion

The discussion of the findings and recommendations drawn from the findings will focus on how the results of the survey can be used to change the teacher education program so that students have the opportunity to meet the sixteen performance criteria in Kentucky’s new technology standard.

The strength areas found in all groups in word processing, use of electronic mail, accessing the Internet and utilizing software are among the most widespread uses of computers. This indicates a success area in our current teacher preparation program. Another explanation of this finding may be related to the fact that word processing, electronic mail and the Internet are helpful for two basic functions of teaching and learning. These functions, accessing and communicating information, were accomplished by teachers in the past using reference books and pencil and paper tasks. Some software programs utilized by teachers may be merely a different form of worksheets and learning centers. This relationship to traditional functions may lead both in-service and pre-service teachers to feel more comfortable with these areas.

Areas of need for all groups surveyed include the use of databases and spreadsheets as well as the technical aspects of technology use such as connecting and installing computers and peripherals, installing software, and troubleshooting minor problems with hardware and software. In addition, a low rating was reported by all groups in using computer manuals and other technology reference materials. These specific areas of need represent a current weakness throughout the teacher education preparation program in relation to the new technology standard.

Three major differences among the survey groups were noted in the analysis of the survey data. First, the students at the junior level in the early language arts course rated themselves lower than the two groups enrolled in senior level methods classes. This was particularly noticeable in the areas of planning and implementing instruction. This finding was to be expected since the students in the junior level group had experienced fewer opportunities in planning and implementing instruction and less exposure to instructional software. These students did report approximately equal skill in word processing with the other groups but less skill in database and spreadsheet applications.
The second difference among the groups, the finding that graduate students were more skilled in using computer software to individualize instruction, is also to be expected. These graduate students are classroom teachers with many opportunities to use computer software with students on a daily basis.

One other difference among the groups was the most interesting and useful finding, that students in the middle grades methods courses were more advanced in skills and usage than the other groups. In examining this phenomena, a model emerged that could be used with other groups of students. The five middle school faculty members worked as a team to decide on technology skills that they felt were important for the middle grades education students to use in the block experience. The instructors conducted technology seminars for students at the beginning of the semester and then expected the students to use the skills in preparation of class assignments. These seminars were developed with the aid of the College of Education technology coordinator, who then trained the faculty members to deliver the seminars to the students. Faculty members became “experts” in teaching one area of computer skills through both the training and delivery of the seminars to five groups of students. Two members of the middle grades faculty had received training in online course development. They used this training and developed an online component for all courses in the middle grades block. This component included resources such as course syllabi, schedule of class times, electronic addresses, forms needed for the course, assignment guidelines, and other materials often given as hard copy handouts. This web enhanced component of the course helped students become familiar with a distance learning application which used online materials for learning.

Recommendations

In considering the new Kentucky technology standard and the sixteen performance criteria associated with it, a plan can be designed for improvement of the teacher education program that is based both on the findings of the survey and on the criteria teachers will now be expected to meet.

Since all students are required to take a basic computer applications course, six of the performance criteria can be met within that course. The faculty who teach this course are now redesigning the course to focus more on the performance criteria related to operating the computer and peripherals; connecting peripherals to the computer; installing software; using computer and technology terminology; uses of technology in business and society; and legal and ethical issues related to technology use. In the future, this course will also focus more on database and spreadsheet skills rather than word processing.

In redesigning the pre-service teacher education program three years ago, a special education course was made a requirement for all education majors. This course seems an appropriate place to incorporate a seventh criteria which is for students to learn about the use of assistive and adaptive devices for students with special needs.

Another existing course into which one performance criteria could be incorporated is a course on assessment in education. The criteria addresses the need to use technology to support multiple assessments of student learning.

A ninth criteria is for students to use distance learning applications to enhance professional productivity and support instruction. The web enhanced format used by the middle grades faculty provides a model for one such application. Since compressed video courses are offered on campus, the compressed video rooms could be used for pre-service teaching majors to communicate with schools as a part of their field experience.

Another group of five performance criteria are specifically related to instructional planning and delivery. These criteria could be addressed in the blocked methods courses. The middle grades model can be used as a base for redesigning the elementary methods block by incorporating training for faculty members, seminars for students, course assignments that require using technology skills, and adding a web component to the courses. In addition, the content areas of mathematics and science within both methods blocks lend themselves to more intense emphasis on utilizing spreadsheets in instruction. The two content areas of language arts and social studies similarly lend themselves to greater emphasis on databases.

The final two performance criteria include applying research-based instructional practices and facilitating lifelong learning of self and others through the use of technology. To address the first of these criteria it is
important to focus on raising skill levels of faculty. Working with the college technology coordinator, seminars addressing needed skills can be developed and delivered to the faculty. If faculty feel competent and comfortable using technology, they are much more likely to use technology and model its use for their students. Facilitating lifelong learning is a natural outgrowth of developing competence and comfort in all the other criteria. With competence and comfort in technology, faculty and students will use and continue to grow in their use and understanding of technology in education.

Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with technology. This purpose is accomplished through the encouragement of scholarship related to technology in education and the dissemination of research results and through AACE sponsored publications, conferences, and other opportunities for collaboration.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high-quality peer-reviewed publications, and conferences.

Membership Benefit Highlights

- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

AACE PO Box 2966 • Charlottesville VA 22902 USA
www.aace.org

Advancing Knowledge and Learning with Information Technology
Journals

Abstracts for all journal issues are available at www.aace.org/pubs

Educational Technology Review
International Forum on Educational Technology Issues & Applications (ETR)
ISSN# 1085-6901

AACE's member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. Its purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. All AACE Professional and Student Members receive ETR as a benefit of membership.

WebNet Journal
Internet Technologies, Applications & Issues
ISSN# 1522-192X Quarterly

Focused on WWW, Internet, and Intranet-based technologies, applications, research, and issues, the WebNet Journal is an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

Journal of Educational Multimedia and Hypermedia (JEMH)
ISSN# 1055-8896 Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the Journal is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

Journal of Computers in Mathematics & Science Teaching (JCMST)
ISSN# 0731-9258 Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The Journal offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

Journal of Interactive Learning Research (JLR)
ISSN# 1093-023X Quarterly

The Journal's published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL and assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality based learning systems.

Journal of Technology and Teacher Education (JATE)
ISSN# 1059-7069 Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. Journal content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

International Journal of Educational Telecommunications (IJET)
ISSN# 1077-9124 Quarterly

IJET serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Information Technology in Childhood Education Annual (ITCE)
ISSN# 1522-8185

A primary information source and forum to report the research and applications for using information technology in the education of children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.
The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

**ED-MEDIA 2000**
World Conference on Educational Multimedia, Hypermedia & Telecommunications

**JUNE 26-JULY 1, 2000 • MONTREAL, CANADA**
**JUNE 25-30, 2001 • TAMPERE, FINLAND**

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications
This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

**WebNet 2000**
World Conference on the WWW and Internet

**OCT. 30-NOV. 4, 2000 • SAN ANTONIO, TX USA**

WebNet - World Conference on the WWW & Internet
This annual conference facilitates the exchange of information in these major topics: Commercial, Business, Professional, and Community Applications; Education Applications; Electronic Publishing and Digital Libraries; Ergonomic, Interface, and Cognitive Issues; General Web Tools and Facilities; Medical Applications of the Web; Personal Applications and Environments; Societal Issues, including Legal, Standards, and International Issues; and Web Technical Facilities.

**INTERNATIONAL CONFERENCE ON M/SET 2001**
Mathematics/Science Education & Technology

**MARCH 3-6, 2001 • ORLANDO, FL USA**

M/SET - International Conference on Mathematics/Science Education & Technology
The conference focuses upon information technology in mathematics, science and computer science education across all levels and settings, including elementary, secondary, college, and teacher education. Learn about the current research, development, classroom applications, issues, theory, and trends.

**SITE 2001**
Society for Information Technology and Teacher Education International Conference

**MARCH 6-10, 2001 • ORLANDO, FL USA**

SITE - Society for Information Technology and Teacher Education International Conference
This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

**Co-Sponsored Conferences**

ICCE/ICCAI—International Conference on Computers in Education/International Conference on Computer-Assisted Instruction

ICCE/ICCAI is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

Preface to the Millennium Edition!

Now that we have had our celebrations about the coming of a new century and a new millennium, purists are pointing out that we are not really in the first year of the new millennium but in the last year of the old one! "What?", you say. I vacationed in Turkey this Christmas (thanks to Dee Anna Willis being willing to shoulder most of the load for getting the section leaders' comments in and organized) and the English language paper in Turkey ran an article about the way the monk who organized the calendar we use today started it. Instead of making the first year, 0, he made it year 1. Thus, the year 2000 is actually not the two thousandth year, it is the 1999th year. So, if we want to do the whole thing over again next year, we can.

What about the Annual? Is this the 9th or the 10th year of the Annual? That too is a bit complicated. The first conference was held in 1990 which means this is the 11th conference. (We did not think far enough ahead to hold the first conference in 1991 instead of 1990 so it would be easy to keep up with.) Everything being equal this should be the 11th Annual, right? Well, not quite. The papers presented at the first conference were not published in an Annual. Instead, they were Issues 1, 2, and 3 of the 1990 volume of the journal, Computers in the Schools. So, when it comes to Annuals, the year and the number of the Annual is consistent. This is the tenth Annual.

Ten years! For the Annual. And eleven for the conference! Not long in the grand scheme of things but a long time when it comes to conferences. I would estimate that there are 80% more "First Annual" conferences than "Second Annual." And, if we extrapolate a bit my guess is that less than 5% of the academic conferences are around for an eleventh incarnation. SITE is a survivor for several reasons. One is that it does a good job of meeting a need. There is a growing community of scholars and professionals who have a strong interest in technology and teacher education. SITE is THE conference if that is your interest. A country singer whose name eludes me had a popular song a few years ago that had the lyric, "I was country before country was in." SITE was here, with a focus on teacher education before that was an "in thing."

Today, technology and teacher education is an in thing. The U.S. Department of Education's $75 million dollar grant program on preparing teachers to use technology has raised the interest level and attention of teacher education, as have a number of other activities such as the AACTE report on technology in teacher education. Technology was not always in the limelight of teacher education, however. In introducing the special issue of Educational Technology Research and Development on technology and teacher education, Bob Hannafin (1999) commented that in the past teacher education and instructional technology "lived quite happily in separate worlds, neither really knowing - or caring to know - what the other was doing" (p. 27). Hannafin edited the special issue of ETR&D on technology and teacher education because he felt this was an emerging field that deserved the attention of the IT community. I am happy to say that of the seven authors involved in writing articles for that special issue, all except one are regular participants in SITE. Two have been or are presidents of the organization and several others have won awards for their papers at SITE.

The USDOE grants program, the work of NCATE, ISTE, and AACTE; and special issues of journals like ETR&D, are all indicators of the changing landscape of technology and teacher education. SITE and its membership has many opportunities to form collaborative relationships with other organizations. The time is right for that, thus the theme of the conference, Bridges Among Professional Associations. I hope you have a productive and enjoyable conference and that you become an active and energetic part of the process of building bridges in this time of high interest and attractive possibilities.

The balancing act of integrating technology, delivering the content, and meeting content standards in language arts and literacy classes is the unifying theme of these papers. This balancing act may require redesigning a course or an entire curriculum. Professors, classroom teachers, and students often lack the necessary technology skills, the time, and the support system to learn to use technology. These papers chronicle the challenges faced and overcome, as well as the challenges that remain. The work and effort required to integrate technology, content, and standards are well worth the effort as these papers show. Progress is being made as professors, teachers, and students work together to infuse technology into the curriculum.

Mary Ann Kolloff at Eastern Kentucky University describes her experiences as she integrated technology into an adolescent literature course for preservice and inservice teachers. She speaks of balancing needed technology skills and delivering course content. Her work highlights how important it is for professors to model technology integration for their students.

Sometimes the integration of technology requires the redesign of the course as Judith Crowe discovered. Materials for her graduate level reading methods course at California Lutheran University were redesigned and placed online. She recounts the challenges and successes encountered in this project. To assist students as they made the transition from text to electronic format for class materials, the final hour of the class sessions were spent in the computer lab where the students worked with partners to access the materials. Two measures of the success of the project are that students reported an increase in their personal technology skills and that they planned to continue to access the course site in the future.

Carla Piper at Chapman University and Susan Eskridge at the University of the Pacific had students create electronic portfolios to assess their performance and achievement of course objectives in a reading methods class. Challenges in this project included the students' lack of technology skills and lack of time to learn to use technology, a concern voiced by others working with preservice teachers. Students reported positive feelings toward the self-assessment and self-reflection required in the project and many expressed pleasure in learning to use technology to creatively express themselves in a multimedia format. George Canney and John Davis at the University of Idaho also used technology to assess students' learning. They developed a computerized test to determine preservice teachers' knowledge of phonics. Their computerized test was found to be a valid, cost-effective alternative to the paper and pencil version of the test.

Graduate students at Griffith University in Australia wrote research grants as part of a class title "Research Issues in Technology and Language Learning." The grant writing was a simulation that required the students to learn about current research and issues in their field. Cristina Matas felt that this simulation provided her students a context for authentic learning in addition to giving them the means to pursue research in their field.

Reading methods students in Kimberly Kimbell-Lopez's class at Louisiana Tech University had first hand opportunities to teach with technology. The preservice teachers and elementary students read and discussed several books on World War II. Then, they helped the elementary students use Inspiration, a concept mapping software program, to extend and organize the elementary students' understanding of World War II.

Carla Piper at Chapman University and Susan Eskridge at the University of the Pacific had students create electronic portfolios to assess their performance and achievement of course objectives in a reading methods class. Challenges in this project included the students' lack of technology skills and lack of time to learn to use technology, a concern voiced by others working with preservice teachers. Students reported positive feelings toward the self-assessment and self-reflection required in the project and many expressed pleasure in learning to use technology to creatively express themselves in a multimedia format. George Canney and John Davis at the University of Idaho also used technology to assess students' learning. They developed a computerized test to determine preservice teachers' knowledge of phonics. Their computerized test was found to be a valid, cost-effective alternative to the paper and pencil version of the test.

Graduate students at Griffith University in Australia wrote research grants as part of a class title "Research Issues in Technology and Language Learning." The grant writing was a simulation that required the students to learn about current research and issues in their field. Cristina Matas felt that this simulation provided her students a context for authentic learning in addition to giving them the means to pursue research in their field.

Nedra Crow and Joan Sebastian, co-directors of the Distance Education ESL Endorsement Program, responded to the growing need for English as a Second Language (ESL) teachers in local school districts. University and public school collaboration lead to an ESL endorsement program for teachers offered via distance education by the University of Utah. Distance education was deemed to be a cost-effective way to deliver a high quality program to a large number of educators. In their paper the researchers shared the challenges they faced and overcame as new technologies were implemented and teachers became familiar with learning via distance education.

Higher education faculty faced with developing technology workshops for their peers will want to read Lorraine Williams' article detailing her experiences at Saint Michael's College. A needs assessment questionnaire, formative, and summative evaluations, in addition to
discussions with faculty members enabled her to make changes in the workshops in order to meet the needs of individual professors. Some professors indicated a preference for one-on-one instruction, something deemed necessary but not often available to faculty as they learn to use technology in their teaching. Lorraine Williams presented technology workshops for language professors, as did Jessamine Cooke-Plagwitz at the University of South Carolina. A non-threatening, supportive environment is deemed essential if faculty members are to incorporate technology into their teaching.

Jackie Jing-Fong Hsu, Yin Mei Wong, and Der-Thanq Chen of Singapore discuss how technology was used to enhance learning in a Mandarin language classroom. Using rote memorization to teach the Mandarin language results in students who cannot use the language in life-based situations. To encourage students to think divergently and apply their knowledge of Mandarin, a technology enhanced Directed Reading Thinking Activity (DRTA) was incorporated into the classroom. At Carey Academy Fabienne Gérard and Mark Newmark examined the Web's impact on learning in a history and in a foreign language class. They found that in the history classes there was more learning on the Web and in the foreign language classes there was more learning through the Web.

Internet resources are changing teaching and learning in classrooms as teachers and students incorporate the Web into the reading/language arts curriculum. Meyer, Steuck, Miller, Kretschmer, and Miller discuss the use of an intelligent tutor, I-Maestrol, to deliver instruction in the writing process via the Internet. This interactive system provides individualized instruction to students as they prewrite, draft, and edit their writing. Rose Yesu and Jennifer Rudolph at Massasoit Community College have successfully combined electronic resources including the Internet with critical thinking activities to enhance the reading and writing skills of students enrolled in developmental classes. Their collaborative efforts include a variety of activities that can be adapted to meet the needs of students in other reading and writing classes. Baines uses a variety of media to involve students in 3-D writing to enhance the quality of their work. Text, images, and sounds are used as students create multimedia presentations to share with their classmates. Jean Casey examines the impact of technology in early literacy learning in a project involving six school districts in Southern California. Technology equipped classrooms, technology literate teachers, and a risk free environment enhance the early literacy learning of students in these six school districts.
THE INFUSION OF TECHNOLOGY into a TEACHER EDUCATION COURSE: ISSUES and STRATEGIES

Mary Ann Kolloff
Curriculum and Instruction
Eastern Kentucky University
United States
Mary.Ann.Kolloff@eku.edu

Abstract: There is no argument that today's pre-service and in-service teachers must incorporate instructional technology into their teaching. However, institutions of higher education with teacher training programs debate the best way to train teachers to use technology effectively. The following paper examines the issues and strategies in infusing technology into a language arts curriculum at the middle grade level for in-service and pre-service teachers. The issues are discussed in view of the four areas of focus for the language arts curriculum according to the National Council of Teachers of English. In the language arts example, it is shown that the student must be able to read and write the media in each of the four areas in order to effectively infuse the technology into the content area.

Introduction

A major issue in teacher education is whether to teach the use of technology to pre-service and in-service teachers separate technology courses or within content area courses. The trend for technology to be taught along with the content area is based on the premise that the acquisition of technological knowledge, skills, and attitudes is greatest when presented in the context of a content area. It is thought that this will lead to a better infusion of technology in the teaching of a particular content. In addition, it is believed that this method will lead to a teaching style and learning environment enabled by technology. Given this position, many involved with teacher education are convinced that infusing technology can improve learning, while, at the same time, they fear that because of the amount of time needed to teach the technology, the remaining time available for content will be significantly diminished. In order to embed technology into the content area, teacher education institutions are today challenged with engendering a positive attitude toward the content/technology combination and providing an environment and resources to maintain and enhance the knowledge, skills and ability to carry out the integration task.

It is the intent of this paper to address the issue of infusing technology into a content area by using as an example a course in a language arts curriculum at the middle grade level for in-service and pre-service teachers. The two objectives for the paper are to: (a) discuss the issues surrounding teaching and applying appropriate technology in this situation; and (b) provide strategies for developing teaching styles and learning environments for a technology-rich, content-based course.

The National Council of Teachers of English (NCTE) in its document, Standards for English Language Arts (1996), suggests four areas of focus for the language arts curriculum. These areas include: (a) obtaining and communicating information, (b) literary response and expression, (c) learning and reflection, and (d) problem solving and application. These areas will be used as a basis for identifying and categorizing various technological applications and experiences for pre-service and in-service teachers. Each technological experience can be categorized as reading the media which refers to such activities gathering, analyzing, and evaluating the information, or writing the media which refers to synthesizing information and producing a product.

Course Description

The example in this paper is adolescent literature and related materials, a course designed to help pre-service and in-service teachers extend their knowledge of authors, literature, and related materials for middle grade students, 10-14 years of age. The course emphasizes literary criticism and the relation of the interests and needs of adolescents to literature. The course assignments focus on: (a) searching, locating, reading and responding to fiction and non-fiction books and materials, (b) interacting with adolescents in
literature circles, (c) performing booktalks, readers theatre, and/or storytelling, and (d) researching, writing, and presenting an author/issue paper. In addition, in-service teachers conduct an action-research project centering on adolescents, their nature and needs, and the literature with its related materials.

Obtaining and Communicating Information

Obtaining and communicating information is the first category for focusing the discussion of integrating content and technology. This category is a major concern of the course since the participants are to engage in such activities as identifying and locating appropriate fiction and non-fiction books and materials for adolescents, becoming familiar with the nature and needs of adolescents, and writing and presenting an author/issue paper. Obtaining and communicating information focuses on the goal of conducting research communication, and presenting the research in some form. Given this goal, the concern becomes the selection of technology activities that would be the most appropriate for the content.

Reading the Media

As a pre-service or in-service teacher reads various forms of technology to obtain information, some of the cognitive activities or process skills required include developing, accessing, locating, searching, watching, analyzing, evaluating, and concluding. These cognitive activities or process skills engage learners if they have ownership of the research. The issue is to engage the students in their own information needs or problems so they sustain an interest in the content. It is different from the teacher compiling research topics and students choosing a topic of interest. The underlying method in obtaining information is to engage students in information literacy skills using the Big Six Approach outlined by Eisenberg and Berkowitz (1988).

Various forms of reading the media to acquire information include using various software programs, CD-ROMs, still visuals, video and audio sources, databases, and web sites to access, locate, gather, and evaluate information. Of course, there are issues surrounding the use of each of the technologies, but because of space considerations, only issues associated with web sites and still visuals will be addressed.

Currently, the most popular technology used to access and locate information is the Internet. The major concern with searching for web sites is quality of content. Access by middle grade students to sites associated with sex, pornography, and hate groups is a concern. A solution to this problem is for teachers to develop web quests for students. These web quests are inquiry-based activities developed by the classroom teacher that are directed toward a clear task. Some web sites are designed specifically for students to visit and obtain information. Although this provides an immediate solution to the problem, there are drawbacks. For example, students are left without developing search strategies when real-life problems arise. Also, students may have difficulty deciding what they are interested in researching and in forming problem statements. Given these two situations, a strategy is to provide a balance by collaborating/team teaching with the library media specialist to develop skills in identifying information needs, locating appropriate sources, and forming conclusions.

Still visuals are used in non-fiction or information books to gain information. Visuals are seldom used in fiction books. Maps may appear in the front cover of a fantasy book so the reader has a sense of the area described in the fantasy. It is an unusual book that incorporates visuals to represent the storyline. Using the literary device of juxtaposition, Paul Fleischman in Dateline Troy successfully uses visuals to connect modern day life to the epic of the Trojan War. Leading questions by the students focused on the manner juxtaposition was used to present the story of the Trojan War. Students were asked whether by having the story presented in this style (modern headlines), if their original comprehension of the story had been enhanced. A typical student response suggested that by having the story presented in that manner, they found the story easier to interpret. Many, not being big history fans, were not looking forward to reading the book. However, after getting started they found that the modern clips helped to keep their attention throughout the story. They felt that modern clippings would make it easier for young readers to remember details because it is related to something that is happening in the present.

Writing the media
The most common form of writing the media is to use word-processing to compose a traditional paper. The challenge is to include other forms of media such as an acceptable means of producing a research paper. On the other hand, the writing process changes as various other media such as flyers, videos, presentation software, or web pages are used to present and communicate the information.

Although various media are read, the challenge comes when students are ready to write the paper in a different medium. For instance, pre-service and in-service students were required to prepare a web page for their author study. In addition, their web pages were to include original visuals to illustrate abstract concepts in the fiction book they read. Students were first introduced to image processing software so they could manipulate photographs or create illustrations. The students found the task difficult for three reasons. First, fleeting images of text are seldom transformed into mental images for the text. Second, students reported seeing words as their mental images. Finally, this was their first introduction to image processing software and web page authoring programs. The students were given guidelines as to the criteria needed in the author study web page. However, the learning of the technology took over the significance of the content since this was their first introduction to the software. Considering that each software program has a steep learning curve, frustration occurred among the students. After the assignment was completed, students reported a satisfaction with their learning and products and increased use of visuals in courses outside of this class.

Literary Response and Expression

Literary response and expression relates to discussing books and accessing materials that are read or viewed. In this particular course, literature circles are the prime means of discussing the books and materials. The discussion of books and materials are categorized into three areas: (a) personal response, (b) topics, and (c) interpretative responses. Pre-service and in-service teachers discuss books and materials among peers in class and with adolescents. Also, the teachers perform booktalks, readers’ theatre, and/or storytelling to provide a literary expression of fiction books.

Reading the Media

Accessing databases on the Internet allows students to read postings of responses to various books. Visiting popular sites such as Amazon.com or Barnes & noble.com allows students to read reviews from sources such as Kirkus Review, Booklist, etc. Often, these reviews offer diversity in the literary criticism of the book. Interviews with various authors and reviews are also accessed through these popular web sites. A web site may include frequently asked questions about an author. Some authors have their own web sites where students may gather information. The pre-service and in-service teachers are required to use these sites for their author/issue paper. This information can provide evidence and support for students’ personal

Writing the media

As students engage in the discussion of books read, materials viewed, or web sites visited, discussion takes place in a text-based environment. Students discuss the books and materials among class members and with middle grade students. Response journals are written on a personal, topical, and interpretative level. Initially, students’ wordprocess papers on a weekly basis as they respond to various books and materials. A listerv is used to structure the class discussion for class members and middle grade students. Presently, web-based discussion forums are used for the conversations about books. The goal for using a listerv or a web-based environment is to provide the basis for creating a learning community of pre-service and in-service teachers, and middle grade students. This community supports a commitment to learning and recognizes that its most important asset is the diversity of the people who form the community.

