The author thanks all the many participants, convenors, and facilitators of the project's activities. Especially thanked for their contributions are Mark Gregory for his website support, Patricia Gustafson for her wide project support, and Hamid Khezmnejat for his evaluation analysis. The project only happened due to funding from the Australian Government CUTSD Committee with the success of a grant application co-authored by Maree Gosper and Stephen Marshall.
Exploring the Use of Virtual Multimedia Examinations in Teaching and Learning: Results from the Fielding Testing

Abstract: This paper discusses a National Science Foundation sponsored project for developing virtual multimedia examination formats for use in sciences. It describes the project and multimedia exam templates, and the results of field-testing of their uses in the classrooms.

Theoretical Framework

The prevalence of technology is experienced in every aspect of our lives. Being able to understand technology and using technological tools have become important expectations of today's and tomorrow's workforce. The Clinton Administration has identified four areas that need to be addressed to meet the challenge of preparing technology literate workforces: (1) making modern computers accessible to all students, (2) making classrooms connected around the world, (3) integrating interactive educational software into the curriculum, and (4) making sure that teachers are capable of teaching with technology (U.S. Department of Education, 1998).

Integrating interactive software into the curriculum calls for the use of innovative software in teaching and learning. Research shows that technology has the potential to facilitate learners' understanding and increase their problem-solving skills if the software is well-designed (Liu & Reed, 1995; O'Callaghan, 1995; Pedersen, Williams, & Liu, 1999; Smith, 1994). However, the use of innovative software as part of teaching is not always accompanied by innovative uses of assessment tools. In most cases, traditional testing using paper-and-pencil is still a norm even for assessing the effectiveness of technology on learning. Although computerized testing and computer adaptive testing have been used more than a decade, in the past two years, there is a much more stronger interest in using online multimedia testing as an alternative assessment to the traditional paper and pencil tests.
This interest is partly sparked by the fact that the explosive uses of internet technology in recent years has made it possible to deliver instruction over a distance and to a wide audience. The number of online courses has exponentiated. The more extensive uses of technology in instruction have prompted educators to reexamine the assessment tools.

**Advantages and Limitations of Computerized Testing**

Supporters of computerized testing maintain that testing on the computers can minimize the error involved in administration of the test by standardizing the testing environment, and therefore increasing the reliability of the test (Eaves, 1985; Wise & Plake, 1990; Zandvliet & Farragher, 1997). It also provides immediate computerized scoring, which facilitates and expedites decisions that might need to be taken based upon the results of the scores. Moreover, computerized testing can provide the examinees with feedback on the correctness of the answer. Additionally, information is provided regarding test-taking behavior. For instance, the examiner can collect data such as how many items have been reviewed by the examinee, or how much time is spent on each item (Wise & Plake, 1990). Computerized assessment facilitates evaluation of test items, including group analysis of the test and item bias, as well as analysis of items' reliability and difficulty (Eaves, 1985). In contrast to paper based testing, computerized based testing gives the examiner the capability to enrich the display of information by integrating multimedia elements. Finally, computerized tests may become individualized and proceed in different ways based upon examinee's responses.

However, using computerized testing has limitations. Will testing on the computers cause anxiety — test anxiety as well computer anxiety—to learners? Is it fair to use computerized testing on everyone, especially those who do not have frequent access to computers? Is it worth the money and effort to put a test on the computer when it is more efficient to use a equivalent paper-and-pencil version? Is it realistic to use computerized testing in the classrooms? Is it realistic to expect instructors to develop computerized tests in addition to their regular duties?

Even though the benefits of computerized testing are evident as discussed above, these limitations prevent the wide use of computerized testing in the classrooms until recently when the ease of incorporating multimedia and internet technologies into instruction becomes a possibility for the majority. The following section looks at the use of computerized testing in the recent years.

**Research Findings**

Zandvliet and Farragher (1997) in their study investigate the equivalence of a computer-administered test (CAT) with a written format of the test. Analysis of the test scores indicated that there were no significant differences attributable to the test format. Although the CAT required more time than the written test, authors attributed this difference to the fact that the students were unfamiliar with the computer format. They also conducted a survey to identify students' attitudes towards computerized testing. The results showed that the students clearly preferred the computer-administered test.

Isham (1997) conducted a study to investigate whether an interactive computerized visualization assessment would help interior design students improve their visualization skills. A paper assessment was first developed to validate assessment problems for the computerized version. The computerized assessment was based on the paper assessment and was similar in content and sequence. It included, however, animations. The results of the study indicated that the average score of students who took the computerized version of the test was higher than the score of those students who took the paper version. The author concluded that the inclusion of animations in the assessment seemed to enhance students' visualization skills.

In another study conducted by Soo and Ngeow (1998), students using a multimedia self-assessment English proficiency course were compared with students in a conventional teacher-taught proficiency class. Factors such as gender, race and learning style (visual, auditory and kinesthetic) were also included in the collection and analysis of data. The results showed that students who used the self-paced multimedia program achieved significantly higher scores as measured by the TOEFL, and in less time than the students who were taught in a traditional course. Multimedia instruction was effective across all genders, races and learning styles. As the authors concluded, “convenience, flexibility, and simulation of interactive multimedia allows learners to learn better and faster compared to learning with human teachers in language proficiency learning” (p.87).
However, incorporating various media into computerized testing and making it interactive is still new. Much research is needed to understand how to make the testing not only an evaluation tool but also a learning tool. Because the making and using of computerized testing requires the knowledge of advanced computer knowledge, the challenge is how to make it possible for any instructors, who are interested, to use such tests in their teaching.

**Purpose of the Project**

The purpose of the project is (1) to develop virtual multimedia examination formats for use in sciences and other disciplines; and (2) to evaluate the use of such formats in classrooms, especially examining students' attitude towards being evaluated by such multimedia exams, and instructors' attitude for using it.

This presentation will describe the project, but will focus on the field-testing of the use of such multimedia exam formats in actual courses.

**Project Description**

Given the challenges of developing interactive evaluation tools to better assess learning and improve teaching, and to make such tools available to instructors in sciences to use in their courses, a group of faculty and students at the University of Texas – Austin, led by the fourth author of this presentation started to develop multimedia examination templates for use in sciences. This is a National Science Foundation sponsored project. It is currently in its second year of implementation. The project is to use recent advances in digital technology to utilize the full range of color imagery, video, two- and three-dimensional animations, and sound so as to produce rich and interactive evaluations. Because the undergraduate teaching in various sciences often shares the use of similar types of student performance assessments (e.g. laboratory assignments, quizzes, mid-term and final exams), it is possible to produce a series of multimedia exam templates that can be customized for use across disciplines. Instructors using these templates can "copy, cut, and paste" their questions into the formats, add multimedia materials, and utilize the interactive question formats to make their own exams.

**The Virtual Multimedia Exam Templates**

The virtual exam templates (VExam) consists of three programs: (1) Exam Builder, (2) Exam Giver; and (3) Exam Reviewer. Exam Builder allows instructors, regardless of their computer experiences, to build their customized exams. It guides the user through exam construction in a step by step manner. Exam Giver allows students to take the computerized exam his or her instructor has created. Exam Reviewer helps students review what he or she has missed in the exams and provides study suggestions.

The exams created with the Exam Builder shares similar characteristics to a traditional paper-pencil exam in that it can contain the same content and sequence as a paper exam, and use the same common testing formats such as multiple choice, true/false and matching items. However, these new exam formats have some innovative features that will be hard to implement in the paper exams. First, the presentation of questions is greatly enhanced through the use of images, video, animation and sound. The use of multimedia is particularly attractive to visual learners who need assistance to understand abstract concepts. The multimedia elements, directly related to the content of the questions, can aid the learner in understanding the questions, and enhance learners' ability to recall the information necessary to answer the questions. The multiple representations of each question, through verbal and non-verbal stimuli, can accommodate learners with different learning styles. This is strongly supported by the dual code theory, which suggests that the retrieval of information is facilitated through multiple stimuli that can cue the right information (Ormrod, 1995).

Another important feature of this new exam format is that it allows a more dynamic and interactive type of questioning. The questions can present real world situations, where the student is asked to make observations and measurements, collect data, form hypothesis and, solve a problem. Students are evaluated both on the end product, as well as on the procedure that the student has followed. The goal of these questions is, therefore, not only for the student to reach a solution, but also to learn from the whole problem-solving process.
In addition, Exam builder allows instructors to generate random questions, alternative forms of the same exam to ensure security and fairness of the exams for all students. Once a test is over, scores are calculated and displayed immediately for the students. Correct answers are explained. Though students cannot retake the same exam after viewing the answers, they can review the content, exam formats and get ready for the next exam. In short, such exams are developed not just to evaluate students' performance, but more importantly, assist students' learning as the ultimate goal.

Field-Testing

Research Questions

After several circles of the formative evaluation, the VExam is being used in several courses at the University of Texas-Austin. Evaluating the efficacy of using these exams as a primary assessment tool focuses on the following research questions:

1. Are these multimedia exams equivalent to the paper and pencil exams in terms of the content?
2. What are students' as well as instructors' attitudes toward using them?
3. Does students' computer experience affect their use of the exams?
4. In what way does the use of such exams influence learning and teaching?

Method

The field-testing reported here consists of two phases: (1) using it in two different science courses where instructors implemented the exam templates in a bit different way; and (2) using it as the assessment for an online self-paced science course. The evaluation examined students' as well as instructors' perspectives. Questionnaires and interviews are the two primary data sources. The actual exams, their content and formats, were also studied.

Phase I. The templates were used in two different undergraduate science courses from fall 98 to spring 99. One instructor is relatively new to the multimedia technology and had used graphics in the teaching. Another instructor is an experienced multimedia user, who has used all media formats in the teaching including video, graphics, animation and sound. Approximately 120 participants returned the questionnaire, who represented several science disciplines and from freshmen to seniors.

A questionnaire was devised to examine students' anxiety and attitudes toward being "tested" using the multimedia exams. It consists of 25 items on a 5-point Likert-scale with 1 being "I strongly disagree" and 5 being "I strongly agree". These 25 items address three issues related with multimedia exams: anxiety towards multimedia exams (9 items), attitudes towards taking multimedia exams (8 items) and attitudes towards multimedia and learning. The items regarding anxiety towards multimedia exams were based upon a modified version of Spielberger's self-evaluation anxiety scale (Reed & Palumbo, 1987). The attitude items were based upon Richards, Johnson, and Johnson's computer attitude scale (1986). Examples include "I feel upset when I take a multimedia exam", "I had difficulties completing the exam because it was a multimedia exam", and "Multimedia exam will enhance my performance." The questionnaire was examined by three experts in instructional technology for content validity and pilot-tested by a group of five students. Comments and suggestions were incorporated. Six open-ended questions were used to ask the participants to express their likes or dislikes of multimedia exams, and to compare the multimedia exams with the traditional paper-pencil exams. Sample questions were "How do you like or dislike taking a multimedia exam", or "Which part of the multimedia did you like the most? Why?" Students' computer prior experience was also surveyed and grouped into novice, intermediate and expert users according to their experiences.

Interviews were conducted with a randomly selected group of students about their opinions of the multimedia exams. Three questions were used to start the interviews, but the researchers made an effort to keep the interview process open, allowing students expressing their opinions freely. Follow-up questions were used if further explanations were needed. An extensive interview was conducted with the instructors using 10 questions.

Phase II. In the fall 99 and spring 00, the multimedia exam templates are being used to create virtual exams for an online self-paced course (http://www.dla.utexas.edu/depts/anthro/courses/99fall/SP301/). This self-
paced course uses the instructor created multimedia CD-ROM as an important source for instructional materials. Students study the materials in their own time, and get evaluated about their knowledge through quizzes and exams created using VExam programs at a time that is convenient to them. Review sessions and Q&A sessions are provided on a regular basis throughout the semester. Because of the self-paced nature of the course and the use of the multimedia CD-ROM as a primary teaching tool, the use of multimedia exams in this case reflects more closely what is being taught. The questionnaire has been revised based upon the results from Phase I and is being incorporated into an online form. Interviews will be conducted with the instructor and the students. In addition, observations of the review sessions and the testing sessions will be made. At present, data for Phase II are being collected and analyzed.

Results and Discussion

Descriptive analyses were conducted for the questionnaire. The interview data were analyzed following the framework by Miles and Huberman (1994). Results from Phase I are reported here.

Typical students' comments from the interviews on their attitudes and anxiety toward the multimedia exams included:

- I like multimedia exam better, because it offers the chance to get instant feedback on the test results.
- Pictures and animations can give you clues when you are trying to remember something.
- Multimedia exam appeals to me visually and therefore, seems easier, although the material may not be. It's more accessible.
- I prefer multimedia exam. It seems to be easier and more interesting to use.
- I like it, because it makes test taking and grading quicker and easier.
I like the multimedia environment, it's less stressful and that helps resolve test anxiety.

The following are typical students' comments on the interactive elements built in the exams:

- Being able to manipulate things, take measurements and things like that where you wouldn't be able to do on a piece of paper.
- [I liked] The interactive part as opposed to the Multiple choice part. I liked the fact that I was able to take measurements, rotate things and see them from different angles. I also liked plotting a graph, because you were able to change your answers, see the different possibilities and estimate which one is the correct.
- [Do you like the multimedia exam?] Yes, because like in the lab and in the class we use these materials and we have these 3D models. And then the professor uses the same things in the exam. And it's like another way to help you remember.
- I like the interactive part, where there was this whole case that you had to work on and do different stuff, collect and analyze data... And each part builds on the previous one. And the good thing is let's say you missed one question and then you move to the next part and you have to use the results of that questions, it will give you the correct one to move from there. I think that's good, because you actually learn something from the test. You do something wrong, but then you realize why it's wrong.
- Yes, because I spent less [time] remembering how something exactly looks like and I was focus [ing] more what its feature[s] mean so that when it comes to application I can use that instead of spending ten minutes trying to remember what it looks like.

The interviews with the instructors revealed that though the instructors recognized that the templates could provide the same content and sequence as the paper exams, they chose to take advantage of the multimedia and interactive features made possible by the new formats. The multimedia exams were enhanced versions of the paper exams according to the instructors. Though the multimedia templates have made it very easy for instructors to use, regardless of their computer experience, it still takes quite a bit of time to assemble and create all media elements. This reinforces the concept that technology has provided enormous new possibilities, but it does not necessarily has made our life easier.

The quantitative and qualitative data suggested the following:

1. The overall attitudes toward the use of the multimedia exams as the primary evaluation method have been positive. Students' computer anxiety, regardless of their prior computer experiences, has been relatively low.
2. Students with more computer experience have a greater preference toward using the multimedia exams.
3. Gender does not seem to be a factor in differentiating the opinions.
4. The use of multimedia elements, especially 3D modeling and animation, and immediate scoring are important reasons for students to like multimedia exams.
5. The interactive nature of certain questions, allowing students to manipulate and analyze the data, focus on solving problems rather than recalling facts, is especially well-liked by the students.

However, some students expressed negative attitudes towards multimedia exams and showed preference towards the paper-pencil exams. There were three main reasons for this negative attitude:

1. valuable time being lost to scan the test. It was more difficult and time-consuming to go back and forth on the computer to get an idea of the whole test and review their answers. One student said, "With the multimedia exam you can see one question at a time, whereas with a paper exam you can scan over all questions and get a feel for the test."
2. the possibility that everyone could look on the screen while taking the test, and see the score at the end. Some students indicated it was stressful and tiring to read the computer screens.
3. the dislike of computer. Though most of the participating college students like and use computers as part of their college life, some do not, as one said, "I don't like computers. I'm not into technology at all. I still
use a typewriter for my papers." Some students mentioned that they were more used to, therefore more comfortable to, paper-and-pencil exams.

Such negative feelings about the multimedia exams indicated the following:

- Using multimedia exams is a relatively new way of assessment. Though colleges and universities are the best places to implement them, sample tests and practices of using the new formats should be made available for students to get familiar with. Students should make an effort to practice using the new format.
- The multimedia templates being developed can be improved and enhanced to incorporate students' suggestions.
- The actual administration of the tests can be further examined to ensure testing security and fairness.
- The effective use of such new assessment depends partly on instructors' willingness to try new things and their experience in using technology in instruction.

The advances in technologies and possibilities made available through internet and multimedia force us to reexamine the ways we teach, we learn, and we evaluate. With more and more courses being offered online, computerized testing is a logical way for evaluation. Examining how to make testing as a part of the learning is an important challenge. After all, the goal of evaluation is not to merely test students, but to help them learn as well.

Page limit of the conference proposals prevents elaborate presentation and discussion of the results, which will be shared more in detail at the presentation. The VExam will also be demonstrated to the audience.

Abstract: It has been demonstrated that an effective strategy for constructing meaning and knowledge about a particular subject area is in the design and production of subject-specific educational resources - particularly computer-based resources (Jonassen and Reeves, 1996). In a continuing effort to explore the effective use of computer-based technologies in the teaching and learning experience, the Faculty of Education at the University of Wollongong implemented a 'learner as designer-producer' model in a senior year physical and health education course. A number of factors -- limited experience using computers, restricted time available to access production equipment and competing priorities related to the final year of study -- provided a challenge to the pedagogical re-conceptualisation of the course to include such a model. However, preliminary analysis of the outcomes of the implementation proved encouraging and has informed further developments.

Background

It has been demonstrated that an effective strategy for constructing meaning and knowledge about a particular subject area is in the design of subject-specific educational resources - particularly computer-based resources (Jonassen and Reeves, 1996). In this concept of 'learner as designer', the learner is engaged in a meaningful task where important aspects of the knowledge construction process such as analysis and reflection are facilitated. Hedberg, Brown and Arrighi (1997) have further explored the impact of such pedagogical strategies in the concept of 'learner as producer'. When the learner is involved in the production of interactive hypermedia-based educational resources they are focused on learning about such production as a body of knowledge with an accompanying set of skills. It follows then that when the learner is involved in both design and production aspects of hypermedia-based educational resource development they actively explore concepts related to the subject matter, hypermedia production and the related skill set.

In a continuing effort to explore the effective use of computer-based technologies in the teaching and learning experience, the Faculty of Education at the University of Wollongong (in New South Wales, Australia) has implemented a 'learner as designer-producer' model in its senior year Advanced Teaching and Learning Studies. The goal of this subject is to foster the importance of professional development for teacher trainees in their final year of study in a four-year Bachelor of Education (Physical and Health Education) degree. The emphasis is on the need to react to change, to continually expand their repertoire of teaching skills and to develop a personal teaching philosophy. Among the specific objectives for the subject are the analysis of senior secondary physical and health education related syllabuses and the ability to translate the policies into teaching and learning environments and the critical examination of the use of technology in the physical and health education classroom.

The delivery of this subject for the 1999 academic year coincided with the New South Wales Board of Studies circulation of a proposed senior secondary school syllabus, which was scheduled to be released for use in next school year. Thus, students enrolled in this subject would likely be securing teaching positions within which they
would be required to have in-depth knowledge of and ability to implement the contents of this draft syllabus. At the same time curriculum was being re-examined, employers were increasingly expecting teachers to be skilled in both the administrative and pedagogical use of computer-based technologies (Ministerial Advisory Council on the Quality of Teaching, 1998).

Thus, it was timely to implement an educational innovation within Advanced Teaching and Learning Studies with the investigation of the impact of learner as designer-producer model. The focus of this innovation was an assessment task which involved the design and production of a Web site with embedded learning activities which related to the proposed syllabus. For this task, students worked in collaborative teams.

The literature regarding collaborative approaches to learning was convincing. Henri (1996) explained that group learning qualifies as cooperative or collaborative when the process is structured to include: interdependent learner interaction; commitment to the learning of each member of group; commitment to fulfill assigned group functions; use of the appropriate social and interpersonal skills to stimulate cooperation; and, continual revising of the group functioning process. Metheny and Metheny (1997) found that such learning approaches help students overcome their fear of technical courses while helping them prepare for today's collaborative workplace. In reviewing the research, Slavin (1989) found cooperative learning to be statistically significant in facilitating academic achievement in 57% of more than 70 studies. 34 of 41 studies that involved a Student Team Learning approach found significantly positive achievement results (Slavin, 1989). Cinelli et al (1994) argued that the application of cooperative learning was especially important for the school health educator who, in the context of a comprehensive school health program, should employ a range of classroom activities to maintain, reinforce, and enhance the health attitudes, practices, and skills of children and youth.

Implementation

In this investigation, students formed teams of three members and choose from among list of topics covered in the proposed syllabus for the focus of their Web site. Assessment of the Web sites was based on:

- **Content** (e.g., relevant to the syllabus topic, current and accurate, at the appropriate depth for the proposed students).
- **Learner engagement** (e.g., the site included learning activities, the activities related directly to the syllabus topic, the activities stimulated the learner to think critically, and a feedback mechanism for learners was evident).
- **Design and functionality** (e.g., easy to use and well organized, users able to easily navigate site, the site was aesthetically pleasing and professionally presented, the reading level and choice of graphics was appropriate for senior secondary students and, all links work as intended).

Intensive hands-on workshops were held to introduce students to the range of skills necessary for Web site development. An authoring tool, Claris Home Page, was used in the workshops for Web site construction. Workshops covered the following:

1. Site map development, file management, Web page creation, navigation systems, and inserting an image.
2. Creating internal and external site links, page backgrounds, and using tables.
3. Creating and editing images and forms of interaction.

Due to the technical resources available (i.e., software and hardware limitations) an alternating peer-tutoring model was implemented. Each week, one member of the team attended the skill development workshop. A paper-based resource was distributed to each workshop participant that related to the skills covered. This resource was also available on the subject Web site. Immediately following the workshop, the team representative peer-tutored the rest of their team members on the skills they had just acquired.

Jacques (1991) has suggested that peer tutoring allows students to be active learners, feel integrated into the delivery of the subject and increases cooperation, motivation and self-esteem. Peer tutoring is a strategy that is often employed in school physical and health education classes. Thus, this investigation allowed for the modeling of multiple strategies that the teacher trainees could implement in their future classroom practices.
**Methodology**

A mixed-mode methodology was utilised to evaluate the effectiveness of the learning experience for students from both a quantitative and qualitative perspective. The data collection strategies were varied and included:

- Pre- and post-implementation surveys of student skills and comfort level associated with using computers.
- Student journals and self-analysis of the experience.
- Post-implementation interviews with representatives of the student teams.

**Outcomes**

Overcoming the barriers of limited experience using computers, restricted time available to access production equipment and competing priorities related to the final year of study, the students rose to this new learning challenge.

Of the 70 students enrolled in the subject, the vast majority self-reported having little or no experience using computers prior to engaging in this learning activity (only 9% reported having "a lot of experience with computers"). For most students, their computer skills were limited to the components of the integrated software package (ClairsWorks) for which they engaged in skill development during their first year of study (e.g., word processing, spreadsheets, databases, draw).

Students reported limited experience using the Internet (only 6% reported having "a lot of experience with the Internet"). In the main, they considered their Internet-related skills in terms of sending and receiving e-mail and searching for and/or accessing information on the World Wide Web. Only two students reported that they had been involved in producing a Web site prior to engaging in this learning activity.

The final Web sites submitted by the learning teams demonstrated that students grasped the basic skills of Web site construction (see Figure 1). All Web sites were functional and with a range of aesthetic designs. Most importantly, all sites included learning activities that were designed to facilitate critical thinking -- an objective inherent in the proposed syllabus.

![Figure 1: Example of student team developed Web site.](image-url)
Prior to engaging in the learning experience students were somewhat split in their comfort level in terms of using computers. However, data collected post-implementation demonstrated that students had moved along the continuum with 85% reporting that they felt “comfortable about using computers.” Importantly, after the learning experience, 75% of the students reported that they felt “comfortable about using computers in the teaching environment.”

Students were also asked to respond to a number of statements about the activity and related assessment task. Table 1 provides an overview of the findings:

This survey data, open-ended comments on the survey and the post-implementation interviews found that students perceived value in the learning activity. One student commented that the task required them to

...critically think and develop a practical instrument that could be used for our teaching. This was much better than a more theoretical based approach that only looked at potential uses of technology in teaching senior classes OR playing around with existing sites or CD Roms. It makes it much more relevant and gave us good practice of working with and seeing what computers can do.

This was further supported by another student who commented,

I guess I really have never thought of using computer technology in the PDHPE [Personal Development, Health, and Physical Education] classroom. The use of computers for use other than writing up assignments is new to me. The web-based learning activity broadened my thinking in terms of learning strategies.

Some students felt the task was time-consuming and some did report frustrations with using the technology. Students reported both positive and negative attitudes toward the experiential learning of group work and peer tutoring. One student explained, “I thought this was very good, it placed some responsibility and sense of ownership with the peer group/tutor. However, it would have been good if this process continued for a longer period.” Some expressed their lack of comfort in playing the role of the tutor. For example, one student noted, “... but I wasn’t confident in teaching my group in case I made a mistake and didn’t know what to do then I would let the rest of the group down because then we all wouldn’t have an idea of those skills. However, others held more positive perceptions about the strategy, for example, “I thought this was a really good idea. It made me really pay attention and not rely on someone else to listen. I liked this strategy and it worked well and I know I’ll use it in my teaching.”
Students felt it important that they were aware of the difficulties of team management processes that their future students might encounter when such strategies were employed. Students appreciated the issues that came from sharing the experience of learning a skill (i.e., Web site construction) that was completely new to them.

Concluding Remarks
The encouraging preliminary results from this first implementation of the learner as designer-producer model has provided scope for refining future implementations within the course. Additionally, it has provided a basis on which to re-conceptualise the pedagogical strategies that might effectively integrate information and communications technologies in physical and health education.

Abstract: While ad hoc, course-specific projects have allowed early adopters to explore possible innovations in the use of information and communication technologies in facilitating flexible learning situations, educational institutions are now exploring more integrated strategies to such developments. This paper describes the development of one such strategy that attempts to foster a community-wide approach for a group of professionals coming to terms with the most effective way to utilise technologies -- physical and health educators. The Faculty of Education at University of Wollongong is developing an on-line learning community to facilitate the pre-service education and continuing professional development of students, faculty and practicing teachers.

Introduction

Institutions of higher education in Australia are involved in the international trend to consolidate networked information and communication technologies (ICT), particularly the World Wide Web, into their teaching, research and community outreach endeavours. Web-based environments can create meaningful experiences where learning is fostered and supported (Khan, 1997).

In the main, these Web-based activities are particular to individual courses or specific research projects and only infrequently involve an organised change process which incorporates multiple activities and various stakeholders (i.e., members of the community) with a common interest.

The challenge

Within the physical and health education profession, the important members of the community include teacher educators, practicing teachers, pre-services teachers (i.e., students), the professional associations and employers of teachers. An existing example of partnership amongst the members of this community is the model for teacher education which utilised links between schools and universities to promote the communication of professional understanding through practicum experience (Goodlad, 1994). However, the effectiveness of the implementation of this partnership model has been the discussion of recent debate and calls for reform (Ministerial Advisory Council on the Quality of Teaching 1998).
While universities are encouraging the implementation of Web-based technologies into teaching and learning practices, employers of teachers (in this context specifically, the Department of Education and Training New South Wales) are expecting their teachers to have the skills to incorporate educational technologies (including Web-based technologies) within their teaching practices.

Pre-service educators within the Physical and Health Education program in the Faculty of Education at the University of Wollongong recognise the importance of exploring the use of Web-based technologies in their teaching. Recent experiences have proven effective (Lockyer, Harper, and Patterson, 1999; Lockyer, Patterson, and Harper, 1999; Lockyer and Kerr, In Press). However, such initiatives have been implemented on an ad hoc basis. As the Faculty of Education at the University of Wollongong evaluated their experiences, it became clear that a conceptually and practically organised implementation plan which included specific contact with the broader profession and its activities was necessary.

It has been noted that the key features of reciprocal partnerships include:
- a recognition of the interdependence and the unique contribution of the various parties;
- constructive and imaginative problem solving; a will to work to change and improve;
- a working relationship which permits risk taking; a tolerance for ambiguity, uncertainty and dilemmas;
- joint responsibility for the planning, implementation and evaluation outcomes;
- joint, commensurable benefits;
- organisational structures which will facilitate the enactment of decisions;
- appropriate resourcing; intercultural understandings (Groundwater-Smith, Parker, and Arthur, 1994).

Thus, the concept of an on-line learning community for physical and health education and which comprised these key features was born. Schwier (1999) explained the power of learning communities "resides in their ability to take advantage of, and in some cases invent a process for exchanging ideas and learning collectively" (p. 282). While the community of physical and health education professionals have traditionally fostered successful processes for the exchange of ideas and mentoring newcomers into the community of practice, change fiscal and social influences require new approaches to be investigated. The use of technologies in sustaining and invigorating the community is timely.

There now exists an abundance of literature to inform us of the nature of virtual communities. Fernback and Thompson help us to understand the value of the community that exists in cyberspace (i.e., using Internet technologies).

_Ideologically, community within cyberspace appears to emphasise a shared belief in the principles of free speech, individualism, equality, and open access... Experientially, community within cyberspace emphasises a community of interests, usually bounded by the topic under discussion, that can lead to a communal spirit and apparent social bonding... they may promote action that is, virtual communities may manifest themselves in real political action, such as educational reform ..._ (Fernback and Thompson, quoted from hypertext document)

The Concept
An on-line learning community for physical and health education has been conceptualised to incorporate these key features of a partnership.

This community will be facilitated by a Web-based environment that encompasses:
- on-line access to the Physical and Health Education program at the University of Wollongong;
- physical and health education teaching resources;
- facilitation of professional development activities; and,
- access to physical and health information sources.
This is a collaborative initiative involving lecturers, students and practicing teachers (Figure 1). The development of
the on-line community is dependent on a student-centred learning model. Students propose learning contracts which
involve collaborative projects that will add to the resource base of the community. It is envisioned that active
participation by students in the development of the on-line community will facilitate a smoother transition into their
chosen profession -- the community of practice of teaching. As Bruffee (1993) argues, collaborative learning in the
university setting provides students with the opportunity to speak the language of their profession and, "speaking the
language fluently defines membership in the community" (p. 130).

Figure 1: Key participants of the Physical and Health Education On-line Learning Community

Through their participation in the development of the virtual community, physical and health education lecturers
will enhance their understanding of the use of Web-based technology for teaching and learning within the discipline.
This translates into the integration of such concepts into the curriculum of the program. As Sherry and Wilson
(1997) suggest "roles and concepts of teaching and learning [should] be restructured" as the Web extends the walls
of the traditional classroom (p.67).

Practicing teachers are in integral component of the project. Physical and health education teacher will develop
skills to implement Web-based technologies into their classroom and participate in the collegial exchange of ideas
and applications of the innovations.

Phase I - On-line Practicum Support
The initial phase of the project has focused on discussion with stakeholder representatives; the design of the Web-
based environment which will support the community; the prioritisation for implementation of components,
activities or features; and the confirmation of learning contracts with students who will contribute to the
development of the community.
Building on the existing collaboration between participants in the form of school-based mentoring and practice teaching for pre-service teachers, a first activity to be explored within the virtual community is an on-line practicum.

The Bachelor of Education (Physical and Health Education specialisation) at the University is conducted over a four-year program. In each year of the program, students engage in practice teaching experiences which involve local schools, supervising teachers and University-based faculty. Anecdotal information gathered from practicum participants (faculty, pre-service and supervising teachers) has called for greater and more consistent communication among participants; access to a variety of information (related to the program specifically and to the teaching profession generally) and access to resources and tools (such as lesson ideas).

The initiative of an on-line practicum provides a model for successive implementations within the community -- the first iteration explored through pilot study with a sub-set of students in the fourth (i.e., final) year of their pre-service teaching studies.

Building on the initial anecdotal feedback regarding the practicum experience, a formalised analysis is being undertaken to clearly identify the needs of the participants. Data collected during the needs analysis will assist in identifying the resources necessary to include in the Web-based environment and, most importantly, the structure that the on-line practicum will take. As suggested by Brehm (1999) it is critical that structure and expectations of involvement of all participants are effectively designed and clearly communicated.

Data collected during the pilot study (in the form of journals, logs of on-line discussions, and post-implementation surveys and interviews) will provide some evaluative indicators and a basis for consideration of extending an on-line practicum component throughout each of the four years of the program.

**Concluding Remarks**

It is envisioned that this on-line community will evolve to encompass increasing avenues for collaboration among the participants. The community is structured to provide an exciting action research environment for innovations in both initial teacher training and ongoing professional development in the area of physical and health education which can then be communicated to inform similar groups initiatives.

Abstract. This paper reviews a distance learning project implemented at Massachusetts College of Pharmacy and Health Sciences, a small private college, to deliver a nontraditional, part-time Doctor of Pharmacy program using interactive video conferencing for students located at two sites. Although it was not a complete match to our needs, this technology was chosen in response to a mandate to replace videotape because of consistently negative feedback related to lack of real-time participation. There was both significant potential and considerable risk in our decision. From the start we had difficulties with the system configuration, lack of knowledgeable technical support from the vendor, training issues, networking/connectivity difficulties, and overwhelming environmental problems with our broadcasting space. What we learned during a very difficult implementation of new technology is worth sharing with others who may be considering a synchronous distance learning solution.

Introduction

Many small colleges face stress and frustration in attempting to implement distance learning because some or all of the prerequisites for success are missing or incomplete. These prerequisites include comprehensive analysis and planning, adequate funding, staffing, technical support, and training. Often it is difficult to secure crucial top-down administrative commitment for a quality distance learning program, and/or to convince administrators to invest the time and money necessary to do the proper amount of research and preparation before a program is put in place (see Robbins 1997 & Wagschal 1998). Studies show that venturing into distance learning without establishing these key elements is a risky endeavor, as outcomes can seriously impact the reputation of the institution (see Carr 2000 & Schneider 1999 & Weiss 1999).

Massachusetts College of Pharmacy and Health Sciences (MCPHS) has been in exactly this situation for the past 16 months. In 1996 MCPHS initiated a non-traditional Doctor of Pharmacy program geared for practicing pharmacists who could not commit to a full-time program. This three-year, part-time program is currently offered at two sites, the Boston MCPHS campus and an affiliated institution, Western New England College located in Springfield, Massachusetts. This program was developed in response to the demands of alumni throughout New England and it was initiated without full administrative support for distance learning. For the first two years of the program, courses were delivered live at the Boston campus.
and these lectures were videotaped. Videotapes were sent to the Springfield students, who also met periodically with their peers for interactive, small group discussions. This method of course delivery was optimal for the Boston-based students, but it was not well-received at the distant site. In mid-1998, the director of the program received administrative support and funding to establish video conferencing between the two sites, and the technology was implemented in January 1999. Despite many obstacles and substantial frustration, this interactive video conferencing program is functioning and improving. We have learned a great deal about doing it right and what to avoid.

We were challenged on all fronts, including:

- locating various funding resources.
- finding a high-quality, reliable video conferencing system for reasonable cost.
- clearly understanding the roles of the ISDN provider and the system vendor.
- existing essentially as an unsolicited beta site, since it was later discovered that the system configuration within our type of environment was the first for our vendor.
- computer networking/connectivity problems.
- lack of appropriately-designed broadcasting space.
- lack of experienced support staff (see Boaz et al. 1999 & SURA Video Development Initiative 1999).
- Scarcity (and expense) of quality training in course preparation (for interactive, student-centered distance learning), and on-camera presentation skills designed for college faculty, not for corporate trainers (see Boaz et al. 1999 & Parker 1999).

Obstacles were encountered from the start of installation, through system testing and throughout implementation of the first broadcast courses. Some of these issues have been resolved or mitigated, while other solutions for improvement are still in progress.

**Program Implementation**

**Technical Problems**

In the beginning we encountered many transmission problems because of:

- our technician's lack of experience with this type of equipment.
- phone company linemen's lack of ISDN experience.
- Intel technician's inexperience supporting a system that was not tested in a real-life environment.
- limited, expensive options for transmitting full-motion video (30 fps) (see Graves 1996).

Because of this unfortunate deficiency in expertise from all of these critical sources of support, those involved with the program at MCPHS during the early stages became discouraged with the technology (see Boaz et al. 1999). A major reason for some of the obstacles we faced was that the system was still in the beta development stage, a fact that was undisclosed to us during purchase negotiations. Technicians at Intel were often unable to help us because this was their first encounter with many of the problems we confronted.

Our first major (and easily avoidable) problem occurred two weeks into the program when we experienced transmission problems. Our system is designed to be portable and originally was located on a rolling cart with the ISDN boxes lying loosely beside the other system components on the cart. We worked tirelessly trying to pinpoint the failure before we realized that the problem was due to the placement of the ISDN boxes. Because the boxes were not in a consistently fixed position, any movement of the wires and boxes affected the transmission signals. Mounting the ISDN boxes on a stable platform inside a closet where the lines run in from the street alleviated this problem. This process took over two months to resolve because the vendor's technical support didn't know what to do. Since that time, we have had only one incidence in
which we lost video during a transmission. That problem was rectified with a simple re-boot of the system.

Technical Specifications

The reasons for choosing the Intel TeamStation for video conferencing included:

- Cost.
- Functionality.
- Ease of use.
- Interfacing capabilities with the Microsoft NT network and other Microsoft applications (Word, Excel, PowerPoint).

The current cost of the system, which ships with a Pentium III 500 MHZ processor running Microsoft’s Workstation operating system and Intel’s proprietary video conferencing software, is between $12,000 to $16,000 per unit, and two units are necessary. Two years ago this system running on a Pentium II 233MHZ processor cost $35,000. As a result of a 1999 agreement between Intel and PictureTel, PictureTel is now the vendor for the TeamStation product line.

Operating and routine maintenance of the system requires minimal technical knowledge. The system is equipped with a Sony video camera with auto-focus and built-in auto-tracking and motion detection, which allows the camera to follow the speaker as she moves about the room. The audio system is hands-free and full duplex, which allows simultaneous speech from both ends. This audio system is optimally designed for an 8 to 10 foot radius. A third-party sound system can substantially improve the audio range of the system.

An Intel technician installed the software and upgraded the system with an aggregator board to allow it to transmit at 384 Kbps, which was the vendor's performance claim. The system was originally designed to transmit at 128 Kbps, which was adequate, but not considered full-motion video. The system may be run in the 128K mode to reduce the ISDN costs. Bell Atlantic charges 75 cents per minute per line, which amounts to a weekly charge to the program of about $675, since actual broadcast time for course activity is five hours once a week. It was discovered that transmitting at this rate can provide adequate video and sound with minimal loss of quality if the presenter significantly limits her movements. With advances planned for Internet II, we may have more options for better broadcast quality in the future (see Graves 1996).

Environmental and A/V Media Issues

As the system problems were resolved or mitigated, a larger deficiency began to emerge as our main obstacle to good video conferencing: a poorly designed broadcasting room at both sites. This is a critical operational component for video conferencing (see SURA Video Development Initiative 1999). The factors that detracted from effective transmission were:

- shape and size of room including ceiling height.
- color of walls and furniture.
- lighting systems and room-darkening devices.
- audio amplification and interference.
- placement of system components.
- conformation/location of instructor platform and general access to instructional devices/student view.
A consultant was hired to conduct a full analysis of the environmental problems and a complete, prioritized report was submitted. Some recommendations have been implemented and the whole program is currently in review.

Installation of a third-party sound system improved audio range at both sites. Indirect and diffuse lighting adaptations were also made. Another major improvement was accomplished by arranging the video devices so that the instructor is looking at both audiences at the same time, while allowing both audiences a direct view of the instructor. This requires that the camera be placed directly in front of the instructor’s designated space (suspended in some way from the ceiling, or mounted within the local audience). Two video displays are required: one behind the instructor large enough for the local audience to see (we use a large projection screen) and a second video monitor placed in front of the instructor and behind or above the local audience.

Limiting the instructor’s movement to a specific zone allows for much more reliable audio and camera tracking. The system components were relocated within the broadcast area so that the instructor had easy access to peripheral devices, such as the document camera, to effectively shift the teaching format while maintaining direct contact with the audience (see Zielinski 1998 & Parker 1999).

We learned that effective communication between all support staff and faculty is a vital requirement in planning and developing a successful program (see Boaz et al. 1999 & Hardwick 1997). For example, it is very important that the staff involved with environmental and audio-visual media work closely with the computer and networking technicians. The placement of ISDN lines may limit the placement of the video conferencing equipment and peripheral devices within the broadcasting space. It is essential that those people designing and locating the A/V and instructional support devices work closely with the networking technicians who will locate the ISDN lines, in order to ensure that the full system is appropriately situated in the space for optimum teaching activity.

Faculty Training Issues

Time became a major issue in the proper implementation of the video conferencing system. Students were so displeased with the existing format of videotapes that directors of the program mandated that the first instructional broadcast would occur in less than five months after the equipment was chosen and purchased. This proved to be a woefully inadequate preparation period given the situation at MCPHS. In August of 1998 none of the following pre-requisites for interactive video conferencing existed:

- A specially designed or appropriately adapted room for broadcasting at both sites.
- Adequate number of support staff trained in this technology.
- Training in place for faculty (focusing on customizing courses for this format, practicing specific teaching/presentation skills for on-camera delivery, coaching on the use of the electronic components, and managing the new instructional environment).
- A vendor with past experience supporting this system configuration in this particular environment.

A one-day training session for faculty was not customized to the needs of higher education and was of little value in preparing to teach using the technology. Faculty faced the camera in January 1999 with little formal preparation on the best practices of successful video conferencing. In the meantime, a grant was funded for a 3-day, customized, formal training seminar. This program took place in April 1999 and was a success — exactly what was needed. The only obstacle was that faculty schedules were so fixed and heavy that only a small number could attend. Nonetheless, as a result of the training, several faculty and support staff are in place to coach those faculty who either couldn’t attend the training or who later transitioned into video conferencing. It was obvious that customized, quality training is a lynchpin in any video conferencing program (see Boaz et al. 1999 & Bray 1999 & Weiss 1999).

The main issues in providing this type of training are (see Parker 1999 & Robbins 1997):
Factor into the distance learning budget adequate funding for a quality training program, or secure funds from an external source.

Work within the timeline and milestones of the overall project to ensure that faculty are comprehensively trained before the first time they have to teach via video conferencing.

Announce the training event well in advance to allow faculty to work it into their calendar.

If possible, have a plan for release time for some faculty who may need to have classes covered.

Do a thorough needs-assessment of your faculty and accept only customized training.

Expect that a good agency/consultant will conduct their own needs-assessment with you.

Demand to talk with other higher education institutions that have utilized this training agency/consultant for the same kind of training.

The three-day seminar that was chosen by MCPHS focused on (see Pike & Arch 1999):

- Innovative course design for video conferencing.
- Interactive, student-centered approach.
- Preparation of visuals for broadcast format.
- On-camera presentation/audience engagement skills.
- Assessment strategies for distance education.
- Many real-life, relevant examples.
- Opportunity to practice using the system.

The consultant provided participants with handouts, a practical workbook of activities, and a handbook of useful techniques and references. All participants delivered 10 minutes of instruction under live broadcast conditions. Each received individualized feedback and a videotape of their performance for self evaluation (see Hardwick 1997 & Robbins 1997 & Zielinski 1998).

As a result of the seminar, participants generated several sets of guidelines, including When the Technology Fails: Guidelines for Creating Plan B, Basic Protocol and Etiquette for Video Conferencing Discussion, Guidelines for Conducting a Distance Learning Orientation Event for Students, and Guidelines for Guest Lecturers. These documents have helped significantly in preparing faculty and also in focusing course coordinators and administrators on the special needs of teaching via video conferencing.

Teaching Experiences and Outcomes

Using video conferencing, five courses have been delivered to the adult learners in this program. Four of the five courses were team-taught and one was taught exclusively by an individual instructor. All courses in the program are structured to include didactic lecture sessions, interactive faculty-led sessions and student-based case discussions. The lectures and interactive sessions are delivered on Saturdays in the morning and early afternoon. For these sessions, the on-site and remote sites are connected via interactive technology. The case discussions, conducted using small groups of students in the late afternoon, do not require the use of video conferencing. The variety of delivery methods used in these courses, and the day-long duration of each course, requires much faculty planning for versatility in the classroom, and adaptation to new, interactive technology (see Hardwick 1997 & Pike & Arch 1999).

When the first team-taught course was offered in January 1999, the course coordinator was not teaching and was available to handle the technical complications that arose. Faculty members using this technology needed to adjust to a number of changes in lecture delivery including time delays, development of an on-camera persona, and adaptation of lecture material to distance learning (see Parker 1999 & Zielinski 1998). Faculty had to learn to deal with a five to ten second delay in transmission of her words to the remote site. This was difficult, even for faculty members who were accustomed to pausing between
concepts to allow for students' questions. It seemed an unnatural amount of time for both the faculty member and the students on site. Furthermore, if students at the remote site had a question, it took the same amount of time for their question to be transmitted. The dialogue became cumbersome. Therefore, most faculty members built small group exercises into their lectures so that students could discuss issues among themselves and try to help each other in answering questions about the lecture material.

Faculty have tested the compatibility of a variety of audiovisual aids with this technology. We have found that PowerPoint presentations project well at both sites and allow students at the remote site to focus on visual representations of the lecture material and not solely on the instructor. We have also found it crucial to provide the students with very structured and detailed handouts (see Pike & Arch, 1999). If the visual projection is ever lost, students are still able to follow the lecture using their handout. Although many of us traditionally use overhead projectors to facilitate interactive sessions in large classroom settings, these projections are not successful using interactive technology. Instead, specialized equipment, such as a document camera, facilitates interactive learning. A limitation of the document camera is that the instructor is no longer visible to the students at the remote site. Because of this limitation and the fact that we have only one camera, it is essential to provide students with a structured handout which includes all graphics and interactive diagrams so that they can easily keep pace with the instructor.

Feedback

Initial comments about the technology from students at both sites were predominately negative. They felt that videoconferencing was disruptive and adversely impacted on discussion during lecture. Students at the Boston campus were frustrated with the intrusion of videoconferencing and students at the remote site were more passive in their participation. Students identified sound and video problems which needed to be resolved by an expert rather than by the work-study students who were assigned to assist broadcasts. Although the work-study students were very reliable, they did not have the level of training to address the inadequacies of the system (see Boaz et al. 1999 & Carr 2000).

As of fall 2000, student feedback has much improved with only a few comments on course evaluations regarding the technology. Faculty have had mixed reactions to video conferencing. Some have adapted better than others to the technology and to the necessary changes they have had to make to their teaching style (see Kirchdorfer 1997).

Conclusions

Program Status

Overall, it has taken almost three semesters for the majority of faculty and students to become comfortable with the process. However, the system still is still not completely reliable and faculty must always have a backup plan in case of technology failure. To further maximize the process, all parties involved, particularly the faculty and technology support personnel, need to work closely together. Faculty need to keep informed of changes in the technology, the availability of new training sessions, and changes in personnel. In addition, the technology personnel need to be well informed of the faculty member's course planning and design requirements (see Boaz et al. & Hardwick 1997 & Robbins 1997).

Faculty Training

Faculty need training in interactive, student-centered course design and on-camera techniques for video conferencing (including hands-on practice) before they use the technology to teach. Adequate funding for
customized, quality training must be factored into the overall project budget (see Bray 1999 & Parker 1999 & Robbins 1997 & Weiss 1999).

Broadcast Environment

A fully equipped, appropriately designed broadcasting room should be established and tested at each video conferencing site. This information is readily available on the internet (see SURA Video Development Initiative 1999 & Pike & Arch 1999), or from established vendors.

Orientation

Whenever a new group of students begins a program delivered via distance learning, a formal orientation program should be presented, before the start of classes (see Pike & Arch 1999). The orientation should take place within the chosen environment for delivering the program (e.g., conduct the orientation session via video conferencing if the instructional program will be video conferenced). This orientation should:

- deliver all necessary information about the structure and schedule of the program.
- describe the key elements of the chosen delivery format that differ from a conventional class.
- demonstrate the operational features of the equipment.
- discuss the roles and expectations of all participants (students, faculty, site facilitators, technicians).
- clarify rules and protocol for questions and discussions, as well as all vehicles of communication such as e-mail, internet, telephone, FAX.

Activities should be planned that help to introduce participants to each other and to the faculty and administrators of the program. Plan B, the backup plan that will go into action if a technology failure occurs, should also be presented (see Pike and Arch 1999).

Abstract: Decision-makers within the U.S. Navy must command vast quantities of information. The bulk of this knowledge is accumulated through personal study of written documentation including Tactical Memoranda (TACMEMOs). This paper describes the theoretical and technical underpinnings of the Tactical Readiness Instruction, Authoring, and Delivery (TRIAD) project, an effort designed to improve the usability of these documents.

Introduction

Decision-makers within the U.S. Navy are faced with increasingly complicated and stressful tactical environments. These environments are characterized by situational uncertainty, time compression, and capable adversaries. To cope with such environments, today's decision-makers must have absolute command of a vast and varied knowledge base. The decision-maker must be familiar with situational cues, own ship capabilities and limitations, those of potential adversaries, tactics at his or her disposal, and those that potential adversaries might employ.

Some of this knowledge comes from formal training. However, the bulk of it is developed through experience and through personal study of tactical publications (including Tactical Memoranda [TACMEMOs]) and combat system doctrine (Cannon-Bowers, 1995; Cannon-Bowers et al., 1994). In this work, we focus on TACMEMOs.

TACMEMOs are developed to provide Fleet personnel with the information necessary to employ a new tactic or tactical concept. They are often developed by relatively junior officers. These officers (and their support staff) may be knowledgeable in the tactical subject-matter in question. However, they have little or no training in effective technical writing or instructional design. Moreover, the documents that are produced suffer from shortcomings that are common in many technical documents: passivity, linearity, and poorly represented spatiotemporal relationship.

We began the Tactical Readiness Instruction, Authoring, and Delivery (TRIAD) project to develop a set of authoring and delivery tools that will enhance the quality of tactical guidance.
Development Context

TACMEMO development begins with the identification of a tactical deficiency and development of a tactical solution that addresses that deficiency. The resultant tactic is disseminated to Fleet units via a TACMEMO.

TACMEMOs are written by middle grade officers with operational experience relative to the assigned tactical project warfare area. These individuals possess a minimum of a bachelor’s degree, and at least some computer skills. They are supported by a staff of senior petty officers, and civilian editors and production specialists. In some cases, tactical project officers may receive analytical support from civilian contractors or government laboratory engineers/representatives.

Project officers are provided with structural guidance\(^1\) (i.e., the sections that a TACMEMO should include, and the order of those sections). However, they are provided with little or no guidance as to how to author a document that efficiently communicates the tactic.

Once written, TACMEMOs are read by personnel ranging from flag-level commanders (i.e., Admirals) down to junior enlisted personnel. At every level, readers must balance the need to read and understand new TACMEMOs against the press of their other responsibilities. Their task is made more difficult by documents whose format is not consistent with the reader’s needs. We recently queried a group of readers on their use of TACMEMOs. Within this group, TACMEMOs are used extensively as reference documents and are rarely studied. Only one participant indicated that he often read the body of the TACMEMO. Most indicated that they did so on occasion. The remainder indicated that they did so rarely if ever. By contrast, a large majority of participants indicated that they consulted TACMEMOs during operations.

It is within this context that TRIAD must operate. In designing TRIAD, we must create tools that augment authors’ typical communication skills to produce documents that meet the task-demands of readers.

TRIAD Overview

The personal computer (PC)-based TRIAD system is being designed and developed to:

- Provide authors with the capability to create an effective multimedia learning environment to support the transfer of tactical knowledge to readers; and
- Provide readers of tactical documentation with a product that addresses their need for efficient and effective tactical documentation that is easy to use and supports self-training.

In this regard, TRIAD will provide authors with an integrated tool set to enable them to create tactical documentation (i.e., TACMEMOs) using a variety of multimedia presentation techniques, and to create associated interactive multimedia instruction (IMI) to support the documented tactic/doctrine. In turn, readers will receive a multimedia tactical documentation “product set” that supports tactic/doctrine presentation and briefing, instruction, quick reference, and facilitation of electronic feedback regarding tactic/doctrine evaluation.

After a tactic has been defined, but before it has been documented, the author uses TRIAD to create a product set. The process consists of three stages: interview, edit, and review.

During the interview stage, the author creates and/or imports media regarding the tactic in response to interview questions. For example, the author might be asked to define the tactic (text), describe the tactic using an illustration (graphics), generate a scenario that supports practice (simulation), and/or import a video that shows tactic evaluation results. As the interview progresses, the TRIAD system adds the information provided by the author to its database.

Using the information gained from the interview, the TRIAD system automatically generates a draft TACMEMO product set consisting of the following components: Base Document (core TACMEMO), Tactic Training Component, Quick Reference Guide (QRG), Feedback, and Brief (PowerPoint® presentation).

Once the interview is complete and the draft product set generated, the edit stage commences. Here, the author is presented with the draft product set, and can choose to edit any or all of the product set components. He can add

\(^1\) Often, even this minimal guidance is violated.
new media and edit existing media (text, graphics, animation, simulation, etc.). The author can import related media from the local TRIAD database, or from a remote database, into a product template and then edit as desired.

The review stage commences after all TACMEMO product set components have been developed. The TRIAD system will integrate the components into a review document with all associated markings. This review version can be distributed via multiple means (paper, local area network (LAN), wide area network (WAN), disk, etc.). Reviewers will be able to comment within the document and return these comments to the author. Comments received electronically will be stored in the TRIAD database for use by the TACMEMO author to revise components as required. The capability to merge comments into the document will be provided. Comments received on paper will be utilized by the author to revise components as required. As in the edit stage, the author can create/import new media and edit existing media (text, graphics, animation, simulation, etc.) in response to review comments.

This process of assembling the product set components into a review document, distributing the document for review, incorporating review comments, and reassembling the product set can repeat as necessary until a final product set is approved. Upon completion of the review process, the TRIAD system will assemble the TACMEMO product set for final packaging and subsequent distribution to readers (compact disk/digital video disk (CD/DVD) or LAN/WAN). TRIAD will support document version control throughout this process.

A reader will receive the TACMEMO in an appropriate electronic format, and will be able to access the multimedia TACMEMO product set (Base Document, Tactic Training, QRG, Feedback, and Brief).