In spite of the technological environment in which the response to the book and materials are prepared, students’ personal and topical responses are generally well written. As pre-service and in-service teachers engage in conversations with middle grade students, the interests of the middle grade students become the focal point of the interchanges. In addition, the middle grade students identify books they are
reading in their language arts classes. The difficult task comes when students form interpretative responses; that is, a critical analysis of the text or material. Providing evidence and supporting material for their statements become more difficult. Moving students from personally responding and finding topics of interest to conducting research and to critically analyze books, materials, and web sites is the major issue. This issue relates to engaging pre-service and in-service teachers in critical thinking skills and to the age-old question of how to teach students to be critical thinkers. Students need to further analyze responses for biases and habits, and to search for critical questions in the personal and topical responses. A strategy to provide students with such an activity is to have the students analyze data in discussion forums and to summarize the information based on biases, opinions and critical questions. Students must revisit the text, materials, and web sites to provided evidence to support statements.

Learning and Reflection

Learning content and technology skills are tightly woven together. At times, acquiring the technology abilities and skills diminishes the focus on the content, leaving the content to emerge in a technology-rich environment. Reading the media and writing the media are closely related as students in this class interact with the content and technology activities.

Reading the Media

Throughout the assignments in the class, pre-service and in-service students are required to engage in conversations that focus on effective ways to teach students to read the media; that is, comprehension of the visual images and verbal information. Activities for reading the media are focused on reading picture books appropriate for middle grade students, developing Web Quests to investigate sensitive and critical issues relating to the nature and needs of adolescents, and evaluating information in all media formats. To teach students to critique what they see and hear in ways that help them make informed decisions is a constant effort. These decisions focus on problem situations as they relate to an integrated curriculum.

Writing the Media

Word processors and web pages allow students to create and communicate information. Use of listservs, web-based learning environments and image-processors support the access and communication of information. Each technology offers opportunities for educators to create learning environments for middle grade students.

For pre-service and in-service teachers to reflect upon their learning of content and technology skills in this course, students are required to write professional goals relating to the content and their technology skills and abilities. The goal is for the students to create a vision as how to teach content using appropriate technology. Professional development goals are generally related to the here and now of using technology in the content areas rather than building a vision for the future. Often the debate of using the technology relates to the dilemma of technology vs. content. Pre-service and in-service teachers often state that the time to learn the technology is overwhelming when content is the main focus of their concern. In-service teachers often state that they feel unprepared to teach with technology. On the other hand, they also believe that technology is an important part of the workforce and teaching with technology is a necessity. Yet, finding the time to acquire the necessary technological skills themselves and then teaching the technological skills to the students becomes almost a difficult task. Their center of focus is on the content, its concepts and principles. Frustration mounts when attempting to use technology since they believe they run out of time to cover the necessary lessons and skills that will prepare students for testing and portfolios. Those teachers who report teaching with technology are, generally, pressured by principals. Some examples reported by in-service teachers include having to incorporate technology once a week in their lesson plans, or their teaching evaluation occurring in a two-way interactive environment.

The major issue of teaching with technology is time. Time to learn about the various means of incorporating appropriate technology activities into content. Time and technology present new problems for teachers as they solve conventional problems of teaching and learning. It is easier to design, organize, and deliver content in the traditional way than to form real-life, problem-solving environments where
technology is used to formulate solutions. Change from teaching in a traditional manner, disseminating information, and preparing drill and practice activities challenges the teachers. A strategy for teachers is to choose one particular technology they would like to concentrate on and use the technology with students. This one-step-at-a-time approach is more likely to enhance the confidence of the teacher than trying to master it all at one time.

Problem Solving and Application

The basic problem for the pre-service and in-service teachers is developing a strategy for finding appropriate titles of books, materials, and web sites for middle grade students to use in the language arts curriculum and in other content areas as integrated units are designed. Often, students in the class feel prepared to design lessons for books used as common reads and materials or web sites discussed in class. However, developing a strategy for finding appropriate books, materials, and web sites is an issue and challenge itself since there are many authors and titles appropriate for middle grade students. This situation can be classified as a curriculum-related problem.

Other problem solving activities for the pre-service and in-service teachers are related to societal and global problems. Violence in schools is a current problem that is highly visible. Students in this class find quick solutions to this particular problem. An approach to protect middle grade students may be not allowing them to read books considered violent such as *The Wringer* by Jerry Spinelli. The media reported *No Tolerance Rule* of the Decatur, Illinois school violence incident may appear as another quick cure for a more prominent problem. Responses such as these lead students to investigate such issues as the role of the media in prompting violence, or how our judgments about the news, its content and placement, direct our thinking about sensitive issues.

Reading the Media

*Reading* the media in both problem situations involves browsing and searching the Internet, newspapers, and print materials to gather, analyze, and evaluate information. A medium often overlooked in gathering information is that of databases. The Internet is considered a huge database along with libraries' on-line catalogs. Furthermore, accessing government online databases allows middle grade students to sample information sources and to choose appropriate information that serves their purposes of determining the factors associated with the prevalence of violence in schools, for example. Students sample data, analyze, predict, discuss, and provide evidence for their conclusions. In reading the media, students develop and refine their information retrieval skills.

Writing the Media

Students may construct and communicate useful insights and implications that result from using information in traditional research papers or by giving presentations using presentation software. Furthermore, *writing* the media can be accomplished by students formulating their own databases to collect information concerning violence in their schools or communities. Local community resource individuals may be contacted and interviewed. The interview may be video taped by students after gaining appropriate permissions. Creating databases and interviewing local community resource individuals give students an opportunity to practice their research skills and abilities to identify information needs as they relate to the stated problem. Skills practiced include critical thinking skills such as identifying criteria, prioritizing, finding and recognizing errors in information and thinking, and testing the accuracy of the evidence collected.

Conclusions

The instructional activities using technology to teach content in this particular course are only snippets of activities to present the content. Infusion of technology into the curriculum assumes that technology is an integral part of the curriculum for *reading* and *writing* the media. Generally, teachers want to match national and state content standards with the technology activities. Enhancing lesson plans
and activities for reading the media is a much easier task for pre-service and in-service teachers. The use of word processing, drill and practice software, and e-mail are regular activities for the pre-service and in-service teachers. On the other hand, writing the media is a totally different process. In spite of teachers, using media everyday, writing in different media formats requires new and different writing skills and attention to specific conventions for each medium. Using presentation software requires students to change their writing format. No longer are sentences or paragraphs written out completely, but phrases and ideas are outlined using bullets. Interviewing a community resource person for a video tape requires planning interview questions and deciding upon appropriate camera shots. These skills are acquired only through first reading and analyzing the medium followed by producing a product such as a computer presentation, video production or a web page. It is learning the writing that becomes the issue for teachers since it is viewed as a time-consuming process. Those responsible for preparing pre-service and in-service teachers need to guide the students in setting priorities for learning to read and write for the various media and putting them to use in the classroom. Each technology provides a rich environment for learning the content and for experiences for middle grade students. The most significant change in teaching with technology will come from the choices pre-service and in-service teachers make when designing and implementing lesson plans and activities that allow middle grade students to interact with content and the technology tools.

When designing a course for pre-service and in-service teachers, one has to be conscious of what might be termed technology fatigue syndrome. The sense of exhaustion may be a result of constantly learning the how-to of a particular application and embedding it in a technology-rich environment. There may be a loss of motivation to learn the skills and abilities because of the pressure to infuse technology while at the same time fearing the loss of content as the technology skills are acquired.

Offering experiences to gain knowledge of skills and abilities in technology in one course is not enough. The knowledge, skills and abilities and concepts of the technology must be addressed in several courses, over time, and required of learners to demonstrate the use of technology skills in their performances.

Project READ: Developing Online Course Materials for a Reading Methods Class

Judith A. Crowe
School of Education
California Lutheran University
United States
crowe@clunet.edu

Abstract: This paper is a report on a study of a project conducted on a graduate level reading methods course. Course materials were redesigned and presented in electronic format. The purpose of the redesign was to increase student learning of course content through hands-on participation, electronic communication and discussion, and extension of resources related to teaching reading. Findings indicate that students increased time spent on using course materials and increased comfort with technology in a number of cases. The expectation that students would increase discussion through electronic communication was not achieved. It was noted that students plan to continue to make use of the materials in future teaching. Educators need to nurture and guide students in using technology and to model and provide time for hands-on practice.

Introduction

The use of technology, and especially the use of telecommunications tools, is changing the process of education. As college and K-12 classrooms begin to employ the latest technologies, both academic performance and student-teacher relationships can be extended and enhanced. California Lutheran University (CLU) is committed to integration of technology throughout the undergraduate and graduate programs. This commitment is extended into the Teacher Preparation program in a number of ways. All course syllabi are available on the World Wide Web through Eres, an electronic reserve system. All faculty have created a profile home page. Several professors use electronic discussion groups as a tool to enrich and expand the educational experience of the students beyond the classroom. Others are exploring the use of electronic portfolios with students. In spring 1999 an opportunity was provided through the Charles J. Culpeper Foundation-sponsored faculty development grants to further implement technology into an existing course design. The purpose of this proposal was to enhance student learning through the use of technology. The grant allowed the faculty member, together with a supporting team, to redesign course materials. The team was composed of the professor as content expert, a member of CLU’s Information Systems Service, an instructional technology expert, and a student intern. This project proposed to convert all course materials into web page format. The course, Methods of Teaching Reading and Language Arts in Diverse Elementary Classrooms, is a required part of the methods block for elementary student teachers. This course redesign provided opportunities for students to experience a model of instruction that spoke to the vision of incorporating technological tools into effective teaching practices. The inclusion of interactive technology provided an opportunity to connect theory to practice by increasing hands-on participation by students. Electronic discussions provided students with opportunities to respect and respond to each other in respectful and empowering ways. Certainly the use of information technology in a course such as this provided a vehicle for students and instructor to participate in educational growth and change, as it modeled techniques that the students, as teachers, would one day use themselves.

There were a number of instructional challenges inherent in the course that could be addressed through the use of technology. Students needed to be prepared for the California Reading Instruction Competency Assessment (RICA), which they must pass in order to obtain a teaching credential. There was a large amount of content area knowledge required (phonics, assessment, diagnosis and intervention strategies for teaching reading, systematic, explicit word attack skills instruction, etc.) necessary for students to master in order to fulfill the requirements for this exam. Readings were dense and challenging, and there was never enough time to thoroughly discuss and practice the theories and connect them to practice, according to course feedback from students. Some concepts taught in this course that students seemed to find difficult to understand included content area strategies such as those listed above; lesson planning, Specially Designed Academic Instruction in English (SDAIE) techniques, and
connecting instruction to the California reading standards. Student feedback from previous semesters indicated that they felt the need for more discussion of content. Successful pedagogies already implemented in the class included modeling teaching strategies, providing handouts that directly related to teaching reading, taking time for hands-on experience with the strategies, and providing opportunities for students to share strategies across grade levels with each other. Course evaluations, coupled with informal, formative feedback garnered from the students during the semester indicated that these techniques were noted and appreciated as being effective. The challenge, then, was to redesign the course so that the use of technology would support already successful strategies while addressing the instructional challenges.

The Process

Development

The development of the course was begun in summer, 1999 and implementation began in the fall semester. The team was to provide design support through converting existing documents into html format, scanning documents, sound clips, and video clips into the pages, creating a CD-ROM, and researching useful links for the course content. In addition, the team would continue to provide support during the implementation semester by providing a smart classroom to support lecture, discussion, and hands-on work during class time as well as campus lab facilities for students to use as needed for electronic discussion and review of materials. This course had a history of implementing technology. A web page version of the syllabus was provided, along with selected readings, PowerPoint slides of lecture topics and lesson plans and links to Internet resources. Students had in the past communicated through email. The redesign made all lectures and discussion topics available in web page presentation format, increasing the interaction between student and text. This included interactive forms for students to practice hands-on strategies, pre-test themselves on concepts, and develop lesson plans connecting theory to practice. Rubrics developed by the instructor were also available electronically.

The team met for weekly planning and update sessions during the summer. The professor's files were ftp'd to the student intern, who used multimedia authoring programs to create a splash page and consistent topic pages. Topics were presented in the form of web page "chapters," the topics including the syllabus, weekly lessons, study guide access, and student work. Each weekly lesson topic, available in web format, included a sample lesson plan, strategies for teaching language arts, and links to the literature topic of the week. The ISS team member greatly expanded the number of topical links available by researching web sites for appropriate material. The professor then reviewed the sites and passed the links to the student intern, who posted the links to the web page. The educational technologist provided hardware and software support to the student intern and began a process of converting videotapes of teaching episodes for CD-ROM or videoclip development. The last project was put on hold due to hardware limitations and has not been implemented to date. In reflecting on the effectiveness of the developmental process, a number of points were noted. First, it was critical that the team met weekly to discuss progress and revise timelines for next steps. Hardware and software constraints such as late delivery and incompatibility were addressed and understood by all members of the team. This helped to deal with frustrations that arose because parts of the project could not be implemented at this time. Secondly, it became apparent that student interns bring a great deal of multimedia expertise and enthusiasm to the project and that they are yet students and cannot be expected to perform at a level of professional development that they have not matured into. Demands from other classes, jobs, and life challenges impeded student intern performance on this project as well as some others. The level of commitment and performance from the ISS team member, on the other hand, was well matched to the role as conceived, and that part of the project was implemented effectively and in a timely manner. Finally, it became apparent during the implementation semester that team members were unable to provide the projected support because they were immersed in new grant projects.

Implementation

The project was implemented during the fall semester. Internet connectivity was available in the designated classroom, and the last hour of class time was reserved for the instructor and students to use the computer lab. There were 21 students in the class, and 12 computers, so pairing was the preferred method of computer use. At the first class meeting, students were taught to log on, access their university account, and use email and a browser. Students were able to view the electronic syllabus, and were pointed to links to online readings required for the next class. It was apparent at the first meeting that a wide variety of expertise and comfort with technology existed among the
students in the class. As the semester progressed, some students became more comfortable, while others continued to show resistance to this form of communication.

Examples and Use of Materials

For the purposes of this paper, a lesson topic example was selected for discussion. The following figure shows the format of the day's activities as presented online. The lesson included a PowerPoint presentation, links to other online sites for the topic which included lesson plans and classroom activities as well as research into the genre, and a sample lesson plan which would be analyzed for content and method, or practiced and used in the field.

Lesson Topic Example

Fig. 1: Opening page for a week's lesson presented in book page format, with agenda items, links to lesson and online resources, and formal lesson plan.

In class, this page would be presented and discussed, then the PowerPoint lesson was implemented. It included opportunities for lecture, discussion, small group work and hands-on activities. For example, in this lesson a Venn diagram was used to compare and contrast the traditional and the alternative versions of the story, then students worked in small groups to read a folktale, select an alternative character, and create a Venn showing similarities and differences in point of view. A follow-up activity was to write the tale from the alternative point of view. Students could later access the PowerPoint lesson from any computer with PowerPoint Viewer and download, print, or add notes pages to the presentation. This possibility moved the use of the software from strictly a lecture aid to a process for interactive learning.
After completing the lesson and activities in the regular classroom, students moved to the computer lab for the next section of the class. There were generally two students per computer, which enhanced sharing and enjoyment of this part of the class activities. Students opened the web page for the lesson and then followed the links to online resources. Since the sites were briefly annotated and categorized, students could select a variety of sites to visit. The instructor could ask them to find a site they would use for their grade level, a lesson plan, a discussion of the genre, and a bibliography or related references. This particular set of links offered lesson plans that integrated other curricular areas gave Cajun and Spanish versions of the story, dramatizations, interactive versions of the story, and an activity for constructing the three houses.

Sample Links
Findings

The course redesign, then, was intended to:

- extend use of the reading content addressed in the textbooks beyond the dimension of class time;
- increase student hands-on participation related to teaching reading strategies;
- increase the number of successful, proven strategies that students shared with each other over the course of the semester;
- add student work samples to the page during the course of the semester, which will allow them to see work "published," receive collaborative feedback from each other; and
- enhance students' teaching portfolios through demonstration of technological competencies.

Students reported that they did use the electronic materials outside of class time. One student wrote, "I did use the electronic course page several times during the duration of the course - quite frequently, as a matter of fact, maybe weekly just to make sure I was still on track." Another stated, "I did use the electronic course pages. At first, I printed out the syllabus and used that in my notebook for the class. Later, as we were assigned things to explore, I ventured through the various links that were provided."

As for increasing student hands-on participation in teaching reading strategies, the researcher expected that this participation would occur within the boundary of class time. That did not happen; it was in fact difficult to include all aspects of the planned work in the time allotted. However, it was found that students used the resources in preparing for their teaching in the field. "I felt that your inclusion of technology in your course was extremely helpful in introducing a teacher to the unimaginable wealth of lesson plans and classroom ideas available through the Internet...." and another replied, "(I) found that some of (the sites) were quite helpful, especially when it came time to write my lesson plans. I found many links to language art sites, as well as math and science." One student reported using it in the classroom, as well: "I have had some of my 5th graders in the morning before school explore your website. They seemed to enjoy some of the sites that linked from Madeline and the three little pigs."

The study did not find that there was an increase in the number of successful, proven strategies that students shared with each other over the course of the semester; in fact, there was less sharing done in class. In past semesters, students had presented at least one strategy each to their peers. One goal of this project was to post all the strategies turned in by students to the 'student work' portion of the web page. This did not occur. It was found that the process of collecting reports in a variety of formats, from email attachments to scannable text documents, and formatting them for inclusion on a web page was too time consuming to be possible. This also impacted the expectation that students would see their work published online and receive peer feedback.

Students did report that they felt their technical competencies had improved through the course of the semester. One stated, "I felt that your inclusion of technology in your course was extremely helpful in introducing a teacher to the unimaginable wealth of lesson plans and classroom ideas available through the Internet, especially someone relatively unfamiliar with how helpful these sources can be (and we did have a few of these people in our class). Well done on your part, I believe." At this point in time it cannot be determined that students' portfolios reflect the technological competencies desired; students have not yet developed their portfolios for the course.

In addition, several students indicated that they planned to continue to use the site in future. Some said they would use the links to RICA study guides, and others planned to continue to use the lesson plans and other links and resources in their future classrooms. Replies such as "(The sites) are useful and the best part about it is that I know they will continue to be of great help to me during my career as an educator," and ", the links are useful and I do plan on using this as a resource when I am a beginning teacher." show that students expect to be able to continue to use the online course materials.

Conclusions and Recommendations
Weekly meetings helped to keep all team members accountable for the work. Even though some parts of the project had to be shelved, all team members were aware of why that happened. In addition, the weekly meetings helped to keep team members accountable for completing their parts of the project. It is recommended that any team project of this type include weekly meetings of all team members. Inclusion of undergraduate multimedia students as part of the team resulted in consistency of presentation and creative design of the presentation. It was noted that an understanding of programming languages would result in a more professional product and enhance the student's future employability. Teams also need to be aware of the difference between adult professionals and undergraduate students as far as accountability is concerned. Part of the education for the student intern could include professional development. The stated expectations for implementation of the online course materials were not consistently achieved. The expected support during the implementation semester was not available. New teams had been created by this time to work on new projects, and personnel were not available for support of implementation. A recommendation could be that funds be set aside to provide some assistance during the semester. In his case, having help to re-format and post the student work could have resulted in students' being able to share strategies during the semester. However, in considering the responses that indicate students plan to continue using the resources, perhaps it is not too late to post their lessons and strategies. Finally, it is recommended that educators planning a similar use of technology in their classes create an instrument to measure how well objectives have been met. The feedback from students in this case was informal, but did show that, although some expectations were not met, others were partially met and still others may be met in future.
Abstract: Preservice Teachers taking a Reading Methods course as part of their elementary program requirements were introduced to a graphic presentation program called Inspiration. The students were shown how to utilize this program as a way of responding to books. This enabled the Preservice Teachers to be exposed to a range of possibilities in how they can use these same strategies and techniques with elementary students to show them how to organize information encountered as part of classroom reading instruction. Through this visual representation of ideas, the Preservice Teachers and elementary students were able to extend and clarify their understandings.

Introduction

The impact of technology on our language use opens up even more diverse ways that language can be showcased and displayed even as it continues to change. Through our students' construction, manipulation, and explorations with language, they illustrate how language exists in interactions with others, how language is a system of multiple signs, and how the meanings of language emerge from the social relationships within which they occur (IRA/NCTE, 1994). As a result, children within a learning community use their social relationships, their personal histories, and their collective memory in order to make sense of the language around them. Using new communication and information technologies, teachers and students are discovering more ways to communicate with others, to make things, to learn about the world, and to express themselves (Bruce, 1998/1999, p. 307). There are multiple opportunities for students to experiment with a myriad of ways to share information as they enhance their understanding of a particular topic. Bruce (1998/1999) states that the range of possibilities by which students learn (i.e. communication, inquiry, construction, and expression) are expanded as a result of these new tools.

Role of Social Constructivism

When exploring the influence technology has for students in our classrooms today, it is helpful to look at social constructivism. As a theory of cognitive development, social constructivism shifts us away from thinking about individuals who construct their own meanings through interaction within their environment to a view of a collectively constructed meaning (Carroll, 1999). Three principal assumptions of Vygotsky's sociohistorical learning theory include: a) the individual’s making of meaning is influenced by the role of the community, b) tools are important in cognitive development, and c) the zone of proximal development (Willis, Stephens, and Matthew, 1996). In a Vygotskian classroom, the collaborative element in the learning process is promoted as students share background knowledge in order to construct knowledge. The use of tools in cognitive development is expanded when technology is available. There are many forms of electronic tools available by which students can construct and communicate knowledge. The use of text, sound, and images found within many programs takes literacy beyond the boundaries of simple pen and paper.

Carroll (1999) discusses two roles of classroom technology in relationship to the social-constructivist perspective. The first role relates to how opportunities can be provided to students so that they can take advantage of multiple symbolic perspectives through participation in the meaning construction process. As students learn to use language as part of their literacy development, they are making use of multiple sign systems as a means of making sense of the world (Carroll, 1990). The second role of classroom technology is for children to have
opportunities to reflect on language. In the social context of the classroom, they learn how to use different sign systems, how these sign systems can take different forms and meanings, and how technology can be used to support the use of multiple symbolic perspectives in writing.

**Semiotic Mediation**

A central tenet of Vygotsky's theory is the concept of mediation by psychological tools or signs (Wertsch, 1990). While engaging in activities with adults and more competent peers, children learn to use signs (e.g. language, numbers) to mediate or, in other words, to shape and define their thinking (Ashton, 1996). The semiotic mediation that occurs is evident as technology facilitates students’ use of multiple sign systems to foster communication and thinking. Bruce (1997) posits a transactional stance when considering technology in relation to literacy practices.

In the case of literacy technologies, a transactional account tells us that technologies do not transform or determine literacies, nor could they ever be irrelevant to literacy practices. Instead, they are part of the continual reconstruction of literacies. As such, they too are constructed out of the evolving literacy practices. (Bruce, 1997, p. 303)

Through her exploration of the transactional stance, Bruce (1997) states that technology within a literacy setting participates in a transaction with other technologies, text, artifacts, physical spaces, and procedures present (Bruce, 1997). She also states that we cannot begin to understand the role of technology in literacy if we set it apart as “only a tool”; instead the picture is more one of multiple literacies, each employing a wide range of technologies that overlap with those of other literacies.

**Semiotics and Critical Thinking**

Through their work on semiotics (i.e. how signs work), Siegel and Carey (1989) propose the notion that thinking critically is a matter of reading signs. Our understanding of critical thinking is a construction of signs, which enables us to think critically about critical thinking itself (Harste, 1989). The role of language in critical thinking is that language allows individuals to name their world, it provides the signs that make thinking public, and it allows language users to distance themselves from their knowing; ideas can be set aside, looked at, thought about, and evaluated (Harste, 1989). Gestures, pictures, monuments, visual images, finger movements, anything deliberately and artificially employed as a sign is, logically, language (Dewey, 1933). Siegel and Carey (1989) refer back to Dewey's description of reflection as involving the movement forward to possible conclusions as well as the more traditional movement back to uncover the grounds or bases for some form of knowledge. The signifying function makes it possible for the simultaneous movement back and forth.

**Ways of Reading Texts**

In literacy development, reading and writing visual texts is an important skill for our students to learn (Moline, 1995). It is possible for information to come in pictures and in words, which is most apparent when considering types of texts that are encountered as students read across content areas. In science, math, and social studies alone, visual texts that combine images with words can range from diagrams to maps to charts to graphs to tables and to time lines.

Moline (1995, p. 7) states that how we read depends on our purpose for reading: a) We can read it front to back leaving nothing out, b) we can browse through the pictures, c) we can search selectively for facts, or d) we can scan, sample, skip, and skim. When we read for the story we start at the front of the book and read to the end of the story, since we want to read the whole text. It is possible to put the book down and return to reading it at a later time. In contrast to this is how we read selectively to locate specific information. A certain part of the text may be chosen, and it is possible to start at the front, the back, or in the middle, since it is dependent on where the information being sought might be located.

In some cases, we may read the same book at a later time for an entirely different purpose as we search for a particular piece of information. The benefits of showing our students how to utilize selected reading such as this
is that they can be shown how to skim and scan as they seek certain information contained in the text. Students can find a way of recomposing as they read the information in one format and attempt to write their own account of the information in a different format (Moline, 1995). When they do this, students learn to show relationships between information through the use of various sign systems (i.e. written, graphic, pictorial, numerical). Sometimes the sign systems utilized are conventional (picture of a chair) and other times they may be invented (semi-circle to depict the chair) as students seek the best way to represent important relationships.

**Representing Information**

In this section, the various support structures provided by a graphic presentation program, *Inspiration*, are used to illustrate how elementary students represented information about World War II. Four groups of 5-6 elementary students were each assigned a Preservice Teacher enrolled in a university reading methods class. Over the course of five weeks, the groups met weekly with the Preservice Teacher to discuss the novel that they were reading. As part of this process, the students would also complete other response activities (e.g. journal entries, character analyses, prediction charts) under the direction of the university student.

The different ways of reading discussed by Moline are reflected in this section in a cross-textual format. These students were reading various narrative and informational books related to World War II as they participated in an in-depth exploration of this topic. Initially, the elementary students read the novels in a front to back format and met weekly with the Preservice Teacher to talk about what they had read since their last meeting. As a culminating activity to the reading of the book, the elementary students were asked to use a template (Figure 1) found within the *Inspiration* software to consider the following questions: a) what immediately precipitated the event, b) causes leading toward the event, and c) factors fighting against the event. During this process cross-textual connections were made as the students returned to the various books (e.g. narrative and informational) they had been reading to seek out and verify particular information they wanted to include in the diagram.

![Figure 1: The History Web 2 template used by students to discuss World War II.](image)

Moline (1995) identifies certain elements of graphic design that should be considered when organizing information. Some of these elements include such features as highlighting, connecting, grouping, organizing and separating. The use of a graphic presentation program such as *Inspiration* serves as a model for students as it guides them into an awareness of design principles helpful in establishing relationships across related information. The following subsections illustrate how this program helped to scaffold students' organization of information through the various support structures found with the software. An important element to this process was the collaboration as the students and their preservice teacher worked and talked together about what information to include in the diagram. Students also actively sought available resources as they looked back for information in their novels as well as in the various informational books that were provided by their regular classroom teacher.

**Highlighting**

The use of color or shading is easily available to students through choices related to overall background, frame background, frame outline, text color, or through the use of bold, italics, or underlining. Another form of highlighting that the students found available was the embedding of a symbol within the frame itself. Students could select one already available in the graphic library or they could create their own. The following frame was used by one group to complement the text they had typed (Figure 2).
Organizing and Separating

In the template used by students in this activity, each of the main headings was divided into three subheadings, which helped to support students as they selected information for each of these areas (Figure 3). In addition, students could easily move frames by clicking and dragging or to enlarge frames to accommodate text.

Grouping

Some groups also selected particular graphics as a way of extending thoughts within the different categories. The placement of each graphic would be grouped alongside the text frame that it best represented. The following example illustrates how one of the groups decided that a cause leading toward World War II was the bombing of Pearl Harbor by Japanese forces. As part of this information, the group went on a search through an available clip art CD-ROM so that they could include a flag of Japan (Figure 4).

Connecting

Basic templates are also available that have a preset structure with connecting arrows. In the previous examples, Figures 3 and 4 illustrate how arrows can link ideas within a major category. Another support feature relates to arrows automatically linking concepts through the use of RapidFire. When selected, this feature enables the writer to input ideas, hit the Enter key, and the information will automatically be connected to the main category heading in the diagram. To continue the writer simply has to type in a new idea, hit the Return key again, and the next idea will also be displayed.
Symbols

In addition to the design elements discussed by Moline, the students also utilized various symbols as a way to enhance or extend their thoughts. In Figure 5, the group selected a conventional symbol to represent the Star of David associated with the Jewish religion. This symbol also represented the main heading for their diagram.

Figure 5. Students’ use of a symbol to enhance information in text frames.

A second group became intrigued with the use of flags to represent the different countries discussed in relation to the three subheadings. Overall, this group included flags to represent France, Great Britain, Germany, Italy, and Japan. One example of this group’s work was shown in Figure 4. This same group also used multiple symbols to represent the topic of the Great Depression (Figure 6). To do so, the students selected a frowning face embedded in the text frame along with the graphic plate with a fork and knife on it. This group’s example represents the use of conventional symbols to depict the feelings and experiences related to this era in American history. The same symbols standing alone might have entirely different meanings, but when grouped together with particular text a new level of meaning can be construed.

Figure 6. Use of multiple symbols to represent key ideas found within text frames.

Conclusions

As students sought to represent information, there was evidence of multiple overlapping literacies that assisted in providing essential support structures:

1. The elementary students and Preservice Teachers illustrate how technology is a literacy in itself as they worked to communicate their ideas with others in order to organize relationships between selected information. Bruce (1998/1999) has stated that the range of possibilities by which students learn (i.e. communication, inquiry, construction, and expression) are expanded as a result of these new tools.

2. The students and preservice teachers learned how to use different sign systems, they experimented with how these sign systems could take different forms and meanings, and they illustrated how technology can be used to support the use of multiple symbolic perspectives in writing. One point made by Moline (1995) is that children should be allowed to experiment with symbols and graphic relationships. These participants took advantage of the opportunity provided through use of the Inspiration program as a way to experiment with graphic and pictorial sign systems to enhance and extend particular relationships within categories.
3. In their reading and writing of texts, the students practiced use of varied selection strategies such as scanning, sampling, skipping, and skimming to think critically about what information to include in their diagram. They drew on their collective background knowledge and made cross-textual connections during this process. Students then utilized the recomposing strategy (Moline, 1995) to write their own account of the information.

4. Throughout this entire process, students utilized critical thinking skills as they made decisions concerning where to seek information, how much information to include, how to represent the information in a text format, and, in some cases, how to represent the information using other sign systems. In his work, Harste (1989) has stated that critical thinking...is what people do in an attempt to understand and act on what they see, read, hear, feel, etc. This process of critical thinking is exemplified in these fifth grade students’ use of critical thinking to assist in their discussions and negotiations to represent information. One belief that Siegel and Carey (1989) hold relates to how understanding the way in which one thing signifies or stands for another is central to understanding reflection and, consequently, critical thinking.

Technology, multiple sign systems, selection strategies, and critical thinking were all overlapping literacies integral to the students’ successful organization of information. The support structure provided by the Inspiration software program as well as the guidance offered by each Preservice Teacher helped students to construct new meanings and establish and verify relationships within the topic they were studying.

Abstract: The question of how to use technology effectively in the assessment of teacher candidates to demonstrate achievement of course objectives based on state certification standards led to the development of the electronic portfolio project in a small university teacher credential program. The process of preparing an electronic portfolio using computer and multimedia technology was examined from the perspective of twelve teacher candidates enrolled in a multiple subject reading methods classes. This research was a multiple case study in which qualitative data was obtained through open-ended interviews with the teacher candidates, the course professor, and the computer lab technician, as well as through analysis of the electronic portfolio product. Whether the electronic portfolio could be considered an effective tool for documenting teacher candidate performance and the achievement of course objectives was the primary question investigated in this study.

Preparing teachers for the 21st Century has been a concern for both political and educational leaders in this country during the last two decades. Public education reform was triggered a decade earlier by a report, A Nation at Risk, which claimed that U.S. students generally achieved at lower skill levels than those of other industrialized nations (National Commission on Excellence in Education, 1983). The Goals 2000: Educate America Act enacted by Congress in 1994, provided the framework for education reform for the 21st Century. This legislation called for the establishment of high-quality, internationally competitive content and performance standards for all students, promoted the use of technology to enable all students to achieve national goals, and emphasized the need for teacher education and professional development. Teachers were to be given the opportunity to acquire the knowledge and skills needed to instruct and prepare students for the next century. They were to have access to programs to improve professional skills and encouraged "to use emerging new methods, forms of assessment, and technologies" (The National Education Goals Panel, 1998).

The National Council for Accreditation of Teacher Education (NCATE) issued a report called "Technology and the New Professional Teacher: Preparing for the 21st Century Classroom" in 1997. The NCATE Task Force on Technology and Teacher Education recommended that NCATE stimulate more effective uses of technology in teacher education programs. NCATE challenged higher education to incorporate technology across the entire teacher education program, not just as a "computer literacy" class added to the existing curriculum. The NCATE Task Force stated that teacher education is in a time of transition, calling for experimentation and a new attitude that is "fearless in the use of technology." NCATE recommended that teacher education programs provide early experiences for their students and that technology be integrated into other education reform efforts. This study focused on the use of technology as a tool for performance assessment of teacher candidates who were enrolled in reading methods courses.

Three themes of significance for this study converged in recent education reform documents concerning the preparation of teachers for the 21st Century: teacher accountability to professional content and certification standards, performance-based authentic assessment for both teachers and students, and the need for educators to have technological expertise. The U.S. Department of Education's New Teacher's Guide stated: "The
highest academic standards, the best facilities, the strongest accountability measures, and the latest technology will do little good if we do not have a teaching force of the highest quality" (1997, p. 1). Providing well-prepared, technologically literate teachers who meet high professional standards has presented a challenge to pre-service teacher training institutions.

An electronic portfolio project was developed in a small university teacher preparation program to explore the possibilities of using computer technology to store artifacts as evidence of achievement of course objectives. The electronic portfolio project was the final assessment for multiple subjects credential candidates enrolled in reading methodology classes during two consecutive semesters. The portfolio provided an electronic framework for documenting the meeting of course criteria, as well as evidence of self-reflection and self-assessment. A portfolio template was designed around specific course objectives based on state standards. Students included artifacts created with computer text, graphics, sound, or video as evidence of meeting each course objective. Students provided a reflective cover sheet in which they defended their selections for each objective. The text of the reflective cover sheets was examined to gain insight into the student’s perceptions.

The course syllabus, designed with emphasis on learning objectives based on current state certification standards, was prepared by the course professor prior to the electronic portfolio project. Two successive groups of teacher candidates were involved in the electronic portfolio project: the spring group of six students (Group I) and the fall group of six students (Group II). The electronic portfolio project was constantly evolving throughout both semesters due to revisions in state credential standards and technological considerations.

The course syllabus was altered for Group II due to revised state standards and the implementation of the Reading Instruction Competency Assessment (RICA). In addition, an attempt was made to solve some of the technical problems that were experienced by Group I. Students of Group II were required to attend a computer training seminar at the beginning of the semester to prepare for the electronic portfolio project.

This study was guided by the following questions:

- What effect does incorporating technology have on the development of a portfolio for teacher candidates?
- To what extent does the electronic portfolio process encourage self-assessment and reflection?
- In what ways does the electronic portfolio provide evidence of student learning and achievement in line with course objectives?
- What are the problems encountered in putting together the portfolio electronically?
- What do students perceive as the strengths and/or weaknesses of creating a portfolio electronically?
- What are the course professor's perceptions concerning the effectiveness of the electronic portfolio as a tool for assessment?

Themes and patterns that emerged from interviews, portfolio reflections, and field records were examined through Ethnograph, a qualitative data software analysis program, in order to gather information concerning the teacher candidate’s experience of collecting and preserving digital artifacts to be used as evidence of demonstrating competencies. The teacher candidate’s perceptions of the strengths and weaknesses, as well as the software and hardware problems encountered during the electronic portfolio process, were explored. Written reflections within the electronic portfolio framework were examined to gain insight into the student’s process of self-reflection and self-assessment. A computer literacy questionnaire was administered prior to the study in order to determine previous experience with and attitude toward technology. The researcher’s process of creating templates in hypertext markup language (HTML) and Hyperstudio, a multimedia authoring software program, provided further insight into the design and implementation of the electronic portfolio project.

The results of this study were presented in an interactive multimedia format. Text, data, literature references, figures, tables, and graphic images were saved as HTML within a portfolio web. Qualitative data
generated from Ethnograph, including sample screens, were linked to an interactive table of contents. A Powerpoint presentation provided the framework for linking directly to the Hyperstudio and HTML portfolios of teacher candidates. The reading methods course objectives were linked to multimedia evidence within each student portfolio. Design templates, narratives, interview questions, the computer literacy questionnaire, and other research data were linked from menu options as well. Narratives were presented in audio format, as well as through interactive text.

The paper portfolio was an established means of assessment in the teaching training courses at this university before the electronic portfolio project began. When the course professor was asked why she implemented electronic portfolios into her class, she stated:

I have worked for ten years to get faculty to infuse the use of technology into their courses and teach students to do so in productive ways—this is just another step along the way. The benefits for me? Not having to carry home 100 pounds of paper portfolios as I have been doing for several years—and seeing that students DO know how to use the technology in their classrooms when they leave—and understand not just the tech part—but the curricular uses. They have to get through the learning/uncomfortable stage before they can connect to the important parts of teaching them how to use technology in appropriate ways—and since the state does not require the computer course until 5th year—that puts all of us at a disadvantage because most do not know how to do anything but word processing and email—and now most know how to surf the net. This was my way of forcing them to learn what I wanted them to know even though I couldn't make them take the computer course.

Narratives from student interviews and portfolio reflections provided insight into the students' perceptions of the electronic portfolio process. Each individual's process varied in terms of approach to the project, the use of templates, working at home, using Hyperstudio or HTML, and the amount of time required for completing the electronic portfolio product. Technical processes varied in terms of how much technical support was needed, what technical skills were gained, and what problems were encountered. Student perceptions varied as to what they perceived as the purpose of the electronic portfolio, what attitudes they demonstrated concerning the process, how they compared electronic portfolios to paper portfolios, and how they felt concerning the use of technology in their future classrooms. Strengths and weaknesses were examined from the perspective of the participating students, as well as that of the course professor. Narratives from student interviews and portfolio cover sheets provided evidence of students' self-assessment and reflective practice. The course professor's discussion of how she evaluated students' portfolios provided further understanding of the potential for the electronic portfolio as a tool for assessment.

The process of collecting artifacts, selecting the work that best matched the course objective, determining how to get the evidence into digital format, and writing a cover sheet evaluation explaining personal achievement of each objective resulted in on-going self-assessment and self-reflection. Generally, students felt they were adequately able to present their artifacts as evidence of meeting course objectives based on standards within the electronic portfolio framework. Students demonstrated that they were guided by the course objectives throughout the electronic portfolio process and believed they were able to demonstrate achievement, competency, and proficiency in the course subject matter.

The course objectives were specifically aimed at teaching reading and literacy. The artifacts included in the electronic portfolios included digitized versions of a variety of assignments from the reading methods class, as well as material from other teacher training courses. The course objectives successfully provided the students with the criteria for assessment in the electronic portfolio project. Upon the request of the course professor, Hyperstudio and HTML templates were designed to place emphasis on the course objectives. Students provided self-reflective statements explaining the significance of the evidence they included in their portfolios. All twelve of the students in the study clearly indicated that they viewed the purpose of the electronic portfolio as a way of demonstrating that they had met the objectives.

In addition to providing evidence of meeting objectives, reflective teaching was considered one of the desired effects of the electronic portfolio project. Results of this research indicated that students were engaged in self-assessment and self-reflection as they described, explained, and defended the evidence they chose to include within the electronic portfolio framework. The student comments supported the researcher's belief that, not only were course objectives considered significant to students, but that the electronic portfolio project stimulated reflective practice:
1. It was a good way for the professor to make sure we had met all of the objectives.
2. I felt that the things in the course pretty well matched the objectives.
3. I liked reflecting on what I was doing and looking back and seeing how my assignments actually matched the objectives.
4. I understand the objectives better now that I have analyzed my work.
5. To think about once we had all this information, how are we actually going to apply it and how do the goals fit with the objectives?
6. I liked having to think about how everything was related in the class because I think a lot of times teachers give you their syllabus, you read the goals and objectives, and you never think about them again.
7. The objectives--when I read them--I thought--well I think this fits and I went back and I read my stuff again and then things that I'd written sometimes gave me a clue as to whether or not I really got the material.
8. I really felt that the electronic portfolio was a great way to organize evidence and artifacts.
9. The other purpose was to show that I had met the necessary objectives for the class and that I understood that I met the objectives.
10. As with any portfolio, I was in the position to review all my work and the initial objectives of the course.
11. If you clicked on course objectives you went to a cover page that had the objective written out and you could go to the explanation page or directly to each artifact.
12. Now I can see where the objective was to make me understand how we met everything.
13. I didn't think that I had met all the objectives...but I think after sitting down and looking at all the work I had done, that I realized that I did meet those objectives.
14. I could demonstrate competency by matching artifacts with competencies. I believe I was very careful in selecting my evidence material to be certain it was adequate--and I did a good job!

One student indicated that she felt the electronic portfolio “tied the class together and gave it a sense of closure.” She said, “It was nice to see the purpose and made it personal.” Another student explained that the process of reflection meant “critically examining your work to determine which way you have met the selected criteria, and how you can best example or highlight your work.” She had described the process of developing the portfolio as “a constant self-assessment.” Another student said that the class helped her feel prepared. She said, “I think sticking it all in one place and making connections between the objectives and the things helped me say, oh look I am prepared. Not only do I think I am, but I can tell you why.”

In terms of assessment, students generally felt that the electronic portfolio was valid and useful. One student referred to the electronic portfolio as a “viable measure of assessment.” Another student remarked, “I guess they [electronic portfolios] are a good form of assessment—rather than a test.” Another student expressed her preference for portfolio assessment over studying for a test. The course professor indicated that she thought students selected artifacts more carefully in the electronic portfolio because they had to “go through the mechanics of digitizing their artifacts.” In her assessment, she said she examined students’ choices of artifacts, the explanations regarding their choices, and indications of personal reflection upon their learning.

The emphasis on self-assessment and self-reflection was considered more significant to this study than the effectiveness of the electronic portfolio as a tool of assessment in terms of course grading or evaluation. One student said, “In doing this I was able to assess my work and reflect upon how the work I completed met these objectives.” Another student stated that she got more out of the electronic portfolio and enjoyed reflecting back on what she had accomplished. Another student thought that the electronic portfolio allowed her to think about what they were supposed to be gaining from the course and the purpose for every class, lecture, and activity.

Results indicated that the primary effect of incorporating technology into the portfolio process was that students gained knowledge of computers and technical skill with software.
and hardware, particularly in graphics and multimedia. The total number of technical references found in interview transcriptions and within portfolio reflections provided further indication that students gained knowledge and understanding of technical processes and terminology used in computer multimedia. References to the digitizing of graphics through scanning appeared 80 times within the text of the student interviews and portfolio reflections. Eight students discussed scanning at least three times within their interviews. One student did not mention scanning, but she discussed another more complex graphic digitizing process, single frame video capture. All students participating in this study demonstrated a high level of technical understanding of the processes of digitizing their graphics. Table 1 shows the number of references to technology made by each student in interviews or within the portfolio cover sheet reflections.

Table 1. Counts of References to Use of Technical Skills

Most of the students were pleased with their final electronic portfolio product and were proud of their accomplishments. Students were able to personalize their portfolios, demonstrate creativity, and show their competencies electronically. Students demonstrated that they were able to self-assess and self-reflect on their learning within the electronic portfolio framework. The cover sheet reflections in which students defended their choice of artifacts placed the focus on meeting of specific course criteria. From the course professor's perceptions, the electronic portfolio project could be considered a viable means of assessment and an effective tool for self-reflection. She has continued to use the electronic portfolio in subsequent courses and indicated that students have learned to use technology successfully. Table 2 includes examples of positive student statements.

The artistic thing was fun. I really enjoyed the drawing part.
Really good way to show off this is what I did.
That was a blast.
You can tell I got a little silly, but it was it was fun so I didn't care.
I did a good job!
The most exciting evidence is my electronic children's book.
It is so fun and fancy done electronically.
I was happy with the way things turned out.
I feel more prepared.
Another Ah-Ha for me.

Table 2. Student Comments Reflecting Positive Attitude

The primary strength of the electronic portfolio was that students could include multimedia artifacts in the form of graphics, audio, video, animation, as well as text, providing a more complete picture of their achievement. Students regarded the aesthetic qualities and the possibilities for personal creativity as strengths of the portfolio as well. The weaknesses included the demands on students' already busy schedules, the lack of previous experience with computers, the lack of time to learn the technology required for multimedia, and the need to work within the school computer lab setting. Problems included lack of time to work on the technology, difficulty with computer lab availability, broken computer equipment, cross-platform compatibility issues with home computers, technical difficulties with hardware and software, lack of computer skills, insufficient previous experience, and the need for considerable technical support.

One of the unexpected patterns that emerged from this study was the students' pleasure in being able to express themselves creatively, artistically, and aesthetically through technology. Previous to this study, the researcher believed that multimedia technology incorporated powerful tools for creativity, particularly in performance areas that are difficult to document through the traditional verbal linguistic modes of expression typically used in academic settings. Many students expressed emotions and attitudes indicating that they enjoyed being able to use multimedia means of expression. In addition, most students believed that these creative new technologies would allow them to enhance their future classroom instruction. The course professor felt that the attitude changed as students began to see the finished product. She said that students appeared to get excited about the portfolios, particularly in terms of being able to show their individuality. She said that they demonstrated personal pride in their final product and indicated that they appeared to see “the benefits of the

The NCATE technology task force suggested that perhaps the best way the teacher education faculty can inspire future teachers to use technology is "to cast themselves as learners and to experiment fearlessly in the applications of technology," making themselves "role models of lifelong learning." The task force stated that re-educating the existing teaching force would require extensive professional development, but that the problem would be compounded if future teachers were inadequately prepared to use new technology. All students who participated in the electronic portfolio project indicated that they had improved their technology skills and understanding significantly through this process. This study furthered understanding of the potential for infusing technology into teacher education through electronic portfolio assessment within a non-technology reading methods course.

A Study of the Effectiveness of Using Computers to Assess the Phonic Knowledge of Preservice Teachers

George F. Canney, Ph.D.
gecanney@uidaho.edu

John C. Davis, Ph.D.
jcdavis@uidaho.edu
University of Idaho

Abstract

For 25 years the undergraduate reading methods course for elementary and special education preservice teachers at the University of Idaho has included a strong phonics component. To demonstrate their grasp of phonic patterns, students have five chances to pass a written phonics test outside class time. The major drawbacks of this assessment led to the development of a self-scoring computerized version. A study was conducted to address the following question: Does a computerized test with an auto-score feature enhance the assessment of students' knowledge of phonetic content compared to an existing paper-and-pencil test? Students in two four-semester-credit, teaching reading in the elementary school courses formed the two treatment groups. The results indicated statistical, practical, and educational significance supporting the use of the computerized assessment as a valid, cost-effective replacement for the pencil-and-paper version.

Introduction

Background

Current research affirms the importance of phonetic instruction in helping children become proficient readers. Developing readers must learn to recognize recurrent spelling patterns within words, including letter-sound regularities (Adams, Foorman, Lundberg, and Beeler, 1998), initial consonant patterns (onsets) and common vowel-consonant patterns (rimes, or phonograms) (Braunger and Lewis, 1997; Burns, Griffin, and Snow, 1999; Cunningham, 2000; Moustafa and Maldonado-Colon, 1999; Snow, Burns, and Griffin, 1998). Most educators also agree that phonetic knowledge is not about learning rules, but about learning common spelling patterns within syllables (Braunger and Lewis, 1997; Stahl, Duffy-Hester, and Stahl, 1998). Part of helping students become fluent readers is understanding both the content of phonics and various instructional approaches explicit and embedded, for presenting phonetic patterns to students (Stahl, Duffy-Hester, and Stahl, 1998). The newly revised Standards for Reading Professionals (International Reading Association, 1998) states that elementary school teachers must be able to:

6.1 teach students to monitor their own word identification through the use of syntactic, semantic, and grapho-phonetic relations
6.2 use phonics to teach students to use their knowledge of letter/sound correspondence to identify sounds in the construction of meaning

Given these standards, it is appropriate for preservice teachers to demonstrate that they understand both the content of phonics and methods for helping their students learn and use phonics to read fluently.

Current Program

For 25 years the undergraduate reading methods course for elementary and special education preservice teachers at the University of Idaho has included a strong phonics component. Students learn phoneme-grapheme correspondences and phonetic patterns, including consonant blends, digraphs and silent letters, and common vowel patterns. The vowel patterns are clustered into five distinct groups—r-controlled, diphthongs, regular vowel patterns (ae, aw, ey, ei, oo, ou, ui), predictable patterns (CVC, CVCE, CVVC, CV), and variant predictable patterns (all, ind, old, igh). This scheme addresses twenty common vowel phonemes and their spelling patterns. Students learn both analytic and synthetic methods for teaching phonics, plus ways to teach whole (sight) words,
structural analysis, and use of context to decode. During five, two-hour class periods, the preservice teachers receive information sheets and direct instruction delineating the various phonic patterns, guided practice exercises to help them identify phonic patterns within syllables within words, and individual help upon request. They discover that their ability to quickly recognize phonic patterns helps them evaluate children's use of phonics when reading aloud or in their writings. They can determine which phonic patterns children know well, know in some contexts but not others, or do not recognize. Since no one teaching method is best for all students (Braunger and Lewis, 1997; Pearson, 1998), such learner-centered, diagnostic teaching prepares them to meet the diverse needs of all learners.