Authoring Component

Although TRIAD will produce a product set that includes much more than is normally considered “training,” we conceptualize it as an instructional design task. As such, TRIAD must automate the instructional design process. As Reigeluth (1993) noted:

> Automating could entail anything from providing a few tools for an instructional designer to use, to entirely replacing the instructional designer. It generally does not refer to replacing the subject-matter expert. The instructional design process could entail anything from the instructional strategy selection process . . . to the entire spectrum of phases . . .

Theoretical Foundation

Instructional design theories relate instructional conditions (student and subject-matter attributes), instructional methods, and instructional outcomes (Reigeluth, 1983). Our focus is on prescribing instructional methods to produce instructional outcomes (given certain instructional conditions). More generally, this could be rephrased to say that we want to devise communication methods that will produce performance outcomes.

A number of others have investigated the process of automated instructional design and TRIAD can certainly benefit from their work [see, for example, Spector, Polson, & Muraida, (1993)]. In general, two classes of authoring systems have emerged.

The first approach seeks to provide instructional design assistance and coaching during development. Gagné’s Guided Approach to Instructional Design Advising (GAIDA) provides one example of this approach (Gagné, 1993). Using information about students, the task, and the environment, GAIDA guides instructional designers through a four-step process of instructional design. Tennyson (1993) offered a similar, albeit more ambitious, approach. He proposed to develop a system that could coach novice users through specific development problems while developing their ISD background. The same system would simply offer advice to more experienced users.

The guidance/assistance/coaching approach is relatively easy to implement and may be applied to a variety of design situations. However, it does require the developer to acquire, interpret, and apply instructional design principles while in the process of development. In the TRIAD context, our authors seldom have the background necessary to use such a tool effectively. Such an approach might impose a significant learning requirement on the authors while not ensuring compliance with instructional design guidance.
An alternative approach is to provide restrictive template structures as the primary mode of development. Merrill’s Electronic Trainer provides a good example of this approach. Within Merrill’s approach (1993), the author uses a defined grammar to specify the training environment and curriculum. Expert systems are then used to select, sequence, and partially populate the appropriate instructional transactions.

The use of a template structure removes many of the burdens imposed by GAIDA. Instructional design prescriptions are built into the templates. Therefore, authors do not have to mastery this material themselves and compliance is assured. However, such systems can be complex to operate and the selection of appropriate templates is not always obvious.

TRIAD developers have selected a hybrid inquiry-based strategy. Within our approach, the majority of development occurs through the use of implicit templates. That is, the templates are used to guide an interview with the author and to organize the resultant content. This approach has the benefits of Merrill’s template approach, while hiding much of the complexity from the author. It ensures a high-level of compliance with theoretically sound instructional design principles without requiring the author to master those principles.

Design Summary

The various theoretical perspectives on decomposing content, establishing learning objectives, and associating learning objectives with communication strategies embodied within TRIAD can be summarized in an overarching design approach. The TRIAD team has organized this approach into three interview-stage phases: Pre-planning, Initial Query, and Elaboration/Augmentation. Each phase satisfies an important goal for the authoring process.

During the pre-planning phase, TRIAD guides the author to establish the basic framework of the TACMEMO product set. That is, starting with a metaphorical “blank sheet of paper,” TRIAD helps the author to identify the primary content areas which must be explored in the product set. This establishes a framework on which later authoring functions can elaborate.

More specifically, the Pre-Planning phase has two goals associated with it. The first goal is to help the developer begin to mentally frame the content of the TACMEMO to be written. TRIAD should not only solicit information from the developer, but also help the developer organize his/her thoughts about the TACMEMO as it is being developed. This will facilitate an active, rather than passive, participation of the developer within the interview.

After considering a range of pre-planning options (full case-based retrieval, exemplar case-based retrieval, TACMEMO taxonomy, traditional knowledge elicitation probes, and scenario-based development), the development team determined that the development of a TACMEMO taxonomy was most feasible. This method relies on the development of a TACMEMO taxonomy that is used by the developer to classify the TACMEMO to be written. The taxonomy decomposes each classification several layers deep, permitting the developer to select those elements applicable to the TACMEMO to be authored. To succeed, it must be possible to classify existing TACMEMOs into a finite number of categories. For TRIAD, we were able to develop on a three-tier taxonomy: categories, anchors, and sub-anchors.

Next is the initial query. The base document represents the primary communication of the tactic and the central product set component. Therefore, step one of the initial query combines sub-anchors into various base document sections and sub-sections. TRIAD will support the author in this process as well as guiding the author to generate a performance goal and associated title for each section.

After reviewing the base document structure, the author will be supported through the process of creating base document content. For example, TRIAD will provide guidance based on effective technical writing techniques, appropriate content sequencing and media selection (based on performance goal verbs).

At this point, authoring will transition from the Base Document component to the Tactic Training component. Together, TRIAD and the author will identify Base Document sections that can benefit from associated instruction. These are likely to be sections that are sufficiently complex or that rely on doubtful background knowledge.

---

2 It should be noted that this focus of performance goals within the base document is likely to lead authors to create a "leaner" and more usable document than was common in previous, unguided attempts.
In any event, when a section is earmarked for instructional support, TRIAD will guide the author through the process of creating verb-based learning objectives. Next, the author will be guided to create assessment items, instructional material, and practice items in support of each objective. This process will work up from content sections to include both lesson- and module-level instruction.

Similar processes will be applied to derive the quick reference guide, Feedback, and Brief components.

When done with the initial query, the author will have produced a complete, albeit immature product set. The maturation process occurs through elaboration and augmentation.

The *Elaboration/Augmentation (E/A)* process is applied in the final stages of TRIAD document authoring. The process consists of three strategies: confirming, elaborating, and fine-tuning. These strategies are designed to help authors refine and augment content. They are applied iteratively.

*Confirmation* assists authors in validating content accuracy and completeness as well as confirming TRIAD-generated structures and sequences. Confirmation is critical because it safeguards the accuracy of both the content and structure of TRIAD-generated documents. *Elaboration* helps authors to extend, amplify, and otherwise augment TRIAD documents. Authors elaborate and add detail descriptions and supporting examples, especially those considered critical to the user's knowing and implementing the tactic. *Fine-tuning* enables the author to clarify information, directions, instruction, and presentation. At this step, the author amplifies key information, reducing or eliminating ambiguity and unclear or non-essential information.

The E/A process is grounded in a set of partially overlapping foundations. E/A in the Base Document is grounded in seven foundations: text structure, text design, text augmentation, usability/transferability, technological, cultural, and pragmatic. In the Tactic Training component, E/A is grounded in five foundations: psychological, pedagogical, technical, cultural, and pragmatic. In both cases, these foundations ultimately help authors develop and fine-tune structure and content drafted during the initial query.

The interview process will create a variety of interconnected content. TRIAD needs a robust process for organizing, maintaining, and using that content. To meet this challenge, we have adopted the use of knowledge objects.

One can think of knowledge objects (sometimes referred to as learning objects or sharable courseware objects) as boxes with labels. The label on the outside of the box tells everyone about the contents inside the box. Knowledge object boxes may contain other boxes, or real contents. As such, the knowledge objects provide an elegant way to store and organize the contents of our TRIAD product sets. The labels help in the organization function. The labels also make it possible to look for a box (knowledge object) that contains desired content.

**Delivery Component**

An elegant authoring process is of little use if the content is delivered to the reader in a form that fails to meet his or her needs. TRIAD will build on Internet technology to create a robust, user-sensitive, and flexible delivery environment. Here, we describe how TRIAD delivery components will rise to meet this challenge.

**Enabling Technology**

An understanding of how content will be delivered to the user requires an understanding of three component technologies.

As noted above, we will be using knowledge objects to organize the output of the authoring stage. In the delivery environment, however, we make use of an Extensible Markup Language (XML) representation of the content. A transformation process will transform knowledge objects into the TRIAD XML representation. XML is a mark-up language that describes the functional/semantic parts of a document (titles, headings, paragraphs, warning, cautions). XML is well suited to the task of representing the structure and interrelationships inherent in a body of content. An XML representation of content is independent of how that content might be rendered to a user.

To render the content, TRIAD will use Dynamic Hypertext Markup Language (DHTML). DHTML is a good tool for rendering content in a browser-based environment and for supporting simple types of interactivity. It is poor at facilitating the storage of content, its content, and its inherent interrelationships. TRIAD needs a mechanism to
The Extensible Style Language (XSL) provides a vehicle for that translation. Stylesheets, written in XSL, describe how different elements of the XML representation are to be rendered. That is, the XSL stylesheet works as a map between XML elements (defined through a document type definition; DTD) and DHTML representations.

Design Summary

Internet browsers are “stateless machines.” That is, they can follow links from one place to another, but they are not designed to have memories about users or their actions. Such a memory is critical to several TRIAD functions. For example, the TRIAD “Quick Pick” TACMEMO list, notes, bookmark, and highlight functions are all user-specific and depend on the system’s ability to recognize a given user. Similarly, the functioning of the Tactic Training component and the management of administrative privileges all depend on user-specific information.

To provide that functionality, TRIAD has adopted a three-part architecture. The most obvious part of the architecture is the browser itself. TRIAD will delivery product set material to the reader through an Microsoft® Internet Explorer 5.0 browser. Rather than operating in a “stand-alone” fashion, the browser will be hosted within a secondary application, the “Presentation Engine”. The Presentation Engine is a piece of “middleware” that serves as a communication bridge between the browser and the third important piece of software, the “Delivery Engine”. The Delivery Engine is responsible for the bulk of TRIAD delivery functionality. This includes activities like maintaining user data, managing information access, preparing knowledge objects for delivery, and system administration.

3 This notion of separating content from rendition is a powerful one within TRIAD. For example, a given idea could be represented in a single XML representation. However, it could be rendered for the user in a number of formats across TRIAD's product set components.
Evaluating the Influence of Web Based Seminar Preparation for Undergraduate History Students

Pauline McCormack, Teaching and Learning Support Unit, University of Newcastle upon Tyne, UK, pauline.mccormack@ncl.ac.uk

Dr Donald A Spaeth, Modern History, University of Glasgow, UK, d.spaeth@modhist.arts.gla.ac.uk

Abstract
This paper discusses the implementation of web-based primary sources in two undergraduate history modules at the University of Glasgow, Scotland. It outlines the purpose of implementing Information and Communications Technology (ICT) and the different approaches taken by lecturers to the use of computer assisted instruction. The implementation employed a range of evaluation instruments both quantitative and qualitative, before and after the modules were taught. The results of the evaluation and the implications of the findings are debated.

Introduction
The School of History and Archaeology at the University of Glasgow recently injected the use of Information and Communications Technology (ICT) into its Level Two history courses in order to introduce all its history students to the potential of computer networks and access to sources. It is hoped that the exposure to ICT will provide a prelude to specialist honours Historical Computing courses which deal with more advanced methodological applications of computers.

The IT Committee of the School had been working on this implementation since the move from full year courses, to a modular system of ten week courses, in 1996.1 It had already ensured the introduction of a School policy which stated that the completion of at least one assessed, computer-based unit within a Level Two course will be a prerequisite for entry into honours in a student's third year, and had run a pilot scheme with one lecturer. 1998 though, saw a number of other developments which were to give a boost to this policy:

1. The complete redesign of the Level Two modules with a new aim to increase students' familiarity with primary sources and to give them skills in interpreting such sources critically. This was entirely independent of any development in ICT and indeed some tutors chose to use paper primary sources like examples of palaeography and works of art in local galleries.
2. The completion of twelve multi-media, history tutorials for use in undergraduate teaching, by the national Teaching and Learning Technology Program (TLTP) History Courseware Consortium which provided the project with a rich starting point in terms of available sources.2
3. The founding of the successor to the TLTP project, the Courseware for History Implementation Consortium (CHIC)3, set up to provide funds and pedagogical advice to UK Universities embedding the tutorials into undergraduate history teaching.

A successful grant application to the CHIC project enabled the provision of in depth support for implementing and evaluating a range of resources within the new modules which were: European Society from 1550 to 1700 (Early Modern); and Society, Culture, Politics and Power in North America from First Contact to the Present (America). The Early Modern module would take place during the first semester with around 200 students registered and the American module was to be taught in second semester to circa 220 students.
The main business of the project was to introduce students to the use of on-line sources to prepare seminar topics but other parts of the project set up data analysis exercises, multi media lectures and a computer mediated conferencing system.

One of first issues to deal with was the different approaches between the two courses, and within the Early Modern module, the differing approaches of individual lecturers, regarding the presentation of the sources and the extent of the skills that would be introduced to the students.

**Early Modern**

Not all the students who enrolled in the Early Modern module used computerised sources. Five tutors took seminar groups and decided their own seminar topics, of these five, only two made the use of web-based sources mandatory. Both of these tutors were highly directive in the instructions they gave to their students. They presented the students with a small number of primary sources per seminar, pre selected from the TLTP tutorials, prefaced with questions that the students should consider for the seminar. Figure 1 shows a section of the instruction for one such seminar question.

Toulouse is a provincial city located in the south-west of France. For five days in May 1562 the streets of Toulouse were the location of religious violence which led to the deaths of many people. Such violence in Toulouse and other cities demonstrated the explosiveness of the political and religious situation in France. It was the prelude to the outbreak of the French Wars of Religion and a foreshadowing of more famous violence such as the St. Bartholomew’s Day Massacre of 1572.

The Reformation was born in Germany in the 1520s. It did not take it long to spread to France, aided by the proximity of the Protestant city of Geneva, home of Jean Calvin. Try each of the following links to find out more. (Remember to use the Back button to get back here.)

The growth of Protestantism can be studied by counting prosecutions for heresy.

- 07.27 Background of accused heretics.
- The distribution of Protestantism can be studied through the origins of refugees from France who went to Geneva. (Toulouse is in south-west France.)
- 07.29 The Geographical Spread of Refugees from France to Geneva.

**Figure 1:** Screen shot from the Early Modern Seminar Preparation page.

One of the tutors conducted some timetabled seminar sessions in the computing labs on the subject of Migration in Early Modern England, where the students were introduced to raw data and to data handling. (The students in these seminar groups explored the sources more deeply and employed higher levels of computing skills than any of the other students.) The second Early Modern tutor requested that his students work through the seminar preparation materials in their own time, with help available from Graduate Teaching Assistants (GTAs) during drop in sessions.
The lecturers on the America module co-operated regarding seminars so that all students covered the same seminar subjects and were required to use on-line sources for seminar preparation throughout the module. The TLTP tutorials were only two of a large bibliography of web links. The students on this module were given far less direction than those on the Early Modern module, but rather were presented with the URLs of four or five comprehensive sites, for each seminar. Figure 2 shows the links for one particular seminar.

**America as a World Power**

- The Great Powers and the Division of Europe (only available locally in the Art
- Albert Beveridge, "The March of the Flag" (1898)
- William Jennings Bryan, "Imperialism" (1900)
- John Dewey, "Imperialism is Easy" (1927)
- Woodrow Wilson, 14 Points (1918)
- Franklin Roosevelt and Winston Churchill, "The Atlantic Charter" (1941)
- Harry Truman, "Address Before Congress" (1947)

**Figure 2:** Screen shot from the American History Seminar Preparation page.

Like some of their Early Modern peers, the students of American history were provided with drop in lab sessions supervised by a GTA and had to use the web resources in their own time. They were also given access to an on-line conferencing system and attended multi-media lectures.

Before this article proceeds, a quick word about GTAs, on whom tutors relied extensively to support undergraduates during their seminar preparation. The GTAs were all PhD history students and three of the four GTAs held on MPhil qualification in historical computing. In addition to this each GTA was provided with four hours paid training solely on the web-based sources that the undergraduates were using.

**Evaluation**

A full evaluation was undertaken with students returning questionnaires on their attitudes to computers and computerised sources before and after they studied the modules. Post course qualitative interviews were conducted with a selection of students and with all staff. Observations were undertaken of laboratory based seminars, classroom based seminars, and a classroom based seminar with students who did not use any ICT in seminar preparation.

The purpose of the evaluation was to identify the best methods of embedding computer-based resources into the courses in order to give the students a deeper and richer learning experience. Inevitably, much of the evaluation focused on student reaction to the computer-based resources and how this compared with their reactions to traditional resources and activities such as lectures, seminars, note-taking, and paper-based materials. Gauging student reaction involves determining more than whether students 'liked' the materials, but whether they found the materials were appropriate to their study approach and whether the technology served as an obstacle to learning. Since the aim of teaching is to enhance student learning, another important aspect of student learning is whether students have a sense that they understood the historical content better. A final component of the evaluation was to assess whether the approach to implementation was effective and, where possible to compare approaches.

**Pre-Module Results**

BEST COPY AVAILABLE

656
The first questions in the pre module questionnaire attempted to measure the students' perception of their level of computer skills against a more formal gauge of software competency decided by the questionnaire designer. Students' assessment of their own skills did not match reality, while 75% professed themselves as having moderate or substantial experience, 89% were actually found to be competent or very competent in software use. When asked about how confident they felt using computers, only 60% of all students and only 50% of the Early Modem students professed to be confident or very confident.

One theory is that this is due to modesty, typical of British students. It is perhaps modesty combined with a lack of experience with computers and different ideas about what constitutes competence. The study was measuring whether students possessed the skills which would allow them to take part in this particular project without further training, eg: experience of web use and word processing. Students perhaps recognise that these are not high level computing skills and it's possible that our measure of competence was relatively low.

When it came to student training it was surprising that only 45% had acquired their skills on the freely provided University Basic IT Certificate course. This means that students are coming to University already skilled or are picking up the skills via peers or self study.

When questioned about their attitude to the use of computerised history sources 58% of Early Modem students were found to have a positive attitude, against only 32% of America students. This can be explained by that fact that the Early Modem students were self selecting as they signed up for the seminar of their choice and could have studied a seminar topic which did not involve the use of ICT. It is interesting that the Early Modem group were less confident but more hopeful about the experience and this contrast is illustrated in figure three below. The proportion of America students who expect a negative experience is alarming but also fits with the generally pessimistic attitudes discussed above. To go beyond conjecture on such issues the evaluation needs to be extended to cover pre course qualitative studies.

In summary, there were two key points from the pre course questionnaire: firstly higher proportions of UK students are coming to University with ICT skills each year, and this trend is expected to continue; secondly,
students still lack confidence in using ICT and it is therefore crucial to provide adequate documentation, support and guidance as well as assurance.

Post Module Results

The post module questionnaire provided information about three sets of questions:

- How did students use the materials?
- How easy did students find the computer-based resources? Did the technology come between them and the subject? Did they have any particular difficulties?
- How helpful did students find the materials in learning about the historical subject? How did these materials compare with others they also were using?

While all of the students studying the Early Modern module actually used the on-line sources to prepare for their seminars, 4% of the America students did not use a computer at all. This difference is probably explained by the highly directive nature of the Early Modern resources whereby the questions, issues and sources related to the seminars were contained on the course web page and nowhere else.

Students were asked whether they had sought help or advice from anyone, including from friends, or neighbours in the computing labs. 70% of students sought no advice at all and almost all of these attributed this to the ease of use of the materials.

The requests for assistance were highest among the Early Modern groups which participated in laboratory based seminars where 50% requested help. Not only were these students undertaking more involved skills based tasks but, being in a lesson with their fellow students and with GTAs meant they automatically turned a peer or teaching assistant for help. Observing one of these seminars it was found that the students ask for help with the historical questions and well as with computing problems. The observation also found that, in contrast with classroom based seminars where the majority of the discussion is directed to and mediated by the tutor, in a laboratory situation the students talked constantly to each other about the data they were analysing and their results. Such student to student interaction is encouraging.

Students rated the computer-based resources very highly. Only one student on each module said they would not recommend them to other students. When asked to compare the usefulness of computer-based materials with other types of resources, such as lectures, books, and their own notes, computerised sources received the highest rating in several respects with 99% of respondents rating these resources positively. In sum, students placed a higher value on computer-based resources than on any other, including traditional methods of delivering teaching. It should be noted that the evaluation was likely to be somewhat biased in favour of computer-based resources, in part because the students knew that they were participating in an experiment and in part because students had already received direct feedback from assessed coursework based on these resources, whereas they had yet to sit an exam (which concentrated primarily on lecture topics). Nonetheless, the highly positive reaction to the computer-based materials is a significant finding.

Students were asked which resources they found most and least helpful. The answers to these questions were less insightful than had been hoped because some students regarded the computer or the computer-based tutorial as a single resource. Their answers therefore provide more insight into student views of the computer than about their approaches to learning. Nonetheless, students identified particular features they valued, including personal histories (i.e. autobiographies) and witness reports, and the analytical advantages of graphs and tables. Clearly, students valued the greater understanding they gained through personal evidence that helped bring the past to life, and the summaries provided by descriptive statistics.

Qualitative analysis via focus groups gives more insight into the differences between the two pedagogic approaches. As might be expected, those students who participated in timetabled lab sessions reported higher
level learning outcomes than the remaining students. In general, students on the Early Modern module assert as positive aspects such things as, forming one's own interpretation based upon an assessment of the evidence, or as some of the students put it, they felt as though they were 'doing' history. The Early Modern students also felt a sense of ownership and relevance about the computer-based materials and they appreciated the amount of preparation they had been spared by being presented with a set of materials which were put together especially for their seminars.

In contrast some of the America students felt the presentation of their materials lacked direction and there were too many resources for them to consider fully. It can of course be argued that the location, selection and assessment of the probity of sources is as much a part of historical methodology as is the analysis and use of a source to answer a historical question. This though must be balanced against the amount of time a student would spend searching for a source in what is essentially an introductory exercise. The most positive aspect of the project for the America students was that the computer-based resources were more widely accessible than library based materials.

Conclusions

The evaluations of both modules have in common four key findings:

- Students appreciated the availability and diversity of the computer-based sources. Not only were the materials more easily available than books from the library, but they provided a stimulating range of sources which would not otherwise be available. Students enjoyed being able to access images, facsimiles and sound as well as texts, and being able to compare contrasting or contradictory evidence.
- Even though some America students felt there were too many resources for them to explore, the majority of students valued the fact that the resources were directly relevant to the seminar subjects.
- It was recognised that the diversity and relevance of the resources offered increased opportunities for deep learning.
- It is crucial that students are provided with adequate training (at least one class hour) and with support in lab sessions throughout the module.

From the post module evaluation then we can see that students' negative expectations of the experience of using ICT in seminar preparation were not borne out the evidence and this is a heartening vindication of the teaching team's belief in being able to deliver a richer learning experience through this project. It would be advantageous to further teaching to undertake qualitative evaluation which attempts to locate the roots of these negative expectations and recommend ways in which the teaching of ICT can be introduced so as best to allay students' fears at the earliest possible opportunity.

Abstract: After implementing WebCT at Mason, the staff of the Instructional Resource Center were interested in determining if students were benefiting from the use of this tool. Twenty-five (25) surveys were collected from a group of graduate students using WebCT. The overall findings were positive and in favor of WebCT. The majority of the students indicated that the online tools provided by WebCT were beneficial to the learning process. Further studies should be conducted to see if a general population of students would yield different results.

Introduction

In January 1999, George Mason University began using WebCT, an online course management system designed to facilitate the creation of web-based instructional material and instructional supports. Currently, WebCT is being used by some faculty and is considered to be in its early stages of implementation. Up to the present time, no systematic assessment of WebCT's implementation has taken place. This paper is the first step in a series of research efforts that address one of three major aspects of WebCT at GMU, student satisfaction with WebCT. The other two are faculty satisfaction with WebCT and institutional support for WebCT. These will be addressed in other papers.

Before beginning a discussion of the data collected on student satisfaction with WebCT, a brief exploration into the definition of an Online Course Management System (OCMS) is provided to establish a mutual understanding of OCMS.

Online Course Management Systems

Online course management systems (OCMS) can be defined many different ways depending on whom you ask. For example, Michael J. Albright (1997) describes OCMS as "integrated packages that provide content presentation, communication, assignment submission, testing, and management functions in a secure environment, easily accessible via a web browser." Murray Goldberg and Sasan Salari (1997), describe WebCT as "a tool that facilitates the creation of sophisticated World Wide Web-based educational environments. It does this in three ways:

- It provides an interface allowing the design of the presentation of the course (color schemes, page layout, etc).
- It provides a set of educational tools to facilitate learning, communication and collaboration.
- It provides a set of administrative tools to assist the instructor in the process of management and continuous improvement of the course."

Related Research
It is one thing to develop an OCMS and use it for either classroom support or full distance education; it is another to say it actually makes a difference in the learning process. The following research tries to flush out how students are reacting and learning via an OCMS.

According to the Institute for Higher Education Policy (1998) “There is a relative paucity of true, original research dedicated to explaining or predicting phenomena related to distance learning.” (Page 2). Much of the body of research that does exist dealing with on-line learning “are more anecdotal than systematically empirical or critical.” (Hara & Kling 1999). In addition Windschilt (1998, as quoted by Hara & Kling 1999) also notes that much of the published literature dealing with computer-mediated on-line instruction consists of descriptions of software or annodotal accounts of how technology was integrated in a course or classroom.

Much of the research that does exist dealing with on-line learning must be looked at with a critical eye, since potential threats to reliability are often present that are not addressed by the author(s). (The Institute for Higher Education Policy, 1998) These include author bias, especially since many of the authors are technology experts or teaching computer-related subjects (Goldberg, Goldberg, Dabbagh & Schmitt 1999) failure to take into account the affect that novelty may have had on student attitudes towards the technology (Goldberg, Goldberg, Pauley & Cunningham 1999, Melron 1998, Fong 1999), lack of a control group (Pauley & Cunningham 1999, Fong 1999, Dabbagh & Schmitt 1999, Pauley & Cunningham 1999), and lack of a random sample of subjects (Goldberg, Goldberg, Pauley & Cunningham 1999, Melron 1998, Fong 1999, Dabbagh & Schmitt 1999, Pauley & Cunningham 1999).

Keeping the above flaws in mind, let us look at what the research does say. Most of the existing research shows that there is no significant difference in student achievement and attitude towards instruction between classes using web-based instruction and those which do not (The Institute for Higher Education Policy, 1998; Morris 1999). Schulman & Sims (1999), for example, found that there was no significant difference in posttest scores of the web-using and traditional instruction groups. Melron (1998) in his study of 3 courses using WebCT to varying degrees, found that student responses were overwhelmingly positive. All of the students wrote that they would take an on line course again. Students were especially impressed with the ability to log-in anytime, quality of discussions, breadth of discussions, and convenience. In studying accounting students’ reaction to WebCT, Fong (1999) found that the students “perceived [WebCT] to be better than traditional course delivery methods in form of paper handouts and lectures in many course elements like course outline, course notes, assignments, presentations, readings & especially multiple choice exercises.” (Page 60). The majority of these students also felt that learning with WebCT were either equal to or enhanced traditional learning methods, with approximately 50% stating that WebCT was “very beneficial” & “very useful.”

In studies where student reaction to on-line learning was measured but not compared to student satisfaction with a traditional classroom, Pauley & Cunningham (1999) reported that 94% of the students survey would take another course using WebCT and 93% would recommend such a course to their friends.

However, Hara & Kling (1999) in their study of student frustrations with on-line learning noted problems such as the lack of non-verbal cues from face-to-face discussion, technical glitches, problems caused by student unfamiliarity with technological tools, lack of proper feedback & directions from instructor, and lack of accessibility to the needed computer equipment. Wermet & Ologes (1999) found that the length of the course was a factor in student satisfaction. They attributed this to the fact that in longer courses, students were more patient with technical glitches since they had not been pressed for time in completing assignments. They also found that access— both in terms of access to the hardware needed and ease of use was a problem. Danchak (1999) found differences in student attitudes to WebCT based on experience with computers and age. Less experienced computer-users tended to enjoy WebCT more than more experienced users, a fact that the author attributed to a sort of “gee whiz” factor. In addition, older students were more likely to prefer on line quizzes than younger students. Danchak also found that the people who posted to the bulletin board most often disliked it the most, possibly because of frustration w/ the technical glitches that one would be more likely to encounter the more that one used the bulletin board tool. Bayram, in a study of virtual classrooms in Turkey, pointed to problems with hardware, navigation, time, web design, cost. However, the biggest barriers were found to be the time and practice with the software required. Goldberg (1997) also found motivation to be a key issue. Although half of the students in the class studied liked the self-paced aspect of an on-line course, the other half felt that they needed external motivation to keep them on track.
and found the self-pacing to be an aspect of the course that they liked least. Merron's (1998) students also found reading all the messages on the bulletin board to be very time-consuming.

In comparisons of completely on-line courses versus courses that combine face-to-face meetings with on-line learning and courses that do not contain any web components, students said that they preferred the mixed course to a completely on-line course (Goldberg, 1997). Students in this type of hybrid class were also more likely to do well than students in a completely on-line course (Goldberg, 1997; Merron, 1998).

An Investigation and Review

After reviewing the various studies already conducted on WebCT and OCMS, the need to conduct research at Mason became very clear. The following sections discuss the methodology used and threats to the validity and reliability of the data collected for this initial study of students at Mason and their experiences with WebCT.

Survey Methodology

There were several steps that needed to be planned and executed. In addition to identifying the actual objective of the study, the audience had to be identified, the data collection process had to be defined, the collection tool had to be developed, and permission needed to be obtained to use the data once collected. Each of these steps is described below.

The objective as stated in the introduction, "... student satisfaction with WebCT," was the over all objective of the study. Because it was not clear what the responses might be, the objective was kept broad. The survey was designed to explore how well Mason students were using WebCT and how well WebCT is was working for the students. It took into consideration the computer experience of the students and their learning process/needs to see if these needs are consistent with what WebCT has to offer. Other interests explored included how the students might use the tools after they have completed their courses.

Several factors were considered when attempting to identify potential participants in the student survey. The factors considered were:

- The overwhelming size of the Mason student population (26,000+) and the fact that not all Mason students use WebCT or a like product.
- The location of the students (most off-campus and part-time)
- The inconsistent use of WebCT across the campus and across the disciplines
- The limited time available to conduct the survey caused in part by the need to collect data about the success or failure of WebCT in time for decision-makers to decide how many resources will be provided to support WebCT.

Based on the above, it was decided that a pre-existing, large group of students new to WebCT would be an acceptable sample audience for this study. The participants in the Graduate School of Education's Initiatives in Educational Transformation (IET) were asked to be the sample student body. They are a dedicated group of 120+ graduate students in one 2-year program using WebCT. They are made up of K-12 teachers seeking a Master's Degree. Preliminary studies conducted by the IET faculty indicated that the participants of this program were limited in their ability to use technology, particularly web-based technology. They were also selected because they could be reached with limited effort. Unlike the faculty population, the student population at Mason is geographically and technologically dispersed and without one or two simple means of being reached. The IET program offered a way to reach a large group via one communication device.

Prior to submitting a Human Subject Review for approval, a meeting was held with the IET faculty and their approval and support was requested. The faculty then had the opportunity to review the survey and comment. There were a total of twenty-six (26) questions asked via a web page survey (23 were a mix of Likert-Scale and Yes/No responses and 3 were written response questions). The answers were collected into a text-based file to be imported into a database for tabulation.
Once the Human Subjects Review was approved, a link was made from the Program's WebCT home page to the web page survey. An announcement was posted in WebCT by the faculty of the program and the students were asked to volunteer their time and take the survey. The survey was online for 15 days.

Threats to Validity and Reliability

As mentioned above in the student survey process section, the participants were not selected randomly and several factors went into that decision. Due to the lack of random and complete selection, threats to validity are relevant. This threat will have to be considered when attempting to make any observations from the survey results. Other possible threats include:

- Impartiality - The IET participants received training on WebCT by the same person conducting the survey.
- Audience - The participants are K-12 teachers and hence do not represent the Mason student population.
- Process - They were asked to survey WebCT via one of WebCT's communication tools.
- Timing - They were surveyed within the first few months of their 2-year program and a follow-up survey could reveal changes in their attitudes as their experiences and skill change.
- Time Constraints - They are all educators using an educational tool and therefore may not be able to give a balanced view of how the tool could be useful in other work-related situations.
- Time Constraints - The fact that a web-based technology is being surveyed via the web can potentially exclude those who are web timid and thus could slant the results more favorably.

Findings

The overall findings are positive and in favor of WebCT. The following sections summarize the results of the survey and how the threats discussed earlier might have influenced the results. Assuming all the participants in the IET program saw the link to the survey, approximately 20% of the participants responded. A total of 25 surveys were collected via the Internet, as discussed above.

Survey Results

In summary, the majority of the respondents agreed that online course management tools and WebCT are beneficial in the learning process. The following was discovered:

- Audience - 100% own a computer and connect to the Internet from home and/or work. Over 50% of those who responded consider themselves proficient in the use of a word processing, database, email, and online communication applications. 72% have taken web-based courses.
- Learning - 76% of the respondents agreed that they were likely to learn more effectively using on-line communication.
- Time Commitment - 56% indicated that they would not spend too much time learning technology in an on-line communication class, while 48% disagreed and felt they would. 56% indicated that they were likely to spend too much time keeping up with on-line communications, while only 28% disagreed.
- Sharing - 92% indicated that they were likely to use the information shared by other students. 96% - 100% of the respondents indicated that sharing the results of an assignment with their fellow learners helps improve the learning process; increases their efforts to do a better job on my assignments; and is comfortable sharing their assignment results with their fellow learners.
- Technology and Learning - 88% indicated that online tools such as chat, discussion forums, and email help in the learning experience. 80% agreed that WebCT would enhance their learning experiences.
- Learning Technology Application - 84% of the respondents agreed that after taking a course that uses online course tools such as those found in WebCT, they would be able to apply these skills in their personal and/or professional life. While 60% indicated that they would incorporate online collaboration into their professional and/or personal life.
- WebCT Interface - When asked if the interface to various WebCT tools was found to be intuitive and/or easy to use:
  - Chat - 56% agreed and 24% had no opinion
  - Bulletin Board - 56% agreed and 20% disagreed
  - Calendar - 92% agreed
Survey Results Analyzed

The following discussing how the results of the survey could have been skewed:

- **Survey Process** - As the results indicate, the 25 respondents are easily connected to the web and agreed that such online tools provided by WebCT are beneficial to the learning process. The process used to collect the data, via a link from WebCT, could have caused the results to be disproportionately in favor of online tools such as those found in WebCT. If the survey had been conducted using a technology neutral process, the results may have been more evenly distributed.

- **Time** - Time was a key-factor in this study. If more time was allowed, participants in the IET program that are not easily connect to the web may have taken the survey and the results could have reflected a different mix of opinions.

- **Audience** - The positive responses with respect to applying their online skills in their personal and/or professional life could reflect an interest in using online tools in their own classroom. If the audience had been more randomly selected, the results could have been much lower because many disciplines may not have a need for such tools.

The Next Step - Future Research

There are two directions that could be taken. One is to include a broader group of students being asked general questions and the other is to get more focused into the world of K-12. Each option presents new opportunities to understanding the impact of OCMS on student learning. The door in still wide open on the pros and cons of OCMS and the more research that is conducted, the better we will be able incorporate its powers appropriately into the learning environments.

Abstract: This paper examines some social implications of the emerging technology of 'intelligent' agents for learning and teaching. The educational potential of this technology is tempered by the potential for stereotype and caricature in an educational multimedia environment, where effects often need to be larger than life, and dynamic content needs to isolate salient features. Believability is a crucial requirement of such agents, and exaggerated features may be associated with increased recognition. Gender provides characteristics that are both easy to represent, and easy to recognize. The paper argues that the hazards of stereotyping in the development of mediated anthropomorphic presences are significant, and need to be explicitly addressed in future guidelines for the design of agents that are to have any role in the education of our children.

1. Introduction
The development and application of personality-rich software agents has been the focus of a great deal of recent research. It has been suggested that such software will constitute the next major metaphor in computing by providing "... capability that will trigger a basic change in the user interface metaphor: computers will become assistants rather than just tools" (Ball et al, 1997). Definitions of agents vary: for the purposes of this paper we consider agents as systems that endeavour to use autonomous and believable characters within a situated context (Franklin and Graesser, 1996).

Computer Based Learning is one application area for these systems. It has been suggested that agents can play a significant role in motivating students (Lester et al, 1997), and that the more life-like the behaviours exhibited by the agent the stronger their motivational impact will be. The goal for many agents is -- as with Microsoft's Persona Project - to create "computer assistants" that are "lifelike" (Ball et al, 1997). The design of educational interactive environments, like that of other virtual worlds, requires the use of characters that can respond in a way that is believable and "intelligent" (Bates 1992). The framework for believability is therefore implicitly anthropomorphic.

In a constructivist model, learning occurs "through interactions with one's environment or culture" (Reiber, 1992). A virtual environment therefore offers potential for learning; and the nature of that environment is critical if successful learning is to take place. We suggest in this paper that the use of personality rich agents in computer based learning environments may lead to simplification that could have unwanted effects. In most situations some simplification of the design must occur to produce a practical and useable environment: however, if learners are presented with stereotypes and set roles, this can set constraints on learning, enquiry, and evaluation. It is important that developers and educators be aware of these issues in developing agents for teaching and learning.
2. Slaves to the user?
Bates (1992), Lester et al (1997), Pisanich et al (n.d.), and Reilly (1997) all suggest that a key to effective virtuality is whether the user is able to "suspended disbelief": believability is expressed as a suspension of disbelief. The social nature of agents is a matter of particular importance within systems that depend on interactive narrativity for their believability (Waraich, 1998). A key to this, in turn, is responsiveness to the user: the user will suspend disbelief only if interactions with the agent occur within the bounds of the user's existing cultural and social norms.

The concepts of believability and user-responsiveness are also essential to the vicarious virtual world of pornography. Characters and scenarios are developed (usually by men for men) that portray women as available: the effect depends on a "believability" that is thoroughly divorced from reality, but which the user willingly buys into by 'suspended' his disbelief. In such worlds the "user" must have at least the illusion of free will if they are to experience some level of presence in the simulated world. While such notions are common terms of reference for the development of believable agents, it may be noted that some users fail to differentiate sufficiently between their vicarious, suspended virtual worlds, and the real world. As agent systems become more sophisticated, and users do suspend their disbelief, agent design will increasingly carry a burden of ethical implications and social responsibilities.

While agents must be able to exhibit some form of personality in order to be believable, the models of representation are themselves culturally determined. Reilly (1997) states that "believable agents are defined to be interactive versions of quality characters in traditional artistic media like film". Stereotypes abound, however, in the world of film: from Almodovar to Zinnemann, Hollywood to Bollywood, female characters are almost always defined in relation to a man (usually in the role of love-interest) and are young and photogenic. These aspects of entertainment do not sit easily with the intention to educate.

While Lester et al (1997) do not explicitly identify stereotyping, they suggest that a key challenge in creating believability in animated pedagogical agents is to ensure that any believability-enhancing behaviour must complement (and be interleaved with) the advisory and explanatory behaviours that the agents perform. The development of sophisticated synthetic personalities is a difficult undertaking. Yet while the use of stereotypes can provide easy recognition, it cannot reasonably be said to complement educational behaviours.

3. Broad Brushstrokes and character aliasing: the problem of stereotypes
Agents may therefore be shaped by social assumptions: these hazards are compounded by the limitations of digital representation. Laurel observes that "[w]hen we anthropomorphize a machine or animal, we do not impute human personality in all its subtle complexity; we paint with bold strokes, thinking only of those traits that are useful to us in a particular context" (Laurel, 1997).

Human personality is 'analogue' in that its 'values' lie on a continuum and cannot be fully quantized, or represented as a series of discrete values. In digitizing personality, the problem of 'aliasing' is inevitable. Where a picture rendered into a finite set of pixels, or a soundwave sampled at discrete intervals, may exhibit jaggy staircasing or noise, the 'jaggies' in a digital personality may manifest as stereotypes.

However, when it comes to the personality of others, such 'aliasing' does not necessarily spoil the effect. As Laurel comments, the illusion of lifelikeness is not necessarily destroyed by "over-simplification": users "can enjoy (and believe in) even one-dimensional dramatic characters" (Laurel, 19xx). Bates too suggests that agents do not have to be sophisticated as long as it does not actively do something to destroy the suspension of disbelief (Bates, 1992). On the one hand such simplification is attractive in that it may well ease the task of designing and implementing an agent yet at the same time produce acceptable results; but on the other hand simplification is likely to exaggerate any stereotypes that have (however inadvertently) been incorporated into the agent. This in turn clearly has the potential to shape attitudes and to reinforce social and cultural bias. This is particularly important in the case of systems that are 'educational', and most especially those aimed at children. Young people are less likely to have the discriminating worldview and social experience required to identify and ignore such features as simplistic or ironic stereotypes, and may well accept them as "normal".
The very real problem facing the designer of synthetic personalities is determining what the effect of the character will be both within the simulation and towards the specific user of the system in the real world. Each learner brings their own prior knowledge and experiences to bear on the interpretation of the interactions with the system.

Categorization is an attractive method for digital analysis and design. Pisanich et al (n.d.) suggest a personality taxonomy, based on the Big Five set of personality traits (Harary et al 1994). These consist of Expressive Style (quiet, introverted), Interpersonal Style (aloof, cruel, warm, generous), Work Style (conscientious, procrastination), Emotional Style (neuroticism, calm, emotionally intense) and Intellectual Style (conservative, creative). It is suggested that the designer of a character can determine a value for each personality trait and thus determine the features of a character’s personality.

Petta defines the Emotional as “the system that in living beings continuously monitors the relationship of the individual to its world”, and indicates that it is “highly relevant to adequately model the Emotional within architectures for synthetic actors, with respect to the agent’s believability, autonomy, sociality, and faculty to engage humans”. His goal is to model “emotional processing” into the agent architecture framework, using principles from “functional appraisal theory in emotion research”. Ad-hoc solutions to “emotions synthesis” are “brittle”.

Reilly (1997), however, suggests that believable social agents cannot be created from parameterized values for personality factors. His own methodology – designed to encompass both psychological and artistic personality factors – identifies personality quirks, variable emotions (as displayed in social behaviour), and attitudes that are responsive to different relationships as features that should be considered in the development of believable agents. Providing such a finer resolution in the rendering of an agent’s ‘personality’ will be more difficult, but is desirable if an agent is to have a degree of context-sensitivity appropriate to an educational environment. Within Reilly’s methodology, attention to social norms and social roles may be imputed to be particularly important factors in the development of pedagogical agents: an informed understanding of what is socially acceptable behaviour, and of the role that teachers play in society.

While Laurel (1997) sees the personification of computer interfaces as attempts to “mediate the relationship between the labyrinthine precision of computers and the fuzzy complexity of people”, it is the need to develop types and discrete elements to represent personality that can very readily result in simplifications and stereotypes.

4. Gender: defaults and stereotypes

Gender is an important instance and illustration of stereotyping. In research into the effects of gender stereotypes on the design of educational software, Huff & Cooper concluded that a) sex bias did exist in software, and that b) its roots lay in the expectations and stereotypes of the designer (1987). A key factor was not just that designers produced software with different characteristics if required to develop specifically for boys or girls respectively, but that the software produced for children in general was similar to that designed for boys.

The 'masculine default' runs deep in most cultures - and is widely reflected in the morphology and usage of language. In the company of the abstract, representational, and imaginary figures that populate children's stories - stick-men, animals, aliens - apparently neutral agents and other 'artificial intelligences' tend to default as masculine. The quality of being feminine is just that - a trait, rather than an essence. An apron, or a set of fluttering eyelashes, usually suffices to ascribe this quality to an anthropomorphized animal or vehicle: markers of gender are only needed for females. If the AI endeavour concerns making computers like us, then what are 'we' like? Gender appears to be fundamental to our social conditioning. Yet there is an obvious danger that the backgrounds, personalities, and, indeed, the graphical representation of agents, will in fact represent very particular values and assumptions.

Within the claim that machines do not have a gender, and that, in designing an agent, it is necessary only to consider architecture, lie the seeds of both the male default and female stereotypes in agent representation.

Agents are frequent participants in on-line Multi-User Domain (MUD) communities. Participants also include a minority of males who identify and pursue characters bearing female names; male characters who log on under female names and behave in the sexually aggressive way that they would like women to behave; and by male characters who assume that a woman will need their help and their company. (Bruckman, 1996): the level of unwanted attention and harassment in virtual worlds is an exaggeration of - although a fulfilment of intentions that
undoubtedly exist in - the real world. Some of the best-known agents - like Julia - are built to respond to this social environment. Agents that are simplistically responsive to the user are frequently shaped by such minorities. A female agent may not have to be young and photogenic like Lara Croft or a Hollywood star: an agent that is even ready to flirt or look pretty builds a particular social environment that is not likely to encourage or motivate women and girls. MUDs of course are also used as environments for teaching and learning - to teach, for example, writing and communication - and for educators and scholars to share experiences and information. While such educational environments could be expected to be more wholesome, educators frequently look to ready-made TinyMUD robots as retrainable and adaptable agents, and it is still necessary to pay attention to the general pitfalls of constructing stereotyped and gendered agents.

There is no particular shortage of female agents. They are often defined as female - whether descriptively or graphically - by details concerning hair and other bodily features. They will have an extensive range of one-liners for sexualized exchanges with males (which appears to pass as 'emotional intelligence'). It may be argued that this reflects the reality of life in a sexist society, and in particular that the defensive strategies are similar to those frequently adopted by women when in the company of predatory males. Yet it may also be argued that there is no need for such strategies on the part of an AI, and that such characterizations shape expectations as much as it reflects reality - that it is a facile way of attaining to the reality of the male 'user'.

5. Julia: robot with sex
One 'female' agent program has many lines - alternately coy, feisty, and flirtatious - for dealing with frequent 'virtual' sexual advances. "Julia" has plenty of self-disclosing loving detail - 'she' has "close-cropped frizzy blond hair". Julia is described as a TinyMUD robot (Foner, 1993). Written by Michael Mauldin of Carnegie Mellon University, Julia logs into MUDs and interacts with other players. While Julia does not operate within a learning environment, MUDs are (as noted above) used as educational environments, and their agents seen as retrainable prototypes. As an autonomous agent, a key part of Julia's 'personality' is sex - about which 'she' is rather obviously assertive:

Robyn says, 'julia, are you a woman?'
Julia says, 'I am female.'
Robyn says, 'and, julia, are you human?'
Julia says, 'Not when I'm having my period, Robyn.'
Robyn laughs
(Quoted in Foner, 1997)

It is as a female that, when pushed sufficiently, Julia takes off 'her' clothes - 'fearfully' - and hands them to an insistent real 'virtual' male. (Because the harasser is 'whispering', his lines are partly invisible):

Julia says, 'Just try to take ’em, buster!'
Julia says, 'Help! Rape!'
Julia says, 'No, I won’t.'
Julia disrobes fearfully and hands her clothes to Brandi.
You say, 'julia, please give me your clothes'
Julia says, 'You’ll have to get them from Brandi.'
(Quoted in Foner, 1997)

This may be ‘believable', but it is hardly desirable: if the broadly-brushstroked, low-resolution nature of virtual personality and environment can be put to positive use, there is in fact every reason for excluding some features of reality.

While Foner reports Mauldin as claiming that 85% of Julia's source code is the same as his prototype robot, Colin (Foner, 1993), he (Foner) also comments that "a large percentage of Julia's code deals with detecting and deflecting passes". One might therefore deduce that this code has been added on to a male-default in order to represent the quality of femininity. Colin's small-talk response repertoire detects matches for 'how are you', 'how do you', 'how's life', 'are you alright', 'are you well', etc (Foner, 1997). Julia (whose code, as a frequent Loebner entrant, is not in the public domain), has added on small-talk that signposts specific femininity:
Robyn whispers, 'how are you feeling?' to Julia.
Julia whispers, 'Terrible.'
Robyn whispers, 'why, julia?' to Julia.
Julia whispers, 'I have PMS today.'

Flirting can appear to go with the territory of feminine psychological attunement. Erin O'Malley, a prototype character described by Hayes-Roth (1998), is endowed with some of the "psychological qualities" necessary for believability: "personality, motivation, emotion and social relationships". Her role is that of a bartender, and as a female who is apparently assumed to work within a male environment, she needs "to flirt a little", even if "she won't let those conversations go too far".

The growth in female agents can perhaps be ascribed in part to the discovery of "emotional intelligence" as a key to the simulation of humanity: a feminine stereotype in itself. Indeed, various commentators believe that AI is a 'natural' place for women's research: its links with cognition and psychology are tied to the stereotyped notion that "women are generally more introspective, attuned to psychology" (Strok, 1992).

Conclusion
When agents are deployed – as they increasingly are – for useful purposes such as education, decisions may be made regarding contextual stereotypes, and in particular the allocation of gender. If the agent is to be a character of no gender, it is necessary to make a point of this – otherwise it will generally default as male. There is no intrinsic problem of believability in a specifically ungendered agent; although the suspension of disbelief in agents contains a strong element of preference and choice on the part of the believer. Female personae may be used often for the same reasons that many service industries have become feminized - to take advantage of the supposed approachability and communicative qualities of women (Strok, 1992). This, however, is something of an 'airline hostess syndrome', and tends to assume both a male customer audience and a young woman with symmetrical and slim features. There is clearly a concern that the application of agents may also be divided on a gendered basis.

The mind has been conceptualized as a machine since the advent of industrialization: and just as our cultures shape the development of responsive, 'believable' agents, so in turn our agent creations are part of a new defining technology, a technology that has the power to shape our self-conception and social attitudes. In developing agents – but most especially where there is an explicit intention to educate and to influence – developers have a broader social responsibility to move beyond simplistic behaviourism and mechanical personality-response, and to explicitly factor out stereotypes before they take root.

The design and development of software personalities is undoubtedly a complex area of intense interest. While the use of broad brushstrokes and parameterised and typed values may be attractive, there is correspondingly a need to consider guidelines for the ethical and social development of educational agents; to recognise that simplifications in general, and stereotyping in particular, can be inimical to the goals of education; and to show appropriate respect and trust for these new personalities who will help us to teach and learn.

Developing professional skills and competencies in tertiary learners through
on-line assessment and peer support

Catherine McLoughlin,
Teaching and Learning Centre, University of New England, Australia
mcloughlin@metz.une.edu.au

Joe Luca,
Edith Cowan University, Multimedia Department, Australia
j.luca@cowan.edu.au

Abstract: In professional organisations, employees are called on to evaluate solutions, solve ill-defined problems and engage in decision making based on actual situations and events. To develop such skills, tertiary learners have to learn to engage in tasks where such skills are likely to develop, and learn to reflect on their own behaviour and that of peers. In the research literature on learning and self-regulation, self and peer assessment are important strategies used to develop problem-solving skills that can be transferred to the workplace. On-line environments utilising asynchronous communication tools and tasks are ideal environments for the refinement of decision making and problem solving skills. This case study profiles an on-line approach to developing professional project management skills for multimedia developers and presents snapshot views of an online learning environment. The study also investigates learners' perceptions of the value of peer work in their own learning and shows that technology can support alternative assessment practices leading to development of professional skills and competencies.

Introduction

This case study presents an argument in favour of fostering personal transferable skills as a defining quality of the learning experience in higher education and demonstrates how technology can be used to support a culture of peer support to foster these skills. The case study was designed in response to current social and economic debates in Australia about the quality of undergraduate education and of the qualities that university graduates should possess (Candy, Crebert & O'Leary, 1994; Assister, 1995). During the last ten years there has been a major reappraisal of higher education, its purpose, outcomes and resourcing. There is now a more pronounced emphasis on the higher education-employment nexus, and particularly on the skills or competencies that can be transferred from a university setting to the workplace. In this changing environment, which is mirrored in New Zealand and Europe, it can be argued that peer assessment and peer learning are an appropriate response to the preparation of tertiary students for the workplace. This study focuses on a context where peer support is integrated with assessment to develop skills through interaction and learning. These skills enable students to move more easily from formal education to the next stage of their lives and are increasingly being demanded by employers.

The role of technology in fostering professional skills

Information and communication technologies have the capacity to support a wide range of learning goals and are now integrated into teaching approaches of many higher educational institutions. Laurillard (1993) for instance suggests that computer-based learning has a major role in promoting:

- self-directed learning and increased student autonomy;
- keeping the educational system in line with technological development;
- increased information literacy, ensuring that graduate skills are in tune with those of employers; and
- increased productivity and efficiency in higher education.
The shift to student self-direction and autonomy means that students need to take more responsibility for their own learning, but many need assistance in achieving this skill. Shaffer & Resnick (1999) maintain that technology can be used to create authentic contexts for learning, and provide resources that give students opportunities for:

- **connectivity**: to connect to the world outside the classroom, to research topics that would otherwise be inaccessible, to access experts and to engage in conversation with peers;
- **computer modelling**: to create simulations that assist the creation of authentic tasks and contexts for assessment; and
- **epistemological pluralism**: to express and represent ideas in many different ways.

Applied to assessment, representational pluralism enabled by computer technology expands the range of channels available to students to demonstrate understanding (Gardner, 1993; Greeno, 1997). For example, instead of using narrowly defined learning outcomes tested by examinations, technology offers a total environment where real life skills, such as written and verbal communication, collaboration and teamwork can be assessed by the team and tutor by giving learners multiple channels of expression, such as visualisation, multimedia presentations, audio and video. Thus, information technologies are closely inter-woven with the quality of the learning experience, and can be used to create authentic tasks for assessment.

**Fostering deep learning through peer work and authentic assessment**

Traditional university education has operated within a “transmissive paradigm”, emphasising the transfer of knowledge from lecturer to student. Such a view of learning is not conducive to meaningful, active learning where students take a pro-active role in questioning, sharing ideas and applying prior knowledge to new ideas. However, the increased emphasis of generic transferable skills has required a re-alignment of teaching practices with desired learning outcomes (Biggs, 1999). This means that if independent lifelong learning and critical skills are expected of graduates, teaching methods must foster such processes and skills.