To demonstrate their grasp of phonic patterns, students have five chances to pass a phonics test outside class time. The phonics test is comprised of 10 paper and pencil forms, each with a 50 running word text; half the texts are from second grade basal stories and half are from published children's books. The number of unique words within each passage varies from 32 to 38 words. The same ten test items with variant text passages are on each of the 10 test forms, yielding 10 equivalent-form tests.

Each item is worth 3 points, for a total possible score of 30 points. For example, under the item, "List all words containing r-controlled vowel patterns", students might select from the text words like February, early, awkward, organized, and steer. According to the scoring rubric, students receive partial credit if their answer is incomplete or includes incorrect words. Percentage correct is determined based upon the total number of correct words selected for an item, minus the number of correct words omitted and/or incorrect words included. If an item response is 80% correct, it earns 2 points; 70% earns a single point. Items with few correct words possible earn either 3 points or 0 points, since the base (denominator) is small. Students' single highest score becomes the points they receive for course grading purposes.

To take a test, students in the paper-and-pencil group went to the College of Education Instructional Materials and Technology Center during regular work hours, which included two evenings and four hours on Saturday. They spun a dial to select one of the ten test forms; if they had previously taken a test form, they spun again until they landed on a new form. The student would sit at a table across from the front desk (for proctoring purposes) and take the test, closed-book. There was no time limit imposed, but most students completed a test in less than 45 minutes. The test was placed in a folder for scoring that evening or the next day. Students' completed tests were kept in individual folders, which they could check out when they wanted to study from their previous tests. At this time they could study alone or with other students in the class, even if the peer had not taken that particular test. A student could stop taking the tests any time he/she decided that the highest score earned to date (from 30 possible points) was satisfactory. Most students, however, took the test at least four times. Students could take up to five forms of the test any time during a five week period, but no form more than once.

Issues and Concerns

Despite our best efforts, there were several major drawbacks to assessing students' knowledge of phonic patterns in this manner. One, the turn-around time between taking a test and receiving the scored form for study was, at a minimum, 24 hours, and typically several days. Two, students were often unable to figure out why they had missed an item, so the instructor ended up putting many hours into individual instruction--valuable, but redundant and time-consuming. Three, resources for hiring and training aides to score the tests were limited and growing harder to find. Four, scorer reliability was a problem; although the aides had scoring keys, it was easy to err, leading students to believe their answers were incorrect when they were not, and vice versa. Finally, it was all but impossible to maintain a current record on how well students were doing as a class, which would have helped the instructor examine teaching practices in light of student learning.

Several options were considered given these four constraints. Clearly, the option that emerged with the highest potential was the creation of a computerized test with an accompanying scoring feature which could reduce administration and scoring time, increase scorer reliability, significantly decrease turn-around time, and standardize results. The main concern and subsequent question for this study, then, was whether such a test would compare favorably to its pencil-and-paper counterpart to determine student achievement related to learning phonics content.
The Study

Research Question
This study addressed the following question: Does a computerized test with an auto-score feature enhance the assessment of students' knowledge of phonic content compared to an existing paper-and-pencil test? Furthermore, it is of interest to the researchers as to whether or not this computerized format increase student achievement as a result of immediacy and clarity of feedback.

Method
Students in a four-semester-credit, first course in teaching reading in the elementary school formed the two treatment groups. Group 1, the paper and pencil group with 52 students, was enrolled during the Fall, 1997 semester. Group 2, the computer group of 53 students, was enrolled in the Fall, 1998 semester. The composition of the two groups was comparable in gender mix, overall grade point average, and age. Most of the students were in their junior year of a four-year teacher preparation program. The previously described pencil-and-paper assessment was modified for use on the computer, with the addition of a scoring feature. A program was written and refined until students could take a phonics test within 30 minutes. The 10 computerized phonics tests were identical in format and content to the paper and pencil tests. The screen format was slightly different than the paper and pencil version, as one would expect.

Each student had a personal user name and password to access just her/his own records. A sign-up sheet permitted them to reserve a 45 minute time slot for taking a new test, or reviewing previously taken tests. The computer program randomly selected a test form not previously taken by the student. For the computer test, the 50 word passages were arrayed at the top of the screen; the unique passage words were also listed alphabetically down a left column. To respond, students highlighted the word(s) they believed contained the phonic pattern requested, then clicked on the on-screen "select" button; if they wanted to remove a word from their answer list, they highlighted it and clicked on the on-screen "delete" button. Students could select the items in any order, and return to previously answered items. When finished, the students clicked on the "score the test" button and their responses were permanently recorded (the scoring feature was designed to mirror the scoring rubric used for the paper-and-pencil test, so that the scoring was the same for Group 1 and Group 2 tests). Students received a total score, including an item by item breakdown of points earned. For each item, they were shown the total possible words correct, words they listed that were correct, and words they listed that were incorrect. After taking five tests, students were blocked from taking additional tests (similar to the paper-and-pencil testing). An electronic record was kept for every student, listing which of the 10 test forms they took, when, and how quickly. When reviewing previously taken tests, students could have course materials in hand to learn why particular answers earned less than 3 points. They could even review together during this study phase.

Both treatment groups received instruction from the same instructor using identical materials, classification system for phonics, and time frame. Students had the same number of weeks to complete the phonics assessment outside class. Upon completion of their studies, Group 1 completed the paper-and-pencil test followed by test scoring. The following fall semester, Group 2 received instruction and completed their phonics assessment via the computers in a proctored environment. In order to ensure standardization of test scoring procedures in this study, Group 1 test responses were entered into the computer as if each student had taken the computerized form of the phonics test. The result was that the scores for Groups 1 and 2 were tallied using a common metric, thereby reducing threats to internal and external validity of the comparison while meeting the necessary constraints for statistical analysis.

Results
An ANOVA test was used to test for statistically significant differences between the paper and pencil and computerized test groups in highest mean score on the phonics tests. No significant difference was determined; students taking the paper and pencil form had a group mean score of 19.38 correct out of 30 points possible (s.d.=5.31), while the computer group's mean score was 19.43, s.d.=5.66 (F=3.28; p>0.833). Statistically the forms were found to be of equivalent difficulty. They used the same ten items, in the same order. Only the 50 word texts varied, and they were taken from basal and literature selections appropriate for second grade developing readers. Group mean scores ranged from 12.37 on Form VIII to 17.56 on Form III; seven of the test forms recorded group mean scores in the 14-15 point range. Post hoc analyses also suggested that the two groups of students did not vary
significantly in number of tests taken (1 to 5 trials). Students in the paper and pencil group took the phonics test an average of 4.4 times; the computerized group took the test an average of 4.0 times.

Based on these data, the computerized test version appeared to be no more advantageous in terms of students learning phonic patterns than taking the same tests in paper and pencil form. The practical significance of the computer format was the overall cost-effectiveness in terms of administration, scoring, and scorer reliability. The computer also reduced substantially the cost of test administration. In terms of educational significance, the time devoted to re-teaching individual students dropped substantially now that they were receiving more feedback about their performance immediately after completing a test. They knew the total number of correct words for an item—information they typically requested for the in-class phonic practice sheets. They also knew which words they listed were correct and which were incorrect, leaving them to study the passages for the correct words omitted in their original answer. Fewer students requested individual instruction, and did so closer to the time when they were approaching their last test trial or two. Then their questions often were about a feature of a phonic pattern, or about particular words that remained confusing to them.

This research continues beyond the results reported here. Three more semesters of students have taken the same phonics tests via computer and, according to our ANOVA analysis of their mean scores, they do not differ significantly from the original paper and pencil treatment group's test performance. Likewise, several years of collecting students' phonics tests scores in the paper-and-pencil form mirror the comparison group's mean phonics test score. A small number of students, perhaps 15-20 percent, score 26 points or higher. About the same percentage of students score below 20 points, leaving the majority of students earning from 20 to 25 points out of 30 points possible. It also appears that, when repeatedly taking the test, there is clear improvement with increase of trials—often across three trials. However, a plateau effect for many students seems to occur around 18-21 points. If they remain confused about features of particular phonic patterns, students at these times are open to instruction and often their next test score jumps several points. These observations need to be examined more closely and systematically; future studies need to include an item analysis to determine which of the ten phonic categories are proving easiest to learn, and which most difficult. An examination of test scores by item suggests that the predictable patterns CVC, CVCE, CVVC, and CV are difficult because some students struggle to remember short and long vowel sounds, especially when local dialect makes some short vowels sound like long vowel sounds (e.g., the /i/ in ring, or the /a/ in bang). Students also struggle to identify vowel patterns that are irregular, such as the /a/ in wander or the /ou/ in famous. The other eight vowel and consonant patterns do not seem as difficult for students to learn well.

In summary, this study compared administering a paper and pencil test of phonic knowledge to preservice teachers with the same test presented via computer. Group mean test scores were comparable, as were number of test attempts. While no improvement in student learning the patterns was evident in these data, significant improvements in cost-effectiveness, scoring accuracy, and scoring objectivity were observed. Future study of this procedure for assessing teachers' knowledge of phonic content may lead to an economical, accessible, and reliable way for preservice and practicing teachers to check their knowledge of phonics as part of their demonstration of content knowledge necessary to effectively teach all children to read.

Empowering Masters Students to Become Researchers: 
An Australian Case Study

Cristina Poyatos Matas
School of Languages and Linguistics, Griffith University, Australia
E-mail: C.Matas@mailbox.gu.edu.au

Abstract: This paper describes a case study in which Masters students at an Australian University, undertaking a subject on Research Issues in Technology and Language Learning (TELL), were involved in the interactive simulation of applying for a small Australian Research Council (ARC) grant in the area of TELL. Through participating in this research simulation students became aware of current research methodologies and issues in the field of TELL, as well as becoming conversant in a meaningful way with the relevant literature of this area. Students gained first class experience as potential candidates and assessors of one of Australia's major research grant schemes. The paper discusses the theoretical framework, method of implementation, outcomes and evaluation of using this type of learning experience in a Masters of Arts in Applied Linguistics.

1. Introduction

Nuthall (1999: 245) discusses that having knowledge is as much a process of engaging in acquiring, sorting, connecting, inferring, reorganizing, using and reusing information as it is possessing some kind of knowledge object. Somehow, in any learning experience the object and procedural knowledge can be present. In order to make more specific these terms, let's think for a minute about my own writing of this paper, a learning experience, in which I am in the first place using my initial object knowledge to write a paper to share with my audience. I am involved in the process of writing the paper and editing it to take into consideration other people's views. As a result of the process, my object knowledge is being changed as I am adding new knowledge or modifying the construction of what I already know notionally as well as about the writing process of papers in itself. The process is taking me to find out where I need to research more in the discipline knowledge to make my point more effectively. Both types of knowledge complement each other and are interrelated by the feedback, which is received from other people commenting on a draft of this paper, or myself providing feedback to myself as I read through different section and drafts of this paper. The feedback makes me think and reflect on what needs to be deleted, changed or improved at different levels to communicate my message clearly to my audience. So what is more important, the object knowledge or the procedural knowledge?

Many teacher education programs in the area of Applied Linguistics seem to have a strong emphasis on students acquiring the object knowledge of the area of study, as they are strongly influenced by teacher-centered models of instruction. According to Johnson (1999:4), "many courses have followed a traditional model, in which the lecturer provides pre-digested course content, in the form of lectures, and all students submit their version of the same assignment". In these traditional models the lecturer is still considered to possess some kind of knowledge object that can be passed to the students and the main focus is on object knowledge. These models of teacher education fail to place learners in authentic real-life situations for active learning to take place. They miss the opportunity of creating learning environments capable of engaging students in the acquisition of procedural knowledge as well as object knowledge, to allow them to become part of the research community not only as consumers but also producers. These models of teaching in undergraduate and postgraduate Computer Assisted Language Learning (CALL) programs foster passivity as students are seldom challenged to take responsibility over their own learning. There is a need to encourage more autonomous learning and self-reflection on learning in teacher education, in the same way that there is a need to advance the research agenda in the effective design and use of CALL. We need reflective autonomous learners who will be able to contribute to our field with their own research. But can our current Master students contribute actively to the advancement of the research agenda in the area of CALL or other areas when they finish their teacher education? And if not, what is stopping them?

1 Lemke 1990
2 Kolb 1984
3 Johnson 1999

1831
The research performance of Masters students has been said to be affected by their lack of confidence and security, due to their limited understanding of scholarly research and writing, as well as never having had a real audience for their academic work, which has been read only by their instructor or lecturer. Moreover, writing at a scholarly level has been identified as creating anxiety and insecurity as in general postgraduate students have very little understanding of the academic research genre and are afraid of academic audiences.

In recent years, we have witnessed innovations in teacher training influenced by learner-centered approaches to attempt to develop graduate and postgraduate students into researchers placing more importance on procedural knowledge. The research reported here was motivated by the desire to explore the implications of using the notion of knowledge as a process as well as an object to design a Masters course in Research Issues in Technology and Language Learning. This would mean that as much attention would be paid to provide the students with the relevant and critical knowledge of the area of study (the knowledge as object), as to provide them with the learning environments necessary to develop and acquire a repertoire of research, writing and publishing skills to be able to participate and contribute to the research body of the area (the procedural knowledge). In order to achieve this, the course was designed to include more real life research simulations to promote the learning of research as a process and as an object of study. It was envisaged that this type of training would also contribute to increase the levels of confidence and security that postgraduate students might experience when considering stepping into the real research community for the first time after completing their studies in a supportive academic environment. This paper is an attempt to empower postgraduate students to become future researchers conversant with the conceptual and procedural knowledge of research by involving them in a research simulation to apply for a competitive small ARC grant.

2. The Small ARC (Australian Research Council) grant: How does it work?
The Australian Research Council is one of Australia's major research grant schemes. In order for a candidate to be successful s/he has to go through a very competitive process made of five stages:

A. Submission Stage. The candidate writes the application and submits it to the selection board of the ARC.
B. The Cull Stage. The submission goes to a general panel of assessors which makes a judgement about whether the submission is worth more detailed consideration by assessors who are expert in the field of the submission.
C. Assessment Stage. If the ARC board selects the application of a candidate, then it would be sent to three assessors in Australia and/or overseas, who have to write an assessment report commenting on the quality of the different aspects of the research proposal and research ability of the candidate/s, which are submitted to the ARC selection board.
D. Rejoinder Stage. The ARC board sends the confidential assessors' reports to the candidate to allow her/him to reply to them with a rejoinder. The reply is sent to the board for its consideration.
E. Final Selection Stage. The ARC board makes the final selection of proposals to be granted by taking into consideration the reports from the assessors and the response of the candidate to those reports.

3. The Small ARC grant simulation
3.1. Aims of the Process
Research can be a satisfying and stimulating experience for many people with a trained and inquiring mind. Researchers contribute to the existing body of knowledge, to solve problems and expand knowledge by using methodical processes to discover non-trivial facts and insights, and conducting the

5 Crawford 1999
6 Crawford, 1999; Johnson, 1999; Mumma, Bentley, & Walker, 1999; Smith & Mandlebaum; 1999
7 Howard & Sharp 1983
8 Drew (1980)
9 Howard & Sharp, 1983
process with a systematic approach. This learning experience aims to help students to increase their research skills, ability and confidence, and requires them to be creative, critical, methodical, communicative and reflective, and to become aware of academic genres and audiences. The use of this learning environment has been influenced by social constructivism, as it is trying to encourage personal learning through using a meaningful social context to create an active learning environment. It aims to promote the development of critical knowledge and skills in students in the areas of TELL and CALL, as well as to create a direct relationship between what is learned in the classroom and what is needed outside the classroom, one of the most valuable principles of the situated learning approach. Furthermore, it encourages experiential learning through exposing students to conceptual and procedural knowledge of research in a simulated real academic situation. In summary, the aims of this learning experience are:

- to help students to learn about what makes a good research proposal in a meaningful context;
- to help students to learn how to develop a sound research grant or proposal through participating in a supportive environment;
- to increase their ability to understand better the research process as they are doing it;
- to become critical about their own research proposal and other students’ research proposals through conversational and reflective experiences;
- to promote awareness of an academic audience by having a real audience;
- to increase the postgraduate student’s confidence and security as potential researchers by having a supportive environment for their first attempt at a grant submission;
- to increase their conceptual knowledge in the area of Technology and Language Learning through their involvement in the process of developing a grant proposal.

3.2. The Participants

There were fourteen students participating in this simulation with a diverse cultural and linguistic background including Australian, British, Chinese, Korean, Samoan and Spanish. A total of 80% of the class was made up of females. Their ages ranged between 26 and 55, eighty per cent of the class being between the age of 36 and 55. The majority of them were experienced teachers in the areas of English as Second Language (ESL) and/or Language Other Than English (LOTE). None of them have had previous knowledge of the area of Technology and Language Learning, and most of them did not have prior experience using computers to enhance language learning and teaching. The research background and experience of the participants was very limited.

3.3. The Process

A. Preparation Stage

(a) In class (in small groups): Students examined the guidelines provided by the ARC to write a small ARC grant proposal. Two samples of small ARC proposals were examined for the students to become familiar with the structure and to identify what were the good elements in each of them and the elements that could be improved. Out of this initial analyses the class as whole ended up writing a list of the characteristic of a good research proposal, which at the same time became the evaluation criteria to assess the research grant proposal, that the students were going to elaborate.

(b) Outside class (individual): Students were given the assessors reports attached to one of the successful small ARC samples analysed in class. They had to write a response letter dealing constructively with the relevant and irrelevant comments made by the assessors.

(c) In class (in small groups): Students shared their response letters and tried to identify the strengths and weakness of each letter. Then they created a single response letter containing the best elements of each member in the group. Each group shared their outcomes with the rest of the class.

12 Bandura, 1986
13 Anderson, Reder & Simon, 1996
14 Kolb, 1984
15 Bouma, 1996
B. Developmental Stage: Each student developed a small ARC grant proposal on a topic of her/his interest and submitted four copies to the lecturer. The lecturer kept one copy and gave the others to the three blind assessors of that proposal.

C. Evaluating Stage: The assessors read the proposal and wrote a report commenting on the research question/s, critical analysis of the literature and references, and evaluation of the methodology and data collection. Their aim as assessors was to provide constructive and coherent feedback to the author on the strengths and pitfalls of their research proposal. The assessor reports were given to the lecturer who gave them to the author of the proposal to keep the refereeing process anonymous.

D. Reflective and Responsive Stage: The author of the proposal wrote in a clear and coherent way a rejoinder to the assessors' reports or evaluations, addressing the different issues raised in the reports in a constructive way and dealing with irrelevant comments effectively. She took this opportunity to reflect on the aims and content of her/his initial proposal and improve the quality of the initial proposal prepared by the candidate. The rejoinder was submitted to the lecturer, who took the role of the ARC board.

3.4. The Learning Outcomes

The Small ARC research learning experience conducted was evaluated based on the results of a student questionnaire, feedback obtained from informal conversations with the participants, lecturer's observations of the process, as well as the analysis of the different documents generated by the students as a result of this research simulation. Due to the lack of space in this paper, only the results of the questionnaires, to which ten participants replied, will be discussed in depth. The questionnaire aimed to gather information from the
participants on their research skills, their participation in the small ARC simulation, their current levels of confidence as researchers in the area of Technology and Language Learning, the place and nature of this item in the course, and the general participant profile. There were ten responses to the questionnaire. Most of the student benefited in one way or another from participating in this learning experience as represented in the following table.

| What did you learn from preparing your own small ARC proposal? | %  
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Gathering information on current research issues relevant to TELL.</td>
</tr>
<tr>
<td>Stating a clear research question for a small ARC proposal.</td>
</tr>
<tr>
<td>Selecting the best research methodology and instruments for a particular research proposal.</td>
</tr>
<tr>
<td>Realizing the importance of good research design and timeline.</td>
</tr>
<tr>
<td>Using electronic media to search for relevant literature.</td>
</tr>
<tr>
<td>Elaborating a current and relevant literature review to support a research proposal.</td>
</tr>
<tr>
<td>Ways of dealing constructively with the research limitations of a research proposal.</td>
</tr>
<tr>
<td>Elaborating a research budget.</td>
</tr>
</tbody>
</table>

In addition the participants reported to have benefited from having assessed constructively the research proposals of other candidates. It is worthwhile to notice how all the participants reported that they learnt to be critical towards other people's research and almost all of them to recognize the elements of a good research proposal as a result of this learning experience, as reported in this table.

| What did you learn from assessing constructively the ARC proposals of other candidates? | %  
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>To be critical about other people's research.</td>
</tr>
<tr>
<td>To recognize the different elements that make a good research proposal.</td>
</tr>
<tr>
<td>To find out inconsistencies in the research methodology and instruments of a proposal.</td>
</tr>
<tr>
<td>To assess the impact that using clear and correct language has in a research proposal.</td>
</tr>
<tr>
<td>To analyse critically the theoretical framework of a research project.</td>
</tr>
<tr>
<td>To determine the soundness of a research proposal.</td>
</tr>
<tr>
<td>To evaluate the soundness and appropriateness of the research question/s.</td>
</tr>
<tr>
<td>To see the importance of using a consistent referencing style.</td>
</tr>
</tbody>
</table>

Replying to the assessors' reports helped some students to become more critical about literature reviews, as well as to adopt the useful suggestions received about their initial proposal, and to gain experience in having to deal with some of the suggestions from assessors with whom they disagree. This experience seemed to help most of them to see things from different perspectives (candidate versus assessor), and to learn that the quality of a proposal can be improved by the comments received from the assessors. I would like to add, based on my own observations of the process and the documentation generated by the participants, that through their involvement in this research process students improved their conceptual and procedural knowledge of research in order to put good grant proposals in place with a sound methodology and research design. Most important of all is the impact that this learning experience has had on the student's confidence as a researcher.

| Confidence as a researcher in the area of Technology and Language Learning | Average

Their confidence and security in their ability as researchers improved substantially after having participated in this learning experience during one semester. The majority of students thought that participating in this simulation should be a component of the subject on Research Issues in Technology and Language Learning.

Learning, because it can be useful for their future careers and provided them with a good research experience in a safe environment. For two of the students, time was too limited to concentrate on this simulation, as there was already enough new content in the subject without the research component. Some of the students mentioned that some of the aspects they liked about the process were having to write a grant application, gaining experience that could help them to avoid any problems in the future if applying for a grant, and gaining confidence. One of the students reported that s/he found stressful having to read negative things and felt s/he did not have enough time to complete the process. Some of the suggestions made by students to improve the process were: that no candidates names should be mentioned on the research proposals, and that the lecturer’s comments on the proposal should be received at the same time as the comments from the three assessors.

4. Conclusion

The ARC grant research learning simulation described in this paper has promoted experiential learning through encouraging students to become familiar with the process and concepts of research in the area of Technology and Language Learning. As a result of participating in this learning experience, their research skills and knowledge have benefited, becoming more critical, methodical, constructive, communicative, and reflective, as well as aware of academic genres and audiences. It helped them to expand their knowledge of research methodologies, design, and instrumentation, but most important of all was that their confidence and security in their ability as researchers increased dramatically as a result of taking part in this experience. This paper advocates the importance of including procedural knowledge and real life learning simulations as part of postgraduate research programs. In this way, we educators will be able to empower our students to become potential researchers able to contribute to the field with confidence and in a constructive manner, and one day being able to add to the object knowledge of us, their educators.

Abstract: This paper describes a three-year collaborative university and public school distance education ESL endorsement program designed to lead to a Masters degree for 450 educators in one rural and five urban school districts. The program uses multiple technologies integrated into an instructional and curricular design plan for 8 graduate level courses. The paper also describes the initial evaluation results gathered during the first year of implementation.

Introduction

With the increasing population and urbanization of city centers within Utah, the complexion of Utah's children is rapidly changing, mirroring the changes taking place throughout the United States. By the year 2005, one of every three school children in the United States will have a primary or home language other than English. These population changes created a growing demand for professional development programs to prepare educators to meet the specific needs of Utah's children. School administrators and teachers in the urban school districts surrounding the capital city of Salt Lake City became more demanding of local teacher education programs to provide quality and large scale professional development programs for the preparation of teachers of ESL (English as a Second Language) students. However, the ESL preparation programs at institutions like the University of Utah were very small endeavors incapable of producing no more that a few ESL teachers. Out of such a dilemma came a unique and innovative partnership among the five urban school districts and the University of Utah. Working together, a collaborative team created and implemented the Distance Education ESL Endorsement Program (DEEEP). Consistent with calls from the literature, "distance education has the capacity to deliver instruction to a wide array of diverse populations, but that capacity will require partnerships among institutions of higher education, and sectors of the community" (Parker, 1997, p.9). Integrating distance education design principles (Garrison, 1990 and Parker, 1997), team members created a program in which technology strategies followed pedagogical and content goals. Taking a distance education approach in an urban setting provided access for a large number of teachers to a quality university program and a more adult centered approach (Crotty, 1994). The program is organized into a three-year format, with each year using distance
education strategies (Collis, 1997). Years One and Three integrate multiple technological delivery systems into the instructional design plan.

The Program

The purpose of DEEEP is to prepare teachers to address the needs of all students in their classrooms. The program assists teachers in working specifically with children learning English as their second language. The overall goal was to develop a high quality program delivered to a large number of educators in an economical manner. The implementation objectives were: 1) to use distance education strategies to deliver an ESL endorsement program on-site to the schools and 2) use a collaborative model in program design, course development, program management, and decision-making. The brief program description below highlights these two implementation objectives.

ESL Endorsement Program: The program consists of eight graduate level courses (26 semester credit hours). These courses are delivered to different teaching sites in one rural and five urban school districts. The DEEEP school districts comprise about 75% of Utah's public school population. There are three courses in Year One delivered using satellite technology and on-site facilitators. Because of the heavy theoretical base of the courses in Year Two, the program developers decided that these courses should be delivered using on-site instruction provided by clinical faculty members from the Department of Linguistics. Year Three consists of three courses delivered to the participants through video-based instruction, web-enhanced curriculum strategies, and on-site facilitators.

Collaborative Model

In operation since 1989, the Utah Education Consortium (UEC) is funded through a joint effort by the Graduate School of Education, the Utah State Office of Education (USOE) and the participating school districts (Davis, Granite, Jordan, Murray, and Salt Lake). An executive committee governs the Consortium consisting of district superintendents and associate superintendents, coordinated from USOE, the dean and associate deans of the Graduate School of Education, and each department chair.

During the past several years, the executive committee of the Utah Education Consortium explored possibilities and guided efforts to develop an ESL program for their educators. As a result, an ESL Task Force was formed and composed of the five district bilingual/ESL coordinators, University of Utah professors from the Departments of Educational Studies, Linguistics and Special Education Program, and key university administrators. From September 1997 through June 1998, Task Force members created DEEEP by planning and overseeing the implementation of all logistical tasks, program design, course development, contract negotiations, personnel selections, and participant recruitment.

Integration of Multiple Technologies

The courses and instructional strategies were designed around several general principles. First, the courses needed to reflect the quality of university graduate level courses. Second, the
courses needed to provide educators with knowledge and strategies relevant for K-12 classroom teachers. Third, the distance education strategies should allow course instructors to teach high quality content to a large number of participants while providing consistent and manageable content and course organization. Fourth, the pedagogy should lead the technology decisions. The resulting program design provided a varied and integrated use of technology and instructional strategies. The program content and distance education delivery strategies are organized into a three-year format based on the four program design principles. The description outlines the program year by year. Additionally, a very brief section describes the program's web site.

Year One

The program participants are taught three courses. These courses are Multicultural Education, Bilingual/Bicultural Education, and Second Language Learner Methods. Each course provides 3 semester credit hours. The courses are delivered to 17 teaching sites in six school districts. Approximately 20-25 students and one on-site facilitator participate at each teaching site. Two courses (Multicultural Education and Bilingual/Bicultural Education) are taught consecutively during fall semester. Each course is 7 ½ weeks long, taught two days/week from 4:30 - 7:30 p.m. Spring semester is host to the Methods course taught one day per week for three hours. Year One courses were taught to 240 students during the 1998-99 school year. Year One courses were repeated to a new group of students during the 1999-00 school year.

Each teaching site is equipped with a satellite dish and receiver box. During the 1998-99 school year, the Year One courses were delivered through the Educational Management Group (EMG) Corporation. EMG was an educationally oriented technology company dedicated to producing and broadcasting educational programs to public schools. Because of corporate restructuring, Pearsons Publishing Corporation obtained EMG and dissolved it. After extensive contract negotiations between the University of Utah, EMG and Pearson representatives, an amended contract with Pearsons provided only satellite transmission of live broadcasts by the EchoStar Corporation. DEEEP tapes, for the Year One courses (1999-00) would be distributed to the teaching sites.

From January 1998 through May 1999, EMG curriculum designers and videographers worked closely with the course professors to create 17 Utah-based videos for a wide range Year One topics. Most of the videos are approximately 20-35 minutes in length. Course professors developed video scripts and gave final editing approval.

A 3-credit semester course at the University of Utah is composed of approximately 33 "contact hours" (university instructor and student contact). The Year One DEEEP courses consist of 10 hours of live professor broadcast time, 3 hours of video broadcast time, and 20 hours of group work and assignments guided by the on-site facilitators. Although the satellite transmission allows for only one-way audio and visual, interaction between students/facilitators and the professor during the broadcast times is achieved through the use of a dial-in 800 telephone number connected to the professor at the University of Utah broadcast studio. Students call in with questions, comments, and reactions to specific professorial directives.

Each course has a Facilitator Guide and Student Guide that outlines each class session's instructional events, group activities, assignments, expectations, and reading assignments. Master ESL teachers from the school districts serve in the role of on-site facilitators supporting student learning and developing a community of learners. The course instructor and 20
facilitators met approximately for 2 days prior to the beginning of each class for the purpose of
the discussing and coordinating class objectives, assignments, and activities. Facilitators and
course professors also met occasionally throughout the duration of the course as well as
communicated almost daily through email interactions.

Year Two

Because the two courses Graduate Survey of Linguistics and the Pedagogical Structure of
English (both 4 semester credit hours) are primarily foundation-type courses, Task Force
members believed that these classes should be taught with face-to-face instruction by clinical
faculty. Like all DEEEP courses, these two classes are taught on-site in designated schools.
The first group of 240 students is enrolled in these courses during the 1999-2000 school year.
The second group of educators/students will complete the courses during the following school
year.

Year Three

The last three courses of the endorsement program incorporate a variety of distance
education technologies and strategies. Working with the University of Utah's multi-media and
broadcast personnel located in a division called Media Solutions, the project directors and course
professors are creating the most technically sophisticated and innovative instructional
components of the project. Currently, in the design and production phases, the three courses will
be on-line for the 2000-01 school year. Year Three courses (all 3 semester credit hours) consist
of Content-Based Language Teaching, Minority Language Issues and Materials
Development/Practicum.

All three courses are being designed using Lotus Learning Space as a framework.
Students access course content and resources through web-based curriculum. Interaction with
course professors, on-site facilitators, and students occur in both synchronous and asynchronous
environments. Video developed specifically for these courses is either streamed through the web
site or provided on-site. For all three courses, there will be approximately 2.5 hours of originally
produced video and 17.5 hours of edited and repackaged short and long video clips obtained
from a variety of sources.

The Year One teaching sites and on-site facilitators will serve as Year Three teaching
sites and personnel. While specific class dates and times for these courses will mirror the first
year schedule, students will also be able to access the materials at times convenient to their
schedules and locales. Email and web-site communication sectors will provide interaction
between professors, facilitators, and Year Three students. In addition to the designated DEEEP
teaching site, all participants will have computer access at their own work sites located in the
elementary or secondary schools. Many students/educators also have computer access in their
homes.

Web Site

The DEEEP web site will provide an array of information and communication links for
program students and those interested individuals not directly involved in DEEEP. Expected to
be on-line around June 2000, the site will enhance the quality of the endorsement courses by
creating an electronically connected learning community. DEEEP students, professors, and
facilitators will be able to engage in conversations through structured class activities or student
Initiated chat sessions. Additionally, open web areas will encourage more free-flowing conversations between DEEEP participants, district ESL coordinators, interested teachers, university faculty, community leaders, parents and K-12 pupils. All DEEEP web participants will be able to pose questions and offer solutions to a variety of ESL and classroom issues. Furthermore, the site will act as a resource area containing K-12 topics such as multicultural education and ESL lesson plans, strategies and classroom-based activities. The resource area will also encourage the exchange of cultural activities, events, and perspectives within the larger community.

Evaluation Findings

For this paper, the evaluation design focused on three major questions: 1) the quality of course instruction using multiple distance education technologies, 2) the effective use of multiple technologies and 3) the characteristics of quality on-site educators responsible for facilitating the technologies and instructional plan. The primary methods of data gathering for questions one and two were a questionnaire completed by all course participants, facilitator focus groups, and informal interviews with a variety of students, facilitators, technicians, and district personnel. For the third question, a research assistant conducted a field study of two teaching sites involving about 50 participants. The assistant used weekly observations and participant interviews as data collecting methods. The findings centered on Year One Courses for 1998-1999.

To understand the quality of instruction and the effective use of technology, course participants completed a 20 question survey administered at the end of each course. The questions covered specific areas of instructional strategies, professor effectiveness, on-site facilitator quality, learning outcomes and technology. The questions asked respondents to show strong agreement or strong disagreement to statements by circling a number from 1-7 (1 indicating strong disagreement and 7 strong agreement). Additionally, three open-ended questions were posed to understand the participants' perspectives of their belief systems as well as the relationship between course instruction to K-12 classroom teaching practices. Finally, general demographic information was obtained from the DEEEP students.

Demographics: On the average, there were 242 student responses per course. Of these respondents, 71% were female. Thirty-eight percent were secondary educators, 59% were elementary school teachers and 3% did not declare. Concerning years of teaching experience, 43% of the respondents had 1-5 years, 19% had 6-10 years, 17% had 11-15 years, 9% had 16-20 years, and 11% of the respondents had 21-31 years of teaching experience.

Course Quality: The participants' responses indicated that they perceived a moderately high degree of quality for all three Year One classes. Almost 98% of DEEEP participants agreed that courses would impact their teaching practices. There was an increased awareness of multicultural, bilingual and methodology issues. The overall mean response was 5.01 regarding the effectiveness of the course in increasing participant understanding of course issues. Additionally, the mean response was 5.7 for participants reporting on an increased knowledge of strategies. Similarly, when participants were asked to respond to the ways in which the multicultural education, bilingual/bicultural, and methods courses would impact their teaching practices, 98% provided positive remarks. Additionally, participants reported the courses would influence their teaching practices by averaging a 6.35 response, the highest response of all the questions asked.
Effective Use of Technology

Of all the evaluation questions, the technology questions consistency received the lowest ratings from students, facilitators, and instructors. Specifically, the question prompt of "satellite lectures were a useful instructional delivery approach" elicited a mean response of 3.67 on a scale of 1-7 indicating that participants were ambivalent about the usefulness of the technology. The second course respondents answered the same question with a mean response of 4.28, and the spring semester course students responded with a mean response of 3.73. In all cases, this technology question elicited the lowest mean average of the 20 questions.

Much of the dissatisfaction occurred because the satellite technology failed to function properly and consistently during the first four weeks of the fall semester course. All of the participants' complaints centered on reception issues of foggy images and poor audio reception. Occasionally, students missed the live and video broadcasts. While on-site facilitators were master ESL teachers and pedagogical leaders, they were not technically trained to troubleshoot and solve difficult satellite transmission and receive site challenges. However, working with EMG engineers, University of Utah broadcast technicians, and satellite repair people, teaching sites were fully operational by the start of the second fall semester course.

Quality of On-Site Facilitators

Several themes directly related to the use of multiple technologies emerged from the field observation work conducted at the teaching sites. First, distance education site facilitators must have cooperation and support of the school building principal and staff. Most facilitators were not classroom educators at the DEEEP teaching sites. Therefore, they needed to establish new and positive relationships with an unfamiliar building administrator and media center coordinators (satellite receivers were located in media centers). These school personnel were the first line of support for satellite and other technological challenges. Second, the actual teaching location must be physically comfortable and equipped with large television sets to view broadcast lectures and videos. Meeting in school auditoriums, cramped classrooms, or multi-purpose media centers distracts student learning and attention during satellite broadcast times. Third, while facilitators were chosen and should be selected because of their pedagogical leadership in adult education, they still must receive basic preparation in managing the technology. During the first few weeks of the fall semester Year One course, facilitators and program administrators were frustrated because the basic technology education received from EMG personnel seemed insufficient. Much of their dissatisfaction occurred because the satellite technology was new and not fully operationally at first. With increased familiarity and function, satisfaction increased among all participants. Throughout the remainder of Year One, facilitators were able to handle site technology problems with more confidence and ability because of increased experience and ease with the new delivery approach.

Note: The authors want to thank Troy Richardson, Research Assistant for his contribution to the evaluation data.

Creating Technology Workshops for Modern Language Professors

Lorraine Williams
Library Information Services
Saint Michael’s College
United States
lwilliams@smcvt.edu

Abstract: This paper describes the process of developing technology workshops for language faculty. First, brief needs analyses were collected to determine faculty preferences for workshop topics. Later, informal interviews were conducted with individual faculty members to learn in more detail about their pedagogical and technological needs. Workshops were designed and taught based on those results. Following the workshops, faculty members evaluated the usefulness of each session. This feedback was then used to improve future workshops.

Introduction

By 1998, the Language Learning Resource Center (LLRC) at Saint Michael’s College had been directed by a series of several employees on a temporary basis over a period of almost five years. When a new position was filled to direct the LLRC with the title Language Technology Coordinator, one of the main tasks of the job was to offer resources and services to better assist the faculty of the Modern Languages and School of International Studies’ English as Second Language (ESL) departments in the use of technology. Traditionally, these two departments had not used the LLRC in the same manner as was reflected in their differing styles of language teaching and in the differences in their respective students’ needs. The intensive ESL program is taught on a rolling enrollment basis with new classes beginning every four weeks, with students in classes six hours a day, while one hour, daily classes in Russian, Japanese, Italian, French, Spanish and German are taught during two sixteen week semesters. Reasons for taking language classes differ greatly as well. ESL students learn English primarily for academic purposes, i.e., to achieve a high enough proficiency level to study other subjects at an American university, whereas the American students, native English speakers, study foreign languages principally to fulfill a foreign language proficiency requirement for graduation. To determine which services and resources would meet the needs of both departments, the Language Technology Coordinator designed a needs assessment questionnaire.

The needs assessment questionnaire asked which tools instructors currently use and would like to use in the future. Questions were asked about the use of audiocassettes, audio CDs, videotapes, software, tools for materials creation, Internet tools and included an open-ended question asking about tools not listed in the questionnaire. The questionnaire was distributed to both language departments, which comprise twelve Modern Languages and thirteen ESL and MATESL instructors. Fourteen questionnaires were returned, evenly divided by department, with seven from each. Current use of technology in language teaching and expectations for future use varied widely between and among departments. Based on the questionnaire results as well as informal one-on-one interviews, the Language Technology Coordinator drew up a list of twelve workshop topics. The twelve topics were sent to instructors via email and further explained at faculty meetings so they could choose which they would like to have offered to them. In this way, the list was narrowed to seven workshops offered during the spring and fall of 1999:
Putting a course syllabus online using a web editor
- Using tracking and revisions features of word processing programs for teaching process writing
- Using alternate character keyboards for Modern Languages
- Creating online quizzes and tests using JavaScript templates
- Evaluating the software selection process
- Integrating Internet resources in language instruction
- Using computer mediated communication: email, threaded discussion, and online chat

Preparation for the Workshops

The first three of the seven workshops involved using features of software programs offered on a campus-wide basis. Step by step instructions for using these programs, developed by Library Information Services (LIS) staff, were posted on a Help Zone web site. These instructions, as well as the date and time of all seven of the workshops were advertised by email. For those who felt comfortable working on their own, these instructions were available for self-taught tutorials. Without the workshop however, discussion of the instructional rationale for why, when and how to use these tools was missing. The idea that each instructional tool should be assessed for its pedagogical usefulness before implementation was emphasized in each workshop as is recommended in the literature of language learning and technology (Bradin, 1999; Levy, 1997; Pusack & Otto, 1997; Warschauer, 1995). The three main goals of all of the workshops were:

- to establish a comfort level with the technological tool;
- to integrate technology into the curriculum; and
- to critically evaluate the use of technology. (Kassen & Higgins, 1997)

Materials for learning to use Hot Potatoes, the JavaScript templates for creating online quizzes, are available at the web site from which one can download the free software so preparation for this workshop did not involve much writing and research. The web site includes a Power Point presentation that offers general information about using the six software programs included in the Hot Potatoes suite as well as an online tutorial that explains how to use the software step by step. The process of downloading and installing Hot Potatoes requires decompressing files using decompression software. This process proved difficult for some instructors who learned to use the templates in one on one sessions, so the workshop facilitator copied all of the decompressed files needed to install the software to a zip disk for easy installation during workshops. Faculty members then used the disk after the workshops for installation on their office computers as well.

The final three workshops involved more research and planning on the part of the Language Technology Coordinator than the previous workshops did. The basic principles of using each tool were researched beforehand and then discussed at the outset of each workshop. Next, examples of how to integrate these tools into existing classes were given, which also needed to be collected ahead of time. For "Evaluating the software selection process," for instance, individual professors requested commercial software programs for learning specific skills, such as pronunciation. Instructors evaluated demonstration copies of these programs using three different evaluation instruments. These instruments were
discussed in terms of how well they assessed both the feasibility and quality of the software. Before this workshop, the facilitator researched the appropriate software programs, ordered demonstration copies, tested the software, and found evaluation instruments for assessing the software’s usefulness. Once the software programs were evaluated and compared, the faculty then discussed which particular needs would be served by these programs for achieving specific goals within the context of their classes. The “Integrating Internet resources in language instruction” workshop also required considerable preparation. Research was conducted into the various web sites available for language learning and appropriate ways to use them in the context of a given class, and an evaluation instrument was developed for assessing their usefulness in specific teaching situations, in much the same way as had been done for evaluating software.

The computer mediated communication workshop required research into the various modes of online communication, the development of written instructions for how to use them and guidelines for how best to integrate their use into existing classes. The Language Technology Coordinator made recommendations about how best to use chat rooms available to instructors, as well as how to create them. Threaded discussions can be created fairly easily using Microsoft Front Page, the web editor supported by Saint Michael’s College, so instructions for adding a threaded discussion to a class web page were written for this part of the workshop. Directions for how to use some of the features of Microsoft Exchange were also written, as well as ideas for how to integrate email into language learning classes following suggestions from Warschauer (1995) and Sperling (1998).

Conducting the Workshops

The Language Technology Coordinator led each workshop in the LLRC, a computer lab with 13 PCs and a ceiling mounted projector, at a date and time that would conflict with the least number of instructors’ schedules. For those who wished to attend, but could not, arrangements were made for one-on-one sessions at a more convenient time. The workshops began with presentation and demonstration, followed by opportunities for hands-on practice and discussion. Most lasted for an hour to an hour and a half. In all workshops except for “Evaluation of the software selection process,” the participants came from both the Modern Languages department and the School of International Studies. The software evaluation workshop was offered to each department separately, since the respective programs evaluated were not applicable to each other. What follows is a description of the way in which each of the workshops was conducted.

Using class web pages seemed to be a daunting task to many language professors since only a few class web pages had been produced by a few of the early adopters in their departments. (Jaffee, 1998) While many instructors were adept at searching the Internet for personal and professional reasons, most did not feel capable of creating a web page of their own. To lessen the anxiety level, the workshop was advertised as “Putting a course syllabus online using Microsoft Front Page” rather than “Creating a class web page.” The Language Technology Coordinator found many opportunities in informal conversation with instructors to reiterate that the workshop could be viewed as a first step toward developing a more elaborate class web page. Since most already used a word processor to create syllabi, converting these files to html format would be easy. Instructors were asked to bring their
sylabii on disks and had filled out an application for a web page before the workshop took place. The facilitator explained the basic principles of using Front Page to the participants and outlined the goals of the workshop: to create a homepage, organize information using a table on that page, add a graphic image, include a link to a syllabus page and a mail-to link. Step by step, using printed instructions with screenshots as a guide, professors were taught how to create their pages.

“Using tracking and revisions features of word processing programs” was offered to instructors teaching writing in language classes at the intermediate and advanced levels. Process writing is an approach to teaching writing that involves stages of planning, drafting, revising and publication. These word processing features allow instructors to make editing comments as part of the process of revising and draft writing without changing the original student text. Instructors are free to write as much as they wish without the restrictions of the margins or the stigma of the red pen. The comments can then be offered as a means to improve subsequent drafts, rather than an evaluation at the end of a finished product. (Grabe & Grabe, 1998) Additionally, these features create a system for keeping track of student drafts to easily review changes.

The use of different character sets for typing in languages other than English had been a source of problems for many of the Modern Languages professors at Saint Michael’s. Suffering through frequent operating system changes and several word processing programs, professors had nearly given up on ever having a consistent set of keyboards to allow them to type easily in the languages they teach, much less having tools for student writing. In 1998, a set of keyboard sets for use with Windows NT 3.5 was purchased and installed. Instructions for their use, along with screen shots of the keyboards were made available to instructors. In addition, it was discovered that the proofing tools (spell check, thesaurus and hyphenation rules) for Spanish, French and German purchased for use with an earlier version of Word would work with Word 97. Instructions for using these tools were written as well. A few one-on-one workshops for using the character sets and proofing tools were offered for those who did not feel comfortable using the instructions on their own. Workshops for using these tools were again offered, this time to classes of students, co-conducted with their language teachers.

Hot Potatoes, a suite of six authoring programs based on JavaScript templates, were developed Arneil, Holmes and Street of the University of Victoria Language Centre. The programs were designed to allow language instructors to easily create their own exercises and quizzes, including cloze, multiple choice, matching, short answer, scrambled sentences and crossword puzzles. Since several instructors indicated a desire to learn how to create their own exercises with immediate feedback and had realized the shortcomings of exercises included in commercially produced software, a set of tools that allowed them to create exercises based on their own choice of content was deemed appropriate. This workshop required two 1 ½ hour sessions to cover the tutorial as well as enough time to practice using four of the six programs.

In the past, commercial software selection for use in language instruction had been a process conducted by individuals within the department of Modern Languages, and by small groups of instructors within the School of International studies. In neither department had a formal selection process with a true evaluation procedure been implemented. Budget changes indirectly forced such a process upon the faculty to some extent when the Library Information Services department became the sole purchasing center for the college and
created a mandatory acquisition procedure that includes critical questions about the necessity and feasibility of using software programs. While the decision to purchase and use a software program lies with the individual instructor making the request, assuming there are no budgetary or technical prohibitions, the role of the Language Technology Coordinator is to guide language faculty in the selection of software to meet their pedagogical goals. Workshops to assist in this acquisition process serve to demonstrate new programs as well as to involve instructors in the process of evaluating these programs.

Ongoing discussions about the kinds of software programs used in language teaching, individual recommendations, as well as the results of the needs questionnaire were used to determine which programs to order for review. Instructors were asked to read articles (Bradin, 1999; Healey & Johnson, 1997; Robb & Susser, 1999) about selecting and evaluating software before the workshop. During the demonstration of programs, each instructor was asked to answer portions of three different evaluation instruments (Bradin, 1999; Healey & Johnson, 1997; Long & Johnson, 1994) in order to assess the usefulness of each program. These instruments included questions about pedagogy, preparation, technical requirements, program design and operation, preview options, pricing options and support issues. Fewer software purchases were made after these workshops than during the previous year without the workshops, as problems were identified during the evaluation process.

It is only in the last two years that language instructors have begun integrating Internet resources into their classes. Four modern language professors have not only put their syllabi on class web sites, but have links to sites through which students complete tasks necessary for homework assignments. For example, a French professor has her students visit online French clothing catalogs and select a wardrobe appropriate to a particular geographic region and season with a limited amount of French currency. This use of authentic materials and tasks provides opportunities for language learning that are not possible in regular classroom-based settings. (Vosniadou, 1994) The impetus for searching for ways to include Internet resources in teaching language, then, like the use of other technologies, has been primarily peer-driven at Saint Michael's College.

The workshop entitled Integrating Internet resources in language instruction began with tours of the course web pages of the instructors' peers to highlight how they had integrated information from the Internet. The discussion then expanded beyond the use of email and links to reading, writing and listening practice pages to include tips for how to use the Internet as a source of authentic material for preparing lessons as well as an interactive medium for student learning. Possible uses included accessing Lexis Nexis and other subscription databases for foreign language articles, finding pictures and music, making use of online news sources, finding an authentic audience for student writing, and using online maps. Finally, textbooks designed for use with Internet sites were displayed for possible adoption and to demonstrate additional ways to integrate online resources. These included Dave Sperling's Internet Activity Workbook and Internet English by Gitsaki and Taylor, which both make use of companion web sites. The companion web site for Prentice Hall textbooks for foreign languages were also demonstrated to make instructors aware of the lesson plan ideas available there as well as additional practice material for students. For evaluation of all of these sites for language teaching, instructors were prompted to ask themselves many of the same kinds of questions they asked when evaluating software, such as those about technical requirements, usefulness in achieving student goals, authenticity of material, difficulty of level of language, etc.

Incorporating email, online chat and threaded discussion into classes recently became important to SIS professors as some began the process of redesigning their MATESL teacher training classes for distance education. As a few of these instructors started experimenting with adding these forms of communication to their face to face classes, in anticipation of conducting classes completely online, others realized the need to educate themselves about possible applications for their classes as well. Most professors already understood how to use email for sending student writing to teachers, posting to discussion groups and sending announcements to students. What teachers wanted to know was how email differs from asynchronous threaded
discussion and synchronous online chat forums. This workshop opened with demonstrations of class web sites using email and threaded discussions to illustrate how they might be used to extend in-class discussion. A hands-on session in a chat room followed, with online classroom management issues as the topic for discussion. Finally, instructors were directed to a Library Information Services web site where they could find instructions for how to create threaded discussions using Microsoft FrontPage and sites to create their own chat rooms.