In contemporary education one influential group of researchers has identified students’ approaches to be either surface level or deep level (Ramsden, 1992). A deep learning approach is consistent with a search for knowledge and understanding, whereas a surface learner is concerned only with passing exams by memorising facts. Applied to assessment and teaching approaches in higher education, the implication is that the creation of an appropriate learning environment can foster a deep approach. This can be achieved by enabling learners to take an active role in learning by initiating, managing, monitoring, reflecting and evaluating learning tasks and processes. Gibbs (1992) emphasises that a focus on process, rather than content, is essential in promoting active learning and that evaluation and assessment procedures are central to these issues as students interpret the objectives of a course of study according to the demands of the assessment system. For example, an exam requiring recall of facts will encourage learners to adopt a surface approach, whereas assessment of collaborative problem-solving or teamwork on a project will emphasise communication skills, planning and decision making and foster a deep approach. The relevance of this to educational technology is that we can use the attributes of technology to increase learner autonomy and independence by designing authentic assessment tasks in order to equip learners with professional skills and attributes. In addition, by making assessment a ‘learning event’ that develops process knowledge (rather than a one-shot examination) we bring it closer to the context of the workplace, where professionals are expected to have self-management skills, and be able to make judgements about their own and other’s work (Erhaut, 1994). Moreover, traditional university examinations do not test for deep conceptual understanding (Entwistle & Entwistle, 1991). Indeed, the capacity of technology to foster professional skills through authentic assessment is an area of research that is just beginning to be explored.

**Alternative assessment using technology**

In recognition of the limitations of traditional university assessment, there is a new wave of pedagogy advocating ‘alternative assessment’ in which assessment is integrated into learning and fosters understanding of learning processes with real-life performance as opposed to a display of inert knowledge (Wiggins, 1998). This form of
authentic assessment is solidly based on constructivism, which recognises the learner as the "chief architect" of knowledge building. In constructivist learning environments there is social interaction, communication, exchange of views, collaboration and support for learners to take more responsibility for the learning process through learner-centred tasks (McLoughlin & Oliver, 1998; Collis, 1998). Socio-cultural theory is based on similar assumptions, and many theorists have highlighted the importance of reciprocal understanding and transactional dialogue where knowledge is exchanged and modified in the light of peer feedback (Crook 1994; Bruner, 1990). Salient features of constructivist learning environments include an emphasis on the following aspects:

- **Authenticity**: learning is located in actual contexts or real tasks;
- **Group work**: social interaction and feedback are instrumental in communication and higher order thinking processes;
- **Learner control**: learners are active in defining and negotiating learning tasks; and
- **Scaffolded learning**: learners are supported as they progress from novice learners to self-regulated experts.

The use of the WWW to create assessment tasks offers greater adaptability and flexibility than traditional assessment procedures as it enables the collection and storage of continuous data, and easily created micro-environments where learners solve real life problems. It can be argued that the move towards alternative assessment paradigms has been accelerated by technology with its capacity to cope with a broad array of activities, tasks and forums for assessment. For instance, alternative modes of assessment encourage the use of multiple assessment tasks, and multiple modes of show-casing student achievement through portfolios, multimedia projects, skills demonstrations and teamwork. A further important contribution made by technology to these new modes of assessment is the capacity to support the evaluation of learning processes, such as communication, group work and collaborative problem solving, as opposed to a narrow focus on a single outcome as an indicator of competence.

**Context of the study: Course description**

The context of the study was a tertiary academic unit called “Interactive Multimedia Development Methodologies” intended to develop student expertise and knowledge in project management for developing multimedia in a team-based environment. Currently, this unit is offered in face-to-face mode using a combination of delivery modes, including small group work, team projects and problem solving tasks facilitated by a tutor. The on-line component provides access to course notes, syllabus, assessment details, access to previous projects as well as group communication facilities such as e-mail, bulletin boards and problem solving tasks. The course objectives were closely linked to the professional competencies required for multimedia development in the industry and integrated authentic assessment tasks where learners could develop multimedia products in a team environment, thus replicating the skills required of them in the workplace. A salient feature of the assessment tasks was the focus on learning processes, rather than mastery of content as this matched the orientation of the course towards skills development. The assessment tasks and associated learning processes are presented in Table 1.

<table>
<thead>
<tr>
<th>Assessment task</th>
<th>Learning processes</th>

<td>Search, analyse and apply relevant knowledge by finding an online resource to support the solution to the problem.</td>
<td>- Analysis, reorganising information testing for useability and application to an authentic task</td>
</tr>
</tbody>
</table>

The objective of the peer assessment component was that participants would evaluate peer responses to problem solving and discuss issues and revisions in order to support each other. The unit thus integrated process-based assessment tasks into the learning environment in order to contribute to the development of team-skills, inquiry and reflection (Biggs, 1999). The unit also aimed to teach content knowledge and thinking strategies using real life
scenarios. This approach to on-line learning can be regarded as _process-oriented_ as it focuses on the processes of knowledge construction and utilisation (Volt, 1995; Vermunt, 1995), as opposed to simple mastery of content knowledge.

**Participants and procedures**

The student participants were all postgraduates and consisted of five females and four males. They were undertaking the project management unit, which represented a core unit in the Graduate Diploma of Interactive Multimedia Technologies. This unit is the second last of the eight-unit Diploma course. The final unit these students complete is an industry project, where the students are required to implement these skills in a ‘real’ environment, with ‘real’ clients and produce a ‘real’ product. The course was designed to maximise peer learning, peer support, feedback and interaction among the group members. This involved groups posting solutions to ill-structured problems on the class web page, monitoring team work and facilitating team building processes by encouraging use of discussion forums where team members could deliberate, plan and exchange ideas. The actual problems were loosely framed, ill-defined and open-ended, and required learners to analyse existing knowledge, suggest a course of action and then post a solution. In addition, students were asked to post a URL or information source that specifically supported the standpoint adopted in solving the problem. This was conducted before students attended a seminar where they presented their solution, justified their approaches and made comments on other students’ solutions.

Students were required to submit their solution at a specific time during the week, and then evaluate each other’s solutions by ranking them. During the seminar the strengths and weaknesses of each solution were discussed and students had an opportunity to defend their approach. The process of developing peer support and feedback was an important part of the project management unit, which replicated a learning community. Sharing of ideas, resources, and offering reciprocal support created social relationships, which helped students to work in teams. McConnell’s (1999) features of an on-line community influenced the design of the whole environment:

- openness in the educational process;
- self-determination in learning;
- a supportive learning environment;
- a real purpose in the peer assessment process; and
- assessment of ongoing learning processes.

The following four ‘Snapshots’ of the peer-support process and the fostering of peer-feedback through assessment show how these elements were integrated into the technology-supported environment of the course.

**Snapshot 1: Students develop criteria for peer assessment**

Students were asked to develop and articulate criteria that they used when assessing other students’ on-line solutions and then defend these in class discussion. It was important that students formulated criteria against which they could measure peer solutions to the problem solving tasks. It was anticipated that students would be able to complete this task without much difficulty as they had experience of writing project specifications and engaging in project evaluation.

The results showed that the majority of students considered the following issues as being the most important when presenting solutions:

- relevance of content to the original problem;
- correctness and validity of content;
- clarity, presentation/format and grammar of writing style; and
- the ability to express an integrated opinion based on the content.

These results were later used as a ‘springboard’ to refine the processes of evaluation and to negotiate agreed on criteria that could be applied to all posted solutions. For example, all students mentioned style and format as
essential criteria in their judgements of others' work. In class, they were asked to justify this response in an attempt to develop metacognitive processes (Lieberman 1991; Schraw & Dennison, 1994). Students recognised the value of this in developing their personal transferable skills.

Snapshot 2: Students reflect on problem solving strategies
Students were asked to reflect on the problem-solving processes they had engaged in while solving problems and then asked to articulate these during class discussions. This enabled the students to reflect on their own strategies, to identify areas of weaknesses and to conceptualise ways of addressing those weaknesses. Students were asked to write down the major strategies used when solving problems. Results indicated that the salient features of student problem solving strategies were:

- researching the topic thoroughly;
- reading the question carefully and considering different angles;
- checking that the content used is correct;
- comparing ideas with other students; and
- appropriate to the development of project management skills.

Snapshot 3: Students negotiate assessment methods used
This example relates to the social function of the learning community, where learners relate the assessment tasks to their own personal goals. It was important that learners came to regard assessment tasks as a way of engaging with the content and a means of developing new skills through ownership and acceptance of the assessment process. Students were asked to renegotiate the tasks to ensure relevance for their own learning. Most of students considered the problem-based tasks to be:

- relevant to the unit objectives;
- helpful in understanding multiple perspective's from other students,
- useful for reflecting on alternative possible solutions; and
- indicators of their own developing skills.

Discussion and implication of results
Online technologies have functionalities that enable display and sharing of ideas, open discussion of solutions and alternatives with articulation of strategies by participants. Such functionalities support greater visibility and openness in the learning process, which in turn foster reflection and conceptualisation among learners. In the study presented here, the integration of technology into an innovative assessment approach resulted in deep learning and the ‘Snapshots’ showed that students were engaged in active, reflective learning. We are continuing to investigate how technology can be used to extend a model of evaluation, which reflects the full range of the experiences of learning. We now have evidence that technology can create contexts and tools for exploration of alternative worldviews, increase the visibility of thinking processes, lead to articulation and refinement of solutions and foster peer dialogue in the learning process. By providing scope for multiple expressions of learning achievement we believe that new models of technology enhanced assessment are just beginning to emerge. These forms of assessment will provide indicators of a broad array of competencies and recognise that learning processes and learning outcomes are inseparable.

Abstract: One important means of assessing the effectiveness of the teaching-learning transaction in technology supported environments is through analysis of the learner support system. Increasingly, as learners utilize the WWW for collaborative learning, support systems contribute to the processes of learning and assist the learner in developing competencies and confidence in self-regulated learning, social interaction and self-evaluation. Traditionally, the most common form of supported learning has been an apprenticeship, where a novice learns through active participation in a task, initially only peripherally and then assuming more control and ownership. Originating in the socio-cultural perspective of Vygotskyan theory and developed by later theorists, the concept of scaffolding has been extended by practical applications in technology-based environments. As the World Wide Web becomes increasingly integrated into the delivery of learning experiences in tertiary institutions, the concept of scaffolding needs to be redefined because it is not readily translated into teaching contexts which are not face-to-face, as in on-line environments. The aim of this paper is to offer a reconceptualisation of the term scaffolding and to provide actual examples of how learners can be supported in the processes of constructivist inquiry in WWW environments.

Introduction: Conceptualising learner support

The term ‘scaffolding’ is increasingly used to describe certain kinds of support which learners receive in their interaction with experts, teachers and mentors as they develop new skills, concepts or levels of understanding. Bruner, Wood & Ross (1976) originally coined the term scaffolding as a metaphor to describe the effective intervention by a peer, adult or competent person in the learning of another person. The term can be traced to Vygotsky’s concept of “the zone of proximal development”, that is the actual developmental level of the learner compared with the level of potential development that can occur with guidance or collaboration with a more competent person. In technology supported learning environments, the metaphor of scaffolding is appealing in principle, yet elusive and problematic. The appeal of the concept lies in the fact that it directs attention to the role of the instructor or teacher in the learning process, and does so in a way which emphasizes that good teaching is necessarily responsive to the state of understanding achieved by particular learners. In earlier research therefore, scaffolded instruction was conceived as a joint interaction in which the teacher and the learner share the responsibility for learning (Vygotsky, 1978; Wood, Bruner & Ross, 1976). In environments mediated by technology, a human tutor, peer-students or intelligent agents can provide scaffolding so that learners attain new skills, concepts and knowledge.

Theoretical perspectives on scaffolding

It is important to trace the early origins of research on scaffolding in order to appreciate its complexity. The socio-cultural approach emanating from the work of Vygotsky has had a major influence on the development of scaffolded instruction and apprenticeship models of learning (Vygotsky, 1978; Wood & Wood, 1976; Rogoff & Lave, 1984; Collins, Brown & Newman, 1989). Much of this work emphasizes the role of social interaction as a cultural amplifier to extend children’s cognitive processes, with an adult or expert introducing learners to the conceptual tools available in society. For cognition to be analyzed, culture and context are the fundamental units of consideration, as human development is seen to be located and immersed in social
practices (Vygotsky, 1978). This perspective resists the separation of the individual from society and the daily environment, and perceives meaningful activity as embedded in authentic and socially-created situations. This perspective has had profound and far-reaching influences on how current practitioners design learning environments (e.g., Jarvela, 1995; Roschelle & Teasley, 1995). Cognitive change can occur through processes of social interaction in which ideas are articulated, shared, revised, modified and adopted because of their relevance to the cultural context (Roschelle & Teasley, 1991; Newman, Griffin & Cole, 1989). Learners progress through developmental changes by attempting successive approximations of the learning task, assisted by peers, more able others or by a tutor. Support offered in the form of dialogue, collaborative tasks, structured questioning and demonstration of skills has been found to be effective in enabling cognitive change (Hmelo & Day, 1999; Palincsar, 1986).

The mechanisms for assisting learner cognition through the zone of proximal development (ZPD) have been extended greatly by technology applications. Originally, the teacher's role was conceived as providing scaffolded assistance through modelling, contingency management, cognitive structuring and feedback (Tharp & Gallimore, 1988). Through modelling, tasks, skills and concepts can be demonstrated while retaining complexity and authenticity, so that learners can become engaged in the acquisition of new skills. Contingency management is concerned with recognizing and rewarding learner actions, while feedback enables students to compare themselves to others. In cognitive structuring, learners are assisted to organize their own experiences following the provision of explanations, or meta-level strategies to enable students to organize their own thinking. An example of cognitive structuring can be constructing a concept-map of a problem situation. Later, these mechanisms are internalized and become metacognitive strategies for students to regulate their own learning. In addition, verbal scaffolds such as instructing, questioning and cognitive structuring enable students to organize their own activities by suggesting meta-strategies that students can acquire so that teacher support becomes "... a heard, regulating voice, a gradually internalized voice that then becomes the pupil's self-regulating 'still small' instructor." (Tharp & Gallimore, 1988, p. 57).

Extending the concept of scaffolding

Some similarities and differences emerge when we compare recent work on scaffolding with earlier research conducted in the 1980's. For example, much of the work of the Cognition & Technology Group at Vanderbilt (CTGV) has emphasized the notion of anchoring instruction in everyday authentic contexts (CTGV, 1993; 1996). However a major difference is that earlier work (Hogan & Pressley, 1997; Newman, Griffin & Cole, 1989; Palincsar, 1986; Rogoff & Lave, 1984; Tharp & Gallimore, 1998; Wood, Bruner & Ross, 1976) has been conducted in face-to-face (F2F) classrooms, where forms of verbal interaction were the most common forms of scaffolding. Teachers and learners in F2F classrooms share the same space, and engage in learning processes in the social context with its prescribed rules, roles and expectations. This may limit scaffolding to teacher initiated forms of intervention. For example, in many traditional classrooms, questioning has been shown to be a form of social control (Edwards & Westgate, 1994). Many of these social constraints are not present in the virtual classrooms or in contexts where learning is asynchronous. In addition, the nature of scaffolding in such face-to-face classrooms was assumed to be asymmetric in that the teacher was regarded as the expert, and the student as novice. Recent advances in communications technology and in pedagogy envisage an active, participatory role for students, as initiators and co-participant in self-regulating learning process (Boeckaerts, 1995; Brown & Campione, 1994), and therefore the concept of scaffolding needs to be extended to include forms of peer assessment.

A consideration of more recent work in technology-supported environments illustrates how the concept of scaffolding has expanded to include many innovative forms of support, increased responsibility for students and a fading of the directive of asymmetrical aspect of earlier work on scaffolding (e.g. Rada & Yazdani, 1998). While Vygotskian theory provides the theoretical anchoring for the concept of scaffolding by making an explicit connection between social interaction and cognitive development, other forms of support can be provided by technology thus enabling learners to engage in cognitive change and skills advancement.

Designing multiple forms of WWW-based course supports

As the World Wide Web becomes increasingly integrated into the delivery of learning experiences in higher education, the concept of scaffolding needs to be redefined because it is not readily translated into contexts
where the teacher is not present, as in on-line environments. This calls for a reconsideration of the nature of scaffolding and for the alignment of theory with practice in higher education (Collis, 1997; 1998). As yet, research focusing on the nature of scaffolds and their functions in specific contexts of technology-supported learning is limited. Through the provision of examples from a range of contexts where technology is used to mediate the teaching transaction, it is possible to show that the notion of scaffolding offers a way of conceptualizing the process of effective learning by:

- Reducing the scope for failure in the task that the learner is attempting.
- Enabling learners to accomplish a task that they would not be able to achieve on their own.
- Bringing learners closer to a state of independent competence.

As technology extends learning beyond the classroom to learning communities, so must roles and concepts of learning and teaching be reconsidered (Collis, 1998). In WWW-supported learning environments, distributed groups of learners can be supported in the learning process by using different technological functionalities, which support dialogue and interaction (see Table 1). With its great potential for collaborative learning, particular forms of scaffolding are needed to provide models, examples and support for the processes of active learning characterized by:

- Self-responsibility for thinking and learning.
- Awareness of social responsibility.
- Thinking and acting scientific processes.
- Relating group process and product with professional practice.
- Articulation of reflection.
- Viewing a problem from multiple perspectives.

Developing WWW functionalities to support, or scaffold group processes and cognition can support collaborative work. Collis (1997) has ‘re-engineered’ academic courses and developed a number of ‘tools’ to enable group work, sharing of resources, ideas and so that processes and products are integrated. Through a shared workspace environment, students can access texts, documents and other resources, add resources and interact with others through conferencing facilities. Table 1 displays a number of scaffolding solutions using WWW tools to enable cognitive outcomes and processes that underpin successful learning. In the right column, a list of scaffolds afforded by WWW tools is provided.

Some examples of key indicators of effective scaffolding in Web-based environments include:

- The provision of learning resources to help students solve their own problems and share them with others (e.g. Guzdial & Kehoe, 1998).
Offering multiple channels of communication should enable conversation, exchange of ideas and discussion.
Provision of support for collaborative tasks and development of higher order cognition.
Embedding scaffolding in the organization of a course as a planned and graded activity (Collis, Winnips, & Moonen, in press).

It is advocated that these scaffolding features are built into the design of Web-based course support environments, since its activities tend to be less structured than face-to-face instruction, utilizing principled design processes (Collis, 1997). Approaches for structuring the activities can be found in existing technological approaches, as described in the next section.

Innovative approaches to assist learning using technology-based scaffolds

Apart from utilizing the functionalities of the WWW to support learning, recent research in technology mediated environments presents an array of possibilities and perspectives on scaffolding. By investigating these applications it is possible to compare and extrapolate common features and propose principles for future research. Four examples of scaffolded instruction using hypermedia provide contrasting scenarios for recent interpretations of scaffolded instruction.

Computer supported-intentional learning environments (CSILES)
This approach, conceived by Scardamalia & Bereiter (1989; 1992; 1993) provides a powerful collaborative medium based on anchored design and discourse space, in which students can negotiate and construct new understandings. In the environment, the teacher's role is transformed from that of manager to facilitator of student collaborative processes. A CSILE is an experimental computer system which can mediate shared spaces for collaborative knowledge building. The basis for this is a shared communal database, which gives students a common space to create and communicate the ideas and representations that emerge from individual and group work. In addition to supporting social interactions needed for shared understanding, it provides facilities required for reaching reciprocal understanding, and facilities for the shared product to be expanded, altered, clarified, elaborated and manipulated for new meanings to emerge. A shared database of text notes and graphics notes allows learners to access and collaborate on the creation of knowledge objects. CSILES have inspired further work and have provided a supportive medium for a number of projects (Cognition and Technology Group at Vanderbilt, 1993).

Intelligent tutoring systems (ITS)
In an intelligent tutoring system, learners are guided through a learning process and provided with a structure and sequences of task to assist them. Well known examples can be seen in the work of Andersen et al (Anderson, Boyle, Corbett & Lewis, 1990; Anderson, Boyle & Reiser, 1985) in which students are taught to solve algebra word problems, develop programs and generate geometry proofs. By reducing the complexity of the task and providing cognitive structuring, an ITS can scaffold learning. In an intelligent tutoring system, a learner's progress is charted against an expert model of the process, which the student is expected to model. Intelligent tutoring systems have been criticized for lack of authenticity in the learning task, and for creating tasks where students do not have to engage in real life problem solving (Gudzial & Kehoe, 1998). In ITS environments, collaboration in learning is less essential than in other apprenticeship settings.

Goal-based scenarios (GBS)
Goal-based scenarios are a learning setting where students have to engage in an authentic setting where they are presented with a goal to achieve. The objective is for students to acquire and develop the prerequisite process skills and conceptual knowledge to attain the goal (Schank, Fano, Bell & Jona, 1992, Acovelli & Gamble, 1997). Students are provided with technology-based resources to achieve these goals, and their performance is compared to that of a successful model of the process. If a learner cannot achieve the goal, scaffolding is provided in the form of process information which gives corrective feedback in story form to help the learner to address the problem. In a GBS students interact with agents embedded in a system, rather than with socially-based collaborators or peers. BGS are nevertheless unable to provide feedback or support for complex abstract processes where there is no single solution.

Design support environments (DSE's)

ERIC
Design support environments are aimed at supporting students through a form of software realized scaffolding tailored to assist students engaged in design of software or instruction. In DSE's the environment is simplified by providing a large number of cases, coaching students in the design process and fading the scaffolding (Gudzial, 1998). Instead of providing students with problems, they simply scaffold the design process. A further feature of some DSE’s is that they provide adaptive scaffolds, where students can choose or turn off various scaffolds that are not required, thereby fading support. A different example is given in Collis, Winnips, and Moonen (1999) where the design process is monitored by delivery of (WWW-based) prototypes. Based on monitoring information of groups, the design process is scaffolded. Scaffolding is done by sending text messages to the groups with personal comments to the subgroup and to individuals within it, via the WWW site, expanding on the prototype that is delivered. Often, for example, the instructor would mention his or her own feelings about the product, give background information, or add some ideas for the design.

Conclusion: Minimum design specifications

Each of these forms of technology-based scaffolds offer a unique perspective on learner support, consistent with the original conception that cognitive growth can be assisted by offering relevant, timely and contextualised assistance (Collins, Brown & Newman, 1989). While each form of scaffolding provides support, each differs in the level of social support, collaboration with peers and type of feedback offered. By considering these forms of scaffolding a minimum design specification might be based on what we already know about effective interaction between tutor and learner, or between learners collaborating in a problem-solving task. These may be summarised as follows for technology supported environments:

- Technology can provide a bridge between a learner’s existing knowledge and skills and the demands of a task; by providing a structure and a link between the known and the unknown, technology can support the learners’ problem solving.
- Technology can provide the representational tools to model or simulate an “out of reach” concept, thus creating an authentic environment for the learner.
- Technology can enable the novice to undertake a task at her/his existing level of competency, and then transfer responsibility to the learner.

These examples, illustrated in our talk with examples from tertiary learning contexts, show that by creating and evaluating forms of scaffolding with technology, researchers are now developing more principled and innovative forms of instructional design to guide the process.

Abstract: Self-regulation is arguably the most enduring and recognised outcome of learning, and is recognised to be so at secondary, tertiary and technical levels of the educational system. Developing self-direction is also essential to success in professional world of work. At the University of New England (UNE), these principles are endorsed and articulated as outcomes or generic attributes that undergraduates need to attain. In order to implement and foster these attributes, design guidelines are specified in order to utilise particular attributes of online technologies to design a learning community characterised by peer support, investigation, collaboration and reflection. Design recommendations derived from constructivist and generative learning theories are applied to online units in area of E-commerce and Accounting Information Systems offered by UNE. Task design is linked to preparation for professional practice. Our experience suggests that in on-line learning settings, development of self-regulation and independent learning requires a focus on social, experiential, propositional and process aspects of learning, rather than on purely cognitive learning episodes.

Introduction

Information technologies and computer mediated learning are now an established part of learning environments in higher education, and much software enables the setting up of bulletin boards, chat and conferencing where learners can engage in discussion, team work and exchange of ideas. However, the changing nature of tertiary education in Australia has resulted in increased emphasis on outcomes, and on skills that are transferable to the workplace. Online design for learning must therefore become more streamlined and outcomes oriented whilst maintaining fundamental integrity. Greater emphasis on generic competencies are now part of the mission statements of universities, and the University of New England has developed a list of generic attributes that graduates of the university are expected to attain. Instead of being focused on acquisition of content and disciplinary knowledge, the generic attributes are expressed in terms of core skills such as team work, information literacy, problem-solving, social responsibility and communication skills. This policy has resulted in a reassessment of the approaches to teaching and learning, activities that cultivate generic attributes, the role of disciplinary understanding and the context in which generic skills are fostered. There is considerable evidence in the literature that that the most important competencies for graduates are critical thinking, adaptability, self-evaluation and the capacity to be self-regulated, while at the same time having the skills to work in teams (Candy, 1994).

Three kinds of knowledge required for professional education
Curriculum planning in the School of Accounting, Finance and Entrepreneurship at the University of New England is underpinned by a strong orientation to preparing students for professional practice and a movement away from a purely content-based focus on acquiring facts, decontextualised knowledge and disciplinary content. Preparation of learners to respond to change and a dynamic workplace are now values that are being integrated into the planning of units for online delivery. The new focus requires different forms of “partnerships” within the school, such as partnerships between staff and students, between staff and real-world professionals and between staff and the different elements of the curriculum. Units are planned to cater for the development of three kinds of knowledge, based on the research of Erhaut (1992):

1. Discipline-based knowledge, concepts and generalisations. However, as this kind of prepositional knowledge base is expanding and becoming obsolete rapidly, judicious selection of content must be accompanied by pedagogies that encourage learners not to uncritically accept knowledge, but to question and evaluate.

2. The second kind of knowledge revolves around the interpretation of experience. Often prepositional knowledge remains inert, unapplied and unchallenged. Through design of tasks and activities, assumptions underlying disciplinary knowledge are brought to the surface so that they can be related to professional practice and real world experience.

3. The third kind of knowledge that distinguishes learning for the professions is process knowledge, or knowledge about how to engage in professional action. Process knowledge includes several different forms of socio-cognitive competencies, ie, the ability to select and implement appropriate method of inquiry, integration and reorganizing knowledge; activities such as planning, problem-solving and decision making, communicating information and self-management.

These forms of process knowledge clearly link with the personal and interpersonal skills that are applied in professional settings. The challenge is to use information and communications technologies to interweave propositional, process and personal knowledge. This is achieved by prioritizing the professional orientation of units and by developing approaches to teaching and learning which prepare students for independent, self-regulated learning.

**Professional learning on the WWW**

In tertiary settings learning is increasingly resource-based and many learners study in the off-campus mode. Technology offers a means by which distance students can join the learning space with their on-campus colleagues (Oliver, Omari & Herrington, 1998; McLoughlin & Oliver, 1998). To date, the many studies describing computer mediated learning support in university settings have focussed on particular learning activities and functionalities that enable students to communicate and share ideas. However, we now need to push beyond present boundaries and paradigms of social learning, and focus on WWW instructional scenarios that maximise learning outcomes such as higher order learning, self-regulation and self-management and professional skills. Constructivist learning theories which emphasise the role of the learner in the learning process are increasingly recognised as relevant, and, according to Reeves (1994) the prime emphasis is placed on the unique interests, styles, motivations and capabilities of individual learners so that learning environments can be tailored to them. However, with the increased emphasis on learning outcomes, educational paradigms for on-line learning also need to emphasise the value of intentional learning and goal directed behaviour where learners take an intentional orientation towards cognition, become aware of their own learning processes and engage in self-directed learning (Scardamalia & Bereiter, 1992). Where networked communications are being used increasingly to achieve the educational outcomes of generic competencies and independent learning, design recommendations are needed to ensure that learning activities are supportive of desired outcomes of transferable, professional skills.

**Research on cognitive self-regulation and higher order thinking**

Existing statements in current research explicitly link students’ self-regulatory processes with higher order thinking and life-long learning skills (Candy, 1994). Self-regulation is regarded as a desirable educational
goal as it is linked to achievement, effective problem solving capacity and greater self-realisation (Boekaerts, 1997; Mayer, 1992). Among the competencies and dispositions which students are expected to develop are generic thinking skills, independent learning strategies and information handling skills such as:

- reflection and analysis to generate and refine knowledge;
- evaluation and synthesis of ideas;
- conducting independent investigations in different subject areas;
- effective communication and group work.

At a theoretical level, there have been several attempts to provide an integrative framework for self-regulation and higher order thinking, (Resnick, 1987) but there appears to be no general consensus in the area. The concept of higher order thinking adopted from the work of Ennis (1987) provides an integrative perspective on the issue of thinking and has been influential in shaping curriculum statements about higher order thinking, defined as problem solving, self-direction and metacognition. In order to suggest strategies and approaches to underpin online learning and development, some theorists advocate that the best approach is to turn to analyses of excellent teaching and examples of people who can demonstrate higher order thinking (eg, Winne, 1995). Pressley (1995, p. 207) concludes that “instruction is best matched to students’ zone of proximal development, includes a great deal of modeling and explanation of mature thought, and involves massive practice doing interesting and authentic academic tasks with teacher and peer scaffolding of such tasks.” In addition, Pressley emphasises that development of such expertise is a long-term developmental process, “with real expertise in academic cognition an unlikely achievement in undergraduates”. The research on how to foster self-regulation has been controversial and lacking in consensus, signaling a need for developmental frameworks for instructional designers to apply to WWW environments, which can be evaluated in practical settings.

**Instructional design: Issues of theory and application**

If we consider the nature and purposes of instructional design, several patterns are evident. The focus of traditional instructional design paradigms has been the creation of a learning event or learning episode for students, in which outcomes are measurable and the process is repeatable in any context. For example, the instructional design models of Dick & Carey (Dick, 1996) have remained fundamentally unchanged, and until the most recent version, the role and importance of the learning context has also remained unchanged. There has been a consistent emphasis on instructional sequences and on prescribing activities for learners, based on the assumption that all learners are similar and that needs can be determined. In contrast, constructivism, which emphasises learning rather than instruction, challenges the instructional designer to go beyond prescribed sequences and isolated learning episodes. Constructivism challenges the fragmentation of learning into steps, and the whole notion of an ISD ‘model’ becomes dubious because the ‘model’ is no longer relevant. Constructivism proposes that learner is the centre of instruction. Jonassen et al (1995) argue that with constructivism, the emphasis has changed to cognition in context, and to the design of the whole learning environment. Other theorists have also supported the notion of a learning environment. For example, Wilson (1994; 35) states that:

*Thinking of instruction as an environment gives emphasis to the ‘place’ or ‘space’ where learning occurs. At a minimum, a learning environment contains:*
  * the learner;
  * a setting or space wherein the learner acts, using tools and devices, collecting and interpreting information, interacting perhaps with others...

Effective planning for learning also requires utilisation of technologies as ‘cognitive tools’ (Jonassen, 1997) and an understanding of theory relating to learning. This holistic perspective sees learner and teachers as co-participants and learning as engagement in joint tasks, with control over sequences, pacing and learning goals (Harper & Hedberg, 1997). The whole social and motivational context becomes part of the design process. Like Laurillard’s (1993) conversational model of reciprocal activities that mediate learning, (interaction, discussion, adaptation and reflection) the emphasis on instructional design emphasised by constructivists is influenced by socio-cultural theory, originating in the work of Vygotsky, (1978). According to socio-cultural theory all learning is embedded in a social context and all interactions that occur in the social context impinge on, and contribute to learning. As an example of design heuristics or design goals, Duffy & Cunningham
(1996) propose several principles to guide instructional design based on socio-constructivist theory. In designing activities for professional learning, these principles were redefined as design guidelines, informed by constructivist and cognitive apprenticeship models of learning (Table 1).

### Designing for self-regulation and authentic learning

Constructivist theory by itself does not provide guidelines for instruction. Eclecticism is essential. Intentional learning theory advocates learning as a deliberate activity, with a strong focus monitoring, self-regulation and goal directed learning (Scardamalia & Bereiter, 1994). The model has been successful in promoting a process-based model of learning at UNE and also in shaping learning interactions from teacher-oriented episodes to joint goal-oriented task between peers and groups of learners (Jarvela, 1995). However, theory needs to be converted into practical and workable design for tasks, forms of interaction and assessment activities. The design of tasks, activities and forms of assessment must be related to learners' needs, employer expectations regarding outcomes and real life contexts.

**Table 1: Design recommendations for self-regulation and professional learning**

Design Recommendations: Task Design in AFM 272 Accounting Information Systems
Based on our experience in developing learning environments for E-Commerce and Accounting Information Systems, we can make explicit design recommendations for other practitioners.

1. Propositional information needs to be proceduralised through application to real life scenarios.
2. Learning tasks should develop strategic skills through their experience with novel tasks.
3. Students should develop process knowledge by communicating about the cognitive strategies they apply to a particular problem.
4. Tasks should be goal directed and enable students to redefine them and formulate their own criteria for successful integration into prior experience.

These design recommendations outlined were operationalised initially in the subject Accounting Information Systems which was offered to a cohort of eighty 2nd year accounting undergraduate students. The propositional information was identified as the design and maintenance of an accounting information system. In addition as second year students the group had eighteen months prior accounting knowledge and experience which the task specifically encouraged them to integrate and reformulate. Focus on this activity was reinforced by a significant assessment mark ascribed to it. To accomplish the design goals:

1. Students were required to set up and maintain a computerised accounting system using the computerised accounting package Mind Your Own Business (MYOB). Highly specific information was given to students about the operation of the program. Little information was given about the accounting elements of the task.
2. Students were required to search the Internet to find the relevance of the program they were using, as well as confer with parents and friends then discuss this with their fellow students using asynchronous online methods.
3. Online discussion forums were set up for students to confer about problems they were having with the task and the solutions they were generating. A system of 'bonus marks' was implemented to encourage students who focussed on solutions rather than simply post 'can't do' messages. It was considered counter productive for the instructor to intervene unless there was a long thread of misinformation.

It was believed that the tasks outlined above incorporated all four design principles and led to an integrated approach to information literacy and encouraged problem solving skills. In addition the real world relevance was demonstrated to them through their own research. Given that the cohort was in the 18 - 23 year old age group it was assumed that their life experience was limited it was thought that the students would benefit from a context to view their knowledge of accounting information systems. This thinking led to the formulation of the second task based on the four design principles and a realisation that students would learn about professional activity by engaging in such activity. Therefore local businesses were approached and students were placed in teams to analyse the accounting information systems of the various businesses. Various sub-tasks were developed to enable students to both contextualise accounting information systems and engage in professional activity. Students were required to:

a. Interview the proprietor/manager of the business. They were required to design a set of and post them to the Bulletin Board for feedback.
b. Dress and speak appropriately for this interview. This created a good deal of discussion about what was 'appropriate' in a workplace context.
c. Document the accounting system for the business.
d. Write a report for the proprietor which first had to be seen by the instructor.
e. Design and post a web page within the confines of the course software about the systems in the business
f. Give a brief oral factual presentation about their findings.
g. Maintain a good working relationship with the team members.

The two tasks combined together gave students a learning experience which led to the development of an acute awareness of what professional activity could mean to each of them. The principles which underpinned the tasks have also been applied to the area of e-commerce course.

Conclusion
In this paper, preparation of students for professional practice in the areas of accounting, e-commerce and financial management is conceptualised as developing expertise in three integrated forms of knowledge, propositional knowledge, interpretation of experience and process knowledge. Each of these forms of knowledge can be developed in online environments though task and assessment design, and within a framework that encompasses intentional, constructivist learning.

References

Abstract. In the rush towards web-based learning, courseware management tools are being promoted as a means of simplifying the creation and management of instructional websites. This paper examines such claims in the light of a unit in Project Management for Interactive Multimedia at Edith Cowan University. The unit was delivered in two incarnations; the first was using the tool WebCT, and in the following semester the course was delivered through a website designed specifically for the unit, by making use of ancillary tools which were custom designed or available as third party products. The two implementations are compared in terms of ease of use for student and course designer, and the potential of each approach to support specific learning strategies. Given the scope of delivering a unit such as this, the authors found that using a customised web approach was more efficient than using a courseware management tool such as WebCT. It is recommended that consideration be given to the nature of the learning environment based upon the proposed learning strategy and pragmatic issues of implementation before the selection of a delivery approach.

Introduction

This paper discusses strategic factors and issues involved in deciding what approaches should be taken to develop on-line units. On-line approaches are being advocated as a means of providing flexible learning environments that deliver learning outcomes in an effective, and above all efficient, manner. Such are the promises of on-line delivery, but as with all implementations of technology in teaching and learning, there is no direct evidence that the Web supports effective and efficient learning any better than traditional methods (Russel, 1999).

It is certainly true that on-line learning can reduce the costs involved in organisational infrastructure such as purchasing real estate and computer laboratory equipment. There also appears to be an assumption that there are economies of scale to be gained in human resources by reducing student-teacher contact time through the implementation of easy to use tools which enable educators to easily develop, maintain, and update learning content. Courseware management tools such as TopClass and WebCT are promoted as “easy-to-use environment[s] for creating sophisticated WWW-based courses that are otherwise beyond the ability of the non computer programmer” (ULT, 1999) and claim to “make it easy to transform existing instructor-led content into online learning materials” (WBT Systems, 1999).

However, such claims are not easy to justify, however. While there are many studies which seek to compare between specific courseware management tools (eg Infoworld, 1998; PC Week, 1997), the efficiency and effectiveness of these products in comparison to customised Web based environments is less easy to define. Where student numbers are small, and the requirements are modest in terms of functionality, it may be that a purpose-built Website may provide a better alternative to implementing a courseware product. The potential of courseware management tools is dependent upon such factors as the ease with which the course can be developed and administered, and the quality of the interface for end users, but also the extent to which the product provides flexibility in the development of on-line learning strategies. It may be that while such tools require less initial investment in time and money, the requirements for implementation, maintenance, and their inflexibility with regard to interface and the types of learning activities they support may lead to less effective design, and consequently less successful learning than customised environments.

This paper examines the use of a courseware management tool, WebCT, in the delivery of a single undergraduate unit in Multimedia Project Management. The course operated using WebCT in the first semester of the academic year, and was then delivered using a customised Web-based environment in the second semester. The two approaches are compared in terms of:

- ease of development and administration by lecturers;
- ease of use and accessibility for the students; and
- potential for supporting instructional strategies appropriate to the unit.

A Taxonomy of Courseware Management Tools

There are many tools available which have been designed to deliver on-line learning, and it is important to distinguish between them. While some products are designed for system wide implementation, and link into existing enterprise systems such as student and financial databases, many are less complex ‘shrinkwrapped’ products which attempt to offer whole solutions to education and training systems. Typically, these maintain student records in proprietary file systems and are designed to facilitate courseware development for novice developers or lecturers.

Examples of courseware management systems are PlaNet Manager (Planet Software, 1999), Southrock GEM (Southrock...
behavioural objectives as well the educational philosophy that underpins the strategy.

Traditional approaches to computer assisted learning have generally been based upon objectivist epistemology and behaviourist methods (Reeves & Reeves, 1997). Contemporary approaches, however, tend to focus more on the multitude of ways in which learning can be mediated through cognition and social interaction. This shift in educational theory has been in tandem with the development of the Internet as a learning medium, and the Internet has been advocated as an ideal tool for social constructivist learning, since it provides the networked communication necessary for the collaboration and dynamic content delivery; all of which were impossible in fixed media such as CD-ROMs (McMahon, 1997).

Constructivist approaches emphasise the role of the individual in generating learning. Rather than a process of stimulus/response, users are actively engaged in making meaning through cognitive accommodation and/or assimilation (Piaget, 1977), or through social interaction (Vygotsky, 1978). Vygotsky argued that learning comes about through social negotiation within a cultural context, with language as the primary enabling tool. This social constructivist philosophy has been expanded on recently, introducing the notion of cognitive apprenticeship (Brown, Collins & Duguid, 1989) through which students learn in a manner similar to traditional apprenticeships. The students access expertise through mentors, whose role is to facilitate rather than teach, and the aim of learning is to solve realistic and practical problems in an authentic setting. Just as in traditional apprenticeships, learners engage in activities 'on-the-job' rather than through the teaching of abstract concepts. The argument is that students are better equipped to approach non-familiar problems and produce solutions that are appropriate to a given culture.

Social Constructivism formed the theoretical basis for this unit with the ultimate view of learners as developing practitioners in the field of Interactive Multimedia. Strategies used in the project management course included:

- having students develop a web site for a client, which simulates how these students will be working when they gain
employment;
• having students form project teams of approximately four students to develop a web site to promote collaboration;
• promoting asynchronous discussion and collaboration by having student task teams (different to the project teams) present a weekly topic on the bulletin boards;
• promoting synchronous on-line discussion through the use of chat facilities;
• having the students work with complex problems which have multiple potential solutions.

WebCT Development

Transferring this course to an on-line environment using WebCT required careful thought and planning. Which WebCT icons would be useful for the design of a home page? How could the required instructional features required by the course be transferred to WebCT? In order to answer these questions it was necessary to firstly learn and understand how to use all the functions and tools available in WebCT. Much reading, advice and experimentation with WebCT was required before settling on a home page which appeared to satisfy all the course requirements. It became obvious that there were many ways of designing the home page. Using different combinations of icons in WebCT could change the instructional focus of the course, or change the way that students accessed the content. Also, careful consideration of interface design issues was needed, as too many or inappropriately designed icons would be confusing to new users and add unnecessary cognitive load.

After much consultation with other WebCT users and experimentation with WebCT icons, the icons shown in Figure 1 were used on the WebCT Home Page. Table 2 below shows the order of importance of each of the icons for the instructional strategy used in this case.

The Bulletin Boards were the most heavily used part of the WebCT environment. As shown in Figure 2, a bulletin board was created for each of the ten weeks that content was delivered. From week 3 onwards, a student task team was responsible for the delivery of this content. The “Main” bulletin board, which had over one third of the total messages was set up to allow students to ask questions or raise issues about anything other than the weekly discussion topic.

There was little intervention by the tutors on the bulletin boards, except to assist when it was obvious that the students would not resolve an issue or question. Tutors would always wait a few days before answering a posted question in order to give other students the opportunity of answering, and hence obtain some marks for bulletin board contributions which accounted for 30% of their total mark. Students were encouraged to develop discussion threads, which were relevant to a weekly topic, or other issues related to multimedia project management, making the environment truly student centred.
The five elements used for assessing student's progress in the unit are shown in Table 3. The student's final mark was a combination of project team, task team, individual, client and peer assessment marks. This provided a rich form of assessment for the students, but was found to be time consuming by all the tutors.

WebCT provided comprehensive quantitative measures for recording the number of messages “Posted”, “Read” and “Hits” made by students. This gives tutors a quick idea of how students are using the WebCT environment i.e. which students are “lurking” and not posting messages. However, while it can provide some valuable data for tutors if they are trying to assess the amount of effort individual students are contributing toward the unit, it does not give a good indication of the ‘quality’ of submissions. In order to assess this, a content analysis model based on Henri (1992), and Gunawardena et al (1997) was implemented. While this was an effective approach, which supported the social constructivist philosophy behind the unit, it was cumbersome to implement, and was used predominantly because bulletin boards are the primary mode of collaboration supported by WebCT.

In semester 2, 1999 the same project management course presented to students in semester 1, 1999 using WebCT, was delivered through the use of a customised web site. The web site (http://www.scam.cowan.edu.au:5425/units/imm3202/default.html) was built using Macromedia Dreamweaver (Macromedia, 1998) and Filemaker Pro (Filemaker, 1999).

As with constructing the WebCT course in the first semester, the instructional strategies required for the unit were carefully...
considered before construction on the site started. The main instructional difference that occurred in the second semester was changing the instructional focus from the bulletin boards in the first semester (as with WebCT) to a problem solving strategy.

![Figure 3: Customised Web Site](image)

Figure 3: Customised Web Site

As shown in Figure 3, the site is relatively simple to access without the use of passwords. There was no need to set up student’s accounts or a database to enable student logins. The options shown were specifically chosen to meet the needs of the syllabus as follows:

- **available projects** option. This was as used to allow students to choose from a list of available project topics that they would develop as a team during the semester. All the topics are related to a project management concept, such as interface design, legal issues, analysis etc. When students selected a project, it then appears in the right hand frame. The blue underline hyperlinks to a description of the project and the circular icon hyperlinks to a student presentation area, where students keep putting up prototypes for peer and tutor evaluation;
- **Registration** option. Was used to collect student details such as e-mail, phone, address, skills, previous employment and other details. Students also entered a password, which then enabled them to go back into the database and change their details if necessary;
- **Message Boards** option. Allowed the use of bulletin boards. However, in this semester this was not a high priority and not used very heavily;
- **Post a URL** option. Allowed students to share useful web site (and also attract bonus marks) by making useful URL’s available to other students. This area was set up in project management categories so that when URL’s were found students posted them to the relevant category, along with a comment about the site;
- **Software** option. Presented students with information and software needed to transmit files from their desktop computers onto the file server to show prototypes and in order to receive feedback;
- **Syllabus Documents** option. Allowed students to down-load syllabus and other resources needed for the unit;
- **Previous Projects** option. Showed past student’s project work, which illustrated the standard of work expected; and
- **The RONSUB Login** button. This gave students access to the problem submission and peer assessment environment, which was a purpose built software application. It provided students with tools to submit their solution and then rank the solutions of their peers. Students who received the highest number of votes were given the highest scores.

**Discussion**

A comparison of the WebCT and customised web site environments can be made according to ease of development and administration by lecturers, ease of use and accessibility for the students and potential for supporting instructional strategies appropriate to the unit.

Given that the WebCT site was not a centralised university initiative, without direct links to the central student database and without central technical support, it was a difficult and time consuming task to set up for only one group of ninety students. Student logins and passwords had to be established for all students and tutors, along with other initial database requirements. Also, any WebCT technical problems were generally complex in nature and often required assistance from the WebCT on-line help facility, which sometimes was not fast enough to solve pressing problems.

In comparison, setting up the customised web site was relatively simple. Even without any technical skills, a site such as shown in Figure 3, can be cheaply and quickly created by a multimedia developer for minimal cost, which would “pay for itself”, as it would not have any royalty payments.

With the customised web site it was easier to add customised features eg the inclusion of “RonSub”, purpose built problem presentation and peer assessment tool, was easily embedded into the customised web page. The inclusion of previous student web projects and web space for students to load working progress of their prototypes was simpler and quicker to implement in the customised web site environment. To present these within the WebCT environment requires files to be packaged or “zipped” and then loaded with the File Manager. In some cases, HTML editing is required to make the web pages work correctly.

Training students to use the WebCT environment required one week of the course getting students on-line with passwords, and also familiarising them with WebCT interfaces for Bulletin Boards, Presentation areas, File Manager, Personal Home Page tools etc. The tutors also needed training to become familiar with the WebCT environment and interface. Students often complained about difficulties in logging onto the WebCT environment (due to incorrect passwords or technical problems) and also about slow response times and screen refresh rates. This has not been the case with the customised web site environment. No login is necessary and there is no extra cognitive load in learning a new interface to access the customised web site, as it allows the flexibility required to make an intuitive interface.
Both WebCT and the customised web site environment supported learning strategies needed for this course, based on social constructivist learning theory. WebCT offered bulletin boards, chat, whiteboard, e-mail (internal to WebCT), public home pages, presentation areas and on-line note taking facilities. The customised environment used a listserv, e-mail (university accounts), presentation areas and problem posting and peer assessment area. The instructional tools used in the customised site were generally easy to obtain, either through the central "Virtual Campus" (Edith Cowan University), by having them custom built (as with "RonSUB") or by accessing tools from different suppliers which are either free, or very cheap to implement (see, for example, the freeware ‘Hot Potatoes’ suite from Half-Baked Software [1999]).

Conclusion

The choice to use WebCT or any other courseware management tool should be carefully considered. The amount of initial training needed for technicians, lecturers, tutors, sessional staff members and students is significant. Also, there are considerable overheads in setting up logins and establishing how to implement the tools for designing a home page.

The following issues should be carefully considered before committing to a courseware management environment:

- will the courseware management system be implemented across the whole university?
- have the courseware tools been carefully considered for their instructional relevance?
- how easy is it to add customised features if needed?
- has a budget been allocated for training lectures and students in how to access and use the new environment?
- has a budget been allocated for central technical support and help desk?
- will an instructional design advisory group be set up for to advise lecturers?
- do all the levels of management support its implementation?

If the answer to some of the above is “No”, then it may be preferable to implement a customised solution which is simpler, cheaper and more efficient on server resources. Customised solutions would still require lecturer training; technical support and instructional support, but may support greater flexibility in design when creating an environment built from the ‘ground up’. Also, customised websites support finding a solution to meet pedagogical needs rather than manipulating content to support the tools available. In the final analysis, the decision must be driven by the outcomes required from the course that is being developed and also the scale of the site being implemented.

Developing Web-based Learning Strategies: a comparison between the Web and traditional learning environments

Mark McMahon
School of Communications and Multimedia
Edith Cowan University, Perth, Western Australia
m.mcmahon@ecu.edu.au

Abstract. Over time, strategies have evolved from learning theory that aim to ensure learning takes place within a given situation. While such strategies are well understood within the context of traditional classroom teaching, and to a certain, if lesser, extent fixed format multimedia (CD-ROM) delivery methods, there has been little study beyond individual case studies as to which strategies work best within Web-based learning environments. This paper seeks to explore the concept of learning on the Web by comparing 10 common strategies across the three media of face-to-face classroom environments, Multimedia CD-ROM software, and Web-based learning environments. The strategies vary from didactic modes such as presentation and demonstration through highly interactive student centred methods such as problem solving and simulations, to collaboration using strategies such as discussion. It is argued that the Web has the potential to deliver learning through a range of strategies, but that the constraints and opportunities afforded by the environment must be taken into consideration.

Introduction – The Web and Learning

Learning is a notoriously difficult concept to define. It can be described as a “persisting change in human performance potential ... [brought] about as a result of the learner’s interaction with the environment” (Driscoll, 1994, pp. 8-9), but in reality, such textbook definitions pose more questions than they answer. How, for example, do learners interact with the environment? What types of experiences enhance learning, and how? As will be seen, these questions are still highly contentious.

Several theories have been proposed to explain the process of learning. Some view it as a process of enculturation (Brown, Collins & Duguid, 1989), a change in behaviour (Gagne Briggs & Wager, 1988), or the acquisition of the cognitive skills required for “purposeful remembering” (Norman, 1982, p. 361). There are obviously many distinctions between these theories; the emphases upon external variables, social processes, or internal mental function are dependent upon the theorists’ attitudes towards learning as a science as well as deeply ingrained epistemological and ontological assumptions.

Such assumptions inevitably carry through to the final learning environment. Classroom environments have formed the basis of formal education for many years, and there are now a number of well understood strategies which can be implemented to enhance learning of various types. In the area of Instructional Technology, too, it could be argued that Interactive Multimedia (IMM) in CD-ROM format has become a mature technology for delivering educational and training content. With this maturity has come an understanding of what works and what doesn’t. IMM’s potential for “multi-sensory delivery, student metacognitive self monitoring assisted by instant feedback, and student control over the pacing of information flow and the pathways followed” (Richardson, 1995) has marked it as a medium with attributes that can go
beyond traditional class based instruction. It has, however, also lacked the social interaction that typifies face to face learning.

In some respects, the World Wide Web appears to bridge these two approaches to delivering learning; providing a nexus between content-based learning through hyperlinked Web pages, and the communication afforded by real-time chat and asynchronous e-mail. Certainly, it seems to have attracted a good deal of attention as a learning medium.

This is particularly true of the tertiary sector, where the demand for flexible modes of study and the need to reduce costs are starting to erode the traditional face to face learning that has previously characterised it. The Web is promising reduced logistical overheads since it is significantly less expensive to produce materials electronically than in printed form, and the material may easily be kept up to date (Eklund, Garrett, Ryan, & Harvey, 1996). While it has been argued that students may not like to learn at a distance (Simonsen, 1995), the flexibility afforded through distance education for the student and the savings to a university in contact time and physical infrastructure are making it an increasingly attractive option for both providers and clients.

It can not be said yet, however, that the Web in its current form is a mature technology. Certainly, the actual use of the Web does not appear to live up to its promise as yet. A visit to the World Lecture Hall (University of Texas, Austin, 1998) would indicate that most sites are based around the use of the Web as a repository for information rather than an actual learning environment. This has lead to the criticism that the Web is simply a “24 hour-a-day glorified whiteboard” (Archee & Duin, 1995).

Clearly, the strategies common to classroom environments and CD-ROM based IMM need to be re-evaluated in terms of their potential for the Web. This paper will examine 10 such strategies. Their relative potential to facilitate learning in these three environments will be discussed, and recommendations will be made on how they may be best implemented.

Learning Strategies

Such examination is made difficult by differing notions of what instructional strategies actually are. At a micro level, they can include Cognitive techniques such as the use of mnemonics, elaboration, and chunking (West, Farmer & Wolff, 1991), but such techniques can perhaps better be defined as tactics since they deal with low level implementation within a broader paradigm. It is the macro level strategies, such as the use of tutorials, drills and simulations which will be the focus of this analysis, since it is these broad approaches which appear to categorise most types of learning environments and impact most heavily on the nature of the learning environment.

Newby, Stepich, Lehman and Russell’s (1996) ten instructional approaches are used as the basis for discussion, and are outlined below:

- Presentation
- Demonstration
- Discussion
- Co-operative Learning
- Discovery
- Problem Solving
- Instructional Games
Simulation
Drill and Practice
Tutorial

This choice is necessarily somewhat arbitrary, and the individual approaches are not mutually exclusive (presentation, for example, may form part of a tutorial). However, they include strategies that are often used in many settings. Some approaches, such as tutorials, drills and simulations, are common strategies for single user computer assisted learning (Alessi & Trollip, 1991), while techniques such as discussion and co-operative learning often form the basis of classroom experiences. An examination of this range of approaches may allow for a more complete discussion of the potential of the Web for learning, while at the same time acknowledging that there may be other strategies available to the instructional designer.

Each strategy will be discussed in terms of their potential of each approach to be implemented via the Web will be explored with the aim of arriving at some conclusions about how best the Web may be used to foster learning.

Analysis of Strategies

In order to compare strategies, their potential for learning within the three environments of the Web, classroom, and stand-alone Interactive Multimedia is represented as a diagram (figure 1). For the purposes of this paper, each environment is treated as a 'stand alone' approach to learning. For example, while both multimedia and the Web may be effective tools in the classroom, the focus is on the features of each environment which make them distinct from each other, rather than ways in which they can be combined. Each strategy may pertain to any of the three orientations in each diagram to varying degrees. The placement of the strategies within the diagrams is at best an interpretation based upon existing literature and is open to discussion. However, they serve a useful role as a heuristic for exploring the relatedness of the approaches to each other and their potential implementations.

Presentation

Presentations “relate, dramatize, or otherwise disseminate information to learners” (Newby, Stepich, Lehman & Russell, 1996, p. 47) and are a very common tool in many learning situations. While a limited strategy, they are an efficient means of delivering information. The most common form of presentation in higher education is the lecture, which is usually supplemented by a workshop or tutorial. In traditional computer based training, too, the act of presenting information is only a component of the learning sequence (Gagné, Briggs, & Wager, 1988). The cost effectiveness of presentations (Newby, Stepich, Lehman & Russell, 1996), however, means that they will continue to be integrated into traditional instruction, in the form of texts and lectures; and the Web is a capable
medium for replicating this method.

One of the best examples of this is the latest version of Microsoft PowerPoint, which allows presentations to be easily converted into HTML. Since this is a common lecture presentation tool, it has been quickly adopted as an easy approach to information presentation. The danger, of course, is that the Web could end up as merely an information resource, rather than a genuine learning medium. In this sense a presentation strategy may even be viewed as ‘no strategy’ beyond the convenience of using the web in the same way as any informational material, such as a text book or encyclopedia.

Demonstration

Demonstrations share some similarities with presentations in that they are content based and transmissive in their approach to learning. However, they differ from presentations in that the information is presented in a contextual manner. Students “view a real or life-like example of the skill or procedure to be learned” (Newby, Stepich, Lehman & Russell, 1996, p. 48) and this can be achieved both on the computer and through face-to-face experiences.

Demonstrations are common practice in the classroom; science experiments, for example, can be shown to students saving the resources in time and money that would be expended in students completing the experiment themselves. Digital video can replicate this experience in a multimedia environment. The high level of realism, and the ability of video to show events in real time make it an ideal medium for computer based demonstrations. It is here, however, that the problems of the Web become manifest. Media intensive environments require high bandwidth data transmission, which, as has been shown, is still an unrealised promise of on-line learning. Virginia University's award winning Interactive Frog Dissection (Kinzie, 1994) exemplifies this. Videos are used within this tutorial to provide safe and authentic demonstrations of frog dissections for use in high schools, but despite these ambitious aims, QuickTime videos prove to be so slow to download that any sense of flow is lost.

Discussion

Discussion “allows students to actively practice problem solving, critical-thinking, and higher-level thinking skills” (Newby, Stepich, Lehman & Russell, 1996, p. 49) thus providing access to deep learning, making use of prior knowledge. It is no surprise that it forms a major component of classroom learning, however, little discussion can be found in traditional CD-ROM based multimedia, which is often designed as a flexible ‘stand-alone’ product. The global networked nature of the Web would appear to make it an ideal medium for this strategy. Traditional Internet communication tools such as E-mail, Newsgroups, Internet Relay Chat, and MOOs offer both the rapid synchronous communication of normal speech (in the form of text) as well as asynchronous interaction which may help to promote a more reflective metacognitive approach. With the use of plug-ins and CGI scripting, such facilities are now becoming available in a more cohesive form on the Web. Examples of learning through communication can be seen in commercial environments such as TopClass (WBT Systems, 1997) which provide the functionality required for this approach.

Co-operative Learning

Group work forms the basis of many classroom activities, and is a highly valued and relevant strategy since it could be argued that most work environments involve a high level of collaboration to achieve a common goal (Brown, Collins Duguid, 1989). As with discussion however, co-operative learning is rare in multimedia environments. The swing away from networked computing in the 1980s and the lack of any practical paradigm for intelligent software limited students’ ability to interact in a co-operative way with each other or the machine.

It is a trend, however, that appears to be reversing with the advent of the Web. E-mail is a common collaborative tool among academics to jointly conduct research and author papers. Such an approach is now trickling down to high schools and primary schools. This author, for example, was recently approached by a high school teacher in the United States of America who wished to initiate collaborative projects between his students and Australian students of geography. Groupware, a collaborative tool that allows users to share work files, has been common across local area networks and is now being ably adapted to the Web through environments such as Lotus Corp’s Notes, which has now made the transition from local area network to the Web (Lotus Corp, 1997).
Discovery Learning

The learner centredness of discovery learning and emphasis on learning by induction rather than deduction make this an attractive strategy where self regulated learning is the goal. A common argument against discovery learning though, is that "for the majority of regular school subjects and most procedural or physical skills, a model that begins with the presentation of information [is] more efficient and demonstrably more successful" (Alessi & Trollip, 1991). Thus, discovery has limited application in the classroom, though many make use of it in a highly structured and guided way. After all, it "is legitimate and necessary for teaching to go beyond the specific experience, to abstract the symbolic representation that allows the learner to use their knowledge in an unfamiliar situation" (Laurrilard, 1993, p. 19).

Such criticisms can also be applied to computer based discovery. Rieber (1993) cites Papert (1980) in arguing that "the computer offers a powerful medium for the exploration and discovery of many ideas, particularly in science and mathematics, just as a young child might explore the concepts of volume given a sandbox, and mass and momentum in marbles" (Rieber, 1993, p. 5). As will be shown later, the multimedia potential of computers for simulations is one way of providing such an experience, however this is not so easily achieved through the Web. In one sense, it may be argued that the Web is an ideal medium for discovery learning. The self directed nature of web 'surfing' may undoubtedly lead to some form of serendipity. However, a great deal of frustration is associated with Web use when a student has not developed effective searching and browsing strategies (Archee & Duin, 1995) and it would appear that care is required when implementing such a strategy.

Problem Solving

Problem solving has much in common with discovery, but is necessarily more structured in that a problem must be solved. Like discovery strategies, problem solving usually involves the generation of learning through active involvement, in this case through a process of trial and error. It can also be used as a tool for the practical reinforcement of abstract concepts.

The use of problems as reinforcement is common to many classroom situations; in a maths class, for example, abstract knowledge of calculus can be applied to problems involving speed, velocity, and acceleration. Situations where learning is actually founded in authentic problems and involves trial and error are less common, despite the potential benefits from the deeper processing required within this paradigm (Reeves & Reeves, 1997) perhaps as much because of time and curriculum constraints as pedagogical philosophy.

It has been argued that one role of the computer is as a cognitive tool that can be used as a generic device to assist the development of problem solving skills. Papert (1993) goes so far as to describe them as tools to teach one to think, and proposes LOGO, a simple programming language as an example of such a tool. It is an environment that is driven by the problem solving process rather than any inherent content. Such highly interactive environments are yet to be seen on the Web, but there would not appear to be any great hindrance to this approach. Indeed, it could be argued that the trial and error use of the Web search facilities to find information can assist students in developing research skills.

Instructional Games

Games can provide an engaging scenario for learning, containing the challenge, curiosity, control and fantasy required for a motivating environment (Malone, 1980)

The fact that games seem under-utilised in the classroom may be because of the difficulty of designing games which intrinsically support learning or that games are simply perceived as incompatible with learning, particularly as students become older (Rieber 1996). It is on the computer that games seem to have found the most support, and in fact are one of the biggest areas of software development. The relative cost and time associated with developing games for specific learning goals as opposed to traditional computer based training, however, means that specifically instructional games are rare.
The same is true for the Web. Rieber's Space Shuttle Commander (1994), an Authorware based microworld, is one of the few games available via this medium. It is without doubt true that instructional gaming via the Web is yet to become a major use of the medium. The high quality of the media rich games available on CD-ROM would suggest that there would be a lot of work necessary before students would accept such environments. This does not mean that it is an impossible task, however. The emergence of servers which provide gaming between remote players of Arcade style games such as DOOM and Quake (Id Software, 1997), show the potential of hybrid combinations where the major media elements and game engine resides on the client computer, data transfer being restricted to player to player interaction. It must also be acknowledged that text based adventure games were once popular despite their lack of multimedia. Whether contemporary players would tolerate the paucity of stimulating graphics and sound at the expense of a rich fantasy scenario is debatable. It is clear, however, that the potential for the Web as a gaming medium needs consideration.

Simulations

Simulations are distinct as an instructional strategy in that “the student learns by actually performing the activities to be learned in a context similar to the real world” (Alessi & Trollip, 1991, p. 119) The increasing capacity of computers to model aspects of the real world, in an inexpensive, safe and self contained scenario has lead to an increasing use of this strategy within IMM learning environments. Examples such as Maxis' Sim City 2000 (1993) show how generic skills can be constructed in a rich multimedia environment.

One variation of simulations is the microworld. “A small, but complete, subset of a specific environment or domain” (Rieber, 1993, p. 6), Microworlds have the potential to provide a highly interactive and motivating environment, but with greater teacher control of contributing variables.

Small-scale microworlds are now possible on the Web. The example of Space Shuttle Commander is testament to this. However, as the requirements for authenticity increase, so do the demands placed upon data transfer rates as a result of the extra media and coding that need to be integrated. Such requirements place a heavy burden upon the current implementation of the Web. Until such issues are resolved it is unlikely that Simulations will be able to replicate the kinds of experiences generated through media rich CD-ROMs.

Drill and Practice

With drill and practice “learners are led through a series of practice exercises designed to increase fluency in a new skill or to refresh an existing one” (Newby, Stepich, Lehman & Russell, 1996, p. 56). Such a strategy can form an important component of learning in the classroom where automaticity rather than reflection is required, as in the use of flash cards for learning multiplication tables or foreign language vocabulary. While computers are quite capable of such interactions, there does appear to be a move away from Drill and Practice as a strategy in IMM, perhaps because of its foundings in behaviourist principles and the fact that it does not make full use of the technology.

While computers themselves are now capable of far more than simple drill and practice interactions the same can not be said of the Web as yet. In fact, it is in this area of computer interaction that the Web appears to excel. Alessi and Trollip (1991) define the anatomy of drill and practice as an interaction involving item selection, question/response, judging and feedback, and such elementary processing can easily be handled by Common Gateway Interface scripting. Even at a more complex level, Authorware, which is designed specifically to facilitate such interaction can be integrated into the Web using Shockwave.

Tutorials

Tutorials are less an individual strategy as an instructional sequence. Specifically, the tutorial “presents the content, poses a question or problem, requests learner response, analyzes the response, supplies appropriate feedback, and provides practice until the learner demonstrates a predetermined level of competency” (Newby, Stepich, Lehman & Russell, 1996, p. 57). This sequence is graphically represented in figure 2.
Tutorials are a common strategy in educational multimedia, and there is no reason why they can not use the medium of the Web. The ease of creating presentations, where large media files are not an issue, has already been shown, as has the power of forms for question/answer episodes. While there appear to be few good examples of tutorials on the Web, most being characterised by excessive use of text and linear, page turning interactions (UT Austin, 1997), they have the potential to provide effective learning where objectives are clearly defined.

Recommendations

Ostensibly, there appear to be few strategies which can not in some way be implemented in all of the environments discussed. In categorising particular environments as supporting certain strategies at the expense of others, due care is necessary. The clustering of strategies towards the centre of the diagram depicting learning environments would suggest that many approaches work equally well on a variety of platforms.

Nevertheless, some conclusions can still be drawn as to what strategies may be more or less effective in a Web based environment than in a traditional classroom or using CD-ROM based Interactive Multimedia. The difficulties of the Web in providing a high level of interactivity, and environments rich in multi-sensory media, certainly limit its effectiveness in implementing demonstration and simulation strategies. Since these approaches are often linked with Constructivist tenets of active and authentic learning, consideration must be given to how these issues can be addressed.

In highly concrete knowledge domains this is a very real problem. A trade such as Plumbing, for example, requires skills that involve enactment on a physical environment. The difficulty the Web has in creating such authentic simulations appears to limit its capacity to accommodate this. Even more ill-structured academic areas such as History and Philosophy require a level of context, even if that context is the academic one requiring the implementation of a culturally specific methodology and use of language. It is here, perhaps, where the Web may be particularly useful. While the Web does not easily support a high level of authenticity in terms of the physical environment that can be created, it may perhaps be used to create an authentic culture for learning. This would involve communication between practitioners of a knowledge domain within a social framework. Thus a high level of interaction is maintained for the learner through the sharing of ideas within an appropriate context.

Traditional Internet communication tools such as E-mail, Newsgroups, Internet Relay Chat, and MOOs offer both the rapid synchronous communication of dialogue in the form of text as well as asynchronous interaction which may help to promote a more reflective metacognitive approach. With the use of Web browser plug-ins and server software such as Ichat (Ichat, 1998), such facilities are now becoming available in a more cohesive form on the Web.

While care needs to be taken in the use of Web based communication tools, it would appear that they do show some promise. Wyld and Eklund (1997), for example, cite Papert (1994) and Betts (1994) in arguing that Web communication has the potential to support “a wide range of learning styles as information is presented in a range of ways that is flexible to students’ needs and abilities” (p. 148). This does raise questions about the actual nature of the Web as a communication medium. How does it differ from the traditional forms of letter writing and face to face interaction? These questions in turn raise issues of whether students need to be taught skills in communication with each other using Internet technologies. Even if this is so, however, the goal of Web communication appears to be one worth pursuing. Secondary outcomes alone, such as the potential to develop “collaborative global relationships and cultural understandings by reducing the existence of stereotypes and prejudices and
the significance of location, gender, age and race" (Caudell, 1994, cited in Wyld & Eklund, 1997, p. 148), make the implementation of Web based communication an exciting prospect.

Abstract: This paper will report on the results of a DETYA*-funded project which investigated the extent of use of computer-facilitated learning (CFL) materials across the higher education sector in Australia in order to determine overall trends. In addition, the project also investigated how an updated national inventory of such materials might be developed in the context of developing a strategy which could lead to a greater adoption of CFL materials in Australian higher education. * Department of Education, Training and Youth Affairs - a central Australian government department

Introduction and Scope of the Study

There has been a great deal of development of electronic educational resources in the last few years, fuelled by a climate in higher education which demands educating more students with less resources. This has occurred together with substantial development of information technology (IT) systems and infrastructure in all Australian universities. However, the evidence is that there is little dissemination of these electronic resources and practices. Greater collaboration and sharing of resources is becoming an increasingly urgent issue. There are several existing databases of computer-facilitated learning (CFL) materials but these databases do not appear to have increased the take-up of CFL materials and strategies a great deal. We need to investigate educational, technological and management issues in designing ways in which more use can be obtained from the valuable resources that exist.

The term computer-facilitated learning (CFL) materials is used to describe materials which use information technology in some way to facilitate teaching and learning, including: educational CD-ROMs, online course content materials, and the use of software for computer-mediated communication within a course.

Methods Used

The study used a multi-method approach, employing online surveys of institutional practice (28 Australian universities responded); a literature survey; and a case study of five universities at project, faculty and institutional levels. The data included survey results, interview transcripts, focus group transcripts, institutional documentation and short descriptions or vignettes.

The study explored issues which facilitated or mitigated against teachers being able to work in an environment which facilitates the adoption of CFL, in terms of:

- appropriate policies, infrastructure and supports within the institution;
- access to information about CFL resources; and
- being able to work collaboratively both within and across institutions.
Existing Information about CFL Resources at Australian Universities

A substantial amount of data was accumulated from a range of sources about the resources which exist to support CFL at Australian universities. It is clear that many universities are actively engaged in producing CFL resources to enhance the educational offerings they have. There is also a clear commitment to developing appropriate infrastructure to support the use of technology. The diversity in universities' structural arrangements made it difficult to compare data across institutions. There is also a variation in the stage of adoption of new IT from contexts where there are a significant number of early adopters and the use of technology is clearly embedded, to contexts where significant use of technology is a newly emerging trend. Precise information about CFL resources may not have been obtained from some universities because the survey was not responded to by the person with most accurate knowledge, or because facilities were devolved and centralised data was not available. The rapid change in the area also means that information provided to the investigators may be soon out of date. Overall the information about existing CFL resources at Australian universities is patchy and incomplete. In particular, there is limited or no information about:

- the educational design of the CFL resources being produced,
- the incentives and support that exist for individuals to produce CFL resources,
- the technical design and access specifications for using these CFL resources,
- the experience of using the CFL resources in actual teaching contexts,
- evaluations carried out to determine how educationally effective these resources are in practice,
- intellectual property and copyright issues which might affect the use by others, and
- how access can be obtained to these CFL resources from either colleagues in the same university or another institution.

Major Issues Relating to the Adoption of CFL Resources at Australian Universities

The major issues were selected from the case studies using three criteria:

- frequency of being mentioned,
- intensity of expression in the interview, and
- who articulated the idea—senior administration and/or teachers.

Three major themes emerged with a considerable overlap between a number of the issues and factors involved in each theme.

Policy

The policy theme looked at specific institutional policies, such as equity and intellectual property, the alignment of policy throughout the organisation, the direction of policy change (bottom-up or top-down) and a number of strategic processes which flowed on from policies such as grant schemes. There was a variation in the direction of policy change across the universities studied. The universities with a traditional emphasis on distance education had a strongly top-down policy direction. Two other universities had a predominantly bottom-up policy direction, and one university was reported by case participants as having essentially no policy with respect to CFL. In the institutions in which adoption of CFL seemed to be progressing most effectively, there was a balance between top-down and bottom-up policy implementation. This reinforces the need for balance between policy, culture and support; policy on its own will not succeed unless it aligns with institutional culture.

Copyright was a particularly complex issue which impacted in different ways according to the contextual level (personal, institutional or sectoral) in which it was being examined. Some individuals, for example, believed university copyright policy presented a personal barrier to the sharing and development of CFL; while from an institutional perspective there was concern and a growing awareness of the complexity of the issues which limited organisational capacity to maximise specific institutional uses of CFL. Finally, across the higher education sector in general there were broad ranging legislative issues, with respect to moral rights, licensing, royalties and payments for use of copyrighted materials, and continuing uncertainties relating to technological capability and usage.
Key issues relating to the policy theme:

- Safety net policies need to be continued, and possibly increased, in order to address the specific needs of the minority who cannot gain access to computing equipment for equity reasons.
- Funding schemes need to take account of earlier experiences - mechanisms are needed for monitoring the progress of initiatives and learning from failure.
- Funding schemes need to explicitly take account of the need for ongoing maintenance of CFL developments.
- Appropriate criteria for teaching performance need to be developed in order to provide an effective incentive for staff to adopt CFL materials and practices.
- University staff need access to a centralised service which provides practical support to staff on intellectual property and licensing issues.
- There needs to be widespread dissemination of the legal situation with respect to online intellectual property.
- If a CFL resource is made available to the academic community, mechanisms are needed to facilitate copyright clearance of CFL materials so that due recognition is given to the originator.
- Legislation relating to the use of online resources in education, the ownership of copyright on materials used in offshore courses, and moral rights is in train. Appropriate legislation should be supported.

Culture

Culture incorporated factors such as collaboration within institutions, and personal motivation of staff to use CFL, as well as particular aspects of funding, staff rewards and time, leadership, teaching and learning models, and attitudes such as ‘not invented here’. The case studies showed a great difference in the organisational cultures of the universities studied and of the infrastructures set up to nurture, develop, deliver and support CFL. The climate of the organisation is made up factors such as:

- strategic vision and leadership,
- attitudes to risk taking and innovation in teaching and learning,
- attitudes to adopting CFL,
- allocation of resources, and
- staff recognition and rewards.

Factors that motivated staff to adopt CFL did not vary greatly over the universities studied. Institutions with large numbers of early adopters had made changes to their cultures and policies, and had well-supported infrastructure. This resulted in a high level of acceptance so that some of the issues were no longer relevant to them. Main barriers to take-up were seen as:

- lack of knowledge about CFL;
- lack of academic time release;
- pressure to keep up the research quantum;
- non-recognition of teaching;
- lack of funding to maintain programs, staff and technical infrastructure; and
- lack of student acceptance of the new approaches.

On the other hand, factors that would motivate staff to use CFL included:

- a university culture which supports new approaches,
- good leadership from academic managers,
- recognition of teaching as of equal value as research,
- appropriate support infrastructures for staff and students,
- workload adjustments to develop materials and become computer literate,
- the opportunity to think about learning and not teaching,
- evaluation studies showing improvements in student learning,
- improving learning opportunities and outcomes for distance students,
- adding value to existing courses,
- providing a means to offer courses offshore,
- the chance to interact more with students,
positive feedback from students,
solutions to problems of large classes and funding cuts,
support and sponsorship from mentors, and
peer pressure.

Changing educational practices and styles can produce many negative reactions and this negativity needs to be acknowledged and managed effectively. Change should be introduced and implemented within a supportive environment. The culture of the organisation needs to be able to embrace change while offering staff opportunities to develop their own levels of comfort with the change. Within the university environment, leaders need to develop vision statements that are clear and well articulated to the staff. Appropriate levels of infrastructure and support should be part of the policy formulation to match the vision.

Key issues relating to the culture theme:
- Universities need to have a clearly articulated vision of the changes to teaching and learning that technology brings.
- This vision should have ownership and commitment from all levels of management.
- The Dean or Head of Department/ School should lead and support moves by the academic unit into increased use of CFL materials and strategies.
- Policies developed from the vision should include positive values and well funded infrastructure to support staff and students.
- Issues of staff workloads in the changeover to use of CFL should be clarified.
- The tension between teaching and research needs to be resolved so that staff gain appropriate recognition for the development and use of CFL materials.

Support

Support incorporated a whole gamut of institutional issues including IT, library and administrative infrastructure, professional development for staff, student support, educational and instructional design support for academic staff, funding and grant schemes, and IT literacy. There was a belief that real efficiencies could be possible with supportive infrastructure and good planning. Many universities are now focusing on an overall systems approach across the university so that infrastructure planning is linked to the development of professional development and support services. At this time, however, all universities are in transition and are grappling with the issues involved in designing and managing new ways of working.

Key issues relating to the support theme:
- Internal structures and funding for CFL development units create tensions between central administration and the faculties; open exploration of this tension is needed.
- Ongoing budget support for CFL development is needed. Funding for CFL development is ephemeral in many universities.
- Institutional development grants should focus on sharing processes and experience, as well as looking for product-oriented outcomes.
- The costs involved in hardware and facilities, and appropriate technical and support staff, are high. Mechanisms are needed to assist universities in managing these costs.
- The diversity of roles of ITS staff are high, and keeping skilled staff is difficult. Schemes to recognise and reward technical staff are needed as much as schemes to recognise and reward academic staff.
- Professional development and training is a complex and multi-faceted area. There is a need for high quality staff developers, for flexible support programs, for using mentors, and allowing adequate time for staff to engage in staff development.
- Student support services cover a wide range of issues, including equity and access, access to academic help (this has implications for funding staff time), access to technical help, and access to computers. Further attention is needed to all these issues.

Adoption and Collaboration
Unless the climate within and between universities supports the development and use of CFL resources, there will not be an increase in appropriate uses of technology in teaching and learning. Staff will use technology in their teaching when culture, policy and support structures are congruent. Some particular issues that were highlighted were:

- Time and scalability: from an institutional point of view, the current situation is that infrastructure and time allowance is possible only for a relatively small number of staff. Mainstreaming the use of CFL has enormous resource implications.
- Good evaluation of existing CFL programs is a crucial aspect of adoption. Late adopters want evidence that CFL materials and strategies can enhance student learning
- Adoption depends on key individuals who can act as role models and mentors for others. Institutions need to recognise and support these individuals.

The tension between collaboration and competition is important. We argue that collaboration can assist healthy competition in higher education. Using resources efficiently in collaborative arrangements can allow institutions to develop their own specialities more effectively. During the next few years each university will need to find its own balance point between external collaborative work and internal work aimed at developing its own specialisations.

Dissemination and Databases

Dissemination of information about CFL resources, and the location of CFL resources via databases were fundamental parts of the study. A framework for the development of a national inventory system is proposed whereby the development of national metadata standards will enable teachers and lecturers to search across a distributed set of interest-group-based databases.

Dissemination of information about CFL resources through marketing programs was seen to be problematic by case study participants, for a number of reasons, some of which are:

- Potential purchasers/users had varying levels of IT skills.
- Everyone is keen to be a seller in the marketplace, but few want to be buyers.
- Some programs proved to be too difficult to transfer to another context—there were technical, content and remuneration barriers.
- Commercialisation often becomes a dead issue; not many people are interested in pursuing this.
- Often there is insufficient kudos involved in disseminating information about CFL developments.
- Intellectual property is an issue, in that some people might not want their material to be used by others. There are concerns about compromising the competitive advantage of universities.

Nevertheless, it was felt that databases of CFL resources could be useful if designed well. A number of features were identified which could characterise a well-designed teaching and learning database. These are:

- The data submission and retrieval process is simplified.
- It has a distributed nature.
- It is maintained in an ongoing sense.
- It is owned by academics.
- Resources are submitted by people with expertise in CFL and knowledge of the discipline, following a scholarly review process.
- Resource submission should not be by the developer of the resource.
- It should contain contextual information about the resource, including a full description of the product; the rationale behind its development; its unique characteristics; the pedagogical approach used; intellectual property details, and how it might be obtained; and evaluation data.
- It should contain a range of experiential information on how the resource was used in a real-life teaching context, both by the developer and others.
- It should return the appropriate level of information to the queries submitted by users.
- Resources successfully submitted to the database should attract scholarly recognition.
The contextual and experiential information required of an ideal database is encapsulated in the idea of metadata. There is a need for cooperation amongst database owners and proponents with respect to metadata standards. The central idea of the framework is that databases can be created which fill a particular market niche, but that a global ‘megasearch’ facility enables academics searching for information to seamlessly traverse a range of databases. The framework we are proposing for the development of a unified, Australia-wide collaborative framework for interoperable online databases strongly urges that international metadata standards be developed.

A prototype distributed Links database has been developed by ASCILITE. This forms a searchable resource that is interoperable with other databases and is sustainable and credible. It allows for distributed maintenance of hypertext links within the system. Loosely based upon a Yahoo-style system, the Links database allows reviewers to moderate categories in which they have expertise. Any person can submit useful links to a particular category. The moderator provides a third-party, quality assurance role that adds value to the to resources maintained within the database.

The recommendations on dissemination and databases are that DETYA support and funding are needed for the development of a high level technical database framework which:

- is implementable;
- encourages open discussion with the various teaching and learning resource database owners to strive to achieve interoperability between their sites;
- develops standards to ensure inter-exchange of metadata between different domain-specific teaching and learning resource databases, by working with the various domain communities;
- works with other DETYA-funded bodies to establish standards and encourage adoption of such standards for resolving intellectual property issues, with the aim of creating of a market for learning artifacts; and
- ensures that all standards are interoperable with emerging international standards.

The framework we are proposing for the development of a unified, Australia-wide collaborative framework involves interoperable online databases. While our considerations have been mainly directed towards databases of CFL materials, we believe that this framework has a wider applicability. To be successful, the development of the framework needs to be a national initiative, funded appropriately, and coordinated through a suitable coordinating body. The coordinating body will need to develop standards for metadata by leveraging off the Dublin Core and IMS standards, and working closely with other Australian interest groups, such as the Australian Library and Information Association (ALIA), the Committee of Australian University Librarians (CAUL) and the Distributed Systems Technology Centre (DSTC).

Professional organisations, such as ASCILITE, can also participate in this national framework of collaboration in areas such as:

- educating the academic community about the need to provide metadata,
- providing pedagogical and educational design advice in the formulation of standards,
- providing a testbed for the implementation of the standards, and
- evaluating the effectiveness of the standards and the impact of the standards on the quality of education.

The size of the Australian economy does not allow us to re-invent the wheel all the time. The Australian education sector needs a collaborative framework to capture the synergy that may be generated by the aggregation effect. Information technology changes the size of a market, as well as the way the market is shared. To remain competitive in the global market, Australian higher education cannot afford to wait for the development of standards which will influence how education will be delivered and how effective the digital education system will be.

Students' Perceptions of Self-Change During an Online Course

Abstract: This paper presents preliminary findings from a two-semester study on the effects of online learning on student perceptions of self-change as well as the impact of online learning environments on student attitudes concerning their learning experiences. There have been several studies that examined distance learning courses versus traditional formats and found no significant differences in grade point averages of students in either format (The Institute for Higher Education Policy, 1999). Overall ratings of courses by students who complete online courses are equal or higher than those for traditional courses (Hiltz, 1997). There have been few studies, however, that examined other components of the learning process such as changes in perceptions and attitudes.

Teaching and learning are not the same as they were even five years ago; the amount and nature of information continues to grow far too rapidly for the old paradigms and systems to function effectively (Hannafin, Hill, & Land, 1997). The World Wide Web offers a myriad of ways to deliver instruction and provide resources and support for learning, but the array of possibilities is confusing for both teachers and students. K-12 schools, institutions of higher education, and corporations are all feeling the pressure to provide online instruction. In many instances the change from a traditional classroom to an Internet-based experience has been instituted with little or no consideration of the effect on student learning.

Concerns about the impact of distance learning courses on educational systems have been addressed in much of the literature to date. These concerns include lack of technological expertise on the part of both faculty and students, resistance to change on the part of some faculty, the cost of developing and implementing programs, hardware limitations, poor instructional design, and learner isolation (Wegner, Holloway, & Garton, 1999; Boettcher, 2000). While they represent legitimate areas of concern, for the most part, these problems relate to training and technology issues that have fairly obvious solutions. It is less obvious, however, what the effect of online learning has on students' perceptions of self-change in teaching and learning.

This paper presents preliminary findings from a two-semester study on the effects of online learning on student perceptions of self-change as well as the impact of online learning environments on student attitudes concerning their learning experiences. There have been several studies that examined distance learning courses versus traditional formats and found no significant differences in grade point averages of students in either format (The Institute for Higher Education Policy, 1999). Overall ratings of courses by students who complete online courses are equal or higher than those for traditional courses (Hiltz, 1997). There have been few studies, however, that examined other components of the learning process such as changes in perceptions and attitudes.
The Problem

As faculty members, we began to see changes in the students who finished an instructional design course online. At first, our feeling was that the changes were limited to one particular class, but each semester that the course was taught, students began to exhibit changes in their perceptions of themselves as learners and users of technology. These changes were evidenced in their online discussion postings, in their attitudes and interactions towards their peers, and in the collaborative quality of their assignments. In some students, the change was subtle, but in others, a more radical transformation took place. As students became more involved in the discussion and using the material and resources, they seemed to be more in control of their learning and more involved in the online experience.

This course is offered to a wide range of students, not only students in the instructional technology program area, but graduate students working on teacher certification as well. The background of these students is very diverse and the common thread that unites the content of the course is the instructional design process. The career goals of these students are varied as well, and range from K-12 classroom teachers to school district technology specialists to business and industry trainers. The course is divided into three modules with fifteen assignments; the last eight are focused on creating a final project, a process that guides the student through the steps of a generic instructional design model. Most students who enroll in this course have little experience with designing and delivering instruction.

As several semesters went by, and this change happened with regularity, we began to look for supporting information that would help clarify what was happening. We began discussing the change with the students after they finished the course. Several of them made comments about the changes that occurred:

This course has been time consuming, and challenging...but what an eye-opening experience, as well. When I realize what we are capable of doing, and all the resources that are available, I feel overwhelmed. This class gave me the incentive to find some of those resources, find better ways to teach content, and a more positive impression of tutorials. (Student One)

I think the class has been beneficial. I now have a clear picture of what an instructional designer does, and I like the process. The support that we have received in this class is phenomenal compared to the classes that I have taken in the past. I never had a question that wasn't answered, and I have never felt as supported by my instructor or my peers. (Student Two)

This change is exemplified by this statement from an online learner at another university:

Within a matter of days of logging on for the first time, I began to see the worth of the experience that exceeded earning a grade and credit. No one was more surprised than I was by the way in which the interactions I became involved in shaped my perception of technology and its applications in my professional life. But more importantly, those online interactions exponentially enhanced my own learning. I believe my experiences were transformational because the online conference exemplified the characteristics of a model learning environment. (Allison, 1998)

Methodology

This study investigated the perceptions students had about self-change during a distance education course taught using the World Wide Web. The objective of the research was to investigate several questions related to change issues as evidenced through pre-course and post-course surveys.

The research questions were:
1. Do students' feelings about technology change during an online course?
2. Do students feel that their teaching and learning abilities and skills change as a result of taking and completing an online course?
This research study focused on a master's level course in instructional design. Components of the course included:

- A Classroom of course information, instructional materials, readings, and examples
- A Library/Resource Center with a glossary, list of Web resources and related articles
- A Communications Center with Web-based discussion groups. These discussion groups included three different areas of interest (general, K-12, adult learning) as well as a technical help group and an area to share homework. There was also an area designed to broadcast course news and updates to all students.

Participants

Data were collected from two different groups of students in spring, 1999 (number=26) and summer, 1999 (number=23). The 49 students involved in this study were enrolled in two sections of an online graduate level course called "Instructional Design." Both classes had the same instructor, used the same materials, completed the same assignments, and used the same learning strategies. Most students stated that they chose an online course over a traditional lecture course because their schedule did not allow them to take an on-campus section (N=16). Several students enrolled in the course because they wanted to experience an online environment. There were 2 students (4%) in the 18-23 age category, 14 students (29%) in the 24-29 group, 9 students (19%) in the 30-35 group, 10 students (20%) in the 36-41 group, 9 students (18%) in the 42-47 group, and 5 students (10%) in the 48-53 group. There were 10 male students and 39 female students. There were 12 full-time students and 37 part-time students. This demographic data is representative of the student population in the College of Education. The majority of the graduate students are part-time students, are employed full-time, and are working toward certification or a graduate degree.

Data Sources

For this initial study, data sources included a pre-course survey and a post-course survey. Other sources that will provide additional data for the next, more in-depth study include reflective journals, time logs, interviews and analysis of course communications and email.

Quantitative analysis included data from a pre-course survey that gathered information about students' expectations of the course as well as perceptions about online learning and level of technological expertise. A post-course survey measured student satisfaction and reassessed both technological expertise and time spent on various course-related activities such as reading the Web-based materials, completing homework assignments, and participating in the online discussions. Both surveys were anonymous, but they were coded so they could be matched for pre-course and post-course analysis techniques. Students responded to various questions by checking answers. There was also space for additional written comments.

It should be noted that validity issues might affect self-reported data from these surveys. Surveys could be biased positively or negatively by how a student feels about the instructor or the course, by feelings that answers may affect the grade for the course, or by other influences such as the novelty of the online learning environment. In order to deal with these issues, students completed both surveys without the instructor being present, and surveys were matched using information that gave no indication of the student's identification. Post-course surveys were completed at the end of the semester, after the presentation of final semester projects.

There were two research questions that guided this preliminary study:

Research Question 1: Do students' feelings about technology change during an online course?

Students were asked to rate their feeling about using technology on a scale from 1: uncomfortable using it, 2: know basics of how to use it, 3: relatively skilled, but not an expert, to 4: expert user.

Research Question 2: Do students feel that their teaching and learning abilities and skills change as a result of taking and completing an online course?

Students were asked to rate their feeling about changes that occurred in their teaching and learning abilities as a result of the course. Students used the following likert scale to indicate their perceptions: 1: strongly agree, 2: agree,
3: no opinion, 4: disagree, 5: strongly disagree. Students could also indicate that they were already proficient in a particular area. These data were not used in the statistical interpretation, but are reported in the accompanying table.

Analysis

Research Question 1: Do students' feelings about technology change during an online course?

Table 1: Results Obtained from the Wilcoxin Signed-Rank Test.

<td>End of the Course</td>
<td>8</td>
<td>2</td>
<td>31</td>
<td>8</td>
<td>9</td>
<td>9</td>
</tr>
</tbody>
</table>

A Wilcoxin Matched-Pairs Signed-Rank Test was used to determine statistical significance. This test is used for correlated samples in much the same way as the dependent sample test.

As shown in Table 1 above, the results from the Wilcoxin Signed Rank Order Test yielded a $T = 2.594$ and a statistically significant $p$ value of .009.

The students' feelings about using technology after completion of the course are significantly higher than their feelings about technology before taking the course. In light of these findings, the following implications are suggested: there is evidence that students' feelings about using technology improve while enrolled in this class. Whether this effect is related to the phenomena of "novelty effect" (The Institute for Higher Education Policy, 1999) is not yet determined. The novelty effect is a reactive effect, and refers to increased interest, motivation, or participation on the part of students because they are doing something different, not better, per se.

Several factors could be responsible for contributing to this perception. Students are required to use a computer to access course materials, to submit assignments and to communicate with their peers and the instructor. As their use increases, it is likely that students' perceptions of their abilities and level of comfort also increases.

Research Question 2: Do students feel that their teaching and learning abilities and skills change as a result of taking and completing an online course?

Table 3: Results of Survey Questions about Teaching and Learning Abilities

<table>

<td></td>
<td>24</td>
</tr>
</tbody>
</table>
become a more proficient internet user & 34 & 1.29 & 1.00 & 0.46 & 24 (71%) & 10 (29%) & 15 \\
become more proficient finding information online & 38 & 1.39 & 1.00 & 0.63 & 25 (66%) & 12 (31%) & 1 (3%) & 11 \\
become a better evaluator of information & 47 & 1.51 & 2.00 & 0.50 & 23 (49%) & 24 (51%) & 2 \\
become a better teacher or trainer & 46 & 1.30 & 1.00 & 0.46 & 32 (70%) & 14 (30%) & 3 \\
become a better writer & 38 & 1.92 & 2.00 & 0.85 & 11 (29%) & 23 (60%) & 4 (11%) & 11 \\
communicate my ideas more effectively & 41 & 1.63 & 2.00 & 0.62 & 17 (42%) & 23 (56%) & 1 (2%) & 8 \\
collaborate with other students more effectively & 37 & 1.59 & 2.00 & 0.49 & 15 (41%) & 22 (59%) & 12 \\

Data in the category “Already Proficient or No Opinion” were not used in the statistical interpretation, but are reported.

As shown in Table 3 above, students overwhelmingly felt that the course helped them become more proficient and competent in a number of areas of teaching and learning. It is not yet clear whether this is also a reactive effect or a real one.

Student comments support the change in perception, but investigating this effect in more qualitative ways will provide a more complete assessment of self-change.

Online learning made me feel that with a very good instructional design, people can learn a lot of things.

I felt more of a part of this class than most.

I prefer this method of learning. While the work load is the same or greater than regular classes, the "self-paced" nature of the instruction is very important to me.

It was wonderful to learn from others as they learn.

Interesting to see others' knowledge and expertise. The variety of interests in the group was amazing.

Learned more about the other students and homework and how they felt about different topics.

Other data collected in the post-course survey indicated that students tend to work harder in this online course. This may be caused, in part, by the anytime, anywhere access to course materials, the ability of all students to read others’ postings and homework, and the motivation to keep up with the class because of increased interactions and connections. These data are also supported by research in other asynchronous learning environments (Hiltz, 1997).

**Table 4: Enrollment in Another Online Course**

<table>
<thead>
<tr>
<th>Would You Take Another Online Course?</th>
<th>Yes</th>
<th>No</th>
<th>Maybe</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>43</td>
<td>1</td>
<td>5</td>
<td>49</td>
</tr>
<tr>
<td></td>
<td>(88%)</td>
<td>(2%)</td>
<td>(10%)</td>
<td></td>
</tr>
</tbody>
</table>

One overall measure of student satisfaction is whether or not students would take another online course; results are shown in Table 4. The majority of students (88%) indicated that they would take another online course; 10% of the students indicated that they might take another online course.
Table 5: Student Perceptions about Learning

<table>
<thead>
<tr>
<th>Strongly Agree</th>
<th>Agree</th>
<th>Disagree</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>I felt that I learned as much in this online class as I would in a face-to-face classroom</td>
<td>33 (69%)</td>
<td>14 (29%)</td>
<td>1 (2%)</td>
</tr>
</tbody>
</table>

Table 5 shows that the majority of students (98%) felt that they learned as much in the online class as in a face-to-face class.

Table 6: Perceptions about Workload

<table>
<thead>
<tr>
<th>Less Work</th>
<th>About the Same</th>
<th>More Work</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>What was the workload for this online course in comparison to an on-campus course worth the same number of units?</td>
<td>0 (19%)</td>
<td>9 (81%)</td>
<td>39</td>
</tr>
</tbody>
</table>

The majority of students (81%) felt that the workload for an online course is more than a face-to-face class. Only 19% felt that the workload was the same; no students felt that the workload was less.

Next Steps

The results of this preliminary study support the hypothesis that students feel that their teaching and learning abilities increased. The general feelings about an online course were positive; students indicated that they felt they learned as much as a face-to-face course and that they would take another course even though they felt that the workload was higher in an online environment.

Other sources that will provide additional data for the next, more in-depth studies include reflective journals, time logs, interviews and analysis of course communications and email. The role of online learning environments as a catalyst for change should be studied and perceived self-efficacy of the students should be measured more accurately.

Supporting Collaborative Telelearning Research using Server Logs

Øyvind Meistad & Barbara Wasson
Department of Information Science, University of Bergen, PO Box 7800, N-5020 Bergen, NORWAY
Email: oyvindm@ifi.uib.no barbara@ifi.uib.no

Abstract: Electronically generated log-files contain a lot of pertinent information, but the information is often hard to access. This paper describes two tools that have been developed to assist researchers in extracting information from TeamWave Workplace (TW) generated server log-files and repositories. SLA reads in one log-file, sorts out a researcher specified group of persons, and then uses the information to calculate some results from the log. TRA, on the other hand, is a tool to help researchers in classifying the use of various tools inside TW, organising their classifications, and registering how the use of the tools evolves over time. Output from both tools is used to complement various interpretation methods being used to identify collaboration patterns in a collaborative telelearning scenario.

Introduction

One challenge for research within collaborative telelearning is what and how to collect and analyse data in a distributed environment. Depending on the research question and study design, various types of data are desired. Traditional qualitative methods such as structured and unstructured interviews, participant observations, and video recording need to be tailored to distributed participants. Once the obstacles in collecting this type of data are overcome, then questions about how to interpret and analyse the data persist. On the other hand, the collection of electronically logged data is relatively straightforward. As Garton et al. (1999) point out, the restrictions are often "the amount of server storage space and the integrity of researchers and programmers in their study design (p. 92)" and electronic data gathering "replaces issues of accuracy and reliability with issues of data management, interpretation, and privacy (p. 92)". Generally, the amount of electronically logged data can easily be overwhelming and again, questions of interpretation and analysis pose real problems.

In project DoCTA (http://www.ifi.uib.no/docta) we are interested in identifying collaboration patterns in various collaborative telelearning scenarios (Wasson & March, 1999; Guribye & Wasson, 1999). A number of evaluation perspectives are taken and numerous data collection methods are used (for a complete report see Wasson, Guribye & March, 2000). The VisArt activity scenario took place during February and March 1999 and provided an opportunity for the DoCTA project to design, deploy and evaluate an authentic collaborative telelearning activity. The VisArt learning activity involved students taking courses at three Norwegian educational institutions (University of Bergen, Nord-Trondelag College, Stord/Haugesund College). Teams comprised of three students, one from each institute, collaborated to design a learning activity through the Internet. There were no opportunities for the teams to meet face-to-face. Collaborative learning tasks and the technological environment were carefully designed. The technological environment comprised their own email system, a word processor of their choice, and a groupware system TeamWave Workplace (TW). One week of training in both using the TW tools and in collaboration proceeded three weeks of design activity. The students were asked to design a room in TW for learning about some subject of their choice. All participants had the option to sign a consent form that enabled us to electronically collect their team emails, questionnaire data, and to use the electronically logged TW data for our research.

Evaluation of the VisArt scenario (Wasson, 1999) took place on several dimensions and the results are currently being written up as Masters dissertations. The evaluation of interest in this paper is how automatically generated log-files contribute to research in understanding collaboration patterns (Meistad, in preparation). Two tools that have been developed to assist researchers in extracting information from TW generated server log-files and repositories are described. The paper begins by briefly describing TW groupware system. Then the tools that have been developed are presented. The paper concludes with a brief reflection on how the extracted data can be used.
TeamWave Workplace

TeamWave Workplace (TW) is based on the metaphor of shared networked places. Using real life physical team rooms (Johansen, 1991) that provide a permanent shared working place for teams as inspiration, the notion of virtual team rooms has been adopted in TW. These virtual team rooms provide a permanent shared space where teams distributed over the Internet can have meetings, store documents, share URL links to web sites, coordinate and communicate with one another and can carry out collaborative activities such as brainstorming or participation in a discussion forum. Each team can build a set of different rooms according to need. For example, they might create a common project room and resource room, and in addition, individual rooms for each team member. TW provides 19 tools that enable teams to easily plan, set up a database, design, share documents, link to the web, chat with one another etc. For a detailed review of TW and for examples of how it was used in the DoCTA project, see Wasson, Guribye & Morch (2000). One feature of TW is that it comes with traditional logging mechanisms such as recording that a user logs in and out of the server, moves between rooms etc., as well as a non-traditional feature, a repository. All room states are saved in the repository, thus it becomes possible to recreate earlier states of any given room using an option called version control. Both these mechanisms (the server log and version control) are used in conjunction with the two prototypes tools described in the next section.

The TeamWave Workplace Server File. All interactions with the TW server are electronically logged in a server log-file called server.log. The file is automatically generated by the TW server on its startup, and is then updated as the various users interact with the server. Each user action in TW is recorded in the file. During the VisArt scenario the file grew from 0 KB to over 2.2 MB and has 38,207 lines. The following are extractions from the VisArt server.log file:

Fri Feb 19 15:25:08 1999 oyvind entered Overview-room
Fri Feb 19 15:25:26 1999 oyvind left Overview-room
Fri Feb 19 15:25:26 1999 oyvind entered Klasse-diagram
Fri Feb 19 15:32:25 1999 oyvind left Klasse-diagram
Fri Feb 19 15:32:25 1999 connection closed for oyvind

As one can see, each line starts with information about date and time. Thereafter, the user is identified and the user’s particular action is recorded. For example, the second entry tells that on Friday, February 19th 1999, at 15:25:26, oyvind left the Overview-room. In addition to logging information about users entering and leaving rooms as shown, the TW server logs users logging in and out of TW, information about the server starting up, the creation of rooms, the writing of rooms, and the server shutting down. Although the structure of the server.log file is rather simple, the large number of users involved (32 students, 3 instructors and 10 researchers) created such a large file that it is difficult to glean information from the file. Therefore, a software tool that interprets the entries has been developed.

The TeamWaveWorkplace Version Control. Every room created in TW resides on the TW server, and is stored in a repository. When a TW user selects the menu option to save the current room, or leaves a room when no other person is visiting the room, the room is saved to the repository. Every tool created in each room is also stored in the repository. As a room is saved, tools that have been changed, or added, or moved around, etc. since the previously saved version of the room, are saved. When a user enters a room, the last version of the room and the last version of the tools residing in the room are automatically retrieved from the repository. TW’s version control enables earlier versions of the current room, or earlier versions of a specific tool to be retrieved from the repository. The average number of versions stored in the repository for a single room at the end of VisArt was approximately 50. Depending on the type of room, however, the number varied a great deal. For instance, the Classroom existed in no less than 498 versions. The version control option enables a researcher to recreate the state of various rooms and tools during one’s analysis. Thus, long after the completion of the scenario, one is still able to follow how the scenario evolved for a particular team. The potentially large number of available versions of one room or tool, does, however, make such an analysis difficult. Therefore a software tool, TRA, was developed to help researchers keeping track of how the various rooms evolved over time.
Tools for Analysing Log-files

There exists a long tradition of using logged data in usability studies focused on identifying events from such as the number of errors occurring or when a menu is selected with the mouse, and graphically visualising the results (e.g., Fjeld et al. 1998; Guzdial 1993; Okada & Asahi 1999). Another interesting approach is to use the logged data in conjunction with video analysis to effectively retrieve parts of a video recording (Badre et al. 1995). Common in these types of studies is the focus on the interaction between a human and a local computer. Another somewhat different tradition is to use logged data to measure the usage of various Internet resources such as FTP-servers, web-servers, etc. This kind of information is likely most interesting for the Internet providers supplying the resources, but it has also gained attention from researchers (e.g., Newhagen & Rafaeli 1997; Garton et al. 1999). The focus on these last studies is on humans communicating through a local computer with a remote computer.

The tradition of using logged data for identifying patterns of collaboration between two or more geographically dispersed persons is in its infancy. Recently, Nurmelea et al. (1999) reported on a study of a CSCL environment where electronically stored files (log-files and documents) served as their only form of data. They used social network analysis with its focus on uncovering patterns in people's interactions, together with information gleaned from log-files. The information was extracted with scripts written in Perl. CSCL is a field of interest for researchers with backgrounds as diverse as computer science and pedagogy. Although most computer scientists will have little or no problem writing a script in Perl, it is likely that a researcher who lacks experience from computer science related fields will experience problems. To address this issue, we explore the possibility of creating tools that use logged data from a distributed CSCL environment to make the data more easily accessible to researchers.

To support the evaluations of DoCTA project scenarios where TW was used, it was necessary to develop two prototypical tools for the analysis. The tools, the Server Log Analyser (SLA), and the TW RoomAnalyzer (TRA), were both developed in Java 1.1 using the Java Foundation Classes 1.1 as graphical user interface components. The programs differ from each other in that SLA reads in one log-file, sorts out a researcher specified group of persons, and then uses the information to calculate some results from the log. TRA, on the other hand, is a tool to help researchers in their classification of the tools inside TW, organising their classifications, and registering how the use of the tools evolves over time. In this study TRA was used in conjunction with the TW version control and the output from SLA. These two tools are described below.

Server Log Analyser

SLA takes as its starting point the server log file. The VisArt scenario was completed by 11 teams and SLA focuses on identifying the times at which a team could have possibly collaborated synchronously in TW (i.e., two or more of the team's members must have been logged on at the same time).

To find out what types of collaboration were possible for a given team at a given time, SLA reads through the server.log using a researcher-specified names of the team members. SLA creates a log for each group member, as well as a group log consisting of every entry from the individual logs, appearing in the same order as found in the server.log. The resulting logs (4 in this case) contain redundant information. SLA removes unnecessary information from the group log, and adds some statistics to the group log. This log is used by SLA to generate a graph that illustrates the times at which the various group members were logged in to TW. If the graph shows that two or more group members were logged in at the same time, they had the possibility to collaborate synchronously. Figure 1 shows a graph for one of the groups from VisArt. The left column of the graph denotes the time of the day. Each day starts on the bottom at 0, and goes up past 23 and up to 0 again. The bottom axis specifies the date that is displayed. If a date is missing (e.g. Feb 26 and Feb 27), it means that none of the group members logged in that day.

Interesting information may be found looking at the graph. First it tells us that from February 25-March 24, there were only three times when it was possible for the whole group to collaborate synchronously. VisArt started on February 25 when the group members were told to download the TW client, and log in to the server. They were given a few days to carry out this task. March 1-7 was a week of training in use of TW and collaboration, and March 8-26 was the period of carrying out the design task. By examining the graphs, it becomes apparent that subject02 did not log in to TW before the fourth day of the training period. It also becomes apparent that the
formerly active subject01, did not log in once between March 4 and March 15. Consequently, even asynchronous collaboration is highly unlikely during this period. To explain why these more or less negative patterns occurred, is difficult using a simple log-file as the only kind of data. It is important, however, that the researcher is aware that one of the three team members disappeared for 10 days in the middle of a 4 week collaborative learning task. This is valuable information that enables the situation to be investigated more closely using, for example, interviews, and/or questionnaires.

![Figure 1 Graph of Team Activity in VisArt](image)

The prototypical version of SLA, discussed here, is completely tied to the server.log of TW, limiting its usefulness to studies were TW have been used. A new version is, at the time of writing, therefore being developed. When ready, the new version will support the addition of all Java classes that implement an interface defined in SLA, and which enable sorting of log-files containing the type of information found in TW's server.log. Although the class that sorts the TW server.log and generates SLA's output (various logs and graphs) in the new version is no larger than 153 lines of code, the approach is not without problems. It require someone to write the new class and to make the class available to those interested. A future goal will therefore be to attempt to implement a feature in which users of SLA can, at a very high level, define how a log-file is organized.

TWW Room Analyzer

TRA is designed to be used in an analysis of collaborative learning environments that use a room metaphor or another analogous structure such as a web-page. In this study, TRA helps researchers in classifying the use of various tools inside TW, organising their classifications, and registering how the use of the tools evolves over time. TRA requires the researcher to use the output of SLA and the TW version control to specify input data for TRA. Ideally it should be possible to retrieve most of the information needed by TRA from the TW repository, but that path has not yet been investigated, and would also make the use of the tool less general. Even then, some of the information needed by TRA, such as a classification of the uses of the tools, would still have to be identified by a researcher. Once the data has been input to TRA, the researcher can use TRA to track changes to rooms and tools over time.

TRA, shown in figure 2, is a dynamic tool that is used to track how a team's learning environment evolved in the course of the scenario. TRA comprises several graphical user interface components that present information about any number of rooms. For each room there may be any number of room versions, with each room version containing any number of tools, and any number of tool versions. As TRA is currently being used during analyses of VisArt, it is possible new features may be required. If so, then TRA will be revamped and the user interface may change.
In order to use TRA, the researcher first uses SLA to obtain information about the times when, places where, and the team members who were logged in (i.e., the date, time and room). SLA also generates information about the people that visited a particular room during the scenario. For example in figure 2 the rooms MyTeam2 and Classroom have been entered, and MyTeam2 room is active. One can also see that MyTeam2 was originally created by Trond Pedersen on January 23, 1999 at 13:59. There have been 12 versions of MyTeam2 entered into TRA. In figure 2, version 10, created by Rune Baggetun, is active. TW's version control is then used to retrieve the active version of the room and the researcher can see which tools are present in the room. This information is entered into TRA along with the number of versions of each tool. In figure 2, version 4 of the Whiteboard tool, created by Helge Underhaug on February 17, 1999 at 16:35 is visible. The researcher also classifies the use of the particular version of the tool indicating information such as if the current use has changed compared to previous uses, if the tool was used synchronously or asynchronously (menu selection), the role of the actor who made or changed the tool, etc. In figure 2, the researcher who classified the use of the Whiteboard believes that the Norwegian phrase written on the Whiteboard, shown in figure 3, meaning "Leave a note that you have been here, remember name and time!" must be seen in conjunction with the Postit also shown in figure 3 (the Postit is refered to as tool 3 in the classification of the use of the Whiteboard shown in figure 2).