Conclusions

These workshops were rated highly in anonymous evaluations for usefulness, quality of delivery and content, averaging 4.5 on a scale of 1 to 5, but suffered from low attendance. Although many professors wanted to attend and learn about these various uses of technology, they could not find time in their schedules between publishing projects, administrative duties and heavy teaching loads. Others preferred to have one on one instruction. Of these professors, some clearly indicated that they felt more comfortable learning individually, some wanted to learn more slowly and others simply wanted a different date and time. After the workshops, between one third and one half of the attendees said they were using the tool learned in their teaching.

Future workshops will be ongoing and offered each semester. Some of the original seven workshops will be repeated to reach those who want more practice, were unable to attend earlier sessions or were previously not ready to learn to use a new resource. Since many teachers preferred individual sessions, even if the number of attendees is low, the workshops will not be postponed or cancelled, as is the policy with other technology workshops offered at Saint Michael's. The workshops will be improved in a number of ways. Although attendees often had to leave immediately after the sessions finished, they also said they wanted more time with each tool. In response to this feedback, some workshops, such as “Integrating Internet resources,” will be divided into two sessions for a slower, more thorough treatment of the material, as well as to allow for more practice time. In addition, a three part series of workshops will be offered on the use of Microsoft Front Page for creating class web pages, including useful links, and adding a threaded discussion page. A three part series with workshops given every two weeks will allow for additional practice of skills that will build upon each other over a six-week period. This series will be offered during the last six weeks of a semester to prepare for the following semester. An additional change will be to include some of the language professors as co-facilitators in more of the workshops, as some feel more comfortable learning from colleagues than those they see as technology experts. The most important lesson to be learned from offering these workshops was that giving instruction in the use of technology is a process, rather than a project with a beginning and an end. This process will continue on as many different levels as there are individual professors with expanding needs and varying levels of experience with rapidly changing technologies.

Educating Foreign Language Teachers in Instructional Technology:
A Report on Faculty Development at the University of South Carolina

Jessamine Cooke-Plagwitz
Mimms Language Learning Center
University of South Carolina
United States
jplagwitz@sc.edu

Abstract: Foreign language instructors are some of the most innovative teachers in education today, and educational institutions worldwide are encouraging their foreign language faculty to increase their use of technology in the classroom. To that end, the University of South Carolina has created a new role for the Academic Director of its Foreign Language Learning Center. One of the key aspects of the position involves conducting a series of instructional technology workshops designed specifically for foreign language faculty. This paper is a report on the nature and design of these workshops, who is taking part in them, and how those participants are then subsequently incorporating what they have learned into their own classrooms.

Introduction

In their article, “Teacher Training for CALL and its Implications”, Curtin and Shinall (1987) assert that “to ignore advances in technology is to be left behind” (p.256). This is especially true for today’s teaching faculty. Not only do instructors in traditionally technological fields, i.e., physics or engineering, need to be current in their knowledge of instructional technology, but faculty in the humanities and social sciences are now equally expected to incorporate technology into their curricula. This challenge fills some faculty with a sense of dread, afraid, as they are, that the computer will sound the death knell for their profession, while in others, it incites a whole new love of teaching and curriculum design. What accounts for the former’s “technophobia” is often the result of a lack of familiarity with very basic technology. A substantial percentage of the teaching faculty in humanities programs has followed traditional “book-based” programs. This is especially true of foreign language teachers. There are still relatively few institutions in North America that offer an instructional technology component to their graduate programs in foreign language. Such programs tend to be literature-based, and, if there is any teacher training at all for graduate teaching assistants, it is often woefully lacking in any mention of or instruction in CAI or other technological applications for teaching. Nevertheless, asserts Michael Bush (1997), “ready or not [. . .], technology will play an ever-increasing role in each of our institutions. It therefore behooves foreign language education professionals to better understand technology and its potential for foreign language learning” (p. xiv).

The result of the present system is that many foreign-language Ph.D.’s enter new assistant professorships without having any real knowledge of technology-enhanced instruction. Furthermore, the pressure placed on new faculty to produce a significant amount of research in order to attain tenure does not leave them with much time to try out new technologies or to be particularly creative with their teaching. Many of the same traditional departments that do not offer adequate training in teaching with technology are also reluctant to accept research done in this area as meeting the criteria for tenure: “Without an excellent research record, one cannot expect a promotion in other than teaching institutions. However, in teaching institutions the teaching load is so high [...] that there is insufficient time” (Solomon, 1994, p.29). Thus the cycle continues.
A New Approach

How, then, do we remedy this situation and assist foreign-language faculty in incorporating technology into their curricula? The University of South Carolina in Columbia has addressed this concern by creating a new job-description for the Academic Director of its Foreign Language Learning Center – a position that I have recently filled. While the position to this point has been more or less strictly administrative, the new job description calls for a foreign language professor as well. As the new director, I, myself, graduated from a literature-based program with very little technology involved in my instructional duties. However, my first post-graduate teaching position involved establishing a German program at a small, two-year college in Georgia. This first assistant professorship afforded me the opportunity to become knowledgeable in many areas of instructional technology. Not only did I do fifty percent of my teaching via interactive distance learning, but I also established a Macintosh-based foreign language lab and a German-studies Web site. The nature of my first teaching position helped me to become proficient at technology-enhanced instruction and, as such, to move into the area of faculty development, where I have held several workshops for faculty in all areas of instruction.

In addition to fulfilling the traditional administrative role of center director, the new position carries an instructional component. As director, I must teach one course per year in my area of expertise, in this case German or French language, and must design and hold a series of faculty development workshops covering a variety of topics in instructional technology.

According to the Department of Education's 1993 paper, "Using Technology to Support Education Reform", the challenges faced by today's faculty include:

- Learning to use a variety of technology applications;
- Using, adapting, and designing technology enhanced curricula to meet students (sic) needs;
- Expanding content knowledge;
- Taking on new roles; and
- Responding to individual students.

Furthermore, Kassen and Higgins (1997) include the following necessities in their list of requirements for faculty development programs:

- Establishing a comfort level with technology;
- Integrating technology into the curriculum;
- Developing the critical skills to use technology effectively. (p.264)

These are the criteria to which I adhere in designing my faculty development workshops. In this first year of the new directorship, most of the workshops will illustrate elements of computer-enhanced instruction. In later workshops, such topics as using audio and video resources in the foreign language classroom will be addressed. The first three workshops I conducted concentrated on uses of Microsoft PowerPoint in the foreign language classroom. Other workshop topics include a series on teaching with the World Wide Web and hypermedia, web course delivery software, html editors and other web development software, authoring programs and courseware creation, and how to work effectively with email and discussion groups. My intention is to provide the foreign language faculty at the University of South Carolina with as much variety and as many topics as possible in the workshop series so that they will be able to decide for themselves which applications fit best into their curricula and teaching styles.

The Workshops

Workshops are set up in the following manner: notices are sent out a month in advance of each workshop, and faculty members are asked to sign up to participate. Attendance is generally capped at ten so that there is adequate time and space for each participant to receive individual attention. The workshops are held in the Foreign Language Learning Center Computing Lab. Participants each work on their own computer, and, depending on the subject of the workshop, are able to choose between PC and Macintosh.
platforms. The instructor machine is connected to a MediaPro LCD projector, and the desktop image projected onto a screen. Workshop participants are asked to follow along with the instruction for the first half of the workshop, and are then "turned loose" in the second half and encouraged to work on their projects on their own. This format has proven to be the most effective in helping faculty to master new software applications. The hands-on structure of the workshop allows them to follow along with the instructor step-by-step, and to learn the basic functions of the new program. Having them subsequently work on their own allows them to learn for themselves further capabilities of the new program while at the same time permitting them to create language-specific materials that they can use in their teaching. Each workshop is tailored towards foreign language faculty and their specific needs. For example, PowerPoint and Web-design workshops include modules covering foreign language fonts and Web-based information sources for individual languages and cultures.

One of the more important aspects of incorporating new technologies into the foreign-language classroom involves identifying student needs and subsequently tailoring the use of technology to them. For example, the student who is a visual learner will likely respond more positively to a multimedia-based grammar lesson that includes several colorful illustrations, while a student who learns a language more easily through aural channels may prefer an application with plenty of audio examples, and so on. The workshop series takes these particularities into consideration and illustrates teaching techniques that utilize several media. Individual professors are free to design their projects using as many or as few media types as they wish. Naturally, in the area of foreign language instruction, audio is the most commonly utilized medium. Video, too, is becoming more and more popular as MPEG cameras come down in price and products such as Real Networks' Real Publisher make digitizing video easier. Naturally, the more media types an instructor can include in her educational materials, the more students she will reach and, thus, assist in language acquisition.

Evaluation

An important aspect of any educational venture is ascertaining whether, in fact, the material covered by one's students is actually learned, and, in the case of faculty development, subsequently used by instructors in their classrooms. In order to measure these criteria, the following questionnaires are distributed to workshop participants, a) immediately after the workshop (Fig. 1), and b) at the end of the semester following the workshop (Fig. 2):

<table>
<thead>
<tr>
<th>Question</th>
<th>Av. Response (24 Respondents)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The workshop was helpful to me.</td>
<td>1</td>
</tr>
<tr>
<td>I will use the technology covered for my teaching.</td>
<td>1.5</td>
</tr>
<tr>
<td>The material covered was easy to follow.</td>
<td>1.16</td>
</tr>
<tr>
<td>I would recommend this technology to my colleagues.</td>
<td>1</td>
</tr>
<tr>
<td>I would like to learn more about the technology covered.</td>
<td>1.3</td>
</tr>
<tr>
<td>I plan on incorporating more technology into my teaching.</td>
<td>1.3</td>
</tr>
</tbody>
</table>

Figure 1: Questionnaire A – distributed immediately after the workshop.
In which workshop(s) did you participate?

<table>
<thead>
<tr>
<th>1=agree strongly</th>
<th>2=agree</th>
<th>3=disagree</th>
<th>4=disagree strongly</th>
<th>5=no opinion</th>
</tr>
</thead>
</table>

I have used the information learned in the workshop(s) I took.
I used the project(s) I produced in the workshop(s) in my teaching.
I regularly use multimedia in my classroom.
Since taking the workshop(s), I spend more time in the Language Center.
I encourage my students to submit their assignments electronically.
I require my students to work in the Language Center.
My students receive an orientation to the Language Center each semester.
I plan to continue using technology in my teaching.
I plan to take more instructional technology workshops.

Figure 2: Questionnaire B – distributed at the end of the semester following the workshop.

As the workshop series has only been ongoing for one semester, questionnaire B has not yet been distributed to foreign language faculty. Initial results of questionnaire A are promising, however, and workshop attendance has progressively increased throughout the course of the semester. While the results of these surveys do nothing to indicate the efficacy of the various technologies used, one must recall that the ultimate goal of these questionnaires is to ascertain whether foreign language faculty are increasing their use of technology both in terms of quantity and variety. Accurate measurements of technology’s effectiveness in improving language learning are notoriously difficult to attain (see Ehrmann 1997 & Trotter 1999), and will not be sought in this series of evaluations.

Conclusion

Traditionally trained foreign language faculty must be given the opportunity to develop their teaching skills in a non-threatening environment where support is available if it is necessary, and where creativity is encouraged and appreciated. All too often, faculty balk at attempting to incorporate technology into their curricula because the amount of technology available is too staggering and the amount of time necessary to learn it is simply unavailable. A program like that currently in place at the University of South Carolina removes some of the unknowns that prevent many instructors from introducing technology into their courses by letting them take the technology for a “test drive” ahead of time. Teachers are free to use the technology introduced according to their own personal instructional needs and wishes. Moreover, while individual departments often hesitate to purchase equipment such as scanners and digital cameras along with large presentation programs for only a few interested faculty, housing such tools in a central location such as the Language Learning Center, allows faculty from all language departments access to them when they need it. Ultimately, I hope that all foreign language faculty at the University of South Carolina will feel comfortable enough with instructional technology to make it a part of all of their courses. In the meantime, it is encouraging to see language professors attending the workshops, working in the faculty development center, and taking an interest in what they can do with technology in the classroom, as

1855
well as what technology in the classroom can do for them.

Abstract: Directed Reading Thinking Activity (DRTA) is a teaching strategy used in English language classrooms through using predicting questions to enhance students’ thinking. Since it is very important for Mandarin language teachers to incorporating thinking into classroom activities, so students can analyze, synthesize, and evaluate information, instead of just drilling information. We conjecture the DRTA can also be used for the Mandarin classroom activities. In this paper, we first describe how the DRTA can be used in the Mandarin classroom to foster students’ divergent thinking with the integration of IT tools. Secondly, we will discuss recommendations for implementation of this approach.

Introduction

Directed Reading Thinking Activity (DRTA) is a teaching strategy developed for enhancing students’ thinking in the English language classroom. We conjecture it can also be used for the Mandarin language class. In this paper, we explore how DRTA can be used in the Mandarin classroom and how IT tools can be used to enhance this strategy and thus students’ divergent thinking.

Singapore is a multi-cultural society and English is the main vehicle of communication among different ethnic groups (e.g., Chinese, Malay, Indian, Eurasians). Also, being an international business center, English is the most common language used in the commercial sector. In Singapore schools, according to Soh and Chia (1997), English is the primary medium of instruction for its practical value, and the mother tongue (i.e., Mandarin, Malay, or Tamil languages) is taught for its cultural significance.

On the issue of learning the Mandarin language, many people still perceive it primarily to be a process of information receiving. This approach has been effective for exam-driven type of learning. Pupils learn the Mandarin language by memorization, accept what they are told and do not ask many questions. However, in this learning process, little thinking is fostered, especially divergent thinking (Chen, 1998). Research has shown that pupils who did well in the curriculum-based tests fail to perform well on life-based
One possible explanation of this discrepancy is that “Mandarin language lessons tend to be more teacher-centered than student-involved” (Soh & Chia, 1997, p. 82).

Lin (1997) suggested that one way to move from teacher-centered to student-centered pedagogy is to encourage students to think actively. Through active participation in the thinking process and by expressing their thoughts using Mandarin in a lively way, pupils can improve their mastery of the language, and develop their thinking ability. Therefore, it is important for Mandarin language teachers to incorporate thinking strategies (e.g., DRTA) into their Mandarin language lessons.

In addition, IT is perceived as a potential tool to encourage and promote pupils’ thinking (Jonassen, 1996). This article proposes an IT-enhanced DRTA that can be used to foster students’ divergent thinking in the Mandarin Language Classroom.

In this paper we first introduce what DRTA is. It is followed by the discussion of potential limitations of implementing DRTA in the Mandarin language classroom. We then suggest two IT-enhanced solutions for DRTA. Finally, recommendations for implementation of this approach are discussed.

**Directed Reading Thinking Activity (DRTA)**

One of the strategies used by Singapore English teachers to develop students’ thinking is DRTA (Tan, 1996). The DRTA is a group comprehension activity that emphasizes the use of predictive questions at the beginning of a story and throughout the reading process (Stauffer, 1980). Many researchers agree that predicting is a fundamental part of the process of comprehending and it should be a strategy regularly used in reading discussions (Person & Fielding, 1991). The DRTA involves breaking a story into sections, and students are encouraged to predict possible outcomes before reading selected sections in the story. Students are encouraged to make use of story clues, own life experience, and prior information. After the prediction, students read the story to prove or modify their hypotheses.

In contrast with traditional comprehension questions which students have to look backward into a story, DRTA increases children’s motivation to read because it arouses their curiosity and involves them actively in discussing it, rather than simply answering a teacher’s question about the story. Specifically, potential benefits of using DRTA are threefold (Temple & Gillet, 1996):

- Foster divergent thinking at the outset (title, illustrations, or small parts of the text)
- Develop convergent thinking as more information unfolded
- Develop inferential and critical thinking throughout the process

**Potential limitations of using DRTA in Singapore Mandarin language classroom**

Although DRTA is good strategy for fostering students’ thinking in English language classroom, there are some potential limitations of using the DRTA in Mandarin language classroom:

- Large class size causing lack of divergent thinking
  The average class size in Singapore primary school is forty students per class. In the predicting stage, if the teacher has to write down all the possible predictions, it will be quite time-consuming. Hence, most students may remain silent because the class size, and the time-limitation only allows the teacher to write out a few predictions on the blackboard. This would defeat the training of developing divergent thinking.
Students’ prior access to stories leading to lack of motivation
The use of DRTA is currently adopted in Singapore English Language classrooms. The materials are pre-printed onto the students’ worksheets booklet known as the PET’S worksheet. In English Language classroom situation, some faster readers are able to read ahead and know the whole story while they are waiting for the slower ones to complete the required paragraph. The nature of using predicting in DRTA is totally killed when the students already know what will happen next in the story.

IT-enhanced DRTA

IT is perceived as a tool which provides students with opportunities analyze, synthesize, and evaluate information in new ways. The tool may offers students practice with certain cognitive strategies for making use of information. These strategies may be important for developing students’ thinking (Sheingold, 1991). The following points discuss the use of IT tools to enhance the effectiveness of DRTA in CL classroom:

- Fostering divergent thinking and promoting active discussion
  The SmarttSchool system is classroom management software. It allows the teacher to broadcast multimedia materials to one, selected or all students. The Mandarin language teacher may pair up the students for discussion and keying in their predictions using the same terminal. The teacher can easily view and project the students’ computer screens onto all students. At that moment, all students can view other students’ predictions and the teacher may ask students to elaborate or explain their thinking behind their predictions. Through SmarttSchool, the teacher could involve more students in the discussion. Therefore, development of divergent thinking is greatly enhanced through the multitudes of variations in the predictions from students, instead of the three or four using the traditional chalk and board approach.

- Restriction of student access to stories to sustain students’ learning interests
  PowerPoint is a multimedia presentation package that allows teachers to produce their presentation slides including in a variety of formats, such as graphics, texts, sounds, video clips, or animations. Using PowerPoint would be a solution for preventing the students reading ahead and knowing the ‘standard answers’. The story would not be printed on the students’ worksheet, but stored in the teachers’ computers. The teachers would present the story, already broken up into different slides through the PowerPoint and show the students only the slide they are required to read. This would maintain students’ learning interest on the ‘suspicion’ of the story while they eagerly predict the next outcome.

Recommendations for Implementation

In order to use IT-enhanced DRTA successfully in Mandarin classroom, there are a number of recommendations for Mandarin teachers to keep in mind (Temple & Gillet, 1996).

- Prepare prerequisite computer skills and knowledge
  The teacher should have PowerPoint and Chinese word processing skills and knowledge. S/he should ensure that students are familiar with Chinese input, so they can key in their answers into their terminal.

- Select fiction rather nonfiction
  It is more difficult to ask pupils to predict what might happen next with nonfiction than in fiction, because the nonfiction is organized differently from fiction. Instead of encouraging pupils’
predictions, the teacher wants them to recall and organize what they already knew in nonfiction. Therefore, the fiction is more appropriate for the DRTA.

- Prepare key questions for prediction. Table 1 lists some key questions for predictions.

<table>
<thead>
<tr>
<th>Stages</th>
<th>Key questions to ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>Look at the title</td>
<td>What might this story be about?</td>
</tr>
<tr>
<td></td>
<td>Will it be a true story?</td>
</tr>
<tr>
<td></td>
<td>How can you tell?</td>
</tr>
<tr>
<td></td>
<td>How can we find out if our predictions are correct?</td>
</tr>
<tr>
<td>Look at the illustrations</td>
<td>What do you think now?</td>
</tr>
<tr>
<td></td>
<td>Do you still think it is a ....?</td>
</tr>
<tr>
<td></td>
<td>What might you find out by reading this story?</td>
</tr>
<tr>
<td>After reading one section of the story</td>
<td>Where does the story say that your predictions are correct?</td>
</tr>
<tr>
<td></td>
<td>Do you like what the author is doing with the story?</td>
</tr>
<tr>
<td></td>
<td>Would you like to change any part of the story?</td>
</tr>
<tr>
<td></td>
<td>What would you write next if you were the author?</td>
</tr>
</tbody>
</table>

Table 1: Key questions to ask at different stages

- Ensure students work collaboratively
  After presenting a question for prediction, the teacher should instruct students to think about possible answers to the question for one minute roughly. Then the teacher pairs the students up and instructs students to discuss in pairs and key in their answers on their terminals. The teacher may ask students to elaborate or explain their thinking behind their predictions.

- Accept all predictions without adding any evaluation
  The teacher should not indicate which predictions are better than others. “Guessing right” is not necessary in the predicting. It is more important for students to come up with possible and reasonable alternatives

- Should not use value terms
  Instead of using terms, such as right or wrong, the teacher may use likely, unlikely, or confirmed.

- Respond positively to all students’ efforts
  Most of Singapore students feel predicting is quite risk-taking. If the teachers can keep giving reinforcement for taking risk of making predictions, students will be more willingly to do it again.

- Have a postreading discussion
  It is important for students to do reflective thinking after a story is completed. Students may evaluate strategies how the group used story clues to make predictions.

- Plan follow-up activities.
  The follow-up activities could be comprehension questions, or ask students to identify events in the story in the chronic order by doing a story map.
• Use audio clues and hyperlinks for comprehension
  Inserting story audio allows students to recognize the pronunciation of the word to enhance their reading comprehension. In addition, using hyperlinks within the text, teachers can explain difficult words which students may face, so students can concentrate on the meaning of the passage.

Conclusion

In Singapore schools, traditionally, most students learn Mandarin language through rote learning, so that they may perform well in tests and examinations. However, this approach focuses less on divergent thinking and application of the Mandarin language outside the school context. Hence, it is very important for Mandarin language teachers to incorporating thinking into classroom activities, so students can analyze, synthesize, and evaluate information, instead of just drilling information. With the integration of IT tools, the DRTA has a high potential be used effectively in Mandarin language classrooms to enhance students’ divergent thinking through active participation.

Abstract:  
It is not difficult to see why the World Wide Web is the latest technological favorite of the educational literature and educational policy makers. Here is a media that can be used as a library, a publishing house, a television, a television broadcast station, a radio, a radio broadcast station, a postal service, a telephone, and as an interactive practice quizzing station. The diversity of the Web is awesome. But to what extent is the Web being used to learn in new ways and to what extent is the Web merely a case of old wine being packaged in new bottles? To ascertain the difference the Web is making in the learning process, this paper will examine the use of the Web in two technology rich classrooms, one a foreign language classroom, the other a history classroom.

Introduction

Networked communications have a fascinating pedigree. In 1961, Leonard Kleinrock published a paper entitled “Information Flow in Large Communication Nets”. The paper essentially introduced the idea of networked communications on computers. Four years later Thomas Merrill and Lawrence Roberts set up the first WAN (Wide Area Network) between the MIT Lab and a California organization. In that same year, Ted Nelson also introduced the word “hypertext”. Four years later, in 1969, the first ARPANET was created between Stanford, the University of California at Los Angeles, the University of California at Santa Barbara, and the University of Utah. In 1971 ARPANET grew to include 15 sites and in 1973, ARPANET expanded to include two international nodes: one at the University College of London in England and one at the Royal Radar establishment in Norway. 
Even with an international networking of computers, no one was yet speaking of the Internet. The term Internet was first used in a scientific paper in 1974 (Cerf and Kahn). Then the break-through. In 1989 at the European Particle Physics Laboratory (CERN) in Geneva, the British computer scientist Tim Berners-Lee developed a protocol that he
called the World-Wide Web. The growth of the Web has been astonishing. In 1994 the number of pages on the Web grew at a mind-blowing rate of 341,634% per year (Anderberg 1999). The advent of Web browsers such as Netscape and Microsoft's Internet Explorer really opened up cyberspace. In the fall of 1994, there were somewhere around 10,000 Web sites around the world. By 1998, there were over 10,000,000!

For the last two decades, educational literature and educational policy makers have been singing the praises of computers. By 1992, speeches stressing the necessity of introducing computers in schools had already become firmly anchored in the political landscape as the President's National Education Goals and AMERICA 2000 Education Strategy makes clear. The goals of that program emphasize the importance of preparing this nation's youth to be productive and thoughtful adults, able to compete successfully in a global economy and to exercise the rights and responsibilities of citizenship, is a key objective of the President's National Education Goals and AMERICA 2000 Education strategy. Achieving this objective will require education students in the uses of computers and other new technologies which are opening career possibilities unheard of just a few years ago.

(U.S. Department of Justice 1992: 2)

American governmental organizations have invested heavily in the effort to place computers in the nation's schools. "There was a time when computers were a luxury item for American schools, but that time has clearly passed." (Bangert-Drown, Kulik, and Kulik 1985 - cited from Cotton K. nd). The use of microcomputers first expanded rapidly during the 1980s (Cotton K. nd). Between 1981 and the end of the decade American schools acquired over two million microcomputers. The placement of computers in schools has escalated even further since. In 1988-89, there was one computer for every twenty-two students in America's schools. By 1995, there was one computer for every twelve students (Hayes & Bybee 1995).

The Internet is the latest technological favorite of the educational literature and educational policy makers. In 1996 President Clinton made schools' connection to the Internet a national priority.

In our schools, every classroom in America must be connected to the information superhighway, with computers and good software, and well-trained teachers. .... I ask Congress to support this educational technology initiative so that we can make sure this national partnership succeeds.