Figure 2 One of many possible views of TRA

Figure 3 Part of the Whiteboard and a PostIt from version 10 of MyTeam2 room
Conclusions

This paper has described two tools developed for the ongoing analysis of collaborative telelearning scenarios using TW. The tools take automatically generated data as their input. SLA does so as a fairly automated process, whereas TRA depends on a great deal of interaction with the researcher. Information produced by SLA is useful for identifying the times at which a team had the potential to collaborate asynchronously or synchronously. To say that it is possible to collaborate is, however, not to say that collaboration occurred. Thus, SLA’s output can be used to focus other methods that are being used to interpret the interaction between users of TW through its various tools.

TRA was developed as aid for studying the learning environment of a team (e.g., the rooms involved, the persons influencing the environment, the available tools, etc.). Incorporating Télé-université’s tool classification model for a virtual campus environment (Paquette et. al., 1995) in TRA, enables TRA to suggest how the particular uses of the tools found in the team’s rooms may be classified. Using these tools in conjunction with other data gathering methods such as interviews or video observation, the researcher will be able to develop a richer picture of collaboration patterns.

Abstract: This paper describes the results of a feature analysis aimed at evaluating how adequate hypermedia models, methodologies and systems are when applied to authoring for education.

The requirements used in our work were identified by educational hypermedia authors and also by existing literature in the field of hypermedia authoring. Our objective was to assess whether or not hypermedia models, methodologies and systems offered features corresponding to the requirements identified by educational hypermedia authors/existing literature.

The results obtained showed that none of the hypermedia models and methodologies used in our evaluation had features corresponding to the essential requirements that have been identified. Among the hypermedia systems, only three presented features which corresponded to requirements considered essential by hypermedia authors.

Introduction

The aim of a feature analysis (Kitchenham and Jones 1997a; 1997b;1997c) is to identify which of several methods/systems/methodologies best fits the requirements of potential users. The requirements are translated into a list of desired features, which later on will be compared against the features offered by the candidate methods/systems/methodologies.

The feature analysis presented in this paper was used to identify: i) which models, methodologies and systems would fit the requirements of potential users; ii) potential areas of research that would improve hypermedia authoring by improving either the models/methods, methodologies or systems selected in the evaluation.

The depth of investigation for the candidate hypermedia models, methodologies and systems was based on published literature. Hypermedia models are, in general, used for the conceptual design of hypermedia applications whereas hypermedia methodologies are used for the development of hypermedia applications. The models and methodologies considered in our work are presented in Table 1:

The feature analysis evaluation was organised using a screening mode approach (Kitchenham and Jones 1997b) and was performed by one person. The screening mode is the fastest and least costly form of feature analysis and the number of different roles is minimised. On the other hand, the whole evaluation is based on the subjective assessment of one person or team, which may bias the results.

The requirements used in the feature analysis were based on published literature in the fields of hypermedia authoring for education and experimentation and on the results of a qualitative evaluation that analysed the process of authoring hypermedia applications for education (Mendes and Hall, 1999).

The remainder of this paper is organised as follows: Section 2.0 describes the feature analysis evaluation and the results obtained. Section 3.0 gives our conclusions and comments on future work.

The Feature Analysis Evaluation

The Assessment Scales Used for Scoring the Features

The first step of a feature analysis is to prepare a feature list, where each feature is classified into simple (S) or compound (CO). Each feature also has a degree of importance associated, which can be: Mandatory (M), Highly Desirable (HD), Desirable (D) and Nice to have (N). Each degree of importance has also a weighting factor associated, which will be used by compound features. The corresponding weighting factors for M, HD, D and N are, respectively, 10, 6, 3 and 1 (Kitchenham and Jones 1997b). Simple features are scored as five (for Yes) or zero (for No).

The judgement scales that we have used to assess a method/methodology/system support for a particular feature are as follows (see Tables 3 and 4):

<table>
<thead>
<tr>
<th>Generic Scale Point</th>
<th>Definition Scale Point</th>
<th>Scale Point Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>Makes things Worse</td>
<td>Causes confusion. The way the feature is implemented makes it difficult to use and/or encourages its incorrect use</td>
<td>-1</td>
</tr>
<tr>
<td>No support</td>
<td>Fails to recognise it. The feature is not supported nor referred to in the published literature available.</td>
<td>0</td>
</tr>
<tr>
<td>Little support</td>
<td>The feature is supported indirectly, by the use of other system features in non-standard combinations.</td>
<td>1</td>
</tr>
<tr>
<td>Some support</td>
<td>The feature appears explicitly in the system and in the published literature. However, some aspects of the feature use are not catered for.</td>
<td>2</td>
</tr>
<tr>
<td>Strong support</td>
<td>The feature appears explicitly in the system and in the published literature. All aspects of the feature are covered, but its use depends on the expertise of the user.</td>
<td>3</td>
</tr>
<tr>
<td>Very strong support</td>
<td>The feature appears explicitly in the system and in the published literature. All aspects of the feature are covered, and the system provides tailored dialogue boxes to assist the user.</td>
<td>4</td>
</tr>
<tr>
<td>Full support</td>
<td>The feature appears explicitly in the system and in the published literature. All aspects of the feature are covered, and the system provides user scenarios to assist the user.</td>
<td>5</td>
</tr>
</tbody>
</table>

The List of Features
The Features Obtained from the Qualitative Survey

This section describes a list of features, which was based on the results of a qualitative survey evaluation (Mendes and Hall 1999). The survey aimed at analysing the processes involved in the authoring of hypermedia applications for education. The list of features and the type and degree of importance associated with each one are presented below (see Table 5). A more detailed explanation of each feature is given in Appendix A:

<table>
<thead>
<tr>
<th>Feature Description</th>
<th>Type</th>
<th>Importance</th>
<th>M, MD, S</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supports structural knowledge design</td>
<td>Compound</td>
<td>Mandatory</td>
<td>All three</td>
<td>04</td>
</tr>
<tr>
<td>Supports structuring different domains</td>
<td>Simple</td>
<td>Mandatory</td>
<td>All three</td>
<td>05</td>
</tr>
<tr>
<td>Supports a top-down approach to structuring the information</td>
<td>Compound</td>
<td>Mandatory</td>
<td>All three</td>
<td>06</td>
</tr>
<tr>
<td>Links are not essential in order to structure the knowledge domain</td>
<td>Simple</td>
<td>Mandatory</td>

</tr>
</tbody>
</table>
Table 5: Feature list obtained from the qualitative survey

<table>
<thead>
<tr>
<th>General Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>This sub-section presents three general features, taken from the literature in hypermedia authoring for education and empirical evaluation. These were considered relevant for the feature analysis evaluation. Each general feature is described below and a summary is given in the end of this sub-section (see Table 6).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>a) Support for ill-structured domains</th>
</tr>
</thead>
<tbody>
<tr>
<td>According to Rand Spiro et al. (1995) all domains which involve the application of knowledge to unconstrained, naturally occurring situations (cases) are highly ill-structured. Even those knowledge domains that are well-structured also have aspects of ill-structuredness, especially at more advanced levels of study, e.g. mathematics.</td>
</tr>
<tr>
<td>Ill-structuredness is not a serious problem for introductory learning as learners are not expected to master complexity or independently transfer their acquired knowledge to new situations. However, when conceptual mastery and flexible knowledge application become paramount, the complexity and across-case diversity characteristic of ill-structured domains needs to be addressed (Carvalho and Dias 1997; Jacobson and Archodidou 1997).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>b) Has been validated empirically using formal experimentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>In a random sample of all the papers that the ACM published in 1993, 40 percent of them contained claims that needed empirical support but had none at all (Tichy 1998). In software-related journals, this fraction was 50 percent. Tichy’s data shows that computer scientists validate a smaller percentage of their claims than other scientists. He also asserts that a balance between theory and engineering with experimentation would have the following benefits:</td>
</tr>
<tr>
<td>• Experimentation can help build a reliable base of knowledge and thus reduce uncertainty about which theories, methods and tools are adequate.</td>
</tr>
<tr>
<td>• Observation and experimentation can lead to new, useful, and unexpected insights and open whole new areas of investigation. Experimentation can push into unknown areas where engineering progresses slowly, if at all.</td>
</tr>
<tr>
<td>• Experimentation can accelerate progress by quickly eliminating fruitless approaches, erroneous assumptions, and fads. It also helps orient engineering and theory in promising directions.</td>
</tr>
<tr>
<td>• Demonstrations can provide proof of concepts or incentives to study a question further. Too often, however, these demonstrations merely illustrate a potential. To obtain evidence, careful analysis involving experiments, data, and replication is necessary.</td>
</tr>
<tr>
<td>According to Fenton et al. (1994) much of what is believed about which approaches are best is based on anecdotes, gut feelings, expert opinions, and flawed research, rather than on careful, rigorous software experimentation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>c) Was proposed using a scientific method of research</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glass (1994) gives a classification of possible research models:</td>
</tr>
<tr>
<td>• The scientific method - Observe the world, propose a model or theory of behaviour, measure and analyse, validate hypotheses of the model or theory, and if possible repeat.</td>
</tr>
<tr>
<td>• The engineering method - Observe existing solutions, propose better solutions, build or develop, measure and analyse, repeat until no further improvements are possible.</td>
</tr>
<tr>
<td>• The empirical method - Propose a model, develop statistical or other methods, apply to case studies,</td>
</tr>
</tbody>
</table>
measure and analyse, validate the model, repeat.
• The analytical method - Propose a formal theory or set of axioms, develop a theory, derive results, and if possible compare with empirical observations.

Most of the research to date in hypermedia authoring uses an analytical advocacy model of research without further empirical justification, transforming the process of authoring into art, rather than into science (Isakowitz et al.1995).

As engineering involves the analysis of measurements (Pfleeger et al. 1997), hypermedia engineering will only become a true engineering discipline when a solid foundation of measurement-based theories is build.

The general feature list and the corresponding type and degree of importance are presented below (see Table 6):

<table>
<thead>
<tr>
<th>Feature Description</th>
<th>Type</th>
<th>Importance</th>
<th>M, MD, S</th>
<th>N</th>
</tr>
</thead>
<tbody>

The Evaluation Profiles

The Evaluation Profile for Hypermedia Models, Methods and Methodologies

None of the hypermedia models, methods and methodologies evaluated supports the structuring of ill-structured domains, which is one of the mandatory features. Consequently, they were all eliminated from the list of candidates. Isakowitz and Turing (1994) corroborate this result:

"These methodologies are apt for structured domains where economies of scale can apply, i.e., there are many objects of the same kind. The key difference between the approaches is that Schwabe and Rossi is object-oriented, while Balasubramanian, Isakowitz and Stohr’s is based on an entity-relationship approach."

The Evaluation Profile for Hypermedia Systems

None of the hypermedia systems, except Microcosm, HyDesign and Webcosm support contextual links. Consequently, apart from those 3, all the others were eliminated from the list of candidates. The evaluation profiles for the three hypermedia systems are presented below (see Table 7):

730
Conclusions and Future Work

All the models, methods and the methodologies and nearly all the hypermedia systems were eliminated. The two main requirements that have contributed to these results were ‘support for ill-structured domains’ and ‘support for contextual links’. The scores obtained by Microcosm and Webcosm were quite similar and higher than the score obtained for HyDesign.

The results of the feature analysis evaluation showed that in practice authors’ requirements are not being mapped by state-of-the-art methods and methodologies, corroborating Fenton’s affirmation that: “best projects do not necessarily have state-of-the-art methodologies or extensive automation and tooling. They rely on basic principles such as strong team work, project communication, and project controls. Good organisation and management appears to be far more of a critical success factor than technology or methodology.” (Fenton 1993).

The feature analysis evaluation also showed that none of the hypermedia system candidates has scored points for the general features ‘being validated empirically using a formal experimentation’, and ‘being proposed according to a scientific method of research’.

Our next step is to apply a scientific approach to the evaluation and proposal of several metrics that will measure the authoring quality of educational hypermedia applications developed using either Microcosm or Webcosm. By applying measurement principles we hope to generate quantitative descriptions of hypermedia authoring processes and applications that will enable us to control and improve the authoring process as a whole.

Appendix A

Supports structural knowledge design - Does the hypermedia system allow the author to structure the application according to the structural knowledge corresponding to a particular domain? The structural knowledge is the knowledge of how concepts within a domain are interrelated.

Supports structuring different domains - Does the hypermedia system allow the author to structure the applications in different ways, corresponding to which subjects (domain) is being taught?
Supports a top-down approach to structuring the information - Does the hypermedia system allow the author to structure the contents using a hierarchy?

Links are not essential in order to structure the knowledge domain - Does the author need to define the links in the application at the same time as (s)he structures the knowledge domain?

Supports the representation of the author's cognitive map - A cognitive map is the graphical representation of the author's structural knowledge. Does the hypermedia system support any graphical representation of the structural knowledge?

Supports the interface design, structural knowledge design and the authoring of the nodes' contents separately - Does the hypermedia system allow authors to design the application's interface, design the structural knowledge and author the contents of each node separately? Or does everything need to be done "at the same time"?

Allows readers to see the author's cognitive map - Does the hypermedia system allow readers to see the graphical representation of the structural knowledge that represents the application's content?

Supports typed links - A typed link is a link that has a description (label) attached to it. In general, types explain what kind of information readers will find when they follow that particular link. Examples of types are 'example', 'definition', 'more information', etc.

Supports contextual links - Context-dependent links are links that are recognised by the hypermedia system within certain boundaries established by the author. A boundary can be a document, the whole hypermedia application, an anchor, a set of documents (nodes).

Supports different levels of information granularity - Does the system support the structuring of information using different levels of abstraction (granularity)?

Supports collaboration in the system - Does the system allow authors to collaborate in the authoring process? Can authors develops the same application at the same time?
The Price a Distance Education Student Pays When Using Electronic Learning Resources

Dr John Messing
School of Information Studies, Charles Sturt University, Australia
jmessing@csu.edu.au

Abstract: While it may be quite usual for proponents of some cause to enthusiastically portray their case in the best possible light, when it comes to changes in education, there is no excuse for not considering the true impact on the final target of those changes, the students. In the push for electronic delivery, distance education students have been found to carry a significant number of costs which rarely find their way into cost-benefit analyses carried out by the institution or its staff. Wasted time and effort, decreased learning access and a variety of social costs are all part of the real price that a distance student often pays.

The Changing Scene

It appears inevitable that more and more education is going to be delivered in the distance mode (National Center for Education Statistics 1998) and that an active debate exists in the move to electronic delivery of education. One only has to look at any of the reports into higher education such as that of the Kellog Commission on the future of state and land grant universities (Stukel 1998) to appreciate how determined university administrators are to take advantage of the use of Information and Communications Technology (ICT). Given all the rhetoric and posturing, one could be forgiven for thinking that this is revolutionary rather than evolutionary. It is significant to note that the advent of another communication technology, public postage, was instrumental in the establishment of early Distance Education (DE) and that while the Internet has challenged the current notions of what DE means and how it is to be delivered, public postage and DE did not totally destroy the existing university order in the last 100 years! History suggests that the Internet will not either. ICT provides many new and exciting prospects that will complement and extend, rather than totally supplant, existing education.

These changes to education make it imperative that the impact of this mode and medium on students be understood and taken into account. Literature such as Twigg (1999) is heavily skewed in favour of the institutional effects and the impact on the instructors. An analysis of the costs and benefits for students such as that carried out for instructors by Collis, Winnips & Moonen (1999) is not easily found. Sibilin et al. (1996 p205) admit that determinations about the future of higher education are "a discourse in which students appear all too irregularly." Hara and Kling (1999) while broaching the topic of student frustrations with using web-based education conclude that the predominantly positive literature emphasizes potential and understates the problems students face. Even more difficult to find is reliable data about the impact on DE students who are not at all like full-time students. DE students are much more heavily influenced by external factors associated with the many different roles that they have to undertake. This alters the learning process for each in a wide variety of ways resulting in a more andragogical rather than pedagogical way of learning. (Roberts 1984, Woodley 1987, Garland 1993)

Determining how electronic forms of learning are to feature in the DE environment cannot be done using just pedagogical, technological or economic criteria. These are necessary and may ultimately limit the scope of what is feasible at any time, but they are certainly not sufficient. The effects that such strategies have on the end user, the learner, are equally important. Key components of DE are learner choice over what, how, where and when to study. Electronic materials have the potential to alter these choices. Whether this changes as learners' exposure to the use of ICT increases, must also be considered. The philosophical changes to educational practice, which are moving to more learner participation in activities and the social impact of such changes are additional concerns.
Costs

It is frequently the case (cf CAUT 1993; Western Governors Association 1996; Bates 1997, Stukel 1998, Sakamoto 1999) that decisions to use technology to deliver education make mention of improved access to higher quality learning materials and better cost-effectiveness of the process. The relationship between costs and quality are not simple, nor clear (Bates 1995, Moonen 1999). Justifications for the use of educational technology sometimes incorporate assumptions that this will result in a better learning environment for the student and suggestions of possibly greater success (Reushle 1995). Such assumptions are not easily challenged because they appear plausible and the collection of reliable data is difficult. There are many factors involved in the quality of the education that a learner receives and improvements in one area with degradation in another may prove inconclusive. Russell’s (1999) collection of reports resulting in the ‘No significant difference phenomenon’ is testament to that.

Better quality learning materials which place greater restrictions on the 'how, when and where' of the learning process may result in a decrease in satisfaction or performance. The interaction of many other variables such as the effect of peer support and face to face context, are difficult to quantify and even more difficult to control. Add in new variables associated with life long learning and flexible 'education on demand' and the ability to accurately predict improvement in educational quality, regardless of the technology, becomes exceedingly difficult.

Changing the focus from the policies of the institution to the needs of the students is exceptionally difficult. While the technology referred to may have altered considerably, the words of Sewart (1981 p172) are no less relevant in the current circumstances.

"...there is an overwhelming tendency within the field of teaching at a distance to offer systems from the standpoint of the institution teaching at a distance, rather than from the standpoint of the student learning at a distance. The response to the individual needs of the student has often become lost in the over-riding requirement to produce a grandiose package of materials."

It is impossible to imagine that the many projects and studies reported in the literature are all genuine responses to student needs. An examination of over 100 successful applications for funding under the National Teaching Development Projects (CAUT 1993) for example, revealed that even though there were expected to be improved learning outcomes in some, all but three were teacher centered. The predominant focus was still on the teaching or institutional standpoint.

The complete costs to the student of the use of these new approaches need to be identified and quantified as accurately as possible. Not all of these may be expressed in financial terms. Additional time and effort, inconvenience and the effects of frustration or poor system performance are very real costs for which it is not always possible to attach some numerical value much less a dollar equivalent. Conversely, as Geasler (1992) pointed out, the failure to develop and use more effective learning environments also represents a cost, for both students and academics, in lost opportunities.

Wasted time

Many current initiatives involve the use of the Internet without even basic consideration of the cost of doing so for the student. Even common IT practices such as estimates of system performance are being ignored in the rush to be seen to be at the cutting edge. Receiving a 100 kilobyte file on an average academic network may not incur any substantial delays but for a DE student, the whole process of starting the computer, making the connection and then reading or printing the file after transfer may add 5 or 10 minutes to the process. The time, effort and financial cost incurred must be considered a burden that the student has to bear. When the network slows down, the cost increases substantially. On economic grounds alone, this is not a good situation. The wasted time and the uncertainty factor which increases anxiety, makes it less than acceptable. What may work exceedingly well in campus laboratories supported by high speed optic fibre networks, may turn out to be a nightmare for students using a modem from home at peak times. Some stories such as that of a class required to download a large file, which repeatedly failed to download in the connection time limit, are beginning to approach legend status. The current joke of WWW standing for World Wide Wait is sadly funny because of its proximity to the truth.
Similar difficulties may arise in the use of electronic learning materials, regardless of the method of distribution. A book has obvious advantages in that it requires no additional hardware, is exceptionally portable, may be quickly accessed and may be used in a diverse range of environments. When access sessions with electronic learning materials are relatively brief, the time taken to start up represents a sizeable proportion of the time involved. On the other hand, for extended sessions, it would be negligible. This either changes the way that students use the materials or disadvantages those who do not want to, or are not able to, adjust to such strategies of extended use.

Inconvenience

Models of the teaching-learning process such as that proposed by Laurillard (1993) emphasize the discussion and interaction between the teacher and the learner. Such models may be appropriate for face to face environments but provide a poorer fit for most DE situations. Attempts to synchronize what is basically an asynchronous paradigm cause some friction. The ultimate challenge of future education is to completely remove synchronization events. Such events include fixed enrolment dates, due dates for assessment items and even expectations by the teachers that students will be "up to topic x" by any particular date. This is especially true if notions of life long learning and flexibility as espoused by many such as Cheng (1999) or Jones (1997, 1999) are also taken into account. Education using ICT also has a different set of protocols to 'traditional' education. Many students have yet to master these and the effort required to cope may be asking too much of the student.

Experience with DE students (Roberts 1984, McLachlan 1999) has shown that most would be characterized by Newble and Clarke (1986) as having a 'strategic' approach. This is supported by studies such as the navigation behaviours of students using an electronic study guide (Messing 1997). For such students, electronic learning materials would have to possess identifiable advantages over traditional resources or they would be rejected.

What is often overlooked in this discussion is the role that the scale of the operation plays in encouraging or discouraging learner engagement. Van der Veen et al (1999) report a situation where the numbers of contributions by students actually discouraged deep reading of the contributions by fellow students. As with face to face teaching, there may be natural limits within which, strategies involving the use of electronic resources may be effective but outside of which, they have little chance of success. The old cliché of "horses for courses" does not appear to have been recognised by many of the grand plans.

Research on product outcomes such as higher performance has been extensive but far from conclusive (Russell 1999) while studies on the costs associated with 'learning access' are scarce. Martens et al. (1997) describe learning access as the extent to which students are able to efficiently achieve their learning goals by means of the affordances available in the electronic materials. The learning access needs to be considered at the level of general principles as well as how these are applied to each case of electronic learning materials.

Perceived problems of not being able to find the desired information or achieve desired learning outcomes may be the product of students not fully understanding the features that are available to them or being aware of the protocols required to engage in the materials. Teachers using electronic learning materials are often closely involved in their design thus giving them a biased perspective which sometimes fails to appreciate the difficulties of novices. Evidence in studies such as Messing (1997, 1999) illustrates the fact that students are not always completely conversant with the features at their disposal. This is manifested in 'wandering' behaviour resulting in wasteful transitions from node to node with very short intervening times, often too short for any purposeful learning. Such situations can easily lead to frustration (Hara and Kling 1999).

The Preference for Paper

The issue of printing is one of the most fundamental in the discussion of the viability of electronic study materials. It is common to find (for example, Mason 1996; Bates 1997) that the reduction of printed material and its associated costs is given as one of the principal justifications for the development of electronic materials. However, that represents only the institutional perspective and may simply transfer the cost of printing in both financial and production senses, from the institution to the student. It has also been pointed out (Mason 1996) that the student printed material is vastly inferior in quality and presentation to the standard that the institution would normally
provide. Such reduction in standard is another cost that the student must bear. In circumstances such as those described by Benson and Vincent (1997) where there was very little functional difference between the electronic and printed versions of the materials, the result was an overwhelming student preference for the printed versions. The 'added value' that electronic materials supposedly provide needs to be objectively evaluated to determine if it is sufficient compensation for the inconvenience of being electronic.

Examining only the functionality of electronic materials would not provide a sufficiently detailed and accurate evaluation. As well as understanding the nature of the printing that takes place, it is important to understand why it is taking place. For DE students this involves issues of learning style, access, portability and social factors which need to be considered as part of the evaluation.

Mason (1996) in a study of 160 UK Open University students and Messing (1997) in a study of 69 Australian DE students both reported approximately half of the students printing extensive sections of the electronic learning materials. Printing large numbers of pages requires the expenditure of considerable money, time and effort over the course of the semester. Other studies (Martens et al. 1997, Benson & Vincent 1997) reported students wanting to have both print and electronic versions of their materials. Given organizations' efficiencies with print production, it is likely that they would be able to provide a printed copy for all the students at a much lower unit cost than any student's personal printing efforts. When only electronic materials are provided, transferring printing responsibility to the student is a cost that needs to be acknowledged.

Access

The question of access to electronic learning materials often arises in the context of a policy question about requiring students to own a computer. Bates (1997 p94) raises the equity issue that: "... a university requiring all students to have access to the Internet can at an administrator’s stroke, deny access to all students who cannot afford a computer, who are not skilled or confident in using a computer, or who cannot get Internet access where they live." The issue of ownership of suitable hardware is often not a real consideration as many students often have suitable systems. Organizations such as the University Grants Committee (French 1999) are very good at building infrastructure and redressing inequity when it comes to hardware. Many universities have similar programs to that of Acadia (MacDougall, Muldner and Tomek 1998) in which they provide an appropriate level of equipment to all incoming students. However, other factors which could also be termed access are every bit as important in determining how any electronic learning materials are to be used. In an environment of electronic learning, the definition of access will need to be extended beyond traditional ownership of hardware. Indeed, for distance education students, access needs to consider issues of where and when students study, as well as the physical and logistical requirements for the use of electronic media.

DE students study in quite an amazingly diverse range of circumstances. Apart from the obvious environment of a set time in a dedicated area of the home, the circumstances in which students in both Australia and Hong Kong (Messing 1997) carried out their study included:

- at work (during breaks, before and after work, on business trips)
- in transit (bus, train, plane, car - presumably as a passenger)
- during 'dead' times (waiting for children, airport and hotel lobbies)
- in bed

While electronic learning materials sometimes confer advantages such as searchability, editability (particularly copy and paste when the system is not locked) and ease of duplication they also severely restrict the physical access that some learners require. Apart from the lack of portability, limitations which have been reported include:

- not being able to spread the materials out on the desk
- not being able to see enough information on the screen at a time
- not having multiple 'pages' open at the same time (without overlap)
- 'overhead' time incurred in starting up
- being restricted to the location of the telephone line (ICT applications)

Screen size represents a cost in the form of an inconvenience. Not only are large screens prohibitively expensive but their bulk would further restrict the physical access in the cramped environments that many students work in.
Some such as Catenazzi (1993), design systems for larger screens but one has to question whether such designs are applicable to any but the most well resourced campus, let alone DE situations.

The central importance of the telephone line, especially in materials that require the use of communications technology, is rarely recognized. The many proposals for delivering electronic learning materials over the Internet (Harasim 1995; Western Governors Association 1996; Daniel 1996; Twigg 1999) all rely on access to a telephone. In most DE situations, the single telephone line into the home both determines the location of the computer (and hence the place of study) as well as the times when it may be used. While in recent times, additional telephone lines, especially in the form of mobile phones, have become more frequent, use of a telephone as part of the study process causes the student to incur a cost in monetary, time and inconvenience terms.

Social costs

Garland (1993) reported that the student's learning environment was a key situational variable in the success of a DE student. The learning process was very heavily influenced by what happened all around the student as well as the multiple roles that the learner was expected to fulfil. Woodley (1987), in examining the causes of adult student drop-out, identified an extensive list of study environment factors that adversely affect the learning process. They included:

- Little time or energy given to other domestic, work or leisure commitments
- Lack of encouragement by spouse or employer
- Personal / domestic changes
- Loss of a quiet place to study
- Work changes

While such influences are often studied, they are seldom, if ever, taken into consideration in decisions regarding the design and delivery of educational materials. Studying in the distance mode affects almost everyone that forms part of the student's social network. At the very least it is a disruption to the established order. Imposing restrictions by tying the student to a computer creates added pressures. Decreasing portability reduces the student's opportunities to participate in social activities that are removed from the computer. Tensions created by demands for resources such as the telephone or the only desk in the home create an extra level of anxiety about the study process. This is exacerbated in situations where such demands result in additional sacrifices by other members of the social network. Examples include the relegation of children to do home work at the kitchen table or loss of social communication ability because the telephone line is in use for long periods.

Such social costs are ones that both the student and those affected must bear. The consequences of electronic delivery of education extend beyond the learning process far more than conventional technologies. Increasing these social costs reduces the likelihood of electronic delivery being a judged a success by the student.

Conclusion

Ellul (1990 p39), in analyzing the ambivalence of technical progress in a technological society set out four propositions which he suggested applied in varying degrees to all technical developments. They were that:

"all technical progress has its price
at each stage it raises more and greater problems than it solves
its harmful effects are inseparable from its beneficial effects
it has a great number of unforeseen effects."

These form an important backdrop for the debate about the future of electronic delivery of education. There is a significant price that students have to pay for such technical 'progress'. The questions raised do not have simple solutions. In the grand scheme of things however, students are rarely asked if they are prepared, or able, to pay that price. It is up to the administrators and educators to consider all the costs in a balanced and fair way, from not just their personal or institutional perspective, but also that of their students.

A Study of the Use of Online Supported Learning Facilities at Charles Sturt University

Dr John Messing
School of Information Studies, Charles Sturt University, Australia
jmessing@csu.edu.au

Abstract: This paper reports on a study of student use of various online learning facilities using comprehensive log data that was collected within Charles Sturt University. Analysis of the data verified that many students were silent users of the system as well as revealing some surprising results regarding features that were not used at all and preferred patterns of access. These results have implications for the design of online learning facilities for other distance education ventures.

Background

Various studies such as OECD (1994), Jones (1997, 1999) predict that future university students will be drawn from wider populations with more varied backgrounds and needs. The higher education system in many parts of the world is changing. Macknight (1996) attributes most of these changes to powerful economic forces; a transition from the current teacher centred instructional model to a learner centred one and the global nature of digital interactions which is changing the scale with which the world is viewed.

Technology has for many years been cited (Goldsworthy 1980; Godfrey 1996; Bates 1997; Sakamoto 1999) as offering the promise of greater learning effectiveness, more learner centred approaches and a better quality of interaction. However, the driving force for change does not come from some technological imperative that many such as Tiffin (1996) would have us believe. The pressures for change derive, as Luke (1996) or Margolis (1998) suggest, from political, social and economic roots. Even though the causes are debatable, one thing is certain. They have been building for some time as governments cut higher education budgets while society expects progressively more and more of its school leavers to aspire to post secondary education. These pressures are complicated by falling entry standards and a perception of anachronistic university practices (Jones 1999).

'Distance Education' (DE) or 'Open Learning' as it is sometimes referred to, is one of the methods by which the high cost of face to face teaching may be reduced. There are also serious doubts about the intrinsic value of some of the traditional face to face methods such as the lecture, that most universities continue to use (Ramsden 1992, Laurillard 1993, Ramsden, Margetson, Martin and Clarke 1995). The appropriate use of technology is a significant component in many DE ventures. Computer technology has been used in education for many years but what is surprising, is the relatively superficial effect that it has had. For more than a quarter of a century, computers were seen as an important tool to be used in the educational process. Society was promised (Suppes 1968) the ultimate in individualized instruction, an infinitely patient tutor, a system that would revolutionize both the educational processes at schools and in the home. Bork (1980), in attempting to predict the future use of technology in education claimed that:

"the computer as a learning device in current classes is, compared with all other learning modes, almost nonexistent - the pace will pick up rapidly over the next 15 years. By the year 2000 the major way of learning at all levels, and in almost all subject areas will be through the interactive use of computers." p53"

While his predictions were clearly well short of the mark, the widespread adoption in recent years, of the Internet and the World Wide Web (WWW) by academic as well as business and private interests around the world has led to suggestions (Daniel 1996) that this is the means by which cost effective delivery of quality education may be achieved. The current social pressures on the education system noted by Voss (1995) make a good case for the rapid development of educational delivery systems which are more flexible in time, space and the type of technology used. The real effect of such radical changes to the role of educational institutions will be felt more by the consumers, the students, than the educational institutions themselves. Some such as Feather
fear that just as printing divided societies on the basis of literacy, this will lead to a further subdivision based on wealth, privilege and an electronic imperialism.

The nature of the electronic learning materials provided by educational institutions is only just being addressed. While there is literature available on many aspects of Computer Based Learning (CBL), current technology requires a re-assessment of what features and functions such learning materials might contain.

Charles Sturt University (CSU) is one of the major providers of distance education in Australia with over 24,000 students, three quarters of whom, study in the DE mode. The Technology Strategy Report (Rebbechi and Barnard 1994) mapped out a comprehensive set of alternatives for the development of technology used in the teaching and administration of CSU students. One of its key recommendations involved the conversion of as many as 1200 subjects from print into electronic form by the year 2000. What has evolved is a system which migrates the existing print based version of the teaching materials into electronic form at the same time as adding hyperlink features that connect different parts of the document to other resources that CSU has placed online. Fundamental to this decision to move to electronic format for teaching materials was the belief that in doing so, students would not be disadvantaged and indeed the provision of 'added value' features such as hyperlinks, would actually make this method of delivery more attractive to students.

CSU has for various compelling reasons such as being a rural university; having three main campuses spread over 400 kilometers as well as a number of smaller campuses even more remote from the main ones; teaching students who predominantly study in the DE mode; and having a significant presence in many Asian countries, made a concerted effort to provide effective communications technology. The problems of isolation are, in theory, ameliorated by developing information technology strategies to compensate.

**Online support at CSU**

Distance education has always placed more of an emphasis on the student taking charge of their own learning than the traditional face to face mode. DE students are given the necessary materials as well as study guides and whatever other help the university deems appropriate and expected to take it from there. The currently popular term, "Resource Based Learning" is an expression that encompasses the concept of students controlling their learning. Without wanting to enter into the debate about the meaning of resource based learning, it is clear that there are two different types of resources that are involved in the process. For want of a better set of terminology, these are referred to as "static" and "dynamic" resources. Failure to differentiate between these types and the role that they play is an all too common cause of misunderstanding of the way that electronic communications technologies might assist the teaching and learning process.

The "static" resources have traditionally been provided in print or some other physical format (videotape, slides, audio cassettes and computer disks). Note that the most important characteristic of these resources is not the medium by which they are delivered but the nature of the material itself. A lecture can be static whether it is delivered en masse to 600 students, comes printed in a book of lecture notes, is read as a word processing file on the student's computer or is downloaded off the network as an HTML document.

"Dynamic" resources involve interactions between student - teacher or student - student. The main characteristic of these is that they are ad hoc and cannot be planned for in advance. They include styles of 'real-time' delivery from the mass lecture, seminars, tutorials where questioning and dialogue are encouraged down to one to one conversations in person, on the phone or via e-mail. What conventional DE students often report is a lack of dynamic resources. They feel isolated and that the concepts of a class, fellow students, peer support and general interaction are not very strong.

Online supported subjects at CSU consist of both the static and dynamic resources. While there are numerous exceptions, static resources, in the main, are material converted from Open Learning Institute (OLI) maintained documents. This material is organized as a subject site on a secure information server. Dynamic resources are provided via e-mail, list servers and the centrepiece of the university's strategy, the subject forum.

Figure 1 shows a typical subject page in a web browser. The left-hand frame serves as a navigation menu for the documents that appear in the right hand frame. On entry, the initial document displayed is always the overview. A great deal of redundancy, seen as a positive factor in human-computer interface design guidelines,
is built into the design so that students may access components from a number of locations. For example, hyperlinks to the subject coordinator may be found in the overview, communications and index pages.

Most of the links in the menu are self-explanatory. While some such as 'library' link to the standard CSU library page, others such as communicate, overview etc. are customized with the information that is specific to that subject.

Typical online supported subject page

![Typical online supported subject page](image)

Figure 1

The forum is a discussion area where everyone may post questions, items of interest, general notes or responses to previous postings. It is typical of this type of communication tool but has the added feature that forums are restricted to students and staff assigned to that subject. The postings are 'threaded' and give the user a considerable amount of control in managing their own interface features. The list of postings and any special attributes of each are displayed. Again, a degree of redundancy has been built into the interface to make it easier to use. For example, a user can initiate the act of reading a message by clicking on the hypertext link, the window icon next to the message or the view all button. The forum software was purpose built at CSU and the current version is a greatly enhanced form of what was used prior to July 1999. Even so, additions are still being made to increase the functionality even further. The investment in developing this system can be viewed as a measure of conviction that this was an important dynamic resource in the delivery of the education of the future.

The study

Despite all the consultation that went into the design and the effort that is involved in producing these subject sites and subject forums, little empirical evidence had been collected to date which analyzed how these features were being used. Answers to basic questions such as:

- How much time do students spend using these resources?
- What effect does the academic involvement have in the usage time of these resources?
- What is the relative frequency of use of various features in these resources?
- What improvements may be made to the design of the resources?

are valuable from both a pedagogical as well as a system design perspective.

System log data is collected for security purposes on all actions that users carry out. This collection of data provided a previously untapped source of information. Based on a rough activity index which was calculated by dividing the number of 'sessions' by the number of students enrolled in the subject, three subjects were chosen:
one with a high activity index (Sub-A), one with medium (Sub-B) and one at the lower end but which still indicated a significant level of activity (Sub-C).

The records from the log files between June 30, 1999 and September 7, 1999 were extracted from the database and processed by custom written programs that discarded superfluous details and coded certain actions. Since this time frame represented a significant proportion of the teaching time during the semester, any trends in usage of the resources should have been evident by that point. This is even truer when one considers the fact that for some of these resources, the initial use might be the only use and one would expect that to occur very early in the semester.

The important components of the records from the log files include the user, the date, time to the nearest second and the command which was executed by the system as a consequence of the user's action. From these records it was possible to reconstruct a particular user's interaction with the online system. By comparing times of successive events for a particular user it was possible to calculate time intervals between events, correct to the nearest second.

Inspection of the usage logs and initial attempts to analyze the data revealed the presence of large time intervals where no action was monitored as part of the online system. Some students in the initial tabulation of data had average use times that were extraordinarily high, but showed very little activity. In the absence of any direct observation notes, some procedure was necessary to account for the possibility that the time logged at the computer was not actually being used as time on task. This phenomenon had been observed in previous studies (Messing 1997) and even in laboratory studies (Messing 1990) in which there was a limited time for the activity. When conducted in the diverse DE environments of this study, it was likely that there may have been tasks unrelated to the use of online facilities, which affected the logged event time.

In order to reduce the impact of such suspect times, all entries in the log that had a time difference from the previously logged event of 15 minutes or more were assigned a value of 15 minutes. This was in line with a similar technique reported in the literature (Chen, Horney and Anderson-Inman 1995). All documents in either the online subjects page or forum could be read within that time period, most of them several times. Students most likely read what they had to and then performed some other activity such as sending e-mail, opening a word-processing document or even leaving the online session with the intention of resuming at a later time but not actually quitting the system. The data were adjusted so that these large, likely to be inactive time intervals, were replaced as indicated.

**Results**

**Time on task**

It is quite reasonable to assume that there are many factors which affect the amount time that students spend in online related learning activities. The nature of the subject, the level of integration of the online resources with the teaching process, the teaching style used by the academic as well as a host of personal factors such as the level of access to suitable equipment, confidence in using the technology or even simply the time available for study are all potential variables which affect usage. The influence of these was not able to be determined. However, from a quantitative perspective, one important factor, the impact of the academics' usage was able to be isolated.

<table>
<thead>
<tr>
<th>Usage time</th>
<th>Avg time (hrs)</th>
<th>Avg time minutes/week</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sub-A-all</td>
<td>247.63</td>
<td>4.27</td>
</tr>
<tr>
<td>Sub-A-students only</td>
<td>239.71</td>
<td>4.44</td>
</tr>
<tr>
<td>Sub-B-all</td>
<td>93.81</td>
<td>1.71</td>

<tr>
<td>Sub-C-students only</td>
<td>36.53</td>
<td>0.65</td>
</tr>
</tbody>
</table>

Table 1
Table 1 shows both the total time on task as defined above, as well as the average time on task for each of the subjects as well as an adjusted value for the number of weeks since first usage was recorded. An additional set of values was determined by removing data that was able to be attributed to non-student entries. This included log records contributed by academics and other CSU personnel. The trend across the three subjects reflected the original basis for their selection in terms of activity ratio. Note however, that in all three subjects, even in Sub-C which has quite a low average usage, when the non-student use is removed, the average increases slightly. The conclusion to be drawn from this is that academic contributions do not markedly dominate the overall usage in terms of time on task. Indeed, the suggestion is that academics access these resources slightly less than the average student does.

Of course, the nature and purpose of an academic's access is quite different from that of a student but there does not appear to be any support in this study for the proposition that the academics dominate the usage. One might even question why the values for academic usage are not higher than they are.

**Static versus Dynamic Resources**

Reference was made above to the distinction between static and dynamic resources. Since the online material represented a static resource and the forum a dynamic one, the data were analyzed on the basis of the number of 'sessions' of each. A session being defined as the existence of an initialization event for either the online subject pages or the forum. This does not represent 'terminal sessions' i.e. how many times the user logged on to the CSU site but how many times the user 'switched into' the online material or forum. The results are shown in Table 2.

<table>
<thead>
<tr>
<th>Numbers of sessions</th>
<th>Sub-A</th>
<th>Sub-B</th>
<th>Sub-C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total sessions</td>
<td>710</td>

<td>70</td>
<td>158</td>
<td>68</td>
</tr>
<tr>
<td>Both</td>
<td>592</td>
<td>262</td>
<td>237</td>
</tr>
</tbody>
</table>

Table 2

The overwhelming number of sessions involved access to first the online subjects page and then shortly after, to the forum. This is not surprising since the online subjects page acts as a 'gateway' to the CSU online resources. The relatively high proportion of direct access to the forum in the case of Sub-B is explained by the use of bookmarks to avoid going through the gateway. It appears that most non Sub-B students were either unaware of how to use this feature or chose to follow the normal entry method.

**Use of Online Subject Components**

Analysis of the data was carried out to determine the number of times various subsections of the online pages were accessed both from the hypertext menu in the left hand frame (see Figure 1) as well as through links embedded in the various documents. The data were reported as the number of accesses per student but made no adjustment for 'transient' actions which are simply navigation actions.

Access to the overview page, both as an introduction or a subsequent selection, accounted for 83.5% of access. No other feature selected was more than 5% of all actions. Five features, Search, CSU Services, Help, Library and the Subjects pages were not accessed even once in the total of 8267 accesses recorded. While this does not mean that students did not use these features from other parts of the CSU site, it does indicate that students did not need to access them from the online subjects pages.

What is more surprising though is the fact that in most cases, less than half of the students engaged in a deliberate action to use a particular feature even once. The averages were calculated on the number of actual users rather than the number of students enrolled in the class. Using the number of students in the class would
have reduced the average values even further. The low average usage was somewhat surprising since one would expect that even from the perspective of curiosity, each student would enter these pages at least once to see what was there.

The most likely explanation lies in the fact that a great deal of what exists in the online subject site is a duplication of the printed subject outline that students also receive. Indeed, this printed subject outline would probably be read before entering the online subject site. If this were the case, there would consequently be little need for students to access many of the sections. While verification of such an explanation by more direct means would be necessary before reaching a reliable conclusion, it does raise the question of the merit of providing the same static material in two media.

Use of Forum Components

In a similar manner to that of the online subject pages, the access commands related to the use of forums were tabulated. The 'posts' that is, the creation of a new message or a reply to an existing message, were separated into those performed by students and those by the subject coordinator while all other data is combined. One complication was that the forum was designed with a number of function buttons representing tasks such as changing the way that the forum index is displayed, setting topics to be 'watched' by sending e-mail notification of new postings and a number of other tasks. These function buttons did not generate a log file entry and consequently could not be included in the analysis.

More than 80% of students in all three subjects, used the forum at least once. The most significant point that these data highlight is the fact that by far the most frequent operation is the reading of posted messages. This action comprised 66.3% of all the actions performed and when compared to postings (1.7%) gives a ratio of almost 40 reads to every post. This high ratio confirms the long held suspicion that there are many 'lurkers' who make use of the forums but predominantly as a means of receiving information rather than contributing. This suspicion is further confirmed by calculating the ratio of the number of students who were 'writers' and 'readers'. These ratios, expressed as a percentage for each of the subjects in the study were calculated as 77.1%, 11.5% and 16.0% respectively.

The result for Sub-A is surprisingly high but this is able to be explained by the nature of the subject and the way that the forum was integrated into the learning process. Students were required to submit contributions for assessment purposes. The data also reinforced the critical role that the subject coordinator has in making postings. The contributions by the subject coordinator far outweighed that of any other student. Even in Sub-A where there was a very high level of posting activity that was student initiated, the subject coordinator was responsible for more postings than the three most prolific students combined. In the context of overall low staff usage, one can only conclude that staff, unlike students, often posted responses to what they read.

Conclusions

The three subjects chosen were not a random sample, nor were they representative of the full range of subjects offering online support. If anything, they were chosen to highlight more extensive use of the online support facilities than the average CSU subject. They each had over 50 students enrolled in the subject and made use of the online facilities in different ways as part of the teaching/learning process. Given the limitations of the way that the sample was selected, the following conclusions are suggested by the data.

* Students did make significant use of the forums as one avenue of receiving 'dynamic' resources.
* The high ratio of reading to writing in the forums was confirmation of the belief that there are many more students who benefit from the postings than one would suspect. Even so, there were still considerable numbers of students who made no use of the system at all.
* The important role of the subject coordinator in contributing to the material in the forum was verified, even in forums where there was a very high level of student activity.
* The access to 'static' resources which were largely the same as the printed subject outline material was extremely limited.
* Little or no use was made from within the online subject pages of links to standard CSU resources such as the search facility or access to the library.
As a consequence of these, a number of recommendations relating to the design of the online subjects pages and a re-evaluation of their usefulness were made. The evidence from this study suggested that the strategy of providing static resources as a set of related HTML documents is not viable, even with the inclusion of a substantial number of cross-linked hypertext links. Other avenues will need to be explored that meet the policy as well as pedagogical requirements.

With respect to the provision of dynamic resources as evidenced by the forums, there appears to be qualified support for the continuation of that strategy. However, the role of the subject coordinator is critical if the forum is to be used effectively. Designing functional systems is clearly not sufficient. All the participants need to be made aware of the strategies available in working more effectively with such tools.

Abstract: New Zealand is a multi-lingual society, and this is reflected in classrooms across the country. Since most instruction (with the exception of some Maori-language instruction) is in English, the large Chinese, Japanese, and Korean (CJK) student population is placed at a distinct disadvantage. Many of these students arrive in the country with the most rudimentary English skills, and it is not uncommon for most CJK students to fare poorly in English medium classes.

This is a case study of collaboration between a K-12 school, a local university, professional translators, and ethnic community groups to address the challenges faced by CJK students in an almost exclusively English medium classroom.

Some background

In 1998, the entire year 12 Computer Studies course as taught at Long Bay College was rewritten for web-based delivery. Students logged in to the school Intranet, ran their Browser, and accessed all course materials online (Meyer & Jacobs, 1998). Until this time, course materials consisted of various text books, journal articles and tutor-written notes. Since effective web-based materials differ substantially from their paper-based counterparts, the materials could not be adapted without being stilted. The opportunity was taken to rewrite the course completely.

While web-based delivery proved extremely effective in:
• accommodating the widely divergent computer skills of the 120 students in the study
• encouraging self-paced study
• providing valuable insights into which technologies were optimal in the K-12 online context

the problems facing CJK (Chinese, Japanese & Korean) students immersed into an English-medium class (which required good English-reading skills) remained unaddressed, since although the course was extremely practical by nature, the students were now expected to read their lessons rather than listen to them. This placed a heavy burden on these students.

This problem is partially dealt with by (Faulkner & Chen, 1999) in a study trialling dual-medium course content. While a step in the right direction, their reproducing the entire course content in an Asian language was (we felt)
1. too labour intensive
2. did not lend itself to regular updates
3. and ignored the students’ own expressed desire to become more familiar with English as their teaching medium.
Our approach – a four-tier system:

We opted instead for a four-tier system, as follows:
1. Glossary Overlays
2. Tapping into the local Asian community for online “mentors” for each student.
3. Eliciting the aid of a local university to host our course on their “Web Shell” server.

1. Glossary Overlays:

Since the original web-based course materials were constructed using NetObjects Fusion, it was a simple matter to identify key words and concepts which appeared in the English text, and to provide (on every page) a Chinese, Japanese and Korean “button” which when clicked popped up a new window which displayed explanatory notes in the appropriate language.

There is an in-built problem with using this technique: if one opens a “child” window, and then moves to another page on the website, that child window simply becomes minimized – it doesn’t go away. After a very short time, one can have a profusion of very confusing minimized windows crowding up the task bar.

Plug-ins:

NetObjects Fusion has the ability to install “plug-in” components, to extend the functionality of the original application. A Fusion component (also available for Macromedia’s Dreamweaver) was sourced which enabled us to create Java-based popup windows in which contained a glossary of the terms used in the main page. These glossary windows are activated by clicking on a button which appears on the main page. Unlike most popup browser windows, however, they automatically close themselves when either another language is selected or the user moves to another web page. Without this automatic closing of “child” windows, this system would soon have sunk under its own weight, since neither Netscape nor Internet Explorer do this by default – leaving in their navigation trail an ever-growing number of orphaned popup help windows.

2. Community Involvement:

In order to establish the viability of the concept, use was made of senior Asian students within the school to translate the glossaries for a single module. This module was published without comment to the school’s intranet, and student reactions to it observed. Encouraged by the ready acceptance of the new feature, we approached members of the Asian communities who were eager to become involved in the project.

Pilot Testing and adjustment:

To test the effectiveness and suitability of the glossaries (as well as the user interface), we had two Chinese, two Japanese and two Korean students work through the course in pairs. The students were asked to vocalise their thoughts as they progressed through the material, so that their comments could be taped, and subsequently played back to a Language professional for translation. Armed with these student comments, final editing was done, and the site published.

Online Mentors

Computer-literate “mentors” were sought in the local Asian communities who agreed to “adopt” one or more students, and to follow their progress through the online lessons. Since the course materials were completely online, their task was (1) to become familiar with these materials, and (2) to be available both to answer emails from their student(s), and to show regular interest in their progress.
Asian (CJK) characters:

It was imperative that the CJK students be able to communicate in their own language with their mentors. To this end, all student computers, as well as those of the mentors, were configured to run Global IME, allowing them to type Asian characters directly into email messages. Most of the CJK students were already familiar with this method of entering Asian characters, and this proved not to be a problem at all.

Orientation:

We arranged an initial orientation meeting at which the mentors, parents, homestay parents, and members of the wider Asian communities could meet both the students and the staff involved in the project. This personal encounter helped put a face to the email communication which was to be fundamental to the student/mentor relationship. This was followed up with regular reviews to renew the personal contacts. In some cases, the mentors were known to the students already; however, these meetings “formalized” their new relationship.

3. Using a “Web Shell”

Secondly, a local university agreed to host the course on one of their servers running “Courseinfo”, so that all administration could be handled online. Students were thus able to continue their lessons from home (if they had Internet access).

Web shells offer many features not available on a simple website - like student drop-boxes (enabling students to submit assignments), secure and private pages displaying each student’s marks, personal student web-pages, online chat, daily notices, a course calendar and so on. While these features certainly could be written into any website, the time involved in doing so would be prohibitive. With a web shell, they are almost “incidental”, significantly enhanced the effectiveness of the online course delivery.

One feature not well implemented in “Courseinfo” was online testing. After a few attempts at getting a class to do tests online within Courseinfo, we elected to use computer-based testing software developed by ourselves (Jacobs & Meyer, 1998) instead. This software is now mature, and able to handle local as well as distance testing in a secure, robust and feature-rich manner.

Fortunately, Courseinfo allows a teacher to manually enter marks in the online gradebook, so that even though tests were conducted using our own testing engine, results could still be entered into the Courseinfo system, where students could access them securely.

4. Web Discussions

Office 2000 comes equipped with a very useful feature called “Web Discussions”. Once these extensions are installed on an NT Server, any IE5 browser with access to this Server is able to add comments to any web page anywhere on the Internet. These comments appear to be part of the target web page, but in reality exist as files on the NT Server, and are dynamically added to the target web page when viewed by IE5.

Using this feature, our staff were able to add extra comments to our already published web-based course materials as the need arose – customizing these materials to the needs of their particular students. Both our students and their mentors were able to see these comments, and to add comments of their own at any stage - creating instant context-sensitive discussions - visible only to those involved in the project.

A valuable feature of these web discussions is that any addition (ie follow-on comment) to a comment already on the web page would trigger an email notification to the author of the comment, alerting him/her to the fact that someone had responded to their posting.
As an additional bonus, these impromptu discussions became rich sources of ideas to be incorporated in the next version of the published course materials.

**Challenges faced in implementing the project.**

**Workload**

1. The year 12 Computer Studies course consists of twelve separate modules. This represented a considerable number of individual web pages which needed to be enhanced with three language-specific glossaries. Each page had to be supported by three independent language popup screens. For some of the larger courses, this ran into hundreds of extra pages which needed to be translated, and published.

2. In addition, to ensure that the popup glossaries displayed the Asian fonts consistently across all browsers and on all computers, we elected to represent the CJK text as a graphic. This required each CJK glossary to be created in a word processor, and copy/pasted into a graphics package before it could be embedded into the glossary pages.

**Language expertise**

Initially, we prepared a single course (Intro to Win9x) using three senior Asian students at the school. However, since staff had little way of gauging the accuracy of the translations, and little or no additional funding to enlist the skills of independent experts, we resorted to a “round-robin” approach. We presented the CJK texts to other CJK native speakers, and asked them to translate them back into English. We used any marked discrepancies identified in this manner to more accurately translate the original texts.

With this course as a “working model”, we were able to approach local interested parties for funding to complete the translation using qualified translators.

**Results/Findings**

We would love to report that this experiment was an unqualified success. However, since we were only able to translate three of the twelve modules in the course, our results are less than conclusive.