(President Clinton 1996)

Clinton's Internet initiative has had mixed results. Internet access in public schools increased from 35 to 78 percent between 1994 and 1997. That said, Internet access in classrooms falls far short of Clinton's hopes. In the fall of 1997, only 27 percent of instructional rooms had Internet access (National Center for Educational Statistics 1998).
It is not difficult to see why the World Wide Web is the latest technological favorite of the educational literature and educational policy makers. Here is a media that can be used as a library, a publishing house, a television, a television broadcast station, a radio, a radio broadcast station, a postal service, a telephone, and an interactive practice quizzing station. The diversity of the Web is awesome. But to what extent is the Web being used to learn in new ways and to what extent is the Web merely a case of old wine being packaged in new bottles?

Historically, as Marshall McLuhan often reminded us, we tend to fill a new medium with old content. Early films seemed like recorded plays. Television was treated like illustrated radio. Word processors were thought of as fancy typewriters (i.e., as still working on paper documents.” (Marcus 1999). The differences that the Web makes in education may be characterized as the difference between learning on the Web and learning through the Web. In learning on the Web, students and teachers use the Web much as they would use another vehicle. A game of concentration placed on the Web to drill French vocabulary items might be an example of learning on the Web. The exercise merely replicates a game of concentration that might be played with cardboard French vocabulary cards. In learning through the Web, students and teachers use the Web in quite a distinct way that is not easily replicable through other media. Take the game of French vocabulary concentration again. If that Web-based game pronounced the vocabulary items each time they came up, it might be offering students something quite distinct, namely an interactive, multi-media resource with both a visual, textual, AND audio component.

To better ascertain the difference the Web is making in the learning process, this paper will examine the use of the Web in two technology rich classrooms, one a foreign language classroom, the other a history classroom.

Use of the Web as a library-like resource center

The use of the Web as a library is almost certainly the most common use of the Web and the experiences of the French classroom and the history classroom are quite similar. The traditional French and history classrooms rely almost completely on textbooks. The Web-connected French and history classrooms do not even use a textbook. Instead, they rely primarily on resources available through the Web. Does this use of the Web as a library fall into the category of learning on the Web or learning through the Web?

Almost certainly the greatest impact of the Web on the history classroom experience has been in the breadth of materials students have to draw from. For instance, in the history class, the Web enable students to carry out in-depth examinations of 18th and 19th century explorers that would otherwise have been possible only with access to a fairly sizable college library. In particular, the Web enabled students to study half a dozen female explorers of that period, women assuredly less important in their immediate impact than many of their male contemporaries, but on the whole, far more remarkable and intriguing.
Perhaps more noteworthy, though, are the individualized learning experiences the Web has allowed. Rather than being limited to four core eighteenth, nineteenth, and twentieth century explorers about whom a school library has sufficient resources, there is now sufficient information to sustain studies of two dozen explorers. Students can choose who they wish to study and tailor their studies to their interests. Thus, a student intrigued by Asia might choose Sir Edmund Hillary, while a student with her eye on Africa might choose Mary Henrietta Kingsley. Finally, the Web seems to allow far greater adaptability to multiple intelligences than would otherwise be available.

A significant advantage of using the Web as a library in French class is that it offers extensive access to complete, authentic texts as opposed to “prefabricated” texts that give a false sense of the language and culture. The use of the authentic texts — and lots of them — provides exposure to a full range of authentic cultural experiences in the foreign language.

A second significant advantage of using the Web as a library in French class is that it compensates for the fact that the normal American school library will have few texts written in a foreign language. Teachers and students can now access complete French literature texts as well as secondary literature in a mouse click. See for example, the primary and secondary sources on Jean-Jacques Rousseau’s Confessions at http://www.lettres.net/confessions/

A third significant advantage of using the Web as a library in French class involves the dynamic features of the Web. The Web creates more discovery-based opportunities than a conventional foreign language textbook offers. For instance, in one French class, the teacher created a web page with two frames. One frame contained the authentic text, the other frame contained questions that help students to pick up linguistic and/or cultural information embedded in the authentic text. An activity using this two-framed method to introduce a unit on hotels may be found at http://faculty1.caryacademy.pvt.k12.nc.us/fabienne_gerard/cyberbook/activits/hotel/carliton_hotel.htm

An activity created to introduce a unit on politics may be found at http://faculty1.caryacademy.pvt.k12.nc.us/fabienne_gerard/cyberbook/activits/politique/inst_default.htm

A fourth significant advantage of using the Web as a library in French class revolves around the interactivity features of the Web being used to provide quick translations. See for instance the document from AZURLINGUA de Nice et le CIEL de Brest at http://www.bonjourdefrance.com/n4/a11.htm.

Use of the Web as a teacher and student publishing house
The Web offers a rich variety of media for students to present their understandings of material. Thus, in both the history and French class, students might make a presentation on their understanding of explorers in a variety of media. One student might create a PowerPoint posted on the Web about his explorer. Another student might create a radio show reporting on the challenges faced by the explorer and on the explorer's triumphs and failures. A third student might create a pretend radio interview with the explorer for broadcast over the Web. A fourth might create a photojournalism essay on the explorer and post it on the Web. A fifth might even create a conventional essay and post it on the Web. What one sees here is a case of the Web offering the unique ability to cater to students with multiple intelligences.

The Web seems to be extremely effective as a publishing house for teachers to present assignments and supplementary materials. Both French and history classes present their homework and supplementary materials on web pages. This use of the Web helps students do their work. Students lose handouts. Fifteen years ago, the in-item on school campuses was something called a Super Trapper, a Velcro notebook that promised never to lose one's papers. One might think of the Web as the ultimate Super Trapper.

Many teachers also use the Web to publish what might be thought of as flat activities, that is activities without hyperlinks and that need to be printed to be completed. These flat activities are particularly prevalent in foreign language classrooms. Examples of flat activities may be found below.

Use of the Web as a radio, an audio archive, a television, a video archive, and a visual museum from which to draw information

The Web is a multi-media resource. In French class, students make particular use of online audio archives and online radio broadcasts to enhance students' skills in aural comprehension. In history class, students use audio materials found on the Web for entirely different purposes. For instance, students use the Web to listen to recorded speeches and songs such as the Marseillaise. These uses of audio bring the history alive, though their role in many cases merely replicates that of a CD player. That said, the Web does offer the unique opportunity for students to practice materials introduced in class at home. For instance, history students in one class are required to memorize the Marseillaise in French and to sing it to the Berlioz tune. They can only get sufficient
practice to do this effectively by listening to the music through a connection to the World Wide Web from home.

The quality of video broadcasted over the Web is of less help at present as video broadcasts are still of rather poor resolution. Nonetheless, videos are of some use in foreign language classrooms where they help students’ develop their skills in oral comprehension. This is especially important in that it allows students to work on their oral comprehension at home through a connection to the Web. Videos available on the Web are also excellent transmitters of cultural information. One French class has made use of a video clip of a Renault commercial that shows the sorts of cars people drive in France. An example of useful video clips filmed and posted by a teacher may be found at Marie Pontario’s terrific web site at http://www.cortland.edu/flteach/civ/vacance/vacan.htm)

Both the history and French classes make extensive uses of the Web as a visual museum from which to draw information. When studying World War I, for example, history students look at Expressionist paintings posted on the Web to get a better understanding of the disillusionment that followed the war. In French class, the web pages of French clothing designers help students expand their vocabulary, as well as to develop that all-important French sensibility for fashion.

Use of the Web as a radio station or television station to broadcast information

The web may also function as a radio station or television station used to broadcast information. Few history or French teachers seem to have made many recordings of moving video images for their classes. Similarly, history teachers seem not to make many audio recordings for their classes. By contrast, foreign language teachers seem to make extensive use of this recording capability. Foreign language teachers frequently use the audio recording feature to record morphemes, phonemes, isolated vocabulary items, and texts. For examples, see Léon’s web page at http://www.jump-gate.com/languages/french/french1.html, Gérard’s at http://faculty1.carvacademy.pvt.k12.nc.us/fabienne_gerard/voca/novice/chp1.htm, or Scheffel’s at http://anarch.ie.toronto.edu/people/patrick/site/html/Simplicite0CM.html

Use of the Web as an interactive practice quizzing station

The Web may function as an interactive practice quizzing station. "Interactivity" is defined here as a dialog activity between the user of the computer and the machine itself through a screen. Once again, foreign language teachers find themselves using a technology little used by history teachers. In French class, multiple choices, fill in the blanks, and matching activities make use of the interactivity offered by the Web. All those activities give immediate feedback to the students. The feedback can be more or less extensive. The feedback might simply note whether the response was right or wrong. The feedback might provide the correct answer. Or the feedback might give not only the correct answer, but also an explanation for why that answer is correct. The advantage of these activities is that the student can have an independent language learning-experience.
Some examples of multiple choices activities in foreign language may be found at the pages below.

Conclusion – Nouvelle Avenue or Vieille Avenue?

In many ways, the World Wide Web has mimicked old ways of learning and teaching, but done so in ways that make the learning and teaching process somewhat easier. The use of the Web as a library, the posting of homework and supplementary materials on the Web, the use of the Web for so-called flat activities, the use of the Web for drills, and the use of the Web as a visual museum are all examples of how foreign language and history classes have merely married old ways of learning with a new technology.

In many other ways, though, the information highway created by the Web has opened up new avenues of learning and teaching. The use of authentic texts on the Web, the use of a range of texts which would not otherwise be readily available, the use of audio and video archives available through the Web, and the broadcasting of phonemes,
morphemes, and vocabulary items on the Web are instances in which the Web has transformed not only what may be learned, but more fundamentally, how it may be learned.

Thus far there has been more learning on the Web in history classes and more learning through the Web in foreign language classes. This may not always be so. The use of the Web by teachers and students is constantly changing. As Seymour Papert remarked, "[i]n the presence of computers, cultures might change and with them people's ways of learning and thinking." (Papert 1993: 23).

Abstract: I-MAESTRO, part of the suite of tutors developed by the Fundamental Skills Training Project, is an intelligent tutoring system designed to deliver adaptive, individual training to increase writing competencies anywhere, anytime via the Internet. I-MAESTRO is an adaptive, supportive learning environment for strengthening the critical thinking skills associated with varying writing tasks. Its comprehensive instructional approach provides instruction in the three stages of the writing process: prewriting, drafting, and editing. While this instruction takes place, the computer-based tutor provides individualized adaptive advice at critical points in each workspace. Incorporating motivational features that address individual characteristics such as learning styles and interests, I-MAESTRO presents dynamic interfaces, tailored instructional modules, and tutoring advice statements. The student's writing process is monitored and coached by an intelligent advice system. I-MAESTRO supports expository, persuasive, research, and practical (business letter, cover letter, memo, and e-mail) writing styles with over 100 challenging, multimedia writing assignments.

Introduction

In recent years much attention has been spent researching the effectiveness of implementing educational technologies, especially distance learning/education. Primarily the effectiveness studies have consistently demonstrated that when used in business, military training, and adult learning, there is no significant difference in effectiveness between distance learning and traditional instruction methods, and student attitudes are generally positive about the experience (http://www.usdla.org/). However, most of this research has been conducted at the collegiate level. Unfortunately, the majority of the efficacy research conducted in the K-12 population has been extremely limited. The existing research, project evaluation, and anecdotal evidence on this population strongly suggest that distance education, in the appropriate environment, is an effective means for delivering instruction just as it has been proven effective in adult learning and training settings (http://www.usdla.org/).

In 1998, with distance learning gaining recognition and accreditation, the Air Force Research Laboratory and the Department of Labor Employment and Training Administration (DOLETA) began a collaborative effort to develop, evaluate, and transition/transfer adaptive Internet-based training systems. Motivated by three related national-level initiatives including the Department of Defense's Advanced Distributed Learning Initiative (ADL), the America’s Learning eXchange (ALX) project, and the Instructional Management System (IMS) project the Air Force's Sustainable Intelligent Training Systems for Global Mission Applications (SIGMA) project was created. SIGMA seeks to provide instructors with the availability of Intelligent Tutoring Systems (ITSs) delivered via the
Internet that have been developed on sound theoretical framework, has proven results, offers instructors in the high schools and Job Corps Centers with a form of distance learning, and provides learners with the opportunity to "learn anywhere anytime."

Background

Since 1990, the Air Force Research Lab and the University of Texas at San Antonio, have been engaged in a long-term research project (Fundamental Skills Training Project) to bring state-of-the-art intelligent tutoring technology to bear on our nation's growing literacy skills problem in areas such as mathematics, writing and science. After nine years of evaluation of the local-area- network (LAN) based intelligent tutor systems, The Word Problem Solving Tutor (WPS), Maestro: the Writing Tutor, and the science tutor, (Instruction in Scientific Inquiry Skills) the Air Force has begun a new endeavor to develop intelligent tutoring systems which are delivered via the Internet.

Software Description

I-Maestro is a student-oriented writing process tutor that facilitates learning through a series of instructional presentations and writing process workspaces. Students complete the assignments in workspaces that, when properly used, help the student acquire the skills underlying effective composition (including goal-setting, generating and organizing ideas, generating a writing plan, drafting, revising, and publishing). I-Maestro guides the learner through the writing process by scaffolding expert support. During use of the I-Maestro composing workspaces, the student’s writing process is monitored, and the student is coached by an adaptive advice system.

I-Maestro includes: 1) tailored instructional modules (TIMs) that are adaptive to the interests and learning styles of individual students for each stage of the writing process; 2) student-controlled workspaces designed to facilitate the development of skills associated with the stages of the writing process; 3) situated assignments that help motivate the students to use the workspaces by using multimedia-based realistic writing tasks; 4) an adaptive advisor that tutors the students by providing diagnostic advice, selecting appropriate TIMs, managing workspaces, and monitoring student progress during assignments.

Advantages of an Internet Writing Process Tutor

I-Maestro has the same instructional approach as the LAN version. In addition, I-Maestro has the capability to deliver adaptive individual training to increase writing competencies anywhere, anytime. I-Maestro operates utilizing a client-server architecture (see Figure 1). The student work is stored on the server side; therefore users can run the software regardless of their location.
Another advantage of I-Maestro is that it is JAVA based and is therefore is a cross platform application. Furthermore, this design is consistent with the ADL initiative which seeks to ensure access to high-quality education and training materials that can be tailored to individual learner needs and can be made available whenever and wherever they are required (http://www.adlnet.org/).

A review of software industry trends indicates that many companies believe that an object-based approach facilitates software reusability needed for the large-scale development and dissemination of powerful and cost-effective applications. These factors are considered essential for the sustained investments necessary to create the kind of dynamic ADL environment that is needed to meet the education and training needs of a 21st century military and national workforce (http://www.adlnet.org/). I-Maestro fits these needs as it platform independent and the software reusable. Currently, it appears that the development of a robust object-based and platform-neutral environment, such as I-Maestro, for distributed learning will become widely implemented over the next 2-5 years.

Lastly, I-Maestro allows teachers to share assignments that they develop. The teacher tool allows the user to add, delete, or modify the assignments in the class lessons. The I-Maestro software also allows teachers to author their own assignments. The instructor may add text files, graphics, or videos to one of the one hundred existing assignments or to one of their own. Teachers will then have the option of uploading the new assignments to a server which will hold a generic pool that will be available for instructors to download and use anywhere anytime. I-Maestro will be distributed with over 100 assignments dealing with expository, persuasive, research, and practical writing assignments.
Implementation

In addition to making this new Internet ITS available to the host of Fundamental Skill Training Sites in the public schools, the SIGMA project has selected a test and evaluation (T&E) sample of 5-7 Job Corps Centers (JCCs) to participate in implementing and evaluating the software. AFRL in conjunction with DOLETA selected the T&E sites so that the entire set has a mix of characteristics. This mix includes student/client demographics, their needs for seeking training, the use and/or availability of technology at that center, and a supportive and cooperative administration towards the use of technology. The current JCCs have each sent two instructors for training and have implemented the three LAN-based FST tutors in those centers. This has allowed the centers to address implementation of technology issues prior to the use of the Internet-based version of the writing tutor. Concurrently, AFRL has been developing and testing the Internet-based version of the writing tutor. After the initial studies, the Internet-based version of the writing tutor will be installed on a Job Corps Data Center server for use by the center instructors and students.

Summary

The development and integration of instructional software has been impeded by many factors such as a lack of standards that would permit sharing across institutions and across a wide range of technical environments (http://www.imsproject.org/). In addition, finding relevant, valuable, and interesting information on the Web is a difficult process due to the lack of an inherent structure or standards for describing available content.

The future of educational software being delivered via the web is dependent on several factors including increasing access, implementing standards, improving quality, and reducing costs of learning environments. Much progress has been made on the hardware side, especially in terms of the global networking potential for linking learners, teachers, and providers of materials and services (http://www.imsproject.org/). What is needed, however, is an increase in the availability of effective distance learning software.

It is through the efforts of the Department of Defense, the White House Office of Science and Technology Policy (OSTP), the ADL initiative and the IMS project that effective software may be created. Software, as guided by the above initiatives, will ensure access to high-quality education and training materials that can be tailored to individual learner needs and can be made available whenever and wherever they are required.

The Professor, the Bookie, and Technology: A Terrific Trio for Developmental Reading and Writing Students

Rose Yesu, English Department, Massasoit Community College, USA, ryesu@massasoit.mass.edu
Jennifer Rudolph, Learning Resources, Massasoit Community College, USA, irudolph@massasoit.mass.edu

Abstract: Critical thinking serves as the foundation for strong, effective reading and writing. And, as the authors of this paper discovered, technology and electronic library resources are excellent vehicles to improve the critical thinking, reading, and writing skills of underprepared community college students. After a brief overview of research on the interrelationship between and among critical thinking, reading, and writing and a mention of the research on the effectiveness of technology to improve the critical thinking, reading, and writing skills of underprepared postsecondary students, the authors discuss their collaborative efforts to implement this research in the community college classroom. The team also shares some library-based projects that incorporate electronic resources, promote critical thinking, improve reading and writing skills, and foster diversity.

Background Information

The work that the authors do as a team is based on the research that finds that critical thinking serves as the foundation for solid reading and writing skills. They’ve also based their work on research that demonstrates that building students’ fund of general information enhances and strengthens students’ reading and writing skills. In addition, their work with developmental reading and writing students stresses the interrelationship between and among critical thinking, reading, and writing. Finally, they began to emphasize and integrate more and more electronic resources into their developmental reading and writing assignments after they read a Chronicle of Higher Education article that touts the Web as an effective tool in developing students’ critical thinking and writing skills (McBride and Dickstein, p. B6).

The authors build critical thinking into all their assignments through the use of Benjamin Bloom’s taxonomy of cognitive skills (1956). Burmeister’s adaptation of this taxonomy (1976) serves as a guide for their research and as a barometer for all their assignments.

The team builds students’ fund of general information through a wide range of print-based or electronic-based assignments. Both work. However, one of the major benefits of electronic library references is that students gravitate to materials at their independent reading level. Because the Professor stresses the interrelationship between and among critical thinking, reading, and writing, her writing students often remind her that she’s teaching a writing, not a reading course, and her developmental reading students often complain about the amount of writing they’re required to do.
Birthday Assignment

In 1982, the Professor developed her very first electronic-based library assignment. The birthday project asks students to find a copy of either The Boston Globe or The New York Times on the day they were born, read it and then either write one paragraph summaries of the front page and two other pages or write an essay that summarizes the front page and two other pages, or write a comparison and contrast essay that compares and/or contrasts the newspaper on the day the student was born and the students' last birthday. This particular project has had many lives. The Professor first introduced it to her developmental reading classes, then to her English Composition I classes, then to her developmental writing classes. She uses this assignment to introduce students to the library and its many resources and to make sure that each student has a library card.

The Professor and Joanne Jones, a senior reference librarian at Massasoit, developed the birthday assignment before the Bookie's tenure at Massasoit Community College began. Their objectives were to incorporate the technology of the time - microfilm - into class assignments, to involve students in locating information, to provide an assignment with student interest, to give students library experience, and to encourage critical thinking.

Considering the giant leaps the form of knowledge has taken over the past few years -- CD's and online sources - - it seems strange now to think of microfilm as "technology." However, this one assignment became so popular with instructors and students alike that it was, and still is, used in many courses at the College.

Newspapers provide a current source of information and are particularly suited to developmental reading and writing assignments. The articles in the papers are short with a lower level vocabulary, giving students early success in their course work. And, for the birthday assignment in particular, the College's newspaper backfiles to 1851, leaving no one's birth date out.

In addition, using the newspapers in the Professor's birthday assignment create interest and a different assignment for each student. On occasion, students find a film reel missing, so the Bookie suggests substituting a different date for the birthday. Because the assignment loses something in this, students prefer a substitute date, a first birthday, for example.

Over the years, Massasoit looked at newer technologies -- CD-ROM's, online sources, subscription services, the Internet, and the Web. Like other college and university libraries, Massasoit had trials with different vendors and discussions about products in the library and at Board of Trustee meetings. Like other colleges and universities, some administrators were not sure that they wanted to spend the money needed on products they saw as relevant only in research universities and libraries.

However, because the librarians and faculty persevered, the College acquired newer technologies - some CD products, online subscription services, and Internet access. As the College acquired these formats, the library staff and faculty saw a rise in student interest. The new technologies did not, however, affect the birthday assignment. There were limited backfiles for the birthday assignment until a few years ago. Now, the Library's CDs and some online sources include access to information back to 1980 - the birth year of the College's traditional entering freshman class!

With this first library assignment, the Professor gives a lesson on plagiarism and citing references using material from Diana Hacker's Rules for Writers (1996) and a lesson on evaluating website sources. All electronic resources must meet the Professor's approval and be turned in with the completed assignment. If the Professor suspects a student has plagiarized, she simply checks the material attached to the assignment. Finding plagiarizers is easy: students who plagiarize usually highlight, underline, or circle the material they're copying.

When the Professor's classes go to the library, the Bookie reinforces the idea of crediting sources. The Bookie also feels strongly that if students search online, they should learn how to tell the difference between good and bad sources of information. Therefore, the team worked with the idea of source evaluation. Although important when using a print source such as a newspaper, evaluation becomes critical when electronic sources are added to the mix. Students need to be fully aware of the idea that online sources provide a vast array of information -- some are not good choices for a college paper; others excellent. While subscription services have a built in safety -- reliability -- as the sources used are recognizable publications, the Web includes information from everywhere and from everyone.

The College's library home page includes a link to several evaluation sites - a good beginning for students. Some Massasoit professors have created evaluation sheets for their classes and the library has put
together, from several sources, an evaluation checklist. Students who carefully evaluate their sources improve their computer skills, critical thinking skills, and their reading and writing skills.

Five-Year Career Plans

The team's second tried, but true and about to be retired library-based assignment focuses on three, five-year career plans. After students complete the Harrington-O'Shea Career Inventory (1998), they select three careers that interest them and research them for the following information: specific career title, education required, area colleges which offer the appropriate courses and/or degrees, skills required, work experience required, demand now and anticipated demand in five years, and annual income now and expected income in five years. Again, this assignment has many lives: the first in the Professor's developmental reading classes, then in her basic writing classes, then in evening English Composition I classes, then back to her developmental reading classes, now in her freshman seminar classes. Although the Professor has had her students write a five-paragraph essay for this assignment — the three different careers in the body of the essay — she generally has them write a paragraph for each career. She recently added an interview paragraph and found it so successful that she's decided to incorporate it into the assignment. In this paragraph, the students summarize an interview with someone in their chosen fields that includes the following information: official job title; time in service; required training, education, and experience; personal qualities and skills need for the field; specific responsibilities; salary range; what interviewee likes most and least about his/her job.

As the Professor's career assignment evolved over time, library sources kept pace. From the beginning, the College's library included new career sources in its acquisitions. The College is, after all, a community college and found that, in addition to enrolled students, community groups needing access to career materials used the Library as a resource. The College's counseling center acquired the Discover (1999) database that allowed students to take an interest inventory and skills profile to determine a good career fit. The same database provided career exploration for students.

The library put together a career guide - first for print sources. Then, as the library acquired computers with online capabilities and as the librarians became more and more computer literate, they included both print and online sources to assist students in their career searches. The guides included web addresses that linked students to the online Occupational Outlook Handbook (1999) and the Dictionary of Occupational Titles (1999). The address plug-ins are a safe way for students to explore the web.

National/International Issue

The third library-based assignment revolves around major national or international issues. The Professor asks students to select a major national or international issue that interests them, to read extensively on the subject, to formulate a position on it. Then, students must write a well-organized 350-400-word essay in which they clearly state the issue and argue their position on this issue. Both members of the team caution students that they must base their arguments on fact, not emotion. The facts for their argument must come from at least three newspaper and/or magazine articles, and these articles must be stapled to their papers. Students' essays must include in-text citations and a Works Cited page. Traditionally, this assignment serves as a final examination.

Evaluating Journalists

The next two library-based assignments are relatively new and inspired by Alexander and Lombardi's Community of Readers (1997) and Brenda Smith's, Bridging the Gap, texts the Professor uses with her lower and upper level developmental reading classes. The first - evaluating journalists - received raspberries from students — much too hard and long, they whined until the Professor thoroughly reviewed the difference between fact and opinion and denotative and connotative meaning of words. Also, the team and their students discussed vacuous papers: shallow, hollow, superficial essays and paragraphs. To help students with this assignment, the Professor had the students examine journalists' objectivity and subjectivity by critically analyzing various
newspaper and magazine articles. After much reluctance, students settled into the assignment and submitted, for the most part, well-documented, strong essays.