**Glossary Overlays:**

Even though only three modules sported the CJK popup windows, students found this feature helpful. Students were interviewed, and asked if they would like future courses to continue to offer this feature. Of the 20 students interviewed 4 thought that the translations were too abbreviated, and should be expanded into full translations of the English text; 14 considered the help “just right”, and 2 thought that although the translations were a good idea generally, they did not personally benefit from them, since their English was already of an adequate standard.

**Community Involvement**

Although the communities met the idea of mentoring with great enthusiasm and interest, and although offers to translate the help pages were many, it soon became apparent that relying on the goodwill of busy people was not a workable solution for a project which was bound by the inexorable march of the school calendar. Deadlines came and went, and students progressed to modules for which there was no CJK popup help available. Since the mentoring program relied heavily on mentors being familiar with the online course content, when this familiarity was not apparent, the helpfulness of their replies was (as some students confessed) sometimes of little value. While the students were unequivocal as the value of being able to email a native speaker of their language with problems
encountered in the course, one of the singular challenges facing us next year, is to identify outside mentors with the
time and expertise to play this role more effectively.

Web Shell

As far as staff were concerned, the Web Shell was a solid success. It streamlined the administration of the course,
allowed them to post regular notices, publish grades on secure student-only pages, facilitate the submission of
student work, and to return the graded assignments both from home and at school. Some of the features provided by
Courseinfo proved to be less than useful in a high school context, and were soon deactivated. One such feature was
the online chat – or virtual classroom feature. Teachers rapidly came to the conclusion that 16 or 17 year old
students were simply too tempted by the technology, and were too easily lured off-task into endless personal
messaging.

Web Discussions

Again, the temptation of students to write fatuous comments rather than to either ask questions related to the text, or
to offer suggestions germane to the task at hand, became immediately apparent. So much so, in fact, that staff were
forced to limit student participation in the web discussions to read-only. Several attempts were made to re-open the
discussions, but with the same results. Even though students knew that every posting carried their login name, they
persisted, claiming that they never wrote the message, but that someone must have discovered their password.

However, even as a tool used by staff only, the web discussions proved invaluable, in that it facilitated the ongoing
comment by staff on the body of the text – sometimes in amplification, sometimes in alternative points of view.
These comments provided rich and useful material for incorporating into future versions of the course.

Funding

One of the rather unexpected outcomes of our search for sponsors, was the discovery that schools enjoy a low
profile in the academic community, and as a result can call on few, if any, research grants. Local private enterprise
saw little to be gained by allocating funds for this academic research, and the school Board of Trustees, while they
thought the idea very interesting, the fact remained that there was little enough money available for other, more
substantial, projects. In short, the project had to be funded on a shoestring, with almost all of the work being done
by teachers in their free time. This was a major reason for not being able to translate the entire course into CJK.

Description of a web-based program suitable for easy adaptation for on-line delivery of many educational resources.

gmeyer@anhb.uwa.edu.au

Abstract: This paper reports the creation of a web-based computer program now used successfully to teach "histology" in our Medical School. Unlike any other similar histology computer program now available, the "template" of this program can be made available to individual course coordinators in their own institutions to create their own "on-line histology course" that reflects the specific and unique learning objectives of an educator's individual histology course. A further objective of this paper is to emphasis that the "program template" is easily adapted for the "flexible, on-line delivery" of many other subject areas in High School and University Curricula.

The "Histology Practical Assistant"

The presentation of this paper will be simultaneously accompanied by an "on-line" demonstration of this teaching resource but a website demonstrating the features of this resource is also available (see below).

The program is called the Histology Practical Assistant" ("HPA") and was created initially to save money! Teaching any histology course has always been an expensive exercise due to:

(a) large numbers of staff required to assist students in the practical sessions.
(b) the need for expensive teaching resources such as high quality microscopes and class slide collections for each student.
(c) the constant maintenance of these resources by staff, or the replacement of these resources due to "wear and tear".

Increases in student numbers in our histology courses over the past few years has meant that we do not have sufficient numbers of quality microscopes or slide collections for each student. We have reluctantly shared these items amongst the students, but sharing is not an ideal teaching and learning exercise. So this dilemma was another reason to develop the "HPA".

The "HPA" was also designed for "flexible delivery"

This program was also created to enhance the effectiveness of teaching and learning. Many students of histology have difficulty visualising a three-dimensional structure from the study of a two-dimensional tissue section. Images in a computer program can be labeled to show important histological features. Diagrams can be added so students can see the plane of section of the image through the organ, and the location of the image in relation to the whole organ.

The "HPA" was also designed for "flexible delivery"

The "HPA" was also designed to allow students to examine histological sections of tissues and organs outside of normal teaching hours and at their own pace in a non-threatening environment. This has reduced the need
for large numbers of microscopes and slide collections (and reduced maintenance) to be available at any one time during the academic teaching week. It also replaces the need for academic staffing in the practical classes by incorporating into the program the "tutor" i.e. a "computerised microscope" which details how to examine each histological section to identify the necessary histological features. This has led to substantial savings in teaching costs. Another feature of the "HPA" is that it provides images of a variety of demonstration material, limited preparations etc. that are not in sufficient numbers to provide in slide collections. This no longer requires staff time and room space to "set up" each week and this material is stored within the computer and hence readily available throughout the course for revision purposes.

The "HPA" provides a comprehensive self-assessment module. This enables students to test their skill in identifying histological structures, or their knowledge of the theory of histology, by answering an extensive quiz following each topic to enhance and not compromise effectiveness in teaching and learning.

Why is the "HPA" so unique?

(a) It is web-based so easy to maintain.
(b) It is interactive in that if students cannot identify features then they can link to extensive use of pointers/labels etc. to indicate relevant histological components to them.
(c) It is written in a language that reflects the personality /sense of humour of the lecturer and so personalises the interface between the computer program and the student.
(d) It is a versatile program and so can be immediately adapted to any changes in teaching emphasis. Additional topics, images, quiz question etc. can be inserted (or deleted) very easily. This is particularly useful so teaching Departments from other Universities can substitute their images - particularly in the "tutor" component of this program.

Because of (d) above, anatomical, plant, insect specimens, etc. can replace the histological content of this program so it can be utilised within any University by a group of educators from many different disciplines. It is designed to be "user friendly". Students can navigate their way through the program very easily. An independent survey has indicated that when students have used this program it has made a very positive impact on student learning.

The major features of the "HPA" will be demonstrated during the presentation of this paper.

There is an On-line demonstration website!

Most features can be seen by visiting the following website:

The "Histology Practical Assistant" is written in javascript and word documents. On opening the program a list including each major topic on the histology curriculum appears within a narrow frame on the left hand side of an 800X600-pixel screen frame - this list of topics is called the "labmap". A welcoming "splash" page also appears on the remainder of the screen.

A "Noticeboard" is available as a link to convey messages to students about any aspect of the study program.

The 1st level of the "labmap" lists major topics of a typical histology curriculum in a medical, dental, or a biological science course. The "labmap" begins with the basic tissues leading down to the major organ systems. Any topic can easily be deleted if it doesn't suit the objectives (or time restraints) of a particular histology course. Conversely, it is easy to add further topics to this "labmap".

By clicking on the + icon, each topic on the 1st level of the "labmap" expands to include the many tissues/organ components of that topic. Many components on this 2nd level, can be further expanded to a 3rd level by once again clicking on the + icon. Clicking the icon again can contract topics.
Each topic generally depicts images at the gross anatomy level; then low to high magnification, light microscope images, and finally electronmicrographs for relevant ultrastructural details. Thus, the computer is imitating student use of their microscope to examine the particular tissue or organ. This feature alone may be sufficient for histology courses where the constant use of the microscope, class slide collections, and associated costs may not be of major emphasis in the course objectives.

The "HPA" is interactive

Students need to interact with the program! By clicking on a topic at any level, an image appears in the middle frame. At the same time, concise text (the "guide") appears in narrower right hand frame, with all the major histological features hypertexted. Students can work individually, or in small groups, to identify each feature and are only tempted to click on the hypertexted feature if they have doubts or wish to test themselves. Once the student clicks on any one hypertexted feature it is immediately labeled and indicated by an arrow or circle, etc. The concise text is written in a language that reflects the personality/sense of humour of the lecturer and so personalises the interface between the computer-aided teaching program and the student. Like all components of this program the text can be easily amended. At the base of the text for each feature are two links; the "more info" link and the "tutor" link.

The "more info" link

This link can have a variety of uses. For instance, it can contain diagrams, information and questions for the student to research in their recommended texts, lecture notes, etc. There is no limit to the length of the material, or method of presentation of the material, inserted into this link. The "labmap" on the left-hand side remains visible at all times which enables the user to open any topic in any order. This is particularly useful when students wish to review a topic before investigating another topic.

The "tutor" link

The other link is the "tutor". The innovation of the "tutor" link has two unique features:

(1) The microscope objective lenses on the computer screen link images (taken at different magnifications) of the student's class tissue section and so simulates the student's use of a typical class microscope. This unique feature has eliminated use of the microscope in most of our practical classes except to reinforce the skill of microscopy in the histological study of body tissues and organs.

(2) Accompanying each image is text to direct the student to locate (on high-resolution images of their class slide) the specific histological feature/s opened on the "labmap". This feature promotes an independent, self-paced learning opportunity for the student and eliminates the need for teaching staff to be present in practical sessions.

Self-assessment is available on-line

After studying each topic a quiz is available. Questions are MCQ, "roll-down" questions, identification of structures on labeled diagrams, or histological images (often requiring a written answer), or requests for functional descriptions of tissues/organs. At the completion of the quiz a student submits his/her answers and receives immediate feedback of his/her success. It is easy to utilise a link that transfers the performances of each student to a secure result sheet where it can be stored and count towards the final grade for each student.

A brief section on clinical considerations and research is included following at the end of each topic of the curriculum. The main purpose of these two features is to impress upon students:

(1) the close relationship of histology to pathology/disease processes.
(2) the variety of current research investigations at the histological level of many tissues.
(3) the use of histological techniques as research tools.
The program "template" is versatile

In the presentation a demonstration will be performed explaining how versatile the "program template" is to access via any major HTML editor and make amendments to the components of the study subject. This will include a demonstration of how easy other subject disciplines eg. botany, geography, many biological science subjects including anatomy, anthropology, genetics; geology and many High School subjects can be included in this "Flexible Delivery" format by a teacher who need not be computer literate!

A Rule-based Method to Shift between Learning Protocols

Abstract: Learning protocols are computational descriptions of collaborative learning policies (strategies). They can help geographically distributed people to overcome the difficulty of coordination by guiding and controlling social interactions in virtual learning environments. To perform a certain collaborative learning activity, a number of strategies can be used to achieve the same goal. However, no one strategy can be effective in all situations, because learning groups are different in group size and group structure, and group members vary in knowledge, skills, interests, learning style, and so on. Furthermore, in learning processes the situation changes over time. Learning groups may want to shift from the currently used strategy to another strategy to fit some changes. In this paper, a rule-based method to switch learning protocols is proposed. This method is implemented and demonstrated in our virtual learning environment CROCODILE.

Introduction

In education a revolution is taking place, in which we see a shift from the teacher-centered approach to the learner-centered approach. The underlying philosophy is that people learn best when they actively engage in learning to acquire knowledge and skills, which they need to solve the problem at hand (Norman96). The advance of technologies accelerates this change and enables many ideas of the philosophy of constructivism to be carried out. In the past decade, many systems have been developed to support learner-centered learning in virtual learning environments, such as CSILE (Scardamalia94), CNB (Edelson95), Web-SMILE (Guzdial97), and Belvedere (Suthers97).

In the same line we developed a virtual learning environment (VLE) based on principles from constructivism and situation theory. We suggest that losing physical contact in a VLE makes it difficult for learners to understand and interact with learning environment, to construct shard knowledge, and to coordinate their contribution. In order to solve these problems, we adopted a development approach that can be characterized as 1) using a virtual institute metaphor to structure shared workspace (Miao99), 2) using learning nets to facilitate collaborative construction of shared knowledge (Miao00a), 3) using learning protocols to mediate social interaction (Wessner99, Miao00b), 4) using learning plan to coordinate tasks performed by different people.

In this paper, we focus on discussing an open issue of learning protocols. A learning protocol is a scripted collaborative learning strategy in computational form that helps people to coordinate a collaborative learning activity in a VLE. In different situations, learning groups may adopt different strategies to perform learning activities. For example, to perform problem-based learning different process models are proposed in the literature (Stepien93). Therefore, a set of pre-defined learning protocols should be available for learning groups, so that they can choose one of them to guide and control their collaborative learning activity in a VLE when needed. However, to shift from the learning protocol currently used at run-time to another learning protocol is an open problem. This paper addresses this problem. First of all, we introduce learning protocols in detail. The main part of the paper discusses the problem of shifting between learning protocols and presents a rule-based method to solve this problem. Then we briefly discussing the implementation of a protocol control tool. Finally, we summarize our work and discuss related research.

Learning Protocols and Protocol Instances

In this section, we briefly present the concept of learning protocols, how a learning protocol is defined and executed.
Learning Protocols

Learning protocols are theoretically based on psychological script theory (Wessner99). According to the script theory, generalized knowledge about a sequential list of the characteristic events involved in a common routine is called a script (Schank77). Scripts can be used to organize knowledge, to assist recall, to guide behavior, to predict likely happenings and to help us to make sense of our current experiences. Learning protocols are computational scripts to guide and control social interaction in collaborative learning processes in a VLE.

A learning protocol is described as an extended state-transition-diagram. A node in the protocol diagram represents a state of collaboration within the learning protocol. In problem based learning (PBL), for instance, the possible states are “identifying problem”, “identifying learning issue”, “applying knowledge”, etc. Each node is labeled by a unique name within a learning protocol. Each state of collaboration is bound to a set of behavior rules. A behavior rule specifies which protocol-role is permitted to perform which operation on which type of object. A protocol-role is protocol specific (e.g., tutor, learner, and expert in PBL protocols). Protocol-roles are assigned to participants of the collaborative learning activity. There are two types of objects in a learning protocol. The first type of object are artifacts that can be manipulated collaboratively in learning processes. Examples of types of artifacts in PBL are “problem”, “learning issue”, “hypothesis”, “solution”, “hint”. Operations on artifacts such as “learning issue” objects, are “create”, “delete”, “modify”, “refer_to”, “I_know”, etc. Such artifact objects carry the knowledge constructed and exchanged in learning processes. The second type of objects are so called coordination objects, which are used to coordinate group interaction (e.g., floor token, state of collaboration, etc). Operations on such objects include, for example, “request”, “drop”, “start”, “finish”, and so on. A link in a protocol diagram represents an event. The occurrence of an event causes a transition between the departure state and the arrival state connected by the link. A link is also bound to a behavior rule in which the object is a coordination object. An event occurs when an allowed operation is performed. Now, we formally describe a learning protocol.

First of all, we define the behavior rule. A behavior rule can be defined as a tuple element of $B = (R \times Op \times O)$, where R is a finite set of protocol-roles; O is a finite set of objects; and Op is a finite set of operations. Hence, a set of behavior rules can be defined to specify all possible behaviors to support a certain collaborative learning activity. We use $B^*$ to denote the set of all subsets of set B. Then, we formally define a learning protocol. A learning protocol is defined as a tuple $P = < S, T, lab, bind, L, B^* >$ where:

- $S$ is a finite set of states of collaboration. Within $S$, there is a start state denoted as $s_0$ that is the access point of a learning protocol.
- $T \subseteq S \times S$ is a subset of relation on $S$ that is called as transitions.
- $L$ is a finite set of names that are represented as strings.
- lab: $(S \cup T) \rightarrow L$ is a labeling function. Notice that the label of each state of collaboration is unique, while a label can be carried by more than one transition. A label of a state $s \in S$ is represented as $lab(s)$ and a label of a transition $t \in T$ is represented as $lab(t)$.
- bind: $(S \cup T) \rightarrow B^*$ is a binding function. The set of behavior rules bound to a state $s \in S$ is represented as $bind(s)$.

Protocol Instances

When group members perform a collaborative learning activity, they can use a pre-defined learning protocol to guide and control the group interaction. A learning protocol can be executed as a protocol instance. One learning protocol can have more than one protocol instance at the same time. Each protocol instance is executed independently following the definition of the chosen learning protocol.

Before or during execution of a protocol instance, the initiator of the protocol instance needs to assign protocol-roles to the potential participants of the collaborative learning activity. When the execution of a protocol instance is initiated, it will begin execution at the start state of the learning protocol. That is, the current state of the instance is the start state. When participants with appropriate protocol-roles perform an operation that is bound to a transition, the corresponding event occurs, which triggers a state transition according to the definition of learning protocol. The destination state of the transition then becomes the current state of the protocol instance. In the current state, participants are guided and controlled to perform operations on the shared artifact according to the behavior rules.
Shifting between Learning Protocols

As discussed above, group interaction is supported at run time by the execution of a protocol instance of a pre-defined learning protocol. However, to support a certain collaborative learning activity (e.g., problem based learning), a family of learning protocols can be defined. As we known, learning groups are different in group size and group structure, and group members vary in knowledge, skills, interests, learning style, and so on. Different learning groups may exploit different learning protocols to carry out their collaborative learning activity, because of the characteristics of the groups or their customs. There is no single learning protocol that is suitable to every type of group and to every problem. Furthermore, as groups conduct a collaborative learning activity, some factors may change over time such as group size, structure of group, the understanding and expertise of learners, etc. Therefore, groups may want to shift from the currently used learning protocol to another learning protocol to fit the changes.

A simple approach to shift between protocols is to terminate the currently executed protocol instance first and then to initiate a new protocol instance based on the target learning protocol. However, in such a way, some data recorded in the current protocol instance will be lost upon terminating the current protocol instance. The participants then have to repeat efforts to reach the equivalent state in the new protocol instance. For example, when a group uses the “first-request-first-take” floor token control protocol, the learners' requests for the floor are recorded in the request queue of the current protocol instance. If the group wants to change the floor token control protocol by stopping the current protocol instance and initiating a new protocol instance of another floor token control protocol (e.g., the “teacher-assigning” floor token control protocol), the request queue of the current protocol instance will be lost. Learners need to request the new floor token in the new protocol instance again.

An alternative approach is to enable end-users to modify the definition of the learning protocol in use at run time. However, our experiences reveal that it is a difficult and time-consume task for end-users to change learning protocol dynamically.

Therefore, we adopted an approach where end-users are enabled to shift between learning protocols by simply choosing another protocol from a family of pre-defined learning protocols for a certain learning activity. Because all learning protocols in a family are carefully defined to support the same collaborative learning activity, they use identical sets of objects, such as the types of objects and their associated operations, and identical protocol-roles. Learning protocols within the same family vary in the definition of the state of collaboration and transitions, and in the binding relation. An analysis of learning protocols in the same family showed that some states of collaboration defined in different learning protocols are bound to the same set of behavior rules, and that some states of collaboration defined in different learning protocols are refined to different degrees. Manually, for any state of any learning protocol from which to shift we can find an appropriate state in any target learning protocol from where to continue execution after shifting. Therefore, a family of learning protocols can be defined by a protocol diagram in which all learning protocols are contained as sub-diagrams. A new shift relation is defined by edges that connect each state in any sub-diagram to a state in any other sub-diagram. This diagram becomes very complex when the number of learning protocols and the numbers of states in these protocols are large. It is also difficult to maintain the diagram when adding or removing or modifying learning protocols.

A Rule-based Method to Shift between Learning Protocols

In order to shift between learning protocols in a systematic manner, we defined a rule-based method.

Readers should remember that a state within a learning protocol is distinguished from other states, because a certain sub set of behavior rules is bound to this state. Within a learning protocol, two different states are bound to two different sub sets of behavior rules. Given there are two states \( s_1 \) and \( s_2 \) \((s_1 \neq s_2)\) in a learning protocol \( P \), then \((\text{bind}(s_1) = \text{bind}(s_2))\) is equivalent to true.
Different learning protocols are defined to support the same collaborative learning activity. That is, the set of protocol-roles, objects and their associated operations are the same. Learning protocols are different from each other because the states in different protocols are defined in different way. That is, in different learning protocols, states are refined or specialized in different degree by binding to different sub sets of behavior rules. According to the sub set of behavior rules bound to states, the relation between two states within two different learning protocols can be fall into one of four categories. Given s is a state of a learning protocol P and s' is a state of a learning protocol P' (P ≠ P'), the relation between bind(s) and bind(s') leads to one of the situations:

- equal: bind(s) = bind(s');
- contained: bind(s) ⊆ bind(s') ∨ bind(s) ⊃ bind(s');
- intersected: bind(s) ∩ bind(s') ⊊ bind(s) ∧ bind(s') ∩ bind(s) ∧ (bind(s) ∩ bind(s') ≠ ∅);
- separated: bind(s) ∩ bind(s') = ∅.

According to these four situations we can establish a shift relation between labels of states instead of establishing a shift relation between states of two learning protocols. For all learning protocols in the same family, we define a unified set of labels and a unique labeling function that is denoted as Lab. In the first case, we label two states by the same name. In the rest of three cases, we have to use different names for these two states.

Generally speaking, given there are m learning protocols in a family P1, P2, ..., Pm, while S1, S2, ..., Sm, denote the sets of state of collaboration of the respective learning protocols. ∀ s ∈ S1, s' ∈ Sj | i ≠ j • bind(s) = bind(s') iff Lab(s) = Lab(s'), that is, these two states will be labeled by the same name. Otherwise, if bind(s) ≠ bind(s'), then Lab(s) ≠ Lab(s'). Now, we define a label relation graph as a directed graph G = < L, U, B > where:

- L is a finite set of nodes that represent the unified set of labels of states for all protocols in the family. U ⊆ (L × L) is a set of uni-directional edges U = { (l, l') | l = Lab(s) ∧ l' = Lab(s') ∧ bind(s) ⊃ bind(s') }.
- B ⊆ (L × L) is a set of bi-directional edges B = { (l, l') | l = Lab(s) ∧ l' = Lab(s') ∧ bind(s) ⊊ bind(s') ∧ bind(s') ⊊ bind(s) ∧ (bind(s) ∩ bind(s') ≠ ∅) }.

It is important to notice that not all intersected states can lead to drawing such bi-directional edges between their labels. In some cases, the behavior rules bound to two states are almost the same but they have subtle difference because they are defined to emphasize or ignore intentionally some details more or less. They can be regarded as mutually shiftable states and a bi-directional edge can be defined between the labels. In other cases, no shift should be possible between two states although the behavior rules bound to the two states are associated to more or less common behavior rules. Thus, the bi-directional edges need to be designed carefully by protocol designers.

After defining the label relation graph, we can shift between protocols by using the algorithm described below. Let P be the currently used protocol and s be the current state (s ∈ S) of a protocol instance of P. If it is desired to shift from the current learning protocol to another learning protocol P' (P ≠ P') we need to find a state in the new protocol. This state s' ∈ S' can replace the current state in the new protocol while maintaining the current protocol instance by using the following algorithm:

1. Try to find a state in S'': If ∃ s' ∈ S' | Lab(s) = Lab(s'), then return s'.
2. Try to find a state in S': If ∃ s' ∈ S' | (Lab(s), Lab(s')) ∈ B, then return s'.
3. Try to find a state in the set of children of Lab(s): C = { c | c ∈ L ∧ (Lab(s), c) ∈ U }
   - If ∃ c ∈ C | s' ∈ S' ∧ c = Lab(s'), then return s'.
   - If there are k labels c1, ..., ck (i = 1, 2, ..., k) (c1 = Lab(s1) ∧ s1' ∈ S') (i = 1, 2, ..., k), search a path in which s1', ..., sk' are points.
     - If the path is not a loop and s' is the start-point of the path, then return s'.
     - If the path is a loop and s' is the nearest point to the start state of the protocol P', then return s'.
   - If there is no such c ∈ C | s' ∈ S' ∧ c = Lab(s'), then recursively search children of elements of C and repeat step 3.
4. Try to find a state in the set of fathers of Lab(s): F = { f | f ∈ L ∧ (f, Lab(s)) ∈ U }
   - If ∃ f ∈ F | s' ∈ S' ∧ f = Lab(s'), then return s'.
If there are \( k \) labels \( f_i \) \((i = 1, 2, ..., k) ((f_i = \text{Lab}(s_i) \land s_i \in S') (i = 1, 2, ..., k))\), search a path in which \( s_1, s_2, ..., s_k \) are points.

- If the path is not a loop and \( s' \) is the start-point of the path, then return \( s' \);
- If the path is a loop and \( s' \) is the nearest point to the start state of the protocol \( P' \), then return \( s' \);
- If there is no such \( f \in F \land s' \in S' \land f = \text{Lab}(s') \), then recursively search fathers of elements of \( F \) and repeat step 4.

5. Return the start state of learning protocol \( P' \) (i.e. no better matching state in the target protocol could be found).

Implementation

The rule-based method to shift between learning protocols has been implemented in a protocol control tool in our prototype VLE system called CROCODILE (an abbreviation for CReative Open COoperative Distributed Learning Environment). It is implemented in VisualWorks Smalltalk and available on Window'95, '98, NT and Solaris.

In Fig. 1, we illustrate the three windows that users see. The lower window is the hypermedia document editor in which learners can build their hyperdocument. The upper left window shows a virtual room in which learners are located. The upper right hand window shows the protocol control panel.

A learner can initiate a learning protocol instance by clicking on the “protocol” icon (see Fig. 1) in the editor window. A dialog window will pop up and the protocol initiator can select a learning protocol from a list of pre-defined learning protocols. In the current prototype we prepared three learning protocols for problem based learning (PBL-protocols). After choosing a PBL-protocol, users currently working in the editor will see that the protocol control panel pops up. Information about the initiated protocol instance is presented in the panel, such as the name of selected learning protocol, current state of the protocol instance, and assigned role membership (which is assigned by using this panel). Learning groups can construct shared knowledge in the editor window by following the selected PBL-protocol. A detailed description of how a learning group conducts problem-based learning by using our system can be found in (Miao00b). It is important to notice that learning group can shift between PBL-protocols by clicking on the “shift” button in the protocol control panel and choosing another PBL-protocol.
Summary

In this paper, we discussed the concept of learning protocols, their definition, and execution. Then, we identified the problem of shifting between learning protocols. After analyzing and exploring possible approaches to solve this problem, we presented a rule-based method to shift between learning protocols. Finally, we briefly described our virtual learning environment CROCODILE, in which the method has been implemented in a protocol control tool.

In terms of related work, Belvedere and Web-SMILE provide students with guidance for the execution of learning processes. The guidance is implemented as something like a protocol description. However, in both of these systems this protocol description can not be instantiated and shifted. In the Workflow Management Systems area, process models are different and cannot easily be used for our purpose of controlling behavior in collaborative learning processes. Also, in WfMS usually the definition of a process is changed instead of replacing the process definition of a running process. Compared to finite state machines our process model differs with respect to the use of behavior rules in the process definition. Exactly these behavior rules form the basis for our algorithmic computation of transitions between protocols.

Our plans for future work include extensive evaluation of our approach. Furthermore, we will use this method to develop other families of learning protocols to support other types of collaborative learning activities.

Abstract: Based on the findings of this study, it can be claimed that the process of acceptance of computer technology is related to gender where the women are far more cautious about exhibiting a positive attitude than men. However, when the functionality of a technology has been demonstrated within the context of a specific process, in this case the 'learning process,' women tend to embrace the technology and are often more positively pre-disposed. Furthermore, there are no specific categories of use where this process appears to become more significant, and the differences between men and women with regards to computer use categories is unevenly and somewhat randomly distributed suggesting again that it is the practice of technology that is more critical than the specific technology itself.

Introduction

Early studies reveal that males are less anxious, more confident, and like using computers more than females. Despite these findings researchers also conclude the opposite; gender does not directly impact a student's attitude toward computers (Rosen, Sears, & Weil, 1985). These findings are a result of taking into account the variable 'computer experience.' Chen (1985) concludes that overall males show more positive attitudes of interest and confidence with computers than do females. However, when the amount of computer experience is controlled, males and females respond with similar levels of interest. Hunt & Bohlin (1993) reported on a research study designed to measure the entry attitudes of students enrolling in educational computing classes and found that previous experiences were the best predictors of student attitudes. Males indicated having more experience with programming and recreational uses of computers but gender did not significantly correlate with any of the attitude variables. Levin and Gordon (1989) confirm the impact of computer experience on attitudes and add that having an actual computer in the home has a greater affect on attitude toward computers than does gender.

Only when the trend that males and females exhibit similar attitudes toward computers was recognized that researchers began asking if these results were the same for all types of computer use. C.R. Scott & Rockwell (1997) explored the role of computer anxiety, communication apprehension, and writing apprehension in predicting future use of computers as communication tools. They found that past computer use appears to be a strong predictor of future use; however, gender differences are rare: male respondents reported a greater likelihood of joining online services and playing video games. These two instances were exceptions; there were no other differences between the genders regarding likelihood to use new (or more traditional) technologies. Rockwell's research points to a fundamental distinction not made in previous research -- the difference in types of computer use by gender. More importantly, this information can be used to determine if there is a difference in attitude toward computers because of specific use patterns between genders.

As this brief review suggests there is some confusion about the relationship between gender and contemporary attitudes and use of computers. In the educational setting, this confusion leads to doubts about the way in which differences in learning in a computer-enriched environment could be related to gender. We argue that there are two areas that need further exploration: 1) there is an alteration in the relation between gender and different kinds of the computer use as computer enriched environments are emerging, and 2) the emergent environments and the cultures that these environments spawn can lead to new areas of differences between genders when computers are considered as the key technology of the new academic environment. These considerations drive us to advance one broad research question:
What are the relationships between gender, categories of computer use, and attitudes towards computers in the emergent computer enriched environments of academic institutions?
Methodology and Data

Given the breadth of the question, we have utilized the data from an ongoing longitudinal assessment of the impact of computerization at a small liberal arts institution that initiated a process of computer enrichment by entering into collaboration with a major computer industry leader. The study used a survey design to collect self-response data from a sample of students and faculty at the University. The surveys continue on an annual basis and use questionnaires that were developed after extensive focus group interviews with students and faculties.

Results

The results of the analysis point towards several inter-related findings. The results are presented here in a thematic order to capture the various relationships between gender, use and attitudes towards computers.

First, the results indicate that before the computer enrichment was initiated on campus, and before the arrival of the laptop students on campus, the men on campus had a significantly more positive attitude towards the use of computers and were also more frequent users of computers. As illustrated in Table 1, men reported that they felt that computers can make the learning process easier, preferred to be in classes where they could use computers, felt more comfortable with computers than women, were less apprehensive about computers than women and were less concerned that computers in teaching would make the teaching process too impersonal. Finally, men reported that computers enabled them to interact more with teachers using computers.

</tr>
</tbody>
</table>

In a similar way, men on campus also reported a more frequent use of computers than women. Computer use was reported as higher by men in all categories of computer use, particularly in the task categories of use ranging from specialized use to the more routine use of the technology. As illustrated in Table 2, this difference disappeared only in the case of the use of electronic mail with teachers.

This trend, continues in the first year of computer enrichment. At this point, a quarter of the students in the University had access to personal laptop computers, the network system, albeit somewhat unreliable, was in place and the computer labs were being phased out. The data suggests that both the legacy and the laptop-program women became less positive towards computers and their use was less than the men (Table 3 and 4) were.
However, at the same time the overall attitude towards computers among both men and women saw an increase in the positive direction (Tables 5 and 6). Furthermore, there were more significant differences in attitude between the legacy women and the legacy men than the laptop women and the laptop men (Tables 7 and 8).

* stands for significant difference between means

The same trend continued in the second year of the computer enrichment with the single difference being that women agreed significantly more to the notion that communicating with professors by electronic mail was generally more gratifying. In all other respects, the women held a more negative attitude towards computers than men or held attitudes similar to the men. This tendency continued with respect of use of computers as well.

The data suggests that the attitude towards computers of women among the laptop students was somewhat less positive than the men in the same group for both the first and second years of computer enrichment. Finally, the data suggests that the general attitude towards computer has become increasingly positive as the computer enrichment progresses and use of computers has increased as well. This finding is a throwback to the earlier days of computing when research had indicated that men were more positively disposed towards computers than women.

Discussion

First, it is possible to claim that, like members of many other institutions, the University students had displayed little differences in attitudes towards computers and use of computers prior to the introduction of a complex and elaborate technological enrichment program. The few significant differences based on gender tended to suggest that the men were more positively predisposed towards computers and tended to use computers more than women. This finding is consistent with previous research on the relationship between gender and computer attitudes. This finding also has to be placed in the context of a liberal arts institution where the thrust of the education was not on skill-development and professional or technical training but on disciplines that traditionally were not highly computer-use intensive. It can be argued that in such environment men and women do not come in with specific expectations and predisposition about computer use. In such environments, the computer remains a "tool" that can be used to advance the learning goals which would not necessarily be learning how to use a computer.
or how to program a computer, but more on how the computer can make a pedagogic and learning goal more efficiently achieved. We would thus make the argument that when the computer was not the center of attention and publicity for the University, the actual difference in computer use level and attitudes towards computers were minimal, even if statistically significant.

The second major finding follows from the earlier one in logical progression. Once the environment was altered and the overall "ethos" of the University shifted towards a technological orientation, albeit, in enriching the campus only and not in revamping the curriculum to make it a "technical" institution, the expectations about the education that could be obtained from the University could have shifted. Given, the way the University altered its image in the academic marketplace, there was a specific emphasis placed on the computerization process as the University geared up for the new Millenium. Thus, the plan called, "Plan for Year 2000," was publicized as one that would technically enrich the University. Indeed, many other significant aspects of the plan, such as the reduction of class size, and the addition of new faculty sometimes were made less important given the emphasis that was placed on the technological aspect of the plan. This, as demonstrated in the content analysis, resulted in well-documented displeasure among the legacy students, and that displeasure could have resulted in the extension of some of the more traditional relationships between gender and attitudes towards computers. Thus the women being less favorable towards computers could be based on the fact that the new environment that was perceived to be emerging did not appeal to the women and the blame was placed on technological enrichment and women became more critical of the process than men.

In association with this change, there could have been a third shift in terms of the expectations about the institution. The laptop students also displayed differences between genders with men being more positive towards computers. This phenomenon could be related to two different processes at work in the University. On one hand, the incoming students now had a somewhat different expectation of the environment that they would encounter at the University. While, there was no evidence, particularly in focus groups, that there was any school-choices based on the laptop program the students did enter the environment expecting that computers would play a significant role in their learning process. This expectation, which was different from the traditional perceptions of liberal arts institutions could in itself have led to the fact that women came in greater trepidation than men. Such a conclusion is somewhat congruent with earlier studies about gender and computing where there was some evidence to suggest that men are somewhat more positively predisposed to computing than men. On the other hand, this positive predisposition was also related to the newness of computers, and as other studies have suggested, as the newness disappears and the computer becomes more ubiquitous the gender difference becomes insignificant or switches to a more positive valence for women. In other words, as the computer becomes an expected and standard part of the process of learning, women are likely to embrace it more readily. In many ways, the computer-enrichment phenomenon could be duplicating, in a microcosm, the phenomenon that used to be observed about the relation between gender and computer technology in the past when computers were being introduced into the practice of our everyday life. If that is the case, it can be hypothesized that the differences observed in the first two years of the computer enrichment will begin to disappear with time.

In conclusion it can be claimed that the process of acceptance of computer technology is related to gender where the women are far more cautious about exhibiting a positive attitude than men. However, when the functionality of a technology has been demonstrated within the context of a specific process, in this case the 'learning process,' women tend to embrace the technology and are often more positively pre-disposed, Furthermore, there are no specific categories of use where this process appears to become more significant, and the differences between men and women with regards to computer use categories is unevenly and somewhat randomly distributed suggesting again that it is the practice of technology that is more critical than the specific technology itself.

The prescriptive aspect of these findings is that technology enrichment needs to be accompanied with a clear description of the way in which the technology would be introduced in the primary practice of an institution. In the case of an academic institution this would suggest that there needs to be a clear rationale explicitly stated about the way in which ubiquitous computing would be utilized in the process of teaching. Such explicit definition of the technology practice and its functionality would generate a more positive affect within women, who otherwise would be far more likely to consider the computer-enrichment with a greater degree of criticism. Such criticism can then translate to a negative affect eventually creating undesirable gaps between genders. On the other hand, if the expectations and functionality of the technology-enrichment is made explicit at the onset, or when in time they become explicit, it can be anticipated that the differences between genders could either disappear or the women could exhibit a more positive pre-disposition than men. All of this suggests, that planners of technology-enrichment need to be sensitive of the gender of the users and consequently make adopt specific planning strategies to ensure that unwanted gender-based rifts do not result from the process of technology enrichment.

Abstract: A growing number of researchers have come to the conclusion that we have moved from an earlier paradigm (computer-based education, CBE) to a new paradigm which will be called network-based learning (NBL) in this article. So far, however, too little attention has been paid to the methodological aspects needed for creating NBL environments. This article aims to analyze these developments by linking them closely to new emerging electronic learning environments and to methodology. As a concrete example we will analyze the use of one integrated distributed learning environment (IDLE) tool called "Future Learning Environments" (FLE). Our focus is on academically oriented university students in a teacher education program at the University of Helsinki, Finland.

Learning Environment as Dialog

Network-based learning relates directly to the concept of learning environments. There are multiple views of a learning environment, each eliciting in our minds different images about teaching, learning and studying. Mononen-Aaltonen (1998) has noted that these are often divided into three categories: learning environments as (i) ecosystems, (ii) places, and as (iii) space. As a novel way of seeing a learning environment, Tella & Mononen-Aaltonen (1998) have suggested that a learning environment should be defined as dialog in its Bakhtinian and Vygotskian sense. In the framework of dialogism (Tella & Mononen-Aaltonen, 1998) and the cultural democracy approach (Appelbaum & Enomoto, 1995), this article argues for dialogic learning environments and dialogic pedagogy. The research focus is based on the concepts of modern media education and social reconstructionism.

Our initial arguments are that

1. Dialog as a learning environment is a social environment, in which knowledge is co-constructed and appropriated.
2. A network-based learning environment is a computer-mediated and technology-enhanced dialog.
3. A prerequisite (or a co-requisite) for empowering NBL environments is the fundamental flexibility of any social environment. An IDLE should be able to enable social interaction between the different communicators.
4. When planning and designing NBL environments, one guiding principle should include the idea of providing the users with structures that they can tailor to best accommodate their own learning needs.
5. Combining NBL environments with undominated dialog contributes to constructing a model of social interaction within an unoppressed and equal study community.

In order to implement these principles, we will have to enlarge the contemporary discussion usually focused on learning into a broader concept of the teaching-studying-learning paradigm (Uljens, 1997) in which theoretical knowledge plays an important role.
The Teaching-Studying-Learning Paradigm

In new electronic environments, the teacher must have a strong and theoretically well justified methodological view of her own. It can be grounded on different theories and conceptions of learning and knowledge, such as constructivism. In the teaching-studying-learning paradigm, we point out the importance of teaching, studying and the emergence of a study community, as demonstrated later in this article. Admittedly, the teacher will change from a 'sage on the stage' to a 'guide on the side'. In an NBL environment, and in our conception of a dialog, this is not quite enough: the real question is the dual stance (Willis 1995, 14-15) of the learner and the teacher, in which the teacher is still on the center stage as an actor and as a moderator of all activities but at the same time (s)he will be on the side, observing the teaching-learning process with an attentive eye, reviewing the whole situation. The teacher, then, is both an actor and a critic. And so is the student: playing his or her part but also analyzing his or her own studying process at the metacognitive level. The teacher can easily contribute to this process by giving cognitive support, such as scaffolding. Tella (1999, 213) has argued that media educators will need a "media educational" eye in the spirit of Bourdieu's reflexive sociology (Bourdieu & Wacquant, 1992, 248). The question, then, is not only of reciprocity and addressivity between the different actors but also of the changes of the changing roles. One way to express this change is to describe the teacher as the student's cognitive coach and as a motivating and emotional counselor. These will also help her to act as an interpreter of the student's relations with the world. This kind of 'eye' is needed when we think of a dialog as the metaphor of an NBL environment, which contextualizes the process of individual empowerment and raises the awareness of individual actors. This is exactly our link to social reconstructionism and to the cultural democracy approach.

The studying component consists of tools and the context, and the context helps the emergence of a study community, in which, again, different tools, like IDLEs, will be used.

Tools and the Context

In the emergence of a study community, the dual stance of teachers and students will facilitate the adoption of a dialog as a learning environment. In this community, certain tools, media and technologies will be needed to support dialog. At the same time, this community will create an educational context in which these tools will be used.

Tools

Tools can be divided into technological and intellectual ones. While it is necessary to have a fair command of 'technological' tools, it is at least equally important for everyone to cope with intellectual tools. These include methods of creating, organizing, and using information and knowledge. Lin et al. (1995) note the ability to critical and sustained thinking and to reason about important content as well as the ability and motivation to lifelong learning and autonomous study. Rieber's findings (1994; cited in Lin et al. 1995, 59) show that learners' personal discoveries, possibility to explore, feeling of ownership, and construction of knowledge can help optimize not only intrinsic motivation but also learning proper. In this sense, intellectual tools, technological tools, and learning are deeply intertwined and in close interrelationship with one another.

Context

We contend that in addition to the tools component, the TSL paradigm is likely to lead to a new kind of thinking of the learning context, which could best be depicted as an "ideal public space" in the spirit of Habermas (1974). This space is important, as it is the meeting point of all learners at the very heart of the study community. At its best, this thinking leads to contextualism, which, according to Pettigrew (1985; also Poikela 1999, 38), is one of the "world hypotheses", whose mission it is to create order to the chaos. History, time and change are the basic principles of contextualism (Poikela 1999, 38). Therefore, the metaphor of contextualism is a historical event, with a special view to the discussion of the independence of time, place and location, which is often regarded as an intrinsic feature of an IDLE.

Technology can be regarded as context, representing and simulating meaningful real-world problems, situations, beliefs, perspectives, arguments, and stories of others. Technology as context also supports discourse among knowledge-building communities of learners (Jonassen 1995, 62) and could therefore be seen as supportive of our argument of a dialog being the learning environment.
IDLEs (Integrated Distributed Learning Environments)

Above, the dual stance of the teachers and students was derived from the TSL paradigm. At the same time, new emerging study communities will greatly benefit from technological and intellectual tools, as well as from seeing the learning environments as a new context. In our thinking, IDLEs (Integrated Distributed Learning Environments; also called groupware tools) are ideal to be used in the framework of contextualism. IDLEs represent two mainstream cultural theories (see Creswell, 1998, 86-87): first, they represent ideational theories, suggesting that change is a result of mental activities and ideas enabled by language. Second, they represent materialistic theories, holding that material conditions, like resources, money, and modes of production, are prime movers. In IDLEs, we believe, these two theories, merge beneficially. Their use call for mental ideas related to teaching, studying and learning, but they also represent a context or a forum of action, a "center stage", on which different actors interact. What counts from our point of view is that IDLEs can be especially designed for communal modes of inquiry and studying, as in our research project. But once on the "center stage", one needs some principles for "acting" properly. We will discuss these in the following.

The Four Basic Elements of the Dialogic Learning Environment, in relation to IDLEs

In our thinking, the four basic elements of a learning environment are the study community, the zone of proximal development, the We relationship and the dialogic field (Figure 1).

<table>
<thead>
<tr>
<th>Study Community</th>
<th>Dialogic Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>We Relationship</td>
<td>Zone of Proximal Development</td>
</tr>
</tbody>
</table>

Figure 1. The basic elements of a learning environment (Mononen-Aaltonen 1998, 195; http://www.helsinki.fi/~tella/montreal4field.html).

In Buber's philosophy, the concept of We is overshadowed by the dominating doctrine of I-Thou, and as a consequence, the We has failed to attract sufficient attention. The Buberian We is animated in the shared speech and finds its beginning when one addresses another on the I-Thou basis. The Buberian We suggests a setting for dialog to realize itself.

It is through a dialogic field that learners discover their ways of thinking, their truths, their belief systems, their fields of vision, which of them they share with others and which are unique to them.

For Vygotsky, the most essential feature of teaching and education is that it creates the zone of proximal development (ZPD). The dynamic movement within the ZPD is a prerequisite for growth and knowledge construction that moves the learner from one stage of development to another. This is done with the help from outside one's mind, with the help of another voice, another mind. Through technological tools, especially when combined with intellectual tools such as cognitive support, coaching, modeling, and scaffolding, we can help elevate learners through their zones of proximal development.

The study community is interpreted in line with Bruner's ideas of the classroom being a subcommunity that specializes in learning among its members-a subcommunity of mutual learning. Mutuality is tangible in the sense that we can feel, notice and see it as well as identify with it.

The Research Project

The Media Education Center of the University of Helsinki has recently launched a research project on dialog, communication and technology in teaching and learning at the university level. The project is carried out in a foreign language methodology research seminar, where the traditional face-to-face mode of studying and learning is complemented with working in an NBL environment by using an IDLE tool called Future Learning Environments (FLE), designed for communal modes of inquiry and studying. The study project is part of the FLE Project, launched in 1998 and co-ordinated by the Medialab of the Helsinki University of Art and Design. The teacher in charge of the research seminar has been Marja Mononen-Aaltonen.

Our aim is two-fold: (i) to create a learning environment that would empower the students to participate in the discourse of educational sciences and to conduct research on foreign language methodology, and (ii) to support each student's research project as a whole within a dialogic frame of reference. We aim at promoting sharing and discussing ideas at all stages of the scientific inquiry process. The research seminar has been chosen for two reasons: First, the students come from other university departments in order to do their teacher
As stated above, our study is based on the notion of a learning environment as dialog in the Bakhtinian and Vygotskian sense. The seminar is conducted in such a way that dialog is likely to become the way to be a seminar member: the way to teach, to study and to learn the culture and the language of the academic community of education, and to participate in its scientific discourse. The study aims at developing general pedagogic principles and teaching practices to support dialog in an academic learning community.

We will now briefly analyze how the four components of the dialogic learning environment (Figure 1) can be worked on as elements of an academic study community.

For instance, when creating the dialogic field, the participants need to be engaged in the dialog from the very first research idea. Then thinking becomes a text and the students as well as the teacher has a 360° field of vision. This might lead to a temporary chaos, which is shown in the unstructured and non-linear nature of the research process.

One more step is to activate the ZPD by making the research process visible and understandable to the learners. More data will be needed, browsed and analyzed during the on-going process than in traditional seminars. Continuous feedback is needed. The target at this stage is telos, the cognizance of common and shared educational aims to be achieved through the research project.

At the same time, an interface to the We relationship needs to be created. It means, among other things, that the openness of the relationship becomes an opportunity and a risk. In this process, the teacher's contribution is crucial. However, the teacher needs to remember that participating in a dialog is voluntary, too much control or pushing will destroy the budding dialogic atmosphere.

**Research Findings**

One of the foci of our research project has been an authentic use of information and communication technologies in the real world and their potential in research-focused teaching in teacher education. The data gathered during the academic year 1998-99 are being analyzed at the moment. Therefore, these findings are preliminary but indicative.

The members of the seminar are interpreted to form a study community. This study community is seen as a 'common obligation' to everybody in the Latin sense of the word: cum (with, together) and munis (duty, obligation), thus, a common obligation, shared by everybody but not imposed on anybody. In this way, the students' minds will be geared towards research and thus the process is more likely to result in a 'minds-on' approach, instead of an earlier more pragmatic hands-on approach. The work is therefore moving from brawn to brain, with a distinctly conceptual character. The many comments by the students indicate that we have succeeded in this.

The support given by an NBL environment to the emergence of a study community and the We relationship is indirect and mediated. In research-focused teaching, NBL appears to be very important as the creator and maintainer of the zone of proximal development and the dialogic field.

We believe that it is through dialog with others that learners discover their ways of thinking, their truths, their belief systems, their visions, all of which they can then share but which will still be unique to them. Their ways of thinking, being, believing and studying open up as a dialogic field. As Bakhtin put it: "What we see can never be what you see, if only because I can see what is behind your head".

Our students participate in a real research project with the aid of an authentic IDLE. From the very beginning, they are aware of belonging to a large research project. They understand that they are not only writing an 'academic piece of paper' but are fully committed to developing a new area of methodology and the tools to be used in it.

The approach we promote also includes a few hazards and threats. The FLE interface consists of each participant's desk, open to everybody else in the same study group. Everybody's documents and other materials are openly accessible by everybody else. Even access to each other's messages is open. In this sense, the FLE functions as a technological and intellectual interface to the We relationship, but, in our case, again in an indirect way: the students knew each other and the teacher before entering the seminar, as they had participated in her other courses before this seminar. The openness of the FLE to all the participants of the seminar with open desks and files is a new opportunity for collaboration and sharing ideas and thoughts. But at the same time the students may find it awkward to go to their co-researchers' desks and open their files. Clearly, more emphasis should be laid on the personality characteristics of learners who find it valuable to use these emerging technologies, such as the IDLEs. We simply refer to Dede's argument (1995, 47) that there might exist a whole new di-
mension of learning styles orthogonal to the visual/auditory/kinesthetic/symbolic categories now underlying pedagogical approaches to individualization.

One of our conclusions is that the metaphor of a desk is not appropriate; rather, we should speak of a public space, like a virtual library, in which everybody can browse through the documents. If the concept of virtuality represents cultures based on the logical rather than the physical (as argued by Agres, Edberg & Igbaria 1998, 72), it seems that ours is one of the cases in which bringing reality into the virtual world might encounter some unexpected barriers at the conceptual level of the learners.

Lin et al. (1995, 54; as reported in Tella 1997) argue that social considerations belong to the second wave of the cognitive revolution, focusing attention on the social contexts of learning that have pervasive cognitive and motivational effects, while the first wave mainly dealt with individual thinkers and learners, de-emphasizing affect, context, culture, and history. In this light, the use of a groupware tool such as FLE is most likely to amplify the relations between the teacher and the students, and between the students themselves, and finally helping construct a study community, in which the second wave cognition and motivation prove indispensable. We would argue that a traditional research seminar is much more likely to point out the first wave emphases, i.e., individual work done without any real co-construction of knowledge.

The teacher’s role seems to prove most crucial in creating a dialogic learning environment in the context of FLE. It is the teacher who either creates the We relationship or destroys the opportunity to establish any relationships on a dialogic basis. The teacher’s role becomes even more important in creating and maintaining successful mediated learning experiences. Importantly, an IDLE may open up the chaotic and non-linear character of almost any research process, but at the same time it helps to give order to this chaos. In the final analysis, then, the mediated learning experience consists of the individual empowerment properly contextualized within the virtual working concept of a study community, and inducive to fostering a better comprehension of individual participation in a mutually shared research project.

Educational Multimedia Systems for Students with Autism

David Moore, Paul McGrath, John Thorpe, School of Computing, Leeds Metropolitan University, Leeds LS6 3QS, UK. Email: d.moore@lmu.ac.uk

Abstract Educational multimedia systems have a potentially important role to play in the education of students with autism. This potential has thus far, however, been largely unexplored. This paper therefore makes a case for the use of multimedia systems for such students, and reviews the current state of the field. It will be argued that a fruitful way of furthering research and development in this area is to develop systems that directly address autism-specific impairments. Proposals for multimedia systems for each of these areas will be put forward, and our current development work outlined.

Introduction – A case for Multimedia Systems for Students with Autism

A commonly held view of the nature of autism is that it involves a “triad of impairments” (Wing 1996). There is a social impairment: the person with autism finds it hard to relate to other people. Secondly, there is a communication impairment: the person with autism finds it hard to understand and use verbal and non-verbal communication. Finally, there is a tendency to rigidity and inflexibility in thinking, language and behaviour. Much current thinking is that this triad is underpinned by a “theory of mind deficit” – people with autism may have a difficulty in understanding mental states and in ascribing them to themselves or to others.

Why might it be thought that multimedia systems could be beneficial in the context of the education of students with autism? First, it has been argued that many people with autism have a natural affinity with computers (Murray 1997) and that pupils with autism tend to enjoy using computers (Swettenham 1992). Indeed, Jordan (1991) has suggested of children with autism that “... it is often valuable to view their thinking and learning as analogous to computers - you only get out what you put in”. Concerning multimedia in particular, it is well known that children with autism are attracted to visual images (Virart 1997) and since it is thought that individuals with autism may not have 3D vision (Grandin 1995) then the world of the flat screen may be more acceptable and less frightening than the real world. Multimedia systems may be beneficial in that they can eliminate the need for reading in order to engage in computer aided learning (CAL) activities (Iacono and Miller 1989) and Murray (1997) suggests that through computer use the student with autism may in fact become motivated to read.

A further advantage is that the computer presents a relatively controlled environment and can eliminate many distractions of the normal classroom (Green 1993); attempting to reduce potentially disturbing stimuli is in line with the “SPELL” approach to teaching (Siddles et al 1997). A further benefit concerns the individualised, one to one tutoring that may be made possible by interactive multimedia systems. Such a teaching mode is often seen as important for students with autism. Peeters (1995), for example, talks of the “unbelievable luxury of individual attention” and Higgins and Boone (1996) see individualisation as “key to appropriate instruction” for students with autism.

Existing Multimedia Systems for Students with Autism

There appears, then, great potential for beneficial multimedia systems for students with autism. And there is a growing body of such applications. Tjus et al (1998) use multimedia for teaching literacy to pupils with autism, allowing the student to construct a sentence in text and receive “immediate multi-channel feedback”. Anthony (1992) discusses a non-oral approach for teaching communication skills to severely handicapped “autistic-like” students. The approach involves “picture communication”, using dedicated communication devices that can be programmed to reflect the daily activities and choices in the classroom. Anthony claims that the results of the approach include reductions in “non-social behaviours” and increased verbal interactions.
In a related approach, Arora and Goodenough-Trepagnier (1989) adopt a game show format in their visual communication systems. Another system adopting a games-based approach is “Danny’s Rooms”. This is a "recreational multimedia application for the autistic population" (Eddon 1992) with seven games, such as a photograph game invoking spoken messages from on-screen photographs of the family and the rooms game in which the user is required to navigate a series of increasingly complex rooms. Another room-based application is “AVATAR” (Enyon 1997), in which the user activates objects in the room which respond with an appropriate sound effect, with the word in writing and in Makaton and with the word spoken.

More generally, Higgins and Boone (1996) have provided a set of software design guidelines for use with CAL systems for people with autism, and a group, ASILeSP (Autism Specific Interactive Learning Software Packages) has been set up to look specifically at “effective ways to use technology to empower and to support individuals with autism”.

Despite this potential, however, the field remains relatively unexplored. Higgins and Boone see educators as in a position only to “begin to explore the possibilities of the new technologies for students with autism” (Higgins and Boone 1996, emphasis added), and the British National Autistic Society (NAS) points to “…. a general lack of computer programs which have been written specifically for children with autism” (NAS 1996). Similarly, Eddon (1992) points to a “void in recreational computer applications for the autistic population” and Enyon (1997) claims a “growing need voiced by parents and professionals for specially developed computer programs”.

**A Proposal for Research and Development**

Given that there is a compelling case for educational multimedia systems for students with autism and that the field is thus far largely un-researched, an important issue concerns delineating areas that might usefully be addressed by such systems. The priority should be, we argue, to develop interactive systems specifically aimed at the core autistic deficiencies. We argue for this in detail elsewhere (Moore et al 2000) but essentially our argument is that such a prioritisation is in line with current pedagogic theory relating to autism. For example, Jordan argues: “of course, it will be a teaching priority to enable the pupil to improve interpersonal and communication skills” (Jordan 1992a).

The importance of targeting autism-specific issues is given greater urgency by the fact that the limited provision of existing software designed for users with autism tends not to directly address the autistic condition as such. Eddon (1992), for example, points out that many applications relate to basic skills such as knowledge of the alphabet, and that these are less appealing to older children who might be slighted by their childish nature. Even Eddon’s own Danny’s rooms itself, though, seems not to be directly targeted at the autistic condition per se, in that navigating rooms or invoking sounds from farm animals is intuitively unlikely to help autism specific concerns such as a lack of social skills. More generally, Trehin (1996) argues that the attempt to act on “one or several specific deficiencies encountered in autism” is “only in its infancy”. This is not of course to deny the worth of the work outlined earlier, far from it, but merely to argue for an urgent need for programs targeted directly at the difficulties characterising the autistic condition.

In the remainder of the paper, therefore, we will consider means by which these difficulties might be addressed by multimedia systems.

**Social Skills Education**

Direct teaching of social skills to students with autism is widely advocated (e.g. Jordan 1991). Multimedia systems with varying levels of interactivity can be developed to assist in this endeavour. The lowest level of interactivity would involve simply observing social events. Even this may be educationally useful. Jordan (1992b) suggests that pupils with autism should be able to observe how non-autistic children play with each other. Jordan points out that the “pupils’ observations need to be directed to salient points”, and this can be aided by multimedia systems in that they can be paused, speeded up and repeated endlessly, and graphics and...
animations can be overlaid to highlight the crucial points. Further, the multimedia facilities provide a readily re-useable resource, which may be important in specialist settings where opportunities to observe play may be sparse (Jordan 1992b). This facility can be further enhanced by creating examples of “good” and “bad” social interactions, asking the user to pick out sub-optimal interactions, and allowing the user to invoke displays of the motives and thoughts of the various participants, in the manner of “bubble dialogues” (O’Neill and McMahon 1991).

A higher degree of interactivity can be created in simulated role play activities. Role-play (which may include the use of video) is used to teach social skills to adults and children with autism (e.g. Yates 1993), and simulated versions can be built. Interactive video disks for management training have been available for some time. Social scenarios are introduced and a number of alternatives offered to the user; the user’s choice invokes further video and further decision points, so that the user is branched through at least some of the on-line material in line with their answers. Similar work has been carried out in connection with more general social skills (Iacono and Miller 1989).

Much of our current development work is centred around building simulations of a similar kind, involving contexts likely to be found particularly problematic by people with autism, such as the school lunch hour (Cumine et al 1998). As an example, one of our prototypes presents the student with a video clip depicting a dining room queue and asks where the queue should be joined. Different clips of video are then shown, consequent upon the selection made, before the system moves onto other aspects of dining room protocol such as choosing an appropriate place to sit. Evaluation of interactive systems for students with autism is, we argue, particularly problematic (Moore et al 2000), but preliminary formative evaluation of the system has proved very encouraging.

To some extent such work involves creating on-line versions of existing practice, and it might be argued that such an approach may diminish the impact of the technology and that it would be better to go beyond what can be done in conventional methods (cf. Green 1990). However, the computer-based simulations do offer the advantages of interactivity, of being repeatable and of offering “safe” experimentation with ideas. Further, they are readily adaptable in that, for example, text can be turned on and off depending on the perceived needs of the user.

**Communication Skills Education**

Here we follow Iacono and Miller’s (1989) suggestion that individuals with poor communication skills “may stand to gain most from computer applications specifically designed to teach or enhance communication skills”.

At the level of the individual word, talking word processors may be useful (NCIP 1995). There has been considerable work in automating symbol systems for speech and hearing-impaired people (Sale and Carey 1995, Anthony 1992) and systems such as Makaton are frequently used by people with autism (e.g. Rutherford 1996). At the semantic and syntactic levels, drill and practice may be valuable, e.g. Iacono and Miller (1989) suggest using drill and practice for initial teaching of, for example, verbs, following which “the verbs can be utilised in computer games, exploratory play and simulations of fantasy then real life”.

At the pragmatic level, Iacono and Miller (1989) suggest computer or video simulations as a way of encouraging communication. Concerning non-verbal communication, Yates (1993) advocates video for the teaching of body language, and video tapes of differing facial expressions are already used, as are graphically based face games (Jordan 1992b, Yates 1993). Tantam (1993), however, suggests that “systematic training of emotional expressiveness has never been carried out in people with autism” and interactive systems may have an important role here.

Our current prototypes in this area seek to address non-verbal communication by requiring users to identify facial expressions and body language. Users are presented with examples, via a mixture of line drawings, on-line still photographs and videos, and asked to identify the likely messages being given. They are then offered explanations and further examples, dependent upon their progress to date. Preliminary formative evaluation results are again very encouraging. A range of similar scenarios can be created, such that the series of
interactions a user might engage in becomes of a drill and practice nature. Drill and practice may be unlikely to
generate a deep understanding of the relevant concepts, but may at least enable the associating of, for example,
expressions with emotions, which may be very helpful: "[people with autism] will not ... directly perceive
someone's joy or despair, although they can come to 'work out' how certain facial expressions and behaviours
are associated with certain given labels such as 'sad' or 'happy'" (Powell and Jordan 1997).

Rigidity of Thought

This impairment can generate a number of learning difficulties. Many of these may be amenable to assistance
from multimedia systems. The problem of lack of imagination (Green 1990) and lack of creativity and
spontaneity (Jordan 1993) may be helped by simulation, by the interactivity and animation of multimedia as
opposed to paper based material and by being able to create one's own multimedia. One approach to the
difficulty of restricted play is to encourage role-play (Jordan 1993), and multimedia simulations may help here.
"Difficulties in sequencing a prediction" (Simmonds 1993) can be helped by multimedia simulations, for
example the sequences in a plant's life cycle may be understood more readily if speeded up in a simulation. The
adverse affect of rigidity of thought on problem solving (Simmonds 1993) can be addressed by the sort of
problem driven interaction to which CAL is well suited.

The autistic tendency to "tunnel vision" (Jordan 1993) and difficulties with enquiry (Simmonds 1993) may be
helped by hypermedia systems. A student with autism may have a major interest in a narrow topic area, such as
deltic trains (Attwood 1998). A hypermedia page about deltic trains could have links from the initial page to
(say) the workings of a diesel engine, and from there into topics from general physics. The student may
therefore be encouraged to take a wider perspective.

A further problem caused by rigidity of thought is "difficulties in accepting the essentially open-minded attitude
that is a feature of scientific enquiry" (Jordan 1992b). Clearly it is essential, with students with autism and
indeed all students, to seek to produce individuals who can think for themselves. Computer programs have been
developed to help teach critical thinking skills (Jordan and Powell 1990) and our current research in multimedia-
based argumentation systems (Moore 2000) may have a role to play here.

Multimedia to Address the "Other Minds Deficiency"

It has been postulated that people with autism have a cognitive deficit in the development of a "theory of mind"
(Swettenham 1996). People with autism, it is held, do not understand mental states and cannot ascribe them
either to themselves or to others. They do not understand what people are thinking or feeling or even that people
are thinking and feeling (Jordan 1993).

Again, multimedia is a potentially powerful teaching medium. Simulations involving predicting people's
emotions in and reactions to different situations can be developed. People with autism may for example hit
other people without realising it hurts, may stare at people without realising it may make them uncomfortable
(Carlton 1993), and such scenarios can readily be modelled in interactive multimedia. One of our current
prototypes, for example, plays a number of videos of youngsters interacting in different ways, e.g. stealing
sweets from each other or helping each other out. It then asks the user to suggest how the participants in the
video might be feeling; this is a preliminary attempt at using multimedia to address the concern of a possible
lack of empathy. Tantam (1993) argues that people with autism, "like people who are not autistic, modify their
behaviour according to its predicted result" and the use of such simulations may help increase the accuracy of
the predictions.

A different but related approach, is to use "bubble dialogues" (O'Neill and McMahon 1991). The essential idea
here is that dialogue participants are provided with an on-screen character, in strip cartoon format, together with a
"say bubble" and "thought bubble" for their character. Participants participate in dialogue by typing their
contributions into the say bubble, and their private reflections into the thought bubble. In all this the aim is to
courage ascription to others of thoughts, emotions, motives and intentionality, in line with claims that, for
example, pupils with autism need to be “specifically taught that others have points of view” (Jordan 1991). The ability of students with autism to understand thought bubbles is controversial, but Parsons and Mitchell (1999) argue that “at least some children with autism are capable of understanding thought bubbles as a representational device”. Further, there is some evidence of the successful use of bubble dialogues with children with autism (McMahon 1999, Rajendran and Mitchell 2000).

Summary and Further Work

This paper has given a brief overview of our on-going research and development work concerning multimedia for students with autism. Many important research issues are raised and are being investigated (cf. Moore et al 2000). Chief among these are how best, if at all, to utilise the apparent attraction of computer games, ways of catering for student differences and deciding a suitable evaluative regime. A particular concern, perhaps, is the danger than computer-based work may itself become a dominant interest of the user with autism and thus fail to ease, or perhaps even exacerbate, the autistic condition. The answer to this, we argue, lies in the successful integration of computer-based work with other aspects of educational provision. How best to manage this integration is an important research question.

Much remains to be done, therefore, but the potential benefits are great. Murray (1997) argues, concerning the education of students with autism, that “the auto didactic possibilities are endless”. The hope is that the research discussed in this paper will contribute in some measure to the achievement of these possibilities.

Abstract: The goal of this study is to test the hypothesis that animated pedagogical agents can promote constructivist learning in a discovery-based learning environment. We do this by first, comparing the learning outcomes of students who learn in the context of social interaction with a computer-mediated character with the learning outcomes of students who learn in a computer text context. Second, we focus on the relative contributions of pedagogical agents' image, voice, and language style in promoting deeper learning.

The Case for Software Pedagogical Agents

Discovery-based learning environments are intended to facilitate constructivist learning through creative problem-solving experiences. However, the characteristics of discovery-based environments which offer the greatest potential for fostering learning also pose the greatest challenge: the complexity of the learning experience, based on the learner's freedom to explore and design artifacts in microworlds, constantly threatens to overwhelm learners. To combat this complexity, discovery-based learning environments should provide scaffolding in the form of highly contextualized problem-solving advice that is customized to each learner. Perhaps the most intriguing vehicle for providing such dynamically individualized scaffolding is the emerging technology of animated pedagogical agents—lifelike on-screen characters who provide contextualized advice and feedback throughout a learning episode (Lester & Stone 1997, Lester et al. 1997).

A Life-Like Pedagogical Agent Example

The discovery-based learning environment used in this study is a microworld called "Design-A-Plant", developed by the Multimedia Laboratory at the Department of Computer Science of North Carolina State University (Lester & Stone 1997, Lester et al. 1997). In this program, the student travels to an alien planet that has certain environmental conditions (e.g., low rainfall, light sunlight) and must design a plant that would flourish there (e.g., including designing the characteristics of the leaves, stem, and roots). It includes an animated pedagogic agent called Herman—a lovable alien with appealing facial expressions, human-like movements, and an amusing voice, who offers individualized advice concerning the relation between plant features and environmental features, encouragement when students encounter difficulties, and feedback on the choices that students make in the process of designing plants. Herman's actions are dynamically selected and assembled by a behavior sequencing engine that guides the presentation of problem-solving advice to learners, as described more fully in Lester et al. (1997). The program starts with Herman introducing the student to the first set of environmental conditions. Then, he asks the student to choose the appropriate root from the library of roots' names and graphics shown on the computer screen. After the student had chosen a root, Herman gives two explanations: first, a narrated explanation, and second a QuickTime movie that contains a similar explanation for the correct root. The same procedure applies to the stem
and leaves, with Herman first asking the student to make a choice, and giving the student feedback afterwards. Once the student was given the last explanation on the leaves for each environment, he is taken to the next environment. The same procedure follows for the rest of the environments.

**Issue 1: Agent versus Text-Based Environments**

Does learning with an animated pedagogical agent in a discovery environment promote constructivist learning? In order to help answer this question, we conducted a preliminary study where the learning outcomes of students who learned about environmental science in the Design-A-Plant microworld (personal agent or PA group) was compared with the learning outcomes of students who received the identical verbal and visual materials in a computer-based text environment (no personal agent or no-PA group).

**Method and Results**

The participants were 44 college students from the Psychology Subject Pool at the University of California, Santa Barbara. Twenty-four participants served in the no-PA group and twenty participants served in the PA group. The computerized materials consisted of two multimedia computer programs on how to design a plant. The PA version was the original multimedia program called "Design-a-Plant", where students see a library of plant parts, pick the plant part that they consider appropriate for the respective environment, and receive spoken feedback in a conversational style from the agent (Lester & Stone 1997, Lester et al. 1997). The no-PA version was presented with the same library plant parts and explanations than the PA version, but Herman's image was deleted. In addition, students in the no-PA version were not allowed to design the plant before reading the verbal explanations, but rather received the explanation directly in a monologue style, similar to when science material is read from a text book.

The participants were randomly assigned to a treatment group and seated at an individual cubicle in front of a computer. First, students were given a questionnaire, which solicited participant's demographic information. Second, the respective version of the multimedia program was presented. After the respective program was over, participants were tested on three important measures of learning: retention--in which we assessed memory for the basic factual information that was presented; problem-solving transfer--in which we asked students to solve new problems based on the principles learned in the respective program; and motivation and interest--in which we asked students to rate their level of motivation, interest, understanding, and the perceived difficulty and friendliness of the lesson. We determined whether the groups differed on measures of retention, transfer, and self-ratings.

Do students who learned interactively with a pedagogical agent show deeper understanding from a multimedia science lesson than students who learned in a conventional environment?

Students in the PA and no-PA groups received identical factual information consisting of the same verbal and visual materials. As a retention test, we simply asked students to name as many types of roots, stems, and leaves as they could--highly relevant information that was prominently displayed in both instructional programs. The mean number of correctly recalled items by the PA group was not significantly different than the mean number of correctly recalled items by the no-PA group. The results suggest that when retention of factual information is the goal of instruction, then environments, which allow for interacting with an animated pedagogical agent are not warranted. Although these results demonstrate that both groups learned the basic factual information, the major prediction in this study is that students in the PA group will learn more deeply than no-PA students. As predicted, students in the PA group produced significantly more correct solutions on transfer problems than students in the no-PA group (p < .005).

The foregoing results are consistent with the idea that students who learn with animated pedagogic agents work harder to make sense of the material than do students who learn in a more conventional text-based environment. Another way to test this idea is to assess students' motivation to continue learning and their interest in the material, so we predicted that the PA group would produce a higher mean program rating than the no-PA group. As predicted, the PA group rated their motivation to continue learning and their interest in the material significantly higher than the no-PA group (p < .01).

**Conclusion**
This preliminary study contributes to multimedia learning theory (Mayer 1997) by comparing the cognitive consequences of students' experience with or without the aid of a pedagogical agent. Students in both groups received identical verbal and visual material presented in the context of social interaction with a computer-mediated character (PA group) or in a non-personalized text context (no-PA group). These findings give preliminary evidence in favor of using pedagogical agents as software mentors, and demonstrate a personal-agent effect in multimedia learning environments: Students are more motivated, interested, and achieve better transfer when the lesson is imparted by a pedagogic agent rather than by on-screen non-personalized text.

How do agents affect student learning? Reeves and Nass (1996) have provided convincing evidence that students view their contact with computer-based characters as social interactions. Congruent with this approach, students' learning with the pedagogical agent could have been promoted by at least three social-cues: the pedagogical agents' image, voice, and personalized language style. Therefore, we investigated first, the role of pedagogical agents' auditory and visual presence in a discovery-based computer lesson. For this purpose, we varied whether the agent's words were presented as speech or on-screen text and whether or not the agent's image appeared on the screen, both with an animated fictional agent (Experiment 1), and a video of a human face (Experiment 2). Second, we investigated the role of the agents' language style in the computer lesson. For this purpose we varied whether or not the agent's words were presented in conversational style (i.e. as dialogue or monologue) both using speech (Experiment 3), and on-screen text (Experiment 4).

Issue 2: The Role of Life-Like Pedagogical Agents' Visual and Auditory Presence

We tested the predictions arising from two opposing hypothesis: the social-cue hypothesis, and the cognitive load hypothesis. According to the former, students communicate better, become more interested, and therefore learn better and rate more favorably computer lessons that include social cues—such as facial expressions or human voices, than those which do not include social cues (Dewey 1913, Rutter 1984). Three predictions can be made for students who learn a multimedia lesson with the image of an agent. First, they will be more likely to remember the materials of the lesson than students who are not provided with the visual presence of the agent; this we call an image effect on retention. Second, they will be more likely to use what they have learned to solve problems than students who are not provided with the visual presence of the agent; this we call an image effect on transfer. Third, they will rate the lesson more favorably as expressed in the program ratings than students who are not provided with the visual presence of the agent; this we call an image effect on program rating.

In contrast, according to a cognitive load of learning (Chandler & Sweller 1991, Moreno & Mayer in press, Sweller 1989), the inclusion of irrelevant adjuncts in a science lesson will divert the limited cognitive resources available for the processing of the relevant materials of the lesson. As a result, learning and problem solving will be impaired.

An additional goal of the present study was to investigate the role of pedagogical agents' auditory presence in a constructivist multimedia lesson. We investigated if prior findings on modality effects in learning—where students learn better from visual and verbal presentations when the verbal information is presented as speech rather than as on-screen text, extend to discovery-based multimedia environments (Mayer & Moreno 1999, Mousavi, Low, & Sweller 1995). Congruent with past research on modality effects in multimedia learning, two predictions can be made. First, students who learn with the voice of an agent will be more likely to remember the materials of the lesson than students who learn the same verbal materials as on-screen text; this we call a modality effect on retention. Second, students who learn with the voice of an agent will be more likely to use what they have learned to solve problems than students who learn the same verbal materials as on-screen text; this we call a modality effect on transfer. An additional prediction was made based on the social-cue hypothesis (Dewey 1913). Students who learn with the voice of an agent will be more motivated and will rate the lesson more favorably than students who learn the same verbal materials as on-screen text; this we call a modality effect on program rating.

Method and Results

In the first study, 17 students learned by interacting with the image of a life-like fictional agent who spoke to them (Group IN), 16 students learned by interacting without the image of an agent who spoke to them (Group -IN); 15 students learned by interacting with the image of a life-like fictional agent who gave explanations as on-screen text (Group IT); and 16 students learned by interacting without the image of an agent who gave explanations as on-screen text (Group -IT). The second study was identical but the video and voice of a human agent replaced the fictional agent. Nineteen students participated in the IN group, 20 students participated in the -IN group, 19...
students participated in the IT group, and 21 students participated in the -IT group. The procedure was identical to that of the preliminary study.

Do students who are presented with the image of a pedagogical agent show deeper understanding from a multimedia science lesson than students who are not presented with the image?

The findings from Experiments 1 and 2 did not provide evidence in favor or against presenting students with the image of a pedagogical agent, failing to confirm what we have called an image effect in program ratings, recall, and transfer: Students who are presented with the image of an agent do not rate the lesson more favorable, recall more, or are better able to use what they have learned to solve problems than students who are not presented with the visual presence of the agent.

Do students who communicate with a pedagogical agent via speech show deeper understanding from a multimedia science lesson than students who communicate with a pedagogical agent via on-screen text?

The findings from Experiments 1 and 2 gave evidence in favor of students' communicating with a pedagogical agent by means of speech by demonstrating what we have called a modality effect in program ratings, recall, and transfer: Students who learn with the voice of an agent rate the lesson more favorably, recall more, and are better able to use what they have learned to solve problems than students who learn the same verbal materials as on-screen text. In both experiments, the mean program ratings for the narration groups was significantly higher than the mean program ratings for the text groups (p < 0.05 for both experiments); the narration groups recalled significantly more than the text groups (p < .005 and p < 0.005 for Experiments 1 and 2, respectively); and the narration groups gave significantly more correct answers in the transfer tests than the text groups (p < .0005 and p = .0001 for Experiments 1 and 2, respectively). These results extend the modality effect in learning from visual and verbal materials to discovery-based multimedia environments and confirm the social-cue prediction according to which students are more motivated and interested in programs, which communicate via speech.

Issue 3: The Role of Life-Like Pedagogical Agents' Language Style

Regarding the language style used by the pedagogical agent, we tested the opposing predictions from the transmission hypothesis and the conversational hypothesis. According to the former, human communication involves encoding an idea into a signal by a sender, transmitting the signal to the receiver, and decoding the signal by the receiver (Reddy 1979). Consequently, as the content material is identical when the language style is changed from a dialogue style to a monologue style, it should not affect students' learning. In contrast, the conversational hypothesis views communication as inherently cooperative and claims that a uni-directional model of communication such as the one supported by the transmission hypothesis, fails to capture the social and individual processes involved in knowledge construction through conversations (Brennan 1990). This hypothesis predicts that students will learn deeper from instructional conversations rather than from non-personalized monologue-style communications.

Method and Results

In the third study, 18 students learned with a personalized conversation spoken by the human agent used in Experiments 1 and 2, (Group P) and 21 students learned with a non-personalized monologue spoken by the same human agent (Group NP). For the fourth study, 21 students learned with a personalized conversation displayed as text (Group P) and 21 students learned with a non-personalized monologue displayed as text (Group NP). In both studies the image of the agent was not presented. The procedure was identical to that of the prior studies.

Do students who communicate with a pedagogical agent via a personalized dialogue show deeper understanding from a multimedia science lesson than students who communicate with a pedagogical agent via an non-personalized monologue?

The findings from Experiments 3 and 4 gave evidence in favor of students' communicating with a pedagogical agent by means of a personalized conversation by demonstrating what we have called a dialogue effect in recall and transfer: Students who learn by communicating with a pedagogic agent via a personalized dialogue recall more and
are better able to use what they have learned to solve problems than students who communicate via a non-personalized monologue. The mean number of ideas recalled for dialogue groups was significantly larger than for monologue groups (p < .005 and p < .05 for Experiments 3 and 4, respectively) and the mean number of correct answers in the transfer test was significantly larger for the dialogue groups than for the monologue groups (p < .0001 for both experiments). In addition, Experiment 4 demonstrated a dialogue effect for program ratings. Students who learned by reading dialogue-style text rated more favorably the lesson than students who learned by reading monologue-style text (p = 0.05).

**General Discussion**

The reported results have important theoretical and practical implications.

First, the modality effect found in Experiments 1 and 2 might be explained as a combination of the superiority in recall when words are processed auditorily rather than visually (Penney 1989), the relatively effortless maintenance of the auditory input in comparison to the visual input provided by text (Anderson & Craik 1974), and the extra emotional cues, which voices carry and text lacks. According to communications research, voices are powerful indicators of social presence and its incorporation in the interaction might promote richer processing by the incorporation of the additional attitudes and beliefs that are attached to the agent (Reeves & Nass 1996). These findings extend pioneering demonstrations of modality effects in learning from visual and verbal materials (Mayer & Moreno 1998, Moreno & Mayer 1999, Mousavi, Low, & Sweller 1995) in three ways: (a) by examining a modality effect in an interactive constructivist computer-based multimedia environment rather than a paper-based or non-interactive computer environment, (b) by employing multiple dependent measures including students' rating of the learning materials, and (c) by using fictional and non-fictional pedagogic agents to deliver the verbal materials of the lesson. The finding that students rated the computer program more favorably when it communicates via speech rather than via text is congruent with the social-cue hypothesis according to which the agents' voice may help students feel an emotional connection with the agent therefore promoting interest in the learning task which in turn fosters constructivist learning.

Second, the failure to find an image effect in Experiments 1 and 2 does not support the social cue hypothesis or the cognitive load hypothesis. Several interpretations for this finding can be offered. First, the lack of image effects might have relied on the strength of the auditory cues given by the voice of the agents which in both applications was extremely expressive and clear. When a voice carries these qualities, it is less likely that facial expressions or lip movements will provide extra information, or help disambiguate the message in the lesson. An alternative explanation may reside on the specific content of the computer lesson: The scientific nature of the lesson used in the reported studies is not essentially emotional and facial expressions may not offer any informational advantage.

Cognitive load predicted that the introduction of the agent's image in the computer lesson would be detrimental to students' learning. This prediction was not confirmed. However, in our studies, the agent's image was never presented simultaneously with other visual materials of the lesson. According to cognitive load theory, a detrimental effect in learning occurs in the cases that students need to split their attention between mutually referring materials. Therefore, it is more likely that if the multimedia lesson contained animations of the agent presented simultaneously with graphics or text, his visual presence would have been detrimental rather than neutral to learning (Mayer & Moreno 1998, Moreno & Mayer 1999, Sweller 1989).

The dialogue effects on retention and transfer found in Experiments 3 and 4 support the conversational hypothesis. We attribute these effects to a combination of less cognitive effort and more active processing. First, it might be argued that students who listen to non-personalized explanations need to work harder than students who listen to personalized explanations because they need to map the agent's generalized explanations to their specific choices in the computer lesson. Second, conversations might act as attention enhancers and produce more active processing of the materials (Reeves & Nass 1996) by creating a state of vigilance in which the participant might be asked to intervene in the dialogue at any time.

It is tempting to conclude that the personal agent effect found in our preliminary study resided in the effectiveness of teaching via instructional conversations (Tharp & Gallimore 1991). However, our focus in the present study was solely on the role that the agent's social cues may have in a multimedia constructivist environment. Although speech and language style proved to help students understanding, other factors, such as students' interaction with the computer program, might play an important role in learning as well. More research is needed to determine the contribution of alternative interactive designs in promoting deep learning from constructivist environments.
The most direct practical implication of our studies is that in a constructivist science lesson where students learn with the help of a pedagogical agent, technological advances in education should focus on extending the capabilities of speech recognition and natural language systems to facilitate instructional conversations. Moreover, the reported findings suggest that an agent interface metaphor might already be present once students interact with a computer, and trying to make it more visually apparent, may not necessarily lead to better results.

Abstract: How can we help students understand scientific systems? One promising approach involves multimedia presentations of explanations in visual and verbal formats, such as presenting a computer-generated animation synchronized with narration or on-screen text. In this paper, we present a cognitive theory of multimedia learning from which principles of instructional design are derived and tested. The split-attention principle states that learning is impaired when the presentation requires the learner to mentally integrate disparate sources of information before the instructional material can be rendered intelligible. The spatial contiguity principle states that it is better to present words and graphics integrated rather than physically separated. The temporal contiguity principle states that students learn better when corresponding words and pictures are presented simultaneously rather than successively. The modality principle states that it is better to present words auditorily as narration than visually as on-screen text. The coherence principle states that adding sufficient amounts of entertaining but irrelevant words or sounds to a multimedia instructional message is detrimental to student learning.

Designing a Multimedia Explanation

Humans can integrate information from different sensory modalities into one meaningful experience--such as when they associate the sound of thunder to the visual image of lightning in the sky. They can also integrate information from different modes (verbal or non-verbal) into a mental model--such as when they watch lightning in the sky and listen to an explanation of the event. Therefore, when the process of lightning formation is to be taught with a multimedia explanation, the instructional designer is faced with the need to choose between several combinations of modes and modalities to promote meaningful learning (Mayer & Moreno, 1998). Should the explanation be given auditorily in the form of speech, visually in the form of text, or both? Would entertaining adjuncts in the form of words, environmental sounds, or music help students' learning? Should the visual and auditory materials be presented simultaneously or sequentially? To help answer these questions, we conducted a series of studies where the learning outcomes of students who viewed alternative presentation formats were compared. In particular, we concentrated on three learning measures: retention of the steps in the cause-and-effect chain (retention test), matching of the pictures and names of parts (matching test), and using what they have learned to solve problems (transfer test). By beginning with a cognitive theory of how learners process multimedia information, we have been able to conduct focused research, which has yielded some preliminary principles of instructional design for multimedia explanations.

A Cognitive Theory of Multimedia Learning
Our cognitive theory of multimedia learning draws on dual coding theory, cognitive load theory, and constructivist learning theory. It is based on the following assumptions: (a) working memory includes an auditory working memory and a visual working memory, analogous to the phonological loop and visuo-spatial sketch pad, respectively, in Baddeley's (1986) theory of working memory; (b) each working memory store has a limited capacity, consistent with Sweller's (1988, 1994; Chandler & Sweller, 1992) cognitive load theory; (c) meaningful learning occurs when a learner retains relevant information in each store, organizes the information in each store into a coherent representation, and makes connections between corresponding representations in each store, analogous to the cognitive processes of selecting, organizing, and integrating in Mayer's generative theory of multimedia learning (Mayer, 1997); and (d) connections can be made only if corresponding pictorial and verbal information is in working memory at the same time, corresponding to referential connections in Paivio's (1986) dual-coding theory.

The Split-Attention Principle

How should verbal information be presented to students to enhance learning from animations: auditorily as speech or visually as on-screen text? In order to answer this question, Mayer and Moreno (1998) asked students to view an animation depicting the process of lightning either along with concurrent narration (Group AN) or along with concurrent on-screen text (Group AT).

According to the cognitive theory of multimedia learning, in the AN treatment, students represent the animation in visual working memory and represent the corresponding narration in auditory working memory. Because they can hold corresponding pictorial and verbal representations in working memory at the same time, students in group AN are better able to build referential connections between them. In the AT treatment, students try to represent both the animation and the on-screen text in visual working memory. Although some of the visually-represented text eventually may be translated into an acoustic modality for auditory working memory, visual working memory is likely to become overloaded. If students pay full attention to on-line text they may miss some of the crucial images in the animation, but if they pay full attention to the animation they may miss some of the on-line text. Because they may not be able to hold corresponding pictorial and verbal representations in working memory at the same time, students in group AT are less able to build connections between these representations. Therefore, our theory predicts that students in group AT perform more poorly than students in group AN on the retention, matching, and transfer tests.

Method and Results

The participants were 78 college students who lacked knowledge of meteorology. They first viewed the animation with either concurrent narration in a male voice describing 8 major steps in lightning formation (Group AN) or concurrent on-screen text involving the same words and presentation timing (Group AT). Then, all students took the retention, transfer and matching tests.

Group AN recalled significantly (p < .001) more, correctly matched significantly (p < .01) more elements on diagrams, and generated significantly (p < .001) more correct solutions than Group AT. These results are consistent with the predictions of the cognitive theory of multimedia learning and allow us to infer the first instructional design principle, called the split-attention principle by the cognitive load theory (Chandler & Sweller, 1992; Mousavi, Low, & Sweller, 1995).

Split-Attention Principle

Students learn better when the instructional material does not require them to split their attention between multiple sources of mutually referring information.

The Modality Principle

Why do students learn better when verbal information is presented auditorily as speech rather than visually as on-screen text? Mayer and Moreno’s (1998) study showed that students who learn with concurrent narration and animations outperform those who learn with concurrent on-screen text and animations. However, concurrent
multimedia presentations, force the text groups to hold material from one source of information (verbal or non-verbal) in working memory before attending to the other source. Therefore, the narration group might have had the advantage of being able to attend to both sources simultaneously, and the superior performance might disappear by using sequential multimedia presentations, where verbal and non-verbal materials are presented one after the other. The next logical step was to test if the advantage of narration over on-screen text resides in a modality principle (Moreno & Mayer, 1999, Experiment 2). If this is the case, then the advantage for auditory-visual presentations should not disappear when they are made sequential.

**Method and Results**

The participants were 137 college students who lacked knowledge of meteorology. They first viewed the animation in one of the following six conditions: one group of students viewed concurrently on-screen text while viewing the animation (TT), a second group of students listened concurrently to a narration while viewing the animation (NN), a third group of students listened to a narration preceding the corresponding portion of the animation (NA), a fourth group listened to the narration following the animation (AN), a fifth group read the on-screen text preceding the animation (TA), and the sixth group read the on-screen text following the animation (AT). After viewing the animation, students took the retention, transfer, and matching tests.

The text groups (TT, AT, and TA) scored significantly lower than the narration groups (NN, AN, and NA) in verbal recall (p < .001), problem solving transfer (p < .001), and matching (p < .005). These results reflect a modality effect. Within each modality group, only the simultaneous and sequential text showed a significant difference in their performance for matching tests (p < .05), with the sequential text groups outperforming the simultaneous text group. This finding might be interpreted as another example of the split-attention effect, where presenting two competing visual materials simultaneously has negative effects on the matching of verbal and visual materials in a multimedia lesson. The results from this study are consistent with prior studies on text and diagrams (Mousavi, Low, & Sweller, 1995), and allow us to infer a second instructional design principle—the Modality Principle.

**Modality Principle**

Students learn better when the verbal information is presented auditorily as speech rather than visually as on-screen text both for concurrent and sequential presentations.

**The Spatial Contiguity Principle**

How does the physical integration of on-screen text and visual materials affect students' learning? Mayer and Moreno's study on split-attention (1998) showed that students who learn with concurrent narration and animations outperform those who learn with concurrent on-screen text and animations. One interpretation for this result is that students might be missing part of the visual information while they are reading the on-screen text (or vice versa). In a review of ten studies concerning whether multimedia instruction is effective, Mayer (1997) concluded that there was a consistent evidence for what was called a spatial-contiguity effect. Students generated a median of over 50% more creative solutions to transfer problems when verbal and visual explanations were integrated than when they were separated (Mayer, 1997). In order to extend these studies to multimedia learning with animations, we conducted a study where the physical proximity of the on-screen text and the animation was manipulated (Moreno & Mayer, 1999, Experiment 1). One group of students had on-screen text that was integrated or physically close to the animation (IT group) while a second group of students had on-screen text that was separated or physically far from the animation (ST group). A third group of students saw a presentation with concurrent animation and narration (N group). This study allows to interpret performance differences between the text groups (IT and ST) in terms of spatial-contiguity and performance difference between the narration (N) and text groups (IT and ST) in terms of modality.

**Method and Results**

The participants were 132 college students who lacked knowledge of meteorology. They first viewed the animation in one of the following three conditions: N, ST or IT. One group of students listened to concurrent narration describing each of the major events in words spoken at a slow rate by a male voice (Group N) and the
other two groups of students learned by reading concurrent on-screen text using the same words and timing as the narration used in the N group. For the separated text version (Group ST), the text was physically far from the animation and for the integrated text version (Group IT), the text was physically close to the relevant part of the animation. After viewing the animation, all students took the retention, transfer and matching tests.

The N group scored significantly higher than the IT and ST groups in the verbal recall, and transfer tests, with the IT group scoring significantly higher than the ST group (p < .001). These results are evidence for both, a modality and a spatial-contiguity effect in recall and transfer. For matching tests, students in group N group scored significantly higher than the IT and ST, which did not differ from each other (p < .05). These results are evidence for a modality effect in matching but not for a spatial-contiguity effect. One possible explanation for not finding a significant difference in the matching scores of the IT and ST groups is a ceiling effect in which all groups did very well on this particular measure. Overall, it is possible to infer a third instructional design principle that extends prior findings on text and diagrams to multimedia learning with animations--the Spatial Contiguity Principle.

Spatial Contiguity Principle

Students learn better when on-screen text and visual materials are physically integrated rather than separated.

The Temporal Contiguity Principle

How synchronized in time do the verbal and visual materials have to be for students to learn better from animations? Congruent with a dual-processing model of working memory, constructivist learning is fostered when the learner is able to hold a visual representation in visual working memory and a corresponding verbal representation in verbal working memory at the same time. The model implicates working memory load as a major impediment to learning. Although all learners may receive identical animation and narration in a multimedia environment, the amount of information that they are forced hold in working memory at one time might affect performance. For example, presenting the whole animation preceded or followed by the whole narration successively (which we will call large bites), can overload working memory such that it is not possible to hold all of the narrative in working memory until the animation is presented (or vice versa). However, if we present one chunk of animation--depicting only a short sequence--preceded or followed by one corresponding chunk of narration and so on (which we will call small bites), and if the size of the chunk does not exceed working memory capacity, then the learner should be able to make connections between the corresponding words and pictures--in the same way as when animation and narration are presented concurrently.

Our prior study (Moreno & Mayer, 1999) failed to find performance differences between the simultaneous and sequential narration groups. Similar results were obtained for learning with geometry examples by simultaneous and sequential explanations (Mousavi, Low & Sweller, 1995). In both cases, the successive presentations of the animation and narration were small bites, only a line or two at a time, and thus unlikely to overload working memory. However, in another set of studies (Mayer & Anderson, 1991, 1992), where large bites of animation and narrations were presented successively, students in the simultaneous conditions outperformed students who learned with sequential presentations. In order to reconcile the above findings, we varied the size of the units that were presented sequentially to the learners (Mayer, Moreno, Boire & Vagge, 1999). One group of students saw a presentation with concurrent animation and narration (concurrent group), a second group of students either viewed the whole animation followed or preceded by the whole explanatory narration (large bites group) and a third group of students either viewed small chunks of animation followed or preceded by small chunks of explanatory narration (small bites group).

Method and Results

The participants were 60 college students who lacked knowledge of meteorology. They first viewed the animation in one of the following conditions: concurrent narration and animation, large bites of narration and animation or small bites of narration and animation. As in our prior studies, after viewing the animation, all students took the retention, transfer and matching tests.

The large bites group scored significantly lower than the concurrent and small bites groups in the verbal recall, matching and transfer tests, (p = .002, p < .0001, and p < .0001, respectively). The concurrent and small bites groups did not differ from each other. These results allow all prior studies in temporal contiguity to be reconciled if
the length of the cycles in the sequential presentations are taken into account. Therefore, a fourth instructional design principle for multimedia learning with animations can be inferred.

Temporal Contiguity Principle

Students learn better when verbal and visual materials are temporally synchronized rather than separated in time.

The Coherence Principle

Would entertaining adjuncts in the form of sounds, or music help students' learning from a multimedia explanation? According to the cognitive theory of multimedia learning, learners process multimedia messages in their visual and auditory channels—both of which are limited in capacity. In the case of a narrated animation, the animation is processed in the visual channel and the narration is processed in the auditory channel. When additional auditory information is presented, it competes with the narration for limited processing capacity in the auditory channel. When processing capacity is used to process the music and sounds, there is less capacity available for paying attention to the narration, organizing it into a coherent cause-and-effect chain, and linking it with the incoming visual information. Based on this theory, we can predict that adding interesting music and sounds to a multimedia presentation will result in poorer performance on tests of retention, matching, and transfer. In short, the cognitive theory of multimedia learning predicts a coherence effect in which adding interesting material—in the form of music and sounds—hurts student learning. In order to test this prediction, Moreno and Mayer (in press) asked students to view an animation depicting the process of lightning either with concurrent narration (Group N), with concurrent narration and environmental sounds (Group NE), with concurrent narration and music (Group NM), or with concurrent narration, environmental sounds and music (Group NEM).

Method and Results

The participants were 75 college students who lacked knowledge of meteorology. They first viewed the animation in one of the four conditions: narration, narration and sounds, narration and music, or narration, sounds and music. After viewing the animation, all students took the retention, transfer and matching tests.

Students scored significantly lower in both retention and transfer tests when music had been presented than when no music had been presented (p < .0001); but there was no significant difference between students who received environmental sounds and those who didn't. There was a significant interaction between music and sounds (p < .05), in which the combination of music and environmental sounds (Group NEM) was particularly detrimental to retention and transfer performance. Supplemental tests indicated that students in Group NEM had retention and transfer scores significantly lower than each of the other groups and that Group NEM had retention and transfer scores significantly lower than Groups N and NE, which did not differ from each other. The mean matching scores for the four groups were no significantly different, with no main effect for music, sounds, and no significant interaction between music and environmental sounds.

This pattern obtained for the retention and transfer tests therefore supports the hypothesis derived from the cognitive model of multimedia learning. Adding extraneous auditory material—in the form of music—tended to hurt students' understanding of the lightning process. Adding relevant and coordinated auditory material—in the form of environmental sounds did not hurt students' understanding of the lightning process. Together with the retention results, these findings suggest that auditory overload can be created by adding auditory material that does not contribute to making the lesson intelligible. The results of this auditory overload are that fewer of the relevant words and sounds may enter the learner's cognitive system and fewer cognitive resources can be allocated to building connections among words, images, and sounds. Therefore, A fifth instructional design principle for multimedia learning with animations can be inferred.

Coherence Principle

Students learn better when extraneous material is excluded rather than included in multimedia explanations.
Conclusion

Multimedia explanations allow students to work easily with verbal and non-verbal representations of complex systems. The present review demonstrates that presenting a verbal explanation of how a system works with an animation does not insure that students will understand the explanation unless research-based principles are applied to the design.

The present studies have important theoretical implications. According to a generative theory of multimedia learning (Mayer, 1997), active learning occurs when a learner engages three cognitive processes—selecting relevant words for verbal processing and selecting relevant images for visual processing, organizing words into a coherent verbal model and organizing images into a coherent visual model, integrating corresponding components of the verbal and visual models. To foster the process of selecting, multimedia presentations should not contain too much extraneous information in the form of words or sounds, and should not present . To foster the process of organizing, multimedia presentations should represent the steps in order and with clear signals for both the verbal and visual information. To foster the process of integrating, multimedia presentations should present words and pictures concurrently using modalities that effectively use available visual and auditory working memory resources. The major advance in our research program is to identify techniques for presentation of verbal and visual information that minimizes working memory load and promotes meaningful learning.

Abstract: We present a description of a fully distributed system that can be used to distribute data among any number of authenticated users. The name server is used only for authentication; otherwise the load is evenly distributed. The system has been used to create a distributed repository of programming examples.

0. Introduction

With the increased availability of the Internet, personal computers and fast networks, there are many research efforts directed at various network applications, and in general, distributed software. Another reason for the interest in this research is the growing number of universities, which have built fully computerized campuses. For example, Acadia University, see (MacDougall et al. 1998), has been involved in building such a campus; it provides fast network connections for all students living on the campus as well as electronic classrooms (a setting in which every student and teacher have access to a personal computer, and all the computers are networked allowing for various types of computer-supported interaction, see (Shneiderman et al 1995)). For another example of a computerized campus, see (Holmes 1996). In this paper we tackle the issue of distributing data among a number of networked computers. We consider both, connected and partially connected computers (the latter are mobile computers that can connect to various networks). This type of arrangement is typical for computerized campuses, but also applies to mobile users who travel with their laptops. There are many applications for which one would wish to distribute information, but here we concentrate on a specific case to support an example-driven learning process; namely a distributed repository of programming examples, for instance examples of programs in C or Java. Examples are useful if they can be easily browsed and searched, and various users can share them. When learning programming, examples are particularly useful because in this case one always learns from examples of small programs.

This paper is organized as follows. In the first section, we provide basic concepts of distributed information systems and discuss various models. The second section presents our system, the Distributed Repository of User-Classified Documents, DRUCO; and the final section describes a case study, a repository of programming examples in C.

1. Distributed Information Systems

A distributed information system can be defined as a system where documents containing some information are distributed across multiple machines connected by a network. Therefore, data (or, documents) are accessible as a shared resource, see (Booth 1981). These systems are useful because the collective storage of multiple computers provides a more powerful system. Additionally, with the duplication of resources, the failure of one component does not necessarily imply losing the entire set of data. Thus, distributed systems provide parallelism and fault tolerance, making them potentially much more powerful than their individual components, see (Mullender 1989). In the context of computerized campuses and a wide accessibility of the
Internet, a distributed information system has an additional important task to fulfill; namely to support information sharing. Below, we review various types of information sharing systems.

The most basic thing we want to be able to do is to exchange and share information. From now on, we will assume that the information is stored in a document, which serves as a persistent medium for this information (and therefore, we will use the term "document" interchangeably with the term "information"). A document is not necessarily the same thing as a file; it could be a file, a number of files logically grouped together, or an entry in a database. (Note that this definition of a distributed system is more general than that of a distributed file system, such as Coda, see (Satyanarayanan 1990)). There are three basic considerations when it comes to sharing documents using an information system: operations on the system, security of the system, and the interface to the system. For a system to be useful, it has to provide various operations such as search, browse, compare, export/import from and to the file system, and others. Some systems support only homogenous information, that is force all the users to use the same type of documents. Other systems may support more heterogeneous documents as long as they conform to a certain standard. The system should be secure by allowing each user to specify for every document, who are the users for whom this document is accessible (for example, to view, copy, traverse, etc.). This functionality can be provided by associating with each document the list of users and their passwords; then the user has to be authenticated before they can obtain any information. As an alternative, digital signatures can be used, see (Greenleaf 1997).

The interface to the system determines one of two possible roles the user has to play to obtain documents that belong to other users. These roles roughly correspond to pulling information and pushing information. If a system supports only pulling information, then the user has to play an active role in obtaining required information. A notification system can be added to notify a user for example when new information becomes available (addition notification) or is changed (change notification). An information push system tries to push required information to interested users. These systems may be profile-based, or context- and situation-based; see (Van de Velde at al. 1997). An alternative would be to consider active, autonomous providers, such as software agents, using planning to search for the required information; see (Huhns 1998). A system of intelligent agents, such as Cooperative Information System, CIS, see (Papazoglou 1992) can actively reason about the information it contains and search for these pieces of information by connecting to other systems.

Now, we elaborate on the push and pull models. In order to describe the task of exchanging and sharing information in a pull model, we consider two kinds of applications, here called respectively providers and fetchers. A provider application gives access to available information for authorized users; a fetcher application is designed to fetch or browse information from one or more providers. Typically, a provider is implemented as a server, and a fetcher as a client; for more information about clients and servers, see (Mullender 1989). A single application may be both a provider (server) and a fetcher (client) at the same time. For an application A to communicate with another application B, A has to be able to locate B, using some kind of a naming system. A standard convention used by the Internet, is to use Universal Resource Locators, URLs. When A provides B's URL, the Domain Name Server, DNS finds B's IP address, and now A can use this address to communicate with B. Unfortunately, the above technique does not work if B is currently off-line, or B uses an Internet service Provider, ISP which provides dynamic IP addresses. Therefore, often we assume that there exists additional name server residing at a "well-known" static IP. When the application B goes on-line, it connects to the name server, which at that time retrieves its current IP and associates it with the application's name. When the application A wants to connect to the application B, it does it through the name server, which guarantees that B is on-line and its current IP address is known. (Additionally, the name server can be used to store user names and passwords, and to authenticate users.)

The best known example of the above model is that of a Web server (provider) and a Web browser (fetcher). The user of a browser pulls information provided by the Web server. Recently, Internet Explorer introduced channels, which are lists of web sites that are regularly (with the required frequency) pushed onto the users desktop. However, this is not a real push model; instead it is a "scheduled" pull. As mentioned above, the push model is best implemented using mobile agents (for the description of mobile agents, see (Wong 1999)). The user interested in an operation, such as search, or compare may create an agent to move to various sites and perform this operation on her or his behalf (the agent may perform some action on that site, if allowed, or it may collect the information and carry it to its home site). While it is easy to see how to specify the required information, it is more difficult to decide where the agent should go to perform the required task. Here, there are several possible solutions. First, a solution similar to one described above, i.e. using a central naming server can be used. The server will know of all kinds of information and the corresponding sites. Of course,
instead of using a central server, a distributed naming service such as JNDI can be used. The problem is that all sites associated with a single type of information will have to be homogenous; for example the information about technical reports will have to be provided in a consistent manner. It would be best, if there is a generally accepted standard for specifying data, and for this reason below we briefly describe XML.

An eXtensible Marking Language, XML, see (David 1999), is a meta-language that allows the user to create a specialized language to define a structure of a document. XML has been used in a variety of applications, for example to define Internet Explorer’s channels, see (Microsoft). The main strength of XML is that it provides a domain specific standard, and XML applications support operations such as search, compare and merge. For each XML-generated language there is a Document Type Definition, DTD, which is basically a grammar for this language. Therefore, an XML document can be verified against its DTD. In addition, an XML document can be easily converted to a different XML format, if the conversion is defined by another DTD. XML is accompanied by an eXtensible Style Language, XSL and an eXtensible Link Language, XLL. XSL provides formatting instructions to display an XML document, while XLL supports links that generalize HTML links, to rectify the problem of maintenance of links, and to allow to create links for read-only media. Therefore, these products; XML, XSL and XLL provide three independent ways to collectively define the document’s structure, format and links. In the absence of XML, one may want to use an information system, in which the user explicitly provides her or his own structure of the document. In the following section we describe a specific example of a general distributed information system, based on user-defined classifications. This system is called Distributed Repository of User-Classified Documents, DRUCO.

2. Distributed Repository of User-Classified Documents

Here we consider a system of documents, in which every user can define her or his classifications. Each document may be stored or classified within one or more classifications, and classifications may be nested. Therefore, in a classical file system, classifications resemble folders, or directories, and documents resemble files. The entire system can be seen as a tree; leaves, however, may have more than one father (classification). The user will be able to make a part of its system available to other users; and pull (download) a classification from another user (this classification corresponds to the node of the tree; and the entire subtree rooted at this node may be pulled). Permissions may be set so that only selected users will have access to some documents. In what follows, we will refer to this specific information system as a distributed repository of user-defined classifications, or briefly as a repository.

DRUCO is a system designed to satisfy the above requirements. In this system, a single unit that resembles a file represents each document. DRUCO documents are stored separately from the file system, but they can be easily imported to, and exported from that system. Now, we briefly describe the design and functionality of DRUCO. It is a program that can operate both, in off-line mode or in on-line mode, and in the latter mode as a server, or as a client. All the operations that can be performed in off-line mode can also be performed in on-line mode. Off-line operations facilitate organizing a repository, that is creating new classifications, modifying and deleting existing classifications, importing and exporting, and browsing and viewing documents; see (Fig. 1). In (Fig. 1) the leftmost pane shows the current state of the repository. Folder icons indicate whether or not they are currently folded, or expanded. The middle pane shows the current state of the DownloadSpace; the outermost folder (Shiv) is a placeholder for all the documents that have been pulled. The rightmost pane can be used to show the contents of the selected file. The user can use menus/right button/drag and drop. Also, in off-line mode, the user may specify "permissions", that is give or revoke the right to access documents. Here, a classification is the smallest unit; that is the user can grant permission to one or more users for a specific classification; then, these users can view and possibly pull all documents in this classification. However, whether or not they will be able to view the contents of any nested classifications, depends on their permissions for these classifications. (Below, we describe how the user can get the list of all registered users.) To manage permissions, the user selects the SecurityManagement pane, see (Fig. 2). The UserList pane shows the list of registered users (see (Fig. 2); the user can select folders and documents in the leftmost pane, and use buttons to assign and revoke permissions.
Figure 1: DRUCO in off-line mode.

Figure 2: DRUCO in off-line mode.
To facilitate the location of other users, especially in the presence of users who use dynamic IP addresses, a central name server has been incorporated into DRUCO. An administrator of this name service manages users, that is registers these users, assigns passwords, etc. The name server is running on a computer with a "well-known" static IP address, which is provided in the configuration file read when the user's application starts. The interface to the name server is shown in (Fig. 3).

![DRUCO's name server interface](image)

Figure 3: DRUCO's name server

The administrator manages the name server; that is adds and removes users, and sets their passwords. On-line operations can be divided into two types; interactions with the name server and interactions with other users. In order to interact with the name server, the user has to login to the server, by providing the name and password. Upon the successful login, the name server retrieves the current IP of this user, and saves this information; therefore DRUCO supports users who have dynamic IP addresses, for example those using ISPs. The user may perform the following operations that interact with the name server: change the password, retrieve the list of all registered users, and retrieve the list of all active users (i.e. users who are currently online). The list of active users is used to start an interaction with another user; to connect to another user it is enough to select this user from the active user list. Note that this connection doesn’t require authentication, because both users must be currently connected to the name server, and therefore they have already been authenticated by that server. Also, the name server provides the current, dynamic IP address of all users. The list of all currently active users can be used to select one user and then connect to them. User A, upon connecting to another user B, may browse these classifications for which have been permitted by the user B, and she or he can also download some of these classifications.

DRUCO has been implemented in Java 1.2, see (SUN 1999a), using RMI, see (SUN 1999b).

3. Case Study: Distributed Repository of Programming Examples

Example-based learning, see (Neal 1989) promotes the idea of using numerous examples to help to understand various concepts, and to move these concepts from short-term memory to long term memory. Examples are
useful if they can be easily browsed and searched, and they can be shared by various users. When learning programming, examples are particularly useful because in this case one always learns from examples of small programs. Consider as an example a specific class for teaching programming in the C programming language, taking place in an electronic classroom. Before the beginning of the class, the instructor (provider) makes available examples of programs in C to all students in the classroom. (As an alternative, the instructor may divide students into groups by giving each group a different example.) Now, the students can pull these examples to their computers. They can view these examples, export them to their favorite compiler, modify them by creating new versions, and making these versions available to all students, or specific students. The entire process can result in collaborative development of a useful repository that can be used not only for learning, but also for real every-day programming.

DRUCO is an ideal candidate to implement a shared repository of examples with a hierarchical structure. It has been used to implement DRUCOC - a repository of examples of C.