The Professor’s use of newspaper and magazine articles for research in this assignment means a class visit to the library for instruction in the use of our on-line subscription services. This is also a time to reinforce the difference between searching subscription services and surfing the web. When using a subscription service, such as InfoTrac Searchbank, students access information from recognizable sources – the New York Times, U.S. News and World Report, New England Journal of Medicine, etc. When surfing the web by using a search engine, such as Altavista, students access information from familiar and unfamiliar sources. If, for example, a student were to search the term “Y2K” in Searchbank, the results would include an article from the Washington Post entitled “A Glitch That Won’t Steal New Year’s?” Because the search was done in a subscription service, the student should feel comfortable with the source and the article. However, a similar search using Altavista brought up the “Y2K Survival, Food, Water and Protection Site”. This site advertises a one-page “kit” of information, has little information about the author(s) and appears biased. Students are encouraged to use a variety evaluative techniques to assist them in making good choices.

Diversity in the Armed Forces

The diversity assignment, the final library-based assignment discussed in this paper, received an A+ from students. In this assignment, the Professor asks students to use print or electronic library reference materials and research diversity in the US Armed Forces during any three of the following military conflicts: the American Revolution, the Civil War, World War I, World War II, the Korean Conflict, the Vietnam Conflict, or the Persian Gulf Operation. Then, students must write a 350-400-word essay that answers the following question: During each military conflict, did the nation’s Armed Forces reflect the diversity of the country?

This is another assignment that uses Web address plug-ins. However, students, accessing the sites, find that there are many links to additional information about their topics. This assignment requires computer skills to move around the web sites and critical thinking skills to determine the relevance of information.

The first time the team used this assignment, the Professor and the Bookie found that students refine something besides their computer and critical thinking skills. When classes visit the Library, there are always more students than there are available workstations. Therefore, the Bookie assigns groups of students to workstations, making sure that each group has at least one computer competent student. In one class, Amelia, an insecure, but computer literate ESL student became the leader in her group and showed others how to manipulate the mouse, where to plug in the web addresses, how to move from link to link, and how to print information. By the end of the period, a beaming, confident Amelia realized that she became a star for that day and the team made its first accidental step into collaborative learning. With the Professor’s encouragement, Amelia’s confidence at the computer screen transferred to the classroom where she became more willing to contribute and a more successful student.

The Professor, the Bookie, and Technology: The Future

Gradually, the Professor plans to move away from developmental reading texts like Brenda Smith’s Bridging the Gap (1997) and Alexander and Lombardi’s A Community of Readers(1997) to nonfiction books and a study skills book for her developmental reading classes and a grammar text and nonfiction books for her developmental writing courses. More and more, library-based assignments, specifically electronic reference-based assignments, will serve as the core for all of these courses.

Writing in 3-d: Using Simultaneous Media to Enhance the Quality of Student Writing

By Lawrence Baines, Berry College, USA, lbaines@berry.edu

Abstract: The traditional “process approach” to writing popularized in the early 1970s restricts students to two-dimensional conceptualizations in which the student must translate abstract thoughts into language. Students who are not particularly successful abstract thinkers do not improve the quality of their writing much using this model. Instead of the two-dimensional model, a group of “remedial” adolescents were given the opportunity to compose using a variety of visual, auditory and other sensory appeals. By utilizing simultaneous media, these “remedial” students were able to transcend the limitations of the two dimensional box and add depth and substance to their writing.

Despite the myriad recent advances in technology, most teachers still follow the process approach to teaching composition made popular through the National Writing Project some thirty years ago. Students brainstorm, draft, peer edit, then turn in their papers for a grade. Obviously, there is much to recommend such an approach. However, as a teacher, even the writing process was not sufficient to reach many of my students, especially those students who seemed to struggle with fundamental aspects of vocabulary and syntax.

For many students, writing is an arduous, frustrating process in which they are constrained by their current grasp of the language and their ability to build words into sentences, then sentences into paragraphs. From years of asking students to revise and reconceptualize their papers, I have come to understand that many students perceive that changing the word large to big or brave to courageous constitutes significant revision. For struggling writers, the process of revision seems even more unfathomable. Once when I asked a group of ninth graders to write a paragraph describing a pizza as accurately as possible, one earnest boy named Jake wrote, “It tastes great!”

I called Jake up to my desk and asked him, “If I told you this pizza tasted great, would you know what kind of pizza it was?”

“All pizza tastes great,” he said.

“But does it have pineapple on it or does it have pepperoni?” I asked.

“I like sausage and mushrooms,” he said.

“Aha! See, I couldn’t tell you were thinking of a sausage and mushroom pizza it was unless you told me that with words,” I said, convinced that I had finally broken through.

For five minutes, I noticed Jake at his desk thinking and writing. Finally, he brought his paper up to my desk.

“The pizza had sausage and mushrooms on it,” is what Jake had written.

Writing in two dimensions

A traditional two-dimensional diagram for the teaching of writing, the one that most teachers use, might look as follows:

Knowledge of the topic, ideas

Text creation

Mastery of syntax and vocabulary

The difficulty with the two-dimensional approach to teaching writing is that it relies upon talents that struggling writers have somehow never managed to develop over the course of their academic careers. To break out
of this routine, we performed a little experiment with a class of juniors in high school that utilized simultaneous media as a way of getting students to truly reconceptualize their thinking about word selection and placement.

The class with whom we chose to work was the lowest level English class at a high school in northwest Georgia. In terms of standardized test scores, these students ranked in the lowest 20% in the state. Although the class had an enrollment of 18, although only between 12 and 15 students would show up regularly. In this article, we will describe the experiment step-by-step and focus upon the works of two students, Derkis and Titus, who showed up for every period during the two weeks we worked with the class.

Derkis was a short, ebullient, young man who played halfback for the football team. Although he was the smallest player on the team, he carried the ball often and was so successful that he had become somewhat of a celebrity within the school. Although Derkis could be cooperative, he had much energy and would often get out of his seat and walk around the room just to expend energy. Sometimes, he broke into spontaneous raps in the middle of class. His teacher, a smart and innovative man, attempted to get Derkis to put his powers of rap to good use by creating and performing a song based upon Poe’s “The Raven,” which the class had studied earlier in the year. But, Derkis said that he preferred making up his own songs and declined.

Like Derkis, Titus had some major difficulties with writing and reading. However in addition to his obvious distaste for writing, Titus was one of the worst spellers we’ve ever seen. Although he seemed to have a relatively sunny disposition, Titus often acted bored and, at times, tried to sleep through class. At the time of the experiment, Titus was the only student in class who had not passed the composition exam with a score high enough to earn him a high school diploma.

The sequence of activities

The idea behind the experiment was to ascertain to what extent students could enhance the quality of their writing through the use of simultaneous media. In other words, we wanted to change the traditional approach to writing so that these students would draw on some of their talents outside of the purely linguistic realm. We wanted the students to write in 3-D. The 3-D approach might be diagrammed as follows:

```
Knowledge of topic, ideas

Text creation

    - mastery of syntax and vocabulary

Multimedia inputs
```

To get students to write at all, we knew we had to choose a topic to which they could relate, as well as one that they would want to share with one another. Also, we wanted a topic ripe for artistic interpretation, something that could be performed. After some discussion, a scripted poem was created with the topic of HOMETOWN. The format required students to write one line of text per prompt. The prompts were as follows:

Name of hometown
Two verbs that fit it
The landscape (hilly? Dry? Buildings?) - 4 words
Smell/tastes of your hometown - 6 words
Music, song, or sounds that remind you of your hometown - 8 words
King of people who live there - 10 words
An important event in your life - 12 words
Another important even (repeat the previous line if you can't think of anything else) - 12 words
A dream or nightmare - 10 words
After a discussion in which I reiterated that poetry used very descriptive words and pared down expression to the bare bones, I read the prompts aloud one at a time, giving all students ample time to respond before reading the next one. After I’d say the line, I’d write the prompt on the whiteboard as well. Sometimes students asked questions and I walked around the room to see what individual students were writing as they wrote.

When all students had finished the poem, I asked them to share what they had written with two other students. Next, I handed out a purposefully bad poem that I had written about my hometown of Dallas.

Dallas

Big, dusty
Flat and gray land
It smells like a bowl of soup
An old, out of tune guitar that plays
Nice people, old people, smart people, and friends
I got my driver’s license there when I was 16 but not before
I got a job that paid me $250 per week part time
A man with an axe was chasing me around a park
My dad used to be 6’5” and mean
Don’t do anything stupid, stupid
It’s cool
Dallas cools.

I asked students to find all the “wimpy words” in my poem Dallas and to suggest revisions. With students’ help, most of the nondescriptive words were replaced with more appropriate terms and some lines were rewritten completely. Then, I asked students to re-examine the HOMETOWN poems that they had just written and revise them individually as we had just done as a class with Dallas. I passed out thesauruses and encouraged students to “make every word pack a punch.”

Using the HOMETOWN format and this revising strategy, Derkis had written the following poem:

Rome

Cheers, bores
7 hills, small, nice weather, smells
sewage, rivers, chiitins
whopper, big mac, pancakes
dumpster beep, birds, sirens, barking, cats, screaming car horns, bus
mean, ghetto, friendly, talkative, nasty, tough, rough, poor, crazy, outrageous
scored my first touchdown of the year on a 58 sweep for 14 yards
I scored my second touchdown of the year when we played ringgold on 59 sweep for 28 yards
My dream is to go to FSU and play football and go to the NFL and play for the Dallas Cowboys.
An important person that I like is Bobby Bowden because he is the best college football coach alive
Never let anybody talk down on you, keep your faith.
Summer when it’s hot
Small rome.

Derkis felt pretty good about the quality of his poem. When I asked him if he needed to revise anything, he said, “It’s perfect, ain’t it?”

Titus’ poem is as follows:

Rome Southside

Small
Gray bumpy street curve
Fresh cold watermelon with hot cocoa
Dogs, cars, winos, train, radio, and the shower
Kind, friendly, outgoing, happy, relax, smooth, bout-bout, and fighting people
On a hot summer day when I first start to take my drive lessons
I first got my three wheeler and phone line for my thirteen birthda
My head was in a shoe box and someone were sticking knives in it
Martin luke king who sacrifice his life for all people.
Don’t go outside with your shoes off
Summer hot steaming weather
Wonderful georgia

As did Derkis, Titus felt fairly confident that he had created a solid poem, though when I asked Titus if he needed to revise anything, he said, “Is it bad?”

Infusing simultaneous media

To begin the next part of the sequence, I told students that I wanted them to illustrate each line of their poems. I brought in several stacks of magazines from the public and college libraries that were going to be thrown out, bunches of scissors, and told students to cut out images in the magazines that fit the descriptions from their poems. Also, I asked each student to draw at least one image themselves. For a day and a half, students scoured through magazines, cutting out photos, making drawings, trying to find images that could fit the lines from their HOMETOWN poems.

After they matched images to lines from their poems, I asked students to paperclip the line number to each image they found. They handed in their collected and numbered images on a Friday. Over the weekend, each set of images was scanned into computer images (either JPEG or GIF files) and inserted into a Powerpoint presentation in the appropriate order. The following Monday at school, we divided the class into four groups. One grad student (Fishel) took those students who had been absent the following week (only one student, it turned out) to catch up with the assignment, while I and two others worked with laptops, showing individual students how their images had been put into the Powerpoint slide format. The students were asked how they wanted to place the text on the screen, about font choice and size, and other matters of aesthetics. About half of the high school students inserted the text themselves. The other half asked me or one of the graduate students to do it.

At the end of the day, we told students that they would be presenting their poems in two days. For their presentations, we told them that they would be reciting their poems to the rest of the class while the images and the words from their poems were cast against a wall. We mandated that all presentations had to have some background music and that presentations should be dramatic and appealing. Students could bring their own music (though songs could contain no cursing or lewdness), or they could select from a variety of CDs that we would provide.

The next day was a final rehearsal day for students. No one brought their own music, so they all chose from among the CDs I brought with me -- Bob Marley, Celtic Harp, DJ bass, guitar and drum mixes, Beethoven, and other (mostly) classical music selections. Students fiddled with the final details for their presentations, listened carefully to a variety of musical selections, and rehearsed. We printed each student’s Powerpoint presentation (six slides per page) and handed them out so that they could practice. Every student in class seemed deeply immersed in the tasks.

For the presentations, we brought in a mini-amplifier and a microphone so that even those students who liked to whisper could be heard. The lights were lowered, the appropriate CD was played, and students recited their work while the images they selected shone against the wall – a scholarly bit of performance art.

In transferring his poems into a Powerpoint presentation, Derkis changed several of his later lines to better match the images that he found – the person he admired changed from Bobby Bowden to Michael Jordan for example because he couldn’t find any photo of Bowden. When learning that his words would be cast against the wall with a projection device, Titus became very conscientious about his spelling. He corrected watermelon (watermelon), luke (Luther), knives (knives), cocoa (cocoa), and deleted winos. For their soundtracks, Derkis chose the bass, guitar, and drum DJ mix and Titus chose a Bob Marley CD.
A return to words

For the final piece of the experiment, we asked students to consider their poems, the images they selected with their poems, and the music they selected to play in the background together. Then, they were asked to communicate the content of the images and the feel of the music back into their poems so that, through the meanings of the words alone, someone reading their poem could visualize the images and sense the sounds that might go with it. Surprisingly, students took to this task with much enthusiasm. They rifled through dictionaries, asked questions, worked very intensely for a day and a half to complete this task.

For his revised poem, Derkis wrote the following:

Rome vaults
Camper searches for the seven hills
Twang of Aunt Jemima’s pancakes in the a.m.
Nimbleness of cars on the highway out
Fastidious and pleasant, a token of remembrance
Milestone celebrated
Carrying pigskin for the seminoles
Hard worker, the desire to win
When people talk, I listen
To pick up stanzas
Hot sun, outstanding looking women
Atom-sized rome

Unfortunately, a day and a half were insufficient time for Titus to completely revise his poem. Although he worked constantly and meticulously during the class time, he never finished revising the second stanza. Still, the changes he made in his initial poem are striking. For his revised poem, Titus wrote the following:

Yearning rome
Small, stainless
Gray impulse street curve
Newness, cold pungent watermelon
Dogs barking, radio playing, shower raining
Smooth and relaxed
Excited when I first began my driving lesson
Thirteen with a three-wheeler and my own line

My head in a shoebox and someone sticking knives through it
Mlk who sacrificed a life
Don’t go otuside with your shoes off
Summer hot steamy
Astonishing rome

Advantages of a Third Dimension

In today’s media-enriched environment, the attention cues of many students begin with the eye and simultaneously engage the ear. Although movies, music, video games, and TV are often perceived as antithetical to students’ intellectual development, aspects of these media could actually enhance learning. During our experiment, using images and sound during the writing process stimulated student interest in writing and revision.

As students created HOMETOWN poems, they focused upon the prompts and their linguistic responses to them. In the next step, they made sure to select images that were reflective of what they wanted to communicate. In essence, the pictures served both as a bridge in the revision process and as a reference point between teacher and student. Instead of having no idea where to begin revising, students were able to use their self-selected images as focal points for the reconsideration of linguistic choices. Students would ask each other and the teacher how exactly to capture aspects of the images that they had selected into words.
Music enhanced the writing process in two ways. First, the music seemed to make it easier for many students to read their poems aloud. Shy or reluctant students who had not read aloud in years seemed fairly comfortable when they were accompanied by background music of their choosing. Second, the music added an intangible emotional quality to the experience that seemed to give students even more opportunities to attach nonlinguistic responses -- emotions, memories, and ideas -- to the existing work.

Although this experiment in using simultaneous media to enhance student writing was dependent upon technology -- laptops, a projection device, Powerpoint software -- much of the same effect could be accomplished through cutting and pasting paper or using videotape. The important lesson to be learned from the experiment with this class of remedial writers is that using simultaneous media seems to enlist students' visual and auditory senses in the cause of the written word.

Somehow, by using visual and auditory appeals, students were able to think in novel ways about their uses of words and the real meaning of what they wanted to communicate. Some teachers routinely go through the stages of the writing process as if it were some kind of inflexible process that will magically transform bad writing into good. Yet, the transformation in the quality of writing done by Derkis and Titus came about only after the use of multimedia prompts. Through their exposure to multisensory and simultaneous media, Derkis and Titus were able to reconsider their uses of language in ways that purely linguistic appeals would never permit.
Technology: The Answer to Early Literacy Success in the New Millennium

Dr. Jean M. Casey

"Imaginative progressive teachers who had computers in the classrooms and were prepared to give students the time and support to learn often created wonderfully fertile learning environments—children can learn to use computers in a masterful way; learning to use computers can change the way they learn everything else." (Seymour Papert, 1993, Mindstorms)

The first question administrators, teachers and parents ask is, "Will computers make a difference in the learning that occurs in the classroom?" Past studies failed to answer this question or answered it negatively because they used standardized reading test scores as their only measure. The Simi Star Project, a collaborative grant between six school districts and IBM tested the effectiveness of computers in the classroom and effects of integrating technology into the curriculum. As a University researcher and reading professor, I was asked to be the evaluator of the Simi Star Project. It resulted from a grant between IBM and Simi Valley, Ventura, Oxnard, Santa Barbara, Orcutt and Point Hueneme school districts all located in Southern California. Six networked computers were placed in 24 kindergarten and first grade classrooms to test integration of technology in the curriculum and measure the effect on writing and reading development of the students. I worked with a team of educators and developed a qualitative study to examine these classrooms. The software used in the study was Writing to Read, Stories and More, Children's Writing and Publishing. The teachers were carefully trained, parents were informed as partners, students were given daily access to the computers for writing their own language experience stories. The students also were given phonemic awareness and systematic phonics support. The researchers used observations, interviews, questionnaires, portfolio assessment as well as reading attitude tests to measure the students writing and reading development. The experimental classrooms were compared to control classrooms without computers but a similar approach to teaching.

The results were significant. All students in the experimental classrooms using Writing to Read, averaged at least two writing levels higher based on a holistic evaluation than those in the control classrooms. The experimental group had a significantly higher positive reading attitude score than the control group. (Casey 1997) Teachers and parents all rated this program excellent on a 5 point rating scale.

These classrooms became writing, reading and publishing labs; the teachers kept samples of the children's daily writing in portfolios that were used as assessment and in parent conferencing.

That was just the beginning. One computer in each room was connected to the Internet and children chose pen pals from other states and Europe. One kindergarten child proudly wrote his daily message to his friend in Alaska. A fifth grade classroom was working on a project about the world environment online with a fifth grade classroom in Paris, France. Children were not only experiencing the meaningful use of writing and reading, but developing life long friendships and understanding of children like them all over the world.

The teachers quickly were caught up in the enthusiasm they saw in their student writers. They produced more communications and newsletters for their parents than teachers in the control classroom were able to do; they also designed lessons and modeled stories that they wrote specifically on the computer and shared on the projection monitor with their students. Teachers became hooked on E-mailing each other, finding lesson ideas on the Internet, asking questions of
the university people pertaining to certain theories and ideas. The teachers spent time reflecting on their teaching with the university researcher and also building a community of support with their peer teachers in the project.

The 6 computers were busy all day. When the language arts block was over and children had written their own stories, it was time to use the computers with HyperStudio, a software authoring program for children to design their own multi-media research reports in science and social studies. Math, art, graph making was all a part of the daily curriculum, there never was an empty seat in front of a computer. Children received 90% more time using computers then those who visit a lab once a week for an hour.

The teachers also discovered that the daily writing of their students offered the best assessment possible of the skills the child had already mastered and those that were needed. Look at Brandon’s work in the figure below. He is a first grade student. Without the computer, based on his immature drawing, a teacher would conclude (using Gesell Developmental Scales) that he was at a 3-year-old maturity level. He would be mislabeled and misplaced. But given the use of the computer we can see that Brandon has the phonemic awareness skills, sentence structure, punctuation and story sense of a six-year-old or older. How many students have we misjudged in the past based only on their underdeveloped motor coordination with a pencil. Giving them a new tool unlocks the intelligence they have and allows them to express it for all to see.

Insert Fig 1 diagram here

At What Grade Level Should We Have Computers in the Classroom?

Some administrators and parents might think that high school is the time to start computer use, some third grade. As the evaluator of the Simi Star Project, reading one thousand writing samples from five and six-year-olds was enlightening and taught me a valuable lesson. These young children could write much more than we ever imagined that children that age were capable of doing. It proved that they had many more ideas than they had been able to express with pencil and paper.

The time to have computers in the classroom is the first day children enter school. The computer is a sophisticated writing tool that gives the student auditory feedback, a visual display and control of their learning. A tool that can allow any student to feel like an author on the first day of school!

When I taught first grade twenty years ago and a child entered the classroom and said, “Teacher when will I learn to read?” We had to say not until you have mastered the three hundred fifty skills on our district reading scope and sequence chart. The first one is consonant b; there are three hundred forty nine more. The discouraged child went back to his seat.

Today when a child enters kindergarten and says, “When will I learn to read?” The professional teacher says, “Today!” Using KidWorks Deluxe (Knowledge Adventure ) the talking word processor, a child can sit down write his name, mom’s name, his dog’s name, letters of the alphabet, whatever he wants to write. He prints it out and has immediate proof of his literacy and authorship. He can take home his printed piece that very day and have it posted on the refrigerator for all to see, he can write, he can read!

Another important aspect in integration of computers into the curriculum is meeting the needs of the mainstreamed students. Some are students who in the past, because they had not yet developed adequate motor coordination were often mislabeled learning disabled, dyslexic, or attention deficit disorder (A.D.D.) The computer really is essential for changing the lives of these children. The following stories are about two of the many children I worked with using the talking word processor.
Dyslexic Nicholas: The heavy label

Nicholas taught me the next lesson. He was coming to the remedial reading clinic at the university. He was flunking his subjects at school, his parents were frantic. I trained the reading clinicians and then they worked weekly one hour a week with the children labeled “remedial readers.” Rose was Nicholas’s tutor and she came to me distressed. She felt she had been trying all the ideas we spoke about in class but they were not working with Nicholas. I agreed to work with him at the next session and Rose would observe through the two-way mirrors. The next week I was waiting for Nicholas, when he arrived I told him I would be his tutor for this one session and asked him to tell me about himself. He said, “My name is Nicholas and I am twelve years old.”

“When I was six they told me that I have dyslexia and would never learn to read and I have not ever learned.” “I not only cannot read, I get an F in handwriting and math.” He couldn’t understand it because he liked math. He was good at it and knew all the answers through mental calculation and could respond with them orally. However, the teacher insisted on written responses on timed tests. This approach made Nick nervous and with his poor handwriting he was always destined to get an F. Because of these grades his dad would not let him play with his friends after school, he was ordered to stay in his room and do homework. Nicholas was a very depressed twelve year old as he stated, “I hate my life; I wish I was dead!”

Amazingly, Nicholas had just diagnosed his problem. He was not learning to read because he believed he could not, he was bright and could respond orally but had trouble with handwriting and got tense under pressure. My first step was to work on this attitude of failure that he had held on to for the past six years. I told him about Albert Einstein, Nelson Rockefeller, Tom Cruise, to name a few who were dyslexic. Nicholas was very surprised to hear that and certainly did not think those men were dumb. I reassured him that he was not dumb either, but had not been given opportunities to learn the way he could most effectively. Nicholas was a case just like Patrick in Denny Taylor’s book, Learning Denied; the school system had failed him (Taylor 1991).

As we continued to work together, I asked Nicholas if he had ever used a computer? “No,” was his reply. I introduced Nicholas to the talking computer with KidTalk software. (Casey 1983) He immediately began to compose his life story. Then he was able to read it and print it out. “You are a very bright boy Nicholas, you just needed a more sophisticated writing tool to help you put all your great ideas down on paper,” I told him. It took more than a talking computer, it took a teacher who understood Nick’s particular learning strengths and needs and cared enough to encourage him and help him learn in other ways. But it was definitely a breakthrough and turned Nick on to learning once more.

David was a student in the first grade at one of the Simi Star Project schools, I entered his classroom and saw a 10-page story on the bulletin board, and I began to read it. David walked up to me and said, “Do you like that story? It’s mine?” Follow me to the computer and I will show you more, it is twenty-six pages long now. I followed him with great interest. He took me to a computer, put headphones on my head and proceeded to play the story for me. I listened in awe as the computer began to read his long story of the Dinosaurs’ lives, George Washington’s life and his grandma’s life.

At recess I could hardly wait to go to the teachers’ lounge and speak with his teacher. “Mary,” I said to her, “David must be a gifted first grader, his story is outstanding, well above what you would expect from an average first grader.” She laughed, “Oh no, she said. You should have seen him at the beginning of the year, he was identified A.D.D. and he couldn’t hold a pencil or write and he hated school. Now he doesn’t want to go out even for recess when he is in the middle of one of his great stories!” I drove home thinking about a technology that had made a student write in a gifted manner even though he had been labeled a poor writer. A technology that
compelled a student, who had been labeled attention deficit disorder, to sit for long periods of time thinking, creating, imagining a twenty-six page story. If he could sit that long writing something of interest to him then sitting still was not the problem, having something worthwhile to attend to seemed more probable. Something is wrong with the labels, I concluded, the students are fine when given the right tools and environment.