Acknowledgments

The implementation of DRUCO described in this paper has been completed as a part the Masters thesis written by the second author.

Finding out the intention of a user of Educational Hypermedia

D. J. Mullier, D. J. Hobbs, D. J. Moore
Faculty of Information and Engineering Systems
Leeds Metropolitan University
England
[d.mullier][d.hobbs][d.moore]@lmu.ac.uk

Abstract: Hypermedia has been identified as a promising medium for education. However, it is beset with problems concerning the complexity of navigation and meeting the individual needs of the user. This paper is concerned with a domain-independent metric that can be used to extract information about a user of an educational hypermedia system with a view to tailoring the hypermedia to meet the user's individual needs. The metric attempts to discover a user's information seeking goal when they are using a hypermedia system based upon the patterns they make as they navigate the hypermedia. Discussed within are the types of patterns that a hypermedia navigator may use and how they may be used to infer the user's information seeking goal. Experiments, used to demonstrate the validity of this approach are described and discussed.

Introduction

Leeds Metropolitan University has been investigating the possibility of producing a tutoring system that offers aid to the student whilst allowing reuse over a number of domains. The use of a generic system reduces the amount of information that can be collected about the student for the purpose of providing aid. In an attempt to solve this problem a prototype hypermedia tutoring system, called “Hypernet”, has been developed to explore issues relating to extracting information about the student in an information sparse environment. A potential candidate for a metric in a generic hypermedia environment has is browsing pattern information. The remainder of this paper is concerned with this metric and describes some experiments that were used to support the contention that browsing patterns are of potential use in this area. Hypernet collects other metrics, these are discussed elsewhere (Mullier et al 1998, 1999, Mullier 1999).

Browsing Patterns and Browsing Strategies

Hypermedia browsing strategies, as outlined by Canter et al (1985) and McAleese (1993), and discussed further in Mullier (1999), are characteristic methods for moving through a network of hypermedia nodes. Canter et al and McAleese are referring to browsing strategies since they are referring to a user undertaking a particular information seeking strategy in order to fulfill some information seeking goal. For example, a user searching for a specific piece of information may induce a "seeking" browsing strategy. Therefore the user may "quickly skip from one node to the next, seldom returning to a previously visited node, seldom spending more than a few seconds at each node and ignoring the associative trails that lead off in varying directions" (Canter et al (1985)'s description of scanning). It is the movements that the user makes as they move through the hypermedia that are termed a "browsing pattern", which can be thought of as a physical manifestation of a browsing strategy. It has been argued previously by Canter et al (1985) and Mullier et al (1999) that browsing patterns offer the potential to extract information about the user's information seeking goal. Research at Leeds Metropolitan University has produced a neural network based system that is capable of recognizing browsing patterns and ascribing meaning to them, a description of this system can be found in Mullier et al (1998, 1999) and a thorough discussion in Mullier (1999). The remainder of this paper is concerned with the potential uses of browsing patterns and some experimental evidence to support the contention that they are of use.
Canter et al (1985) and McAleese (1993) have formally identified five browsing strategies.  
1) Scanning - covering a large area without depth.  
2) Browsing - following a path until a goal is achieved.  
3) Searching - striving to find an explicit goal.  
4) Exploring - finding out the extent of the information given.  
5) Wandering - purposeless and unstructured “globe trotting”.

Uses for Browsing Patterns

Canter et al (1985) suggest that browsing patterns represent some “important psychological information about the user”. Since the browsing pattern is a result of the user’s information-seeking goal it may be possible to identify this information-seeking goal from the browsing pattern. The information-seeking goal may then be used to tailor the hypermedia system to aid the user. For example, current web agents use keyword matching to aid a user of the World Wide Web, by offering pages with similar content (keywords) (Armstrong et al 1985). Further, offering web pages of similar content is only useful for certain information-seeking strategies, namely those that involve the location of specific information. However, as Cartledge and Pitkow (1995) point out, keyword matching can not take into account the possible dynamic behaviour of the browser, in terms of the potential for the browser to change their goals and strategy at any instant. Similarly, Armstrong et al (1995) note that their browsing support system “Web Watcher” is restricted to being an adviser only because it “might not perfectly understand the user’s information seeking goal”. Information-seeking strategies, such as general browsing, are not aided, and may be hindered, by keyword matching. The identification of browsing patterns may therefore provide additional information for a web agent (or hypermedia agent) so that keyword matching can be enabled or disabled, as the situation requires.

The Meaning of Browsing Patterns

Once a particular browsing pattern has been identified it is necessary to link the pattern to information that can be used to directly aid the student. It is envisaged that identification of the browsing pattern could be employed to tailor the presentation of information to a user in such a way so as to model their interests more closely. For example, if the student is generally interested in the domain then it may be useful to present them with a selection of different topics from the domain, whereas it would be better to offer more detailed information if they are looking for a specific item of information. The Hypernet system developed at Leeds Metropolitan University to explore issues relating to educational hypermedia (Mullier et al 1998, Mullier 1999) contains a sub-system (the Browsing Pattern Recogniser) which is able to identify browsing patterns. Browsing patterns are then mapped onto a student ability level (obtained by Hypernet is response to a student’s interactions with tutorials) and the task the browsing pattern is employed for (as provided by the Hypernet), by a second sub-system termed the Fuzzy Rule Base (FRB). It is an advantage that Hypernet is a tutoring system, since this enables a dialogue with the student, the results of this dialogue can then be used to ascribe meaning to a browsing pattern. For example, if a novice student uses a particular browsing pattern to solve a particular problem (and the type of student and type of task are known) then it may be that this type of browsing pattern is often used in such a way. Obviously it is not desirable to make such a distinction based upon one example, therefore the Hypernet system has been designed to map general trends from a large number of examples. Hypernet achieves this by using a combination of fuzzy logic and neural networks, this is discussed further in Mullier et al (1998 and 1999) and is discussed in detail in Mullier (1999).

Recognising Browsing Patterns

Canter et al (1985) suggest that browsing patterns are formed from lower level browsing structures (constructs); termed “spikes, “rings”, “paths” and “loops”. These constructs connect together to form higher level browsing patterns (searching, scanning etc.). These browsing patterns may then form part of a user’s overall browsing strategy. This presents a problem for automatic recognition, since it is not readily apparent where one construct ends and another construct begins. It could also be argued that constructs merge into each other. For example, a large loop can also be thought of as a path, until the point where it crosses a previously visited node. Further, the diagrammatic representations of browsing patterns are not accurate representations of the actual constructs and browsing patterns. This is because the diagrams are drawn in two-dimensional space, whereas the constructs themselves do not exist in such a space. For example, the ring diagram shows a trail arcing over upon itself until it crosses a
previously crossed node. In reality, it is only because one node has been visited twice that this construct becomes a loop. Although Canter et al (1985) do not note this deficiency in representation explicitly they do provide a mechanism for overcoming the problem. They do not attempt to identify constructs individually, instead they describes a user’s browsing pattern as being comprised of several indices, namely the path, spike, ring and loop indices, identified on figure 1 as Path PQ, Ring RQ, Loop LQ and Spike SQ. However, they admit that their indices present "calculation problems" since indices can overlap and become fuzzy in nature and there is therefore a requirement for "more complex and subtle algorithms". It can be seen then that the low-level browsing constructs merge into one another to form the complex browsing patterns. The task then, is to identify these constructs and relate them to the overall browsing pattern. The browsing pattern may then be used to infer information about the student’s overall browsing strategy.

Automatic recognition of browsing patterns, however, presents several problems and their interpretation several more. Firstly, recognising the high level patterns is made complex because a user may adopt more than one pattern for a particular session and may appear to be utilising different patterns depending upon how many movements are examined (Bates 1989). For example, a student may be involved in an overall “searching” strategy (and thus invoke a searching pattern), i.e. they are looking for a specific piece of information. However, they may become interested in a piece of information that they have discovered whilst engaged upon their “searching”. The student may then make a short deviation from their current “searching” strategy and "browse" around the area that has caught their interest, before returning to their original strategy. How then is this to be interpreted? Are there three distinct strategies? Are there two? Or is this to be interpreted as one complex strategy? If a symbolic artificial intelligence (SAI) approach to pattern recognition were to be employed then the answer to such questions must be decided upon before a student uses the system. For the SAI designer must decide beforehand the construction of every browsing pattern (that is invoked by a particular strategy) that the system must recognise and encode appropriate production rules.

FATHINESS - A route through the nodes that does not visit any node twice

RINGINESS - A route that returns to the start node (can be nested)

LOOPINESS - A ring which contains no other rings

SPIKINESS - A route with a return journey retracing the original path

Figure 1

A further problem is that a student may use a particular strategy at one instant and then swap to another in response to some stimulus from the hypermedia domain itself. The rate of sampling, i.e. how many movements the user makes before the system determines the browsing pattern, can therefore result in the system providing differing results. For example, a user may be involved in an overall browsing strategy that is built up of several smaller browsing strategies, in that the student’s overall information seeking goal may be served by the employment of several distinct strategies. It is difficult to say whether the student has engaged one overall browsing strategy or several strategies. It is therefore difficult to determine exactly what the student is doing at one particular instant in time. The result of these problems is that different results are obtained from a number of recognition methods.

Low-level Constructs to Browsing Pattern

In order to combat the above recognition problems it is necessary to identify high-level browsing patterns since the low-level constructs do not provide enough information about the student, since they are only formed in a relatively short time period and encompass a small amount of the domain (in
comparison to an overall browsing pattern formed by the student to solve a particular information seeking problem). This is possible in Hypernet because it can identify the start of a browsing pattern. The start point can be defined as the point at which time the student leaves a tutorial node, i.e. they have been given a task to complete by the tutoring system. They then engage upon a browsing strategy, which induces a browsing pattern, in order to complete the requirements of the tutorial node. Once they have satisfied the requirements, the browsing pattern has concluded. Once the high-level browsing pattern has been identified, in terms of its start and end points, then the system may process it. It is stressed that Hypernet is a research system and is used here to extract these browsing patterns (and record them) so that they can be used afterwards in other systems (such as the WWW). It is therefore not necessary to always identify the start and end points of a browsing pattern, once Hypernet has recorded a representative sample the start and end points are patterns themselves within the sample. This situation is analogous to recognising the handwriting of an unknown script, in that enough examples should make the script clear. This is similar to the Case-Based Reasoning approach used by Micarelli and Sciarrone (1998) to identify content-based browsing patterns, in that recognition of the current case is based upon similar cases encountered previously. A possible criticism of this approach is that browsing patterns recorded as part of Hypernet may be specific to Hypemet and may not exist in other systems. As McAleese (1993) points out certain browsing strategies are facilitated by certain interface styles (graphical browsers and text-based browsers), it therefore follows that the interface style (in this case Hypernet’s interface) has a direct influence upon the browsing pattern produced by the student’s browsing strategy. However, it is likely to be the case that there is a core of patterns that are common to all styles. The recognition system may therefore record general information as part of Hypernet and may then adapt to individual browsing systems that it may subsequently be employed within.

In order to demonstrate that relationships exist between the browsing patterns made by similar types of user, in terms of interests (information seeking goals) and abilities, several experiments were undertaken. This information is to be collected by Hypernet as it is used over a prolonged period. However, this is a long-term goal of the current research project, in the meantime a smaller scale study was performed. This study is described below.

**Browsing Experiments**

The purpose of the browsing experiments is to establish whether different types of students browse the hypermedia in different ways and whether similar abilities of students show similarities in their browsing behaviour. The experiments have provided some interesting information that warrants further study.

The initial results demonstrate that, for the population of subjects tested, there are distinct differences between expert browsers and novice browsers. Further, results have demonstrated that there are two distinct types of novice students. A novice student may show reticence to move away from the initial node and therefore does not explore the domain. By contrast another type of novice student recklessly moves away from the initial node and become quickly lost.

**Method**

A simplified astronomy domain was dispatched to volunteers contacted via Internet news groups. The domain has a few tens of nodes representing information to varying depths. High-level nodes represent such items as planets and satellites, detailed nodes represent such items as weather systems, plate tectonics and probe missions. Volunteers were required to grade themselves into one of three grades of expertise with the solar systems domain: 1) Expert, 2) Intermediate, 3) Novice. Volunteers who described themselves as experts were obtained from astronomy related news groups on the Internet. Novice were generally the children of the expert volunteers. Intermediate users were people who had a passing knowledge of Astronomy but had not studies it at University.

The prototype system, supplied to the volunteers, recorded all browsing information and stored it on the volunteer's hard drive. The volunteer could then email the browsing data back for examination. Information recorded by the system was a real number value representing whether a node had been previously visited or not. Every time a student moves from one node to another the current node has its "visited value" set to one, whilst all other nodes that have been previously visited have their visited values reduced by a small amount. The actual amount is a function of the number of total nodes in the
domain. This method allows for the representation of all of Canter et al.’s (1985) browsing patterns and provides some measure of temporal information.

Volunteers were given two tasks to accomplish, the first gave them a certain piece of information to find, the level of difficulty being dependent upon their self-perceived ability level. The second task was to browse the hypermedia for as long as they liked. Participants then emailed the results back at their leisure.

Results
The results described below are from a population of 11 volunteers. These were separated into three categories: 6 novices, 2 intermediate and 3 expert.

Results for expert level browsers demonstrated that they tended to use rings and loops with a high degree of pathiness. This is indicative of them being sure of the layout of the domain (since it is organised in a structured manner) and they are only crossing previously visited nodes as a means of getting to their destination, which could be determined because they only spent a second or so at each node on their return journey. The free browsing exercise produced more spikes, although these tended to be more distinct than for the novice levels of browser, in that they were likely to be returning along the same path to get to their next point of interest.

Novice browsers were more complex than expert browsers. They tended to be more chaotic in their behaviour, in that it was more difficult to discern regular patterns, although several distinct patterns did emerge. Novice browsers tended to use spikes much more than expert browsers. These spikes also tended to be short and often centred on a small cluster of nodes. This is indicative of the browser being reluctant to leave an area with which they are familiar. Novice browsers tended not to use loops and rings, suggesting that it is important to have an understanding of the structure of the domain before the browser can return to a previously visited node via a different path. It is also important to note that returning to a previously visited node is easily accomplished by selecting the "back" button (as in most hypermedia systems). This will automatically produce a spike. Hence novice students could return to a known point by the easier option of selecting the back button (and hence producing a spike), whereas intermediate and expert users were more likely to navigate themselves, perhaps via a shorter route which was already known to them.

Novice browsers tended to fall into two categories, the first category are reluctant to leave the area with which they are familiar. The second category tended to be more adventurous and move away quickly from the area. It is not a simple matter to determine which strategy is generally the more productive. The reticent browsers were obviously intent upon the domain and did not want to lose themselves, thus demonstrating their interest. It is possible that the more adventurous browser was just aimlessly wandering (a strategy identified as being undesirable by Canter et al (1995)). It was not possible to determine this with the free browsing task, since if the browser is not tested then it is impossible to determine whether they are involved in their own novel browsing strategy. The given task did however, provide some information with which to make a determination on a particular browsing pattern, in that the student’s success with the task is an indication of the usefulness of their strategy. Results demonstrated that some browsers were indeed wandering, in that they were unable to fulfil the task or took much longer to accomplish it than other browsers of the same level. Obtaining this browsing pattern information whilst the student was using the system may have enabled the presentation of material to aid the student. However, some low-level students that appeared to be adventurous, did accomplish the task and often in times much quicker than reticent browsers. There were not enough examples of each type of novice browser to make a further determination about how these types of pattern differ and may be independently recognised. However, it is likely that there are differences that could be determined, given a larger set of example data. This is a major reason why a mechanism has been developed as part of the current research project to automatically obtain this information.

In summary then, novice browsers tend to use spikes, probably because they are unsure of the structure of the domain and need to use navigational cues. More expert users tend to use rings and loops, probably because they are more certain of the structure of the domain and know which node to return to in order to further their travels. Therefore there may be a strong correlation between spikes and more novice students and rings and more advanced users. Larger path values indicate the more adventurous types of user. However, even this small-scale study demonstrated that all levels of user did exhibit all
of the browsing constructs to some degree, it is therefore not just a matter of relating a particular construct to a particular ability level.

Discussion
The experiments were limited in that they employed a restricted domain of only a few tens of nodes and only a few people were involved. However, the results have demonstrated some interesting relationships between individual browsing constructs and certain ability levels of student. This, along with research conducted by Canter et al. (1985) and Micarelli and Sciarrone (1998), indicates that different types of student may use different browsing patterns and goes some way therefore, towards justifying the use of browsing patterns as a method for extracting information about the users of information resources.

An important outcome of this study was the identification of two types of novice student, namely adventurous and reticent browsers, with the possibility of the adventurous browsers being wanderers or "advanced novices". It should be stressed however, that this was a small study and this result may be unique to the study. It may also be that larger studies reveal more distinctions between people of the same level.

The experiments give some evidence that Canter et al.'s (1985) low-level constructs are utilised to different degrees by different types of student. Expert students tended to use loops and rings with a high degree of pathiness and not to use spikes as much as more novice students. However, it must be remembered that the domain in use was highly structured. It may be that different patterns emerge for different types of domain.

Conclusion
This paper has discussed the patterns made by users of hypermedia systems and means of identifying and utilising them in order to determine information about the student, this information may then be used to aid them use the hypermedia. The browsing experiments suggest that different types of student do use low-level browsing constructs to different degrees and that a method for recognising these patterns is a potentially interesting and useful method for extracting some information about students and users of information structures. Further research is currently investigating a method for collecting browsing data over the World Wide Web, which potentially offers the large amount of browsing data required to make some determination as to what each pattern is used for.

Abstract: The computer program PROSA is an instructional environment for learning legal case solving. PROSA stands for PROblem Situations in Administrative law. PROSA enables the student to engage in legal case solving. PROSA supports, guides and evaluates the student’s activities and outcomes.

The Computer Program PROSA

The computer program PROSA is an instructional environment for learning legal case solving. The instructional environment consists of two horizontal layers and three vertical columns (see Fig. 1).
In the upper layer the stimulus materials to elicit the required performance are presented specified to type of material in the different columns. In the lower layer the learner guidance and response are presented specified to type of support. In PROSA the student is required to engage in legal case solving. Legal case solving is the construction of a legal solution for a specific legal case. In the construction process the legal rules are the legal problem solving tools. To construct a legal solution for a legal case the student has to select legal rules. A distinction is made between legal case solving activities, the process, and the legal solution constructed, the product. Both process and product are assessed in PROSA. PROSA offers two types of support: elaborations and response. An elaboration presents prerequisite knowledge and examples. The student may request an elaboration at any moment in the legal solution construction process. A response is a reaction of PROSA to an activity of the student or to an outcome produced by the student. A legal case solving session in PROSA is described in more detail to see how the instructional environment makes a student perform in legal case solving.

A Legal Case Solving Session in PROSA

The student has to carry out a series of activities to solve a specific legal case. The student has to use the output of the activities to construct the legal solution. There is one series of activities that is classified as the most recommended route. However, there is some variation possible in the sequence of activities. These routes are classified as possible routes. Variations of activities that are not desired are not possible in PROSA. The description of a session in PROSA is based on the most recommended route.

Constructing a Legal Solution

In PROSA legal case solving starts when the student has selected a legal case. The student first has to select a legal case from the set of available legal cases using the menu button legal case. The legal cases in PROSA are arranged to topic. Within each topic the legal cases are arranged to level of difficulty. The selected legal case is presented in the upper layer in the legal case part (e.g. the Alexander Boer case topic: interested party; difficulty level: easy). At the same time the question that belongs to the case is presented in the upper layer in the construct legal solution part (e.g. Is Alexander Boer an interested party according to the General Administrative Law Act? see Fig. 1).

The Process Activities Select and Match
The student now has to construct the legal solution for the legal case presented. This construction process involves using the buttons process and product in the construct legal solution part in the upper layer. The student first has to select the menu button process. The process button shows the two basic legal case solving activities: select and match. The first activity to carry out is select. Being presented with a legal case either a legal rule or a fact from the legal case has to be selected. The option select causes a change in the construct legal solution screen. A distinction is made between select legal rule and select fact. There also appears a specific part in the construct legal solution screen that is titled legal solution. This is where the student has to put the outcomes of the various activities, and so construct the legal solution (see Fig. 1).

Select a Legal Rule

The student now has to select a legal rule by choosing the legal rules button in the legal rules part in the upper layer. This button shows three different source categories of legal rules: statutes, other regulations and precedents. Within the statute option a further classification of statutes is made based on the area of law the statutes belong to. The student selects the option statutes from the legal rules button and then selects the statute that is applicable given the specific legal case and question to be answered (e.g. the General Administrative Law Act). The selected statute is presented in the legal rules part of the screen. Then the student has to select an applicable article (e.g. Interested party means the person whose interest is directly affected by an order).
This article has to be dragged to the construct legal solution part of the screen, in the specific sub part select legal rules. The student can then bring this article to the legal solution (see Fig. 1).

**Match Article Component and Fact**

An article is still too abstract to be matched to a specific case fact. Therefore the student has to decompose the article in its article components (e.g. the person; an order; interest is directly affected). The selection of an article component is followed by the selection of a fact from the legal case that can be related to the article component (e.g. Alexander Boer). Using the match option in the process menu relates the article component to the selected fact (e.g. the person = Alexander Boer). This relation is then automatically placed in the legal solution.

**Answer the Question**

The select activity has to be repeated until there are no statutes, articles, article components and facts left. The match activity has to be repeated until there are no more article components or facts. At that stage the student has to formulate the final answer to the question. She has to select the menu button product and choose the option answer (e.g. A. Boer is not an interested party in the meaning of the GALA) (see Fig. 2). The product button available in the construct legal solution part in the upper layer of the screen offers a set of options. These are: bring to solution, cut, up, down, large screen and answer. The option large screen is offered to enlarge the legal solution part to get a better overview of the legal solution constructed so far.
Elaborations and Response

In the lower layer the support is presented. There are two types of support: elaborations and response. The student may request support at any moment in the legal solution construction process. An example of an elaboration available in the legal case part of the lower layer in the form of a list of domain concepts is presented in Fig. 3. When selecting a particular domain concept, for instance interested party, the background knowledge about the concept and a reference to statutes and articles within statutes are presented. The student can use the assess button in the construct legal solution part in the upper layer to ask for an assessment of her activities (the process) and her legal solution (the product). The process is assessed according to the route followed. The product is assessed on completeness, correct sequence and correct answer. The assessment results, specified to process and product, are presented in the construct legal solution part in the lower layer.
Implementation of the computer program PROSA

The program Authorware is used for implementing the specification of the design of the instructional environment. Authorware is an authoring environment for creating and publishing interactive information and can be used for the construction of interactive learning and training applications. Authorware has many evaluation functions that make it possible to handle all kinds of input. The program Authorware has been chosen for the realization of PROSA on the basis of these specific Authorware aspects: interactivity and evaluation of input. As Authorware is an icon-based authoring tool, a program is made by assembling icons on a flow line. Different types of icons contain different types of objects like text, graphics or a set of instructions and herewith the content of a program. The way in which these icons are arranged on the flow line forms the architecture. In Fig. 4 the top level of the architecture of PROSA is shown. The icons on the main flow line are visible at this level.

Figure 3: presentation of an elaboration
When PROSA is run, Authorware executes the icons from top to bottom along the flow line. The first icon that is executed is the **map icon** 'initialize'. This map icon contains a number of **display icons** that contain the first screen, the so-called startup screen. Furthermore the variables used in PROSA are defined and initialized in a **calculation icon**. These variables are used to keep track of the students’ actions and to store and use general PROSA information like available items for the menu buttons. And finally the ‘initialize’ icon contains **display icons** which contain the standard PROSA screen with the two layers and three parts (see Fig. 1). This ‘initialize’ icon is executed only once per session.

**Perpetual interactions**

The second icon ‘perpetual interactions’ (see Fig. 4) contains two kinds of so called **perpetual interactions**. An interaction is an **interaction icon** with different types of response type symbols attached to it. These response type symbols tell the interaction icon whether to display a button, a menu, a text-field or some other element. An interaction monitors the actions of the student and sends that information to the response type symbols attached to it. If Authorware encounters a perpetual interaction it activates the interaction and immediately continues down the flow line. This is used in PROSA because the student is given personal control in learning to solve legal cases. The first perpetual interaction displays the menu buttons available for the six different parts and defines the reaction of PROSA when the student uses the buttons. The student throughout the whole session of solving a legal case can use these buttons. The second perpetual interaction defines the responses of PROSA to the students activities regarding the construction of a legal solution in the sub parts select rule, select fact and legal solution part in the construct legal solution part of the screen. An example of such a student activity is dragging an article to the ‘select legal rule’ sub part of the construct legal solution part.

**Main loop**

After the perpetual interactions the main loop of the program occurs, the so called **decision icon** ‘legal case’ with **map icons** for every case topic attached to it. Within each case topic map a similar **decision icon** for the different levels of difficulty is used. When Authorware encounters a decision icon it branches to a path according to certain criteria. In PROSA these criteria are the choices the student makes. The student uses the
menu button legal case and the choices she makes are stored in two variables caseTopic and caseDifficultyLevel. On the basis of these variables Authorware first branches to the map icon of the chosen case topic and then to the map icon of the chosen difficulty level. A difficulty level map icon contains (1) display icons which contain the legal case text and the accessory question (2) a calculation icon in which the correct legal solution is stored in a variable (3) an interaction icon to monitor the students activities specific to the chosen case. In the architecture a specific legal case and the accessory question are considered to be the basic element, because it is the current problem to be solved by the student and in this way PROSA is able to give case- and student specific feedback. Also many student characteristics can be recorded per case, like, for instance, the sequence of the students activities in solving the legal case, the legal solution the student constructs and the cases the student selects. These student characteristics are an example of characteristics that are recorded and maintained during all sessions of the student working with PROSA. In this way a student history is built to be able to adapt to the individual students activities and to evaluate the individual student.

Subroutines

The last icon at the top level flow line is the map icon ‘subroutines’ and Authorware never automatically encounters it. This icon contains a number of subroutines implemented as map icons attached to framework icons. These subroutines appear only once in PROSA, but are called many times by various parts of the program. An example of a subroutine is adding a student activity to the list that is used to keep track of the series of activities the student carries out to construct a legal case solution. Because of the way the main loop in PROSA is structured, new legal cases of the existing topics and difficulty levels can be added easily. Furthermore, legal cases of new topics and difficulty levels can be added. For each new case topic and difficulty level a new map icon containing the case specific display, calculation and interaction icons has to be added. The same structure can also easily be used for a different domain if the problems to be solved can be divided in a hierarchy of topics and difficulty levels.

Abstract: In this study, we identify the characteristics of project-based learning activities in an online environment. Based on the data collected from 17 students in a Web-based graduate telecommunications course, we found that the project-based activities were authentic and useful in terms of gaining a variety of skills like group collaboration and communication, facilitation of online activities, and intercultural communication. We describe the strategies used by the instructor and by the student facilitators and participants in project-based learning activities in this online course. We also stress the importance of these kinds of characteristics and strategies of project-based learning activities in terms of course design and implementation.

Introduction

The surge in Web-based and Web-supported courses has prompted course designers and instructors to identify appropriate ways to adapt traditional courses to a Web environment (Khan, 1997). An instructor's typical responsibility is to design, develop, and teach courses and to conduct research. However, in online learning environments, the focus tends to change: the instructor's role shifts from that of the sole dispenser of information to that of facilitator and resource for learning activities (Gunawardena, 1992). The online environment is constructivist in nature, providing an arena for collaborative learning and learner-centered activities. Active construction of meaning (Vygotsky, 1978) about experiences should take place through "experiential exercises followed by interpersonal interaction in small groups, and with facilitators to guide the group towards useful conclusions" (Romiszowski, 1997, p. 33). Project-based learning involves students working collaboratively to solve a problem that results in a product. Project-based learning on the Web presents special challenges and opportunities that groups in conventional settings may not encounter.

This case study describes a Web-based course in instructional telecommunications at Texas A&M University. The following questions guided the inquiry into project-based learning on the Web:

1. What are the characteristics of project-based learning activities that produce the desired learning outcomes in a Web-based course?
2. What are the strategies that the instructor, student facilitators, and student participants use to prepare and conduct project-based learning activities in a Web-based course?

Theoretical Framework

Two theoretical assumptions frame this study about Web-based courses: learner-centered instruction can foster positive learning outcomes, and project-based learning can encourage learner-centered instruction.
Learner-centered instruction. Researchers have described a role change among distance education faculty from the instructor as a content expert to a facilitator of learning and an accompanying shift from teacher-centered to learner-centered instruction (Gunawardena, 1992; Harasim, Hiltz, Teles, & Turoff, 1995). Providing learner-centered instruction requires the instructor to understand the distance learner. In the introduction to her edited book about distance learners in higher education, Gibson (1998) challenges faculty to "do more than provide access to information. We need to truly understand that learner and design learning environments that facilitate learning, environments that enhance access to and success in higher education" (p. viii).

In constructivist learning environments, the instructor provides the overall structure and the parameters for the course. In computer conferencing environments, "course design becomes more important, and preparation entails the structuring of conferences and topics, and the design of activities and small group work" (Romiszowski & Mason, 1996, p. 447). Students in learner-centered settings construct their own learning within the framework of the course in their attempts to make sense of their experiences.

Project-based learning. To meet learners' needs and allow them to profit directly from their learning experience, instructors need to provide authentic activities. Such "coherent, meaningful, and purposeful activities" (Brown, Collins, & Duguid, 1989) are similar to those that Romiszowski (1997) recommends for developing learners' critical thinking skills: small-group discussions, simulation games, project-based work, and collaborative problem-solving activities.

One of these activities, project-based learning, is described as learners working collaboratively over an extended period of time to solve an authentic and challenging problem that results in an end product (Fung, 1996; Moursund, 1998). Project-based activities have explicit educational goals and are typically learner-centered, rooted in constructivism, and facilitated by a teacher who acts as a facilitator. The "rich environments for active learning" in which project-based learning is likely to occur engage learners "in a continuous collaborative process of building and reshaping understanding" (Dunlap & Grabinger, 1996, p. 67). Fung (1996) lists the following advantages of project-based learning—the encouragement of student initiative, self-directedness, inventiveness, and independence.

The literature has identified ideal characteristics and responsibilities of learners and instructors involved in project-based learning. For example, a study of British Open University students participating in project-based learning in a telecommunications environment found that the students were required to have heightened levels of self-confidence, motivation, and the ability to organize their own work plans (Fung, 1996).

The Project

"Applications of Telecommunications in Education" is a Web-based graduate course that focuses on instructional applications of telecommunications; the analysis of characteristics of varied systems, both dedicated and public networks; and the design of appropriate instructional strategies and methods using those systems. The course is designed to help learners apply the latest developments in telecommunications technologies to specific education or training contexts.

The instructor designed the Fall 1999 course for students to engage in constructivist learning through a combination of independent and project-based learning activities. The course materials were available on the Web, and the students used FirstClass™ computer conferencing software to communicate with their classmates and the instructor and to do all of their coursework. The students sent private messages through the FirstClass closed email system and public messages to the conferences, and they used the chat function to hold scheduled and impromptu real-time text-based discussions with their project groups. FirstClass also allowed them to attach files and work together on collaborative documents.

Students had three independent activities in this course. The major independent activity was a "report for action" addressing an educational or training problem that might be solved through the application of telecommunications. Students were also required to keep a telecommunications journal for their reflections on learning and teaching in an online environment. The students' classmates and the instructor could read these "public" journals. Finally, the students completed pre-existing evaluation forms for group presentations, Web sites, formative evaluations, and pre- and post-course surveys.

Two project-based learning activities that took place in small groups—generally three to four students per group—were facilitating the unit activities and developing a Web site. The five two-week units were based on the assigned readings and included discussions, role-play, case-study analysis, Web site evaluations, and panel discussions. The students were told in advance which type of activity would be used for each unit theme. This project was designed to assist students with their individual action reports, to guide them through the content of the course, and to foster skills in communicating effectively with co-facilitators in planning, implementing, and
synthesizing the unit. The other project-based learning activity was creating and publishing a Web site about an issue critical to telecommunications in education. The students selected their topics from a list of options including equity issues, digital libraries, futuristic issues, literacy, and copyright issues and were assigned to those groups on the basis of their common interests. The five critical issues Web sites were designed to be used by future classes as well as by the general public.

**Methods**

This study is an investigation of two project-based learning activities in a graduate level Web-based course. We asked about—(a) the characteristics of project-based learning activities that produce the desired learning outcomes, and (a) the participants' strategies for preparing and conducting the project-based learning activities.

**Participants.** The participants were the 17 students enrolled in the Web-based course in Fall semester 1999. Thirteen of the students were females and only four were males. Ten were master's students primarily in the educational technology program, while the seven doctoral students represented three departments in the College of Education, and one was from Computer Science. The class consisted of an unusually high percentage of international students: nine of the students were from the United States, while the other eight were international students who spoke English as a second language (ESL).

No students had taken a Web-based course before enrolling for this course, though two of the students were taking a second Web-based course simultaneously from the same instructor. The students' previous experience with taking coursework at a distance was limited to two-way interactive videoconference in combination with computer conferencing. Their telecommunications skills were varied: one student used email only rarely prior to the beginning of the course; most were accustomed to using computers and telecommunications in their studies; and a few had jobs that were based on telecommunications.

**Data sources.** The data sources included: (a) students' online communication through FirstClass threaded computer conferencing messages, collaborative documents, and real-time chats; and (b) students' evaluations and assessments, and interviews with the students via FirstClass.

Evaluations and assessments were used prior to beginning the course, during the semester, and at the end of the semester for varied reasons. The pre-course surveys provided participants' background information and their perceived readiness for an online class. During the semester, students assessed their own and their group members' contributions to the two group projects by completing and sending private group evaluation forms directly to the instructor. Formative evaluations took place as a single collaborative document, to which the students contributed anonymously. Beginning in the fifth week of the semester, the instructor asked the students to "assess how things are going" by contributing to the formative evaluation. During the last two weeks of the semester, the instructor asked the students to contribute to another collaborative document "Final Thoughts" to get feedback on the various aspects of the course, including the books, assignments, and the use of FirstClass for communication and the Web for obtaining course information. Students also completed an online course evaluation administered by the university.

The graduate assistant used FirstClass to conduct the interviews. Interviews were open-ended and included questions about students' experiences as facilitators and participants in project groups. The questions aimed to uncover perceptions about the different types of activities.

**Data Collection and Analysis.** The investigation relied on case study methods, which are characterized by rich description of processes (Merriam, 1998). The case study describes the characteristics of problem-based learning activities and the strategies used to prepare and conduct these activities in a Web-based course. We conducted the electronic interviews and downloaded all of the electronic evaluations and assessments from FirstClass conferences and from the Web, copying them into individual files for each data source. We conducted content analyses of the data sources (Krippendorff, 1980). This process consisted of coding the data by categorizing them according to the two research questions, using QSR NUD*IST (Non-numerical Unstructured Data*Indexing Searching and Theorizing) qualitative data analysis software. For each major theme regarding the research questions, we created "nodes" or categories; and for each sub-theme we created "child nodes" or sub-categories. We generated four nodes (i.e., Website Projects, Group Activities, Facilitator Strategies, and Participant Strategies) and 40 child nodes (e.g., Preparation in Advance and Periodic Contact for the node Facilitator Strategies).

We reported on the data using the participants' verbatim accounts. We established the following method to identify messages that are quoted verbatim in the text: the data source and the author of the message (if known). The data sources are: I=Interview, F=Final Thoughts, and S=End of Course Surveys. Each student was assigned a
Results

The results of the two research questions are addressed in this section. These questions are concerned with the characteristics of project-based learning activities that produce the desired learning outcomes, and the participants' strategies for doing project-based learning activities.

1. What are the characteristics of project-based learning activities that produce the desired learning outcomes in a Web-based course?

The intended learning outcomes for project-based learning activities were based on the learning objectives specified at the beginning of the course. The project-based learning objectives were:

- In a small group, create and publish a well-designed research-based Web site that focuses on a critical issue facing telecommunications.
- Demonstrate proficiency in participating in and facilitating online activities and discussions.

We identified four characteristics of project-based learning activities that produce the desired learning outcomes in a Web-based course: (a) authentic activities; (b) collaborative work and communication via telecommunications; (c) opportunities for knowledge enhancement and skill building; and (d), intercultural communication skills.

First, the learning experiences were designed to be authentic, i.e., the students were to engage in actual real-life situations. The students created real Web sites, which were research-based, published on the Web, and used by others to obtain needed information about critical issues in telecommunications. Most students responded that the Web site activity was fairly authentic, although many students "would have liked one less group activity and more time to improve on those completed" (F-anon). The students perceived the unit group activities to be somewhat more authentic, as they planned, implemented, and synthesized the activities related to the assigned readings. One student shared that, to him, authentic "means purpose was generated by the learner and acted upon ... in terms of learner arranged tasks, i believe it was authentic" [I-12]. However, he continued to explain that "to be truly authentic, the students would have had to recognized the problem" [I-12], possibly conveying that the students didn't select their own topics and instead were presented with a list from which to choose. Two students wrote in the final course survey that the course was strengthened by projects that were "meaningful" to them [F-anon].

Second, the project-based learning activities provided opportunities for the students to work as a team, which is an activity encountered frequently in real-life. By participating fully in these activities, the students learned how to work collaboratively in a group and communicate via telecommunications. An ESL student explained how the group projects helped her: "By working with my partners, I improved my language skills, ability of organizing my thinking, and rate of interactions with others, also technological skills for handling online communications" [I-17]. To another ESL student, the projects were "a means of learning how cooperate and exchange ideas, knowledge, materials" [I-8]. The same ESL student continued to explain how the Web site project provided a good opportunity for a "teamwork learning environment":

1) It has several different aspects such as site development, presentation to content selection; 2) Many times group members need to decide things for its group and a compromising decision process happens; 3) Each group member has strengths and weaknesses. When members working together they can learn to improve weakness and creating new ideas with strengths. [I-8]

Third, the activities fostered the development and enhancement of a variety of skills. Some students referred to their learning gains in terms of objectives, while others identified a variety of skills they gained as an outcome of these activities. They referred to having built content knowledge, even becoming an expert, as one student expressed, "at the end, I became an expert in that issue to some extent" [I-8]. They also referred to the dual benefit of applying new content knowledge to Web site creation. One student claimed that "the project was a good one because not only was I learning about the topic, ... but I was also becoming better at making web pages" [I-5]. Similarly, "It not only help me understand the topic itself, I also learn a lot about how to design a web site" [I-4].

Fourth, the activities provided for the development of intercultural communication skills by working in a multicultural environment. The American students developed the skills as "a conscious effort to keep from regressing into Texas slang and colloquialism" [I-12]. Another American student reflected, "I believe that in the planning and implementation of the activities, groups had to be sensitive to the differences among cultures" [I-5]. On the other hand, the ESL students encountered difficulties in online communications, particularly in real-time.
chats, when they "cannot express what [they] really meant and understand what other meant" [I-5]. Still, they reported several benefits of group projects. For example, an ESL student acknowledged, "When we had a chat to discuss our project, my language skill prevented me from exactly expressing my thinking. However, the members in my group encourage me a lot and helped me when I encountered some difficulties" [I-17]. This effort to pay attention was described by an American student who said, "I did realize that my informal writing tends to include many terms people from other countries might not understand - and caught myself many times backspacing and pondering a more understood phrase!" [I-4].

2. What are the strategies that the instructor, student facilitators, and student participants use to prepare and conduct project-based learning activities in a Web-based course?

The instructor, the students as facilitators, and the students as participants used a variety of strategies in preparing and conducting project-based learning activities in the Web-based course.

Before the course began, the instructor, who acted as a facilitator of learning rather than as a content expert, developed the course with project-based learning activities in mind. Preparation for project-based learning involved structuring the conferences and topics, and designing the activities and small group work. The instructor arranged for the students to develop group learning contracts to govern their group behavior. During the semester, the instructor had real-time chats with each group to help plan the unit activities. The instructor also monitored the progress of groups, gave feedback to the groups, and contacted specific individuals and groups as needed.

The co-facilitators scheduled and posted periodic live chats before, during, and after their two-week unit activities. The facilitators saved and posted a total of 17 live chats for the 5 group activities during the semester. One chat strategy was "to wait for other group members who didn't type as fast as I do, or who needed more time to formulate a response" [I-1]. One facilitator gave value to the group learning contracts written at the beginning of the semester, explaining that she needed "to finish all the required reading in time and not break the contract in the group work" [I-14]. The facilitators posted drafts of communications, instruction, and syntheses; and they edited each other's work. They used collaborative documents to develop their plans and create outlines and documents, often taking care to be "very detailed in the writing of the procedures for the activity ... I was forced to look at every detail of the process ... from the perspective of the participants" [I-5]. The same facilitator explained her strategy:

I think as the prepare of the information, it's best come at the information asking "What is that I would hope to get out of this web site?" "How will I provide the content for the audience?" and "What can I do to make it more real to the audience?" "Are there other technologies that can be used?" "Are there other sites I can take them to?" [I-5].

The co-facilitators monitored their activities by replying, weaving responses, and sending private email to individual participants to encourage them to participate by "more than just post[ing] a response" [I-5]. They even covered for each other when co-facilitators had a conflict or problem during the activity.

The students as group project participants deciphered the instruction that the facilitators developed and posted, and they logged in frequently to maintain their participant role. One participant explained, "I tried to check email frequently and respond immediately, whether I knew the answer to the question being asked or not - 'I'll get back to you' is better than not hearing from someone at all" [I-1]. They also assisted other participants by contributing their ideas and editing their work, and they conducted peer reviews of the other groups' work. In the group projects, they recognized the importance of giving "enough time to other participants for conducting learning" [I-2]. They needed this time for preparing to participate in the group activities, as one student described:

As a participant, I have to read and organize the thought in the books, then answer the questions and observe the discussion among all participants and facilitators. The best stance of a participant is always be ready to answer and give feedback, so it is natural that I have to finish all the reading for joining the discussion [I-15].

Educational Significance

Answers to the research questions provide insight for Web-based course designers and instructors as well as students in Web-based courses. Knowing important characteristics of project-based learning activities will assist those who plan to incorporate such activities into the design of a Web-based course. The strategies that the instructor, student facilitators, and student participants used to prepare and conduct project-based learning activities are transferable to other types of activities.

The findings of this study support the developing body of literature on designing for online environments. Researchers posit that there are six design considerations for computer conferencing, two that involve administrative
design considerations--grading system and grouping--and four instructional design considerations--collaboration, relevance, learner control, and technological preparation (Cifuentes, Murphy, Segur, & Kodali, 1997). Based on the data collected from the students in a Web-based graduate telecommunications course, we found that the project-based activities were authentic, or relevant--useful in terms of gaining a variety of skills like group collaboration and communication, facilitation of online activities, and intercultural communication. The students in this study recognized the value of trying to understand each other as they worked toward common goals. For example, one ESL student concluded, "I also listened to the others and saw the difference and similarities among us. Sometimes I needed to compromise with others and sometimes I needed to stick to my opinions. Whatever I did was to show I am a responsible and collaborative person to work with others for the goals of successfully finishing the project" [1-15].

Abstract: For most students inquiry-based learning environments such as problem-based learning (PBL) comprise a major shift away from approaches to learning with which they are most comfortable and familiar. We have been observing PBL students in situ with particular focus on the cognitive processes with which they are having greatest difficulty, the processes that students need help with, and specifically when in the PBL process they require this help. The outcomes of this empirically-based understanding of the cognitive processes with which students have difficulties, is assisting us with the development of cognitive support tools for incorporation into the inquiry-based learning environments.

Research Context and Background

Problem-Based Learning (PBL) which represents a form of inquiry-based learning is being widely adopted as a powerful teaching and learning strategy at all levels of education. Situated in a constructivist paradigm, PBL is a learner-centered pedagogical strategy where the students themselves assume major responsibility for their learning. Generally PBL is divided into several phases spread over periods of small group work and independent study (Barrows & Tamblyn, 1980; Schmidt, 1993). The PBL process begins with an encounter of a problem situation through the use of a case study or incident, which the learners analyze. During this phase learners generate hypotheses about the occurrence of the problem in the case or incident. Based on this exercise learners identify what they already know about the problem and determine what they need to know, and develop plans to research the information. Students then embark on a period of self-directed learning where they research or investigate issues that emerged in the first phase. During the next phase, the findings of individual inquiry are shared with the group, which results in a re-evaluation of the problem and perhaps revision of their first perceptions of the problem. Through this iterative process, students develop the required content knowledge and problem-solving skills. Central to the PBL process are the following cognitive processes: (1) activation of prior knowledge, (2) elaboration of content, (3) restructuring of semantic networks/schemata, (4) development of an intellectual scaffold.

Activation of Prior Knowledge

The first step in PBL involves the presentation of a problem, which the learner relates to his/her prior knowledge. Schmidt (1993) suggests that the extent of prior knowledge about a subject is one of the major determinants of the "nature and amount of new information that can be processed" (p. 424). Ausubel (1968) has suggested that the essential factor in the acquisition of knowledge is that content must be linked to what is previously known. The exchange of ideas between participants of the PBL session, under the guidance of the PBL tutor, assists in activating or mobilizing prior knowledge of students. This has the effect of creating 'learner readiness' for subsequent stages of learning by asking students to generate hypotheses for the problem.

Elaboration
This comprises exploration of alternative interpretations of the problem and an understanding of relationships among concepts. The storage and retrieval of information is said to be enhanced when elaboration of the material takes place (Schmidt, 1993). This elaboration of the content by the student may take the form of listening to other students' hypotheses and determining the merit and worth of these different hypotheses. The cognition involved in evaluating these different perspectives begins the process of elaboration. Use of other learning resources such as journal articles, books, multimedia teaching modules and relevant websites should also help elaborate the student's understanding of the problem.

Restructuring

Depending upon the existing knowledge of the student, a process of accretion, tuning or restructuring occurs to actively change existing schemata. Gagne (1986) defines schemata as "a set of interconnected propositions centering around a general concept, and linked peripherally with other concepts" (p. 8). Schemata are not static but continually evolving in content and structure. When new learning occurs, new schemata develop or old schemata undergo structural changes. When more information is incorporated into an existing data structure, accretion occurs. Tuning refers to the adjustment of existing schemata. The continual tuning or modification in categories of interpretation occurs to bring the categories more in congruence with the functional demands placed on them (Gordon & Rennie, 1987). Restructuring is an important process for changing existing schemata or developing new schemata to interpret new information (Keppell, Elliott & Harris, 1998).

Group discussion is an asset to this process. Brown and Palincsar (1989) assert that change is more likely when individuals are required to explain, elaborate or defend their positions to others as well as to themselves, which gives rise to cognitive conflict in the individual. Cognitive conflict arises when the learner is exposed to disagreement between existing knowledge and new anomalous information. Through observation and explanation, learners can elaborate and integrate knowledge in new ways. Chin and Brewer (1993) attribute conceptual change to the following: status of the anomalous data in the perception of the students; characteristics of prior knowledge; learner's perception of the credibility and validity of the new information; and processing strategies. Problem-based learning attempts to create and induce cognitive conflict within learners with the aim of bringing about conceptual change. This conflict may emanate from a disagreement or mismatch between existing knowledge of learners and the knowledge that is generated from the problem situation. In fact this is an axiom of PBL. Typically, alternative explanations are not provided by tutors but are constructed in small group discussions, based on a combination and evaluation of the knowledge of all group members and verified later on, during self study.

Scaffolding

In the process of PBL the student will develop a framework for use with subsequent clinical problems. Ausubel (1960) referred to this framework as an "intellectual scaffold". Intellectual scaffolding is an infrastructure of information to which new material can be anchored (Ausubel, 1960). "By beginning a task embedded in a familiar activity, it demonstrates to students the legitimacy of their implicit knowledge and its availability as scaffolding in apparently unfamiliar tasks" (Brown, Collins and Duguid, 1989, p. 38).

Challenges and Constraints

While PBL has substantial advantages for teaching and learning in practice-based professions (Barrows & Tamblyn, 1980; Barrows, 1994; Koschmann, Kelson, Feltovich, & Barrows, 1996), for most educators PBL comprises a significant shift away from approaches to teaching with which they are most comfortable and familiar. For most students, at least in the beginning stages, PBL is somewhat disorienting. So for all its promise, problem based learning poses a number of challenges for both teachers and students alike. A major barrier to the success of PBL is students' initial discomfort with the increased degree of freedom they experience in a PBL environment. Students have generally been enculturated into a model of schooling in which their role is more or less limited to comprehension and synthesis of instructor-specified information, based on instructor-formulated learning objectives, and participation in instructor-led learning activities. Many students often lack the skills even to know where to
begin when confronted with ill-defined, real-world problems, let alone manage the complex cognitive processes that are part of PBL.

Aims

The aims of this research program have been to observe PBL students in situ. The focus of this observation has been the above-mentioned cognitive processes associated with PBL: (1) activation of prior knowledge, (2) elaboration of content, (3) restructuring of semantic networks/schemata, (4) development of an intellectual scaffold.

- Our goal has been to pinpoint the cognitive processes and/or components of these processes with which students have been having difficulties.
- We expect to be able to identify the cognitive processes that students need help with, as well as specifically when in the PBL process they require this help.

Significance of this Research

The use of PBL as an instructional method reflects the rise of teaching and learning programs, which encourage students to take responsibility for their own learning. Such programs commonly present students with an ill-structured subject area and require them to conduct their own inquiry which involves formulating hypotheses, developing questions, gathering and interpreting data, and communicating their findings to peers and tutors (Schank, 1997; Glasersfeld, 1987; Brown, Collins, & Duguid, 1989; Linn, Songer, & Eylon, 1996). Our work seeks to understand the challenges and constraints of these processes so that as educators, we are better prepared to help students achieve the desired learning outcomes. Results from this study should highlight the phases of PBL and the cognitive processes with which students are having real difficulty. These results are being used to develop software-based support tools to help students with their learning. By focussing on cognitive processes with which students are experiencing difficulties, such tools have the advantage of being tailored to the specific learning needs of students. The immediate benefits of this work accrue to students and educators associated with the course principally being investigated. However, we believe that our work has significance for any course which supports student-centered learning in inquiry-based educational environments either here at the University of Melbourne or elsewhere.

Software-Based Support Tools

While a considerable amount of work has gone on in supporting student learning with various types of cognitive tools and strategies (see for example, Jonassen, Peck, & Wilson, 1999; Kommers, Jonassen, & Mayes, 1992; Pea, 1985; Salomon, Perkins, & Globerson, 1991; Naidu & Bernard, 1992; and Bernard & Naidu, 1992), there has been little work carried out on the area of "software-based cognitive support tools or strategies". Existing software-based cognitive support tools for ill-structured learning environments is believed to impose an inflexible structure on students' learning (see Edelson, & O'Neill, 1994; Scardamalia, & Bereiter, 1991). These support tools can help students organize arguments for presentation after they have reached a critical summary point in their inquiry, but they are less useful in guiding students in cognitive processes associated with PBL. However, before we can begin building any such software-based support tool to provide students with the kind of cognitive support they need for learning in ill-structured learning contexts, we need to know exactly what cognitive processes students have problems with, and what is the exact nature of these problems. These are the preliminary questions, which this research program has been seeking to answer.

Expected Outcomes

The expected outcomes of this research program are as follows:

- An empirically based and reliable understanding of the cognitive processes that students have difficulties with, while engaged in the PBL process.
- To be able to identify the specific stages in the PBL process, where students are having these difficulties.
• Assist students and educators identify areas/phases where learners require assistance and areas/phases where courses require refinement.
• Empirical data from this investigation provides the foundation for the design and development of suitable software-based cognitive support tools. These tools will be incorporated into the PBL curriculum, and their effectiveness will be evaluated in terms of their use as well as benefits to the learning and teaching process.

Research Plan, Methods, and Techniques

Research plan and methods

This research utilizes a "case study" approach. The classes that we observe comprise the case studies. Yin (1994) defines the case study as an empirical inquiry that investigates a contemporary phenomenon within its real-life context. Case studies are able to explain the causal links in real-life situations that are too complex for the survey or experiment.

Study sample and procedure

The study sample is a group of second year Agricultural Science students. An instructional package using multimedia materials designed for Intranet/Internet delivery is under development for application in this subject area. The students will be the first trial group for the multimedia materials. Data from the trial group will be used to formatively evaluate the multimedia package, in preparation for its implementation with students on several campuses. The study will focus on the cognitive processes the students engage in while learning within a PBL framework. The multimedia package introduces the students to a range of real scenarios, presented using photographs and interviews with farmers. Students need to interpret the farmer's conception of the problem, and develop a solution using the range of resources built into the program. These resources include interactive maps, databases, maps, spreadsheets, and a pasture growth simulator developed during a research project, and interactive tutorials on key concepts. Students select whatever they feel they need to solve the problem from this range of resources.

In this trial, students will work individually to cover the conceptual base, and come together in small groups to reach their resolution of the problems. As the students will be all together for this formative trial, group work will be face to face. The multimedia materials, however, are structured to allow computer conferencing for problem solving. This will enable students to work collaboratively with students on other campuses or external students to work in collaborative groups.

Development of data gathering instruments

Data gathering in case study research typically uses multiple sources of data. For this study direct observation, questionnaires and a focus group will all be oriented to the identification of difficulties that the students encounter, that may hinder their problem solving processes. Any technical problems will be identified by observation and, hopefully, rectified at the time. The questionnaire and focus group will address issues relating to the learning method and the resources. The questionnaire will be oriented towards providing some quantifiable data that can be used to identify proportions of students who encounter specific difficulties or, conversely, feel that the range of aspects of the materials work well. The focus group will be oriented towards more subjective issues such as how the group functioned in the problem solving process, and how realistic the experience of working this way is perceived to be.

Data gathering and analysis

Data from direct observation will be analyzed to identify any major impediments to problem solving that the students appear to be encountering. This data tends to reveal significant issues such as technological problems or major misconceptions caused by inadequacies in the project materials or in the students' perception of the nature of
the task. An example of this is that the students must feel that the topic is important to them, rather than that they are actually testing software. If there are problems of this nature then they need immediate rectification. If the situation cannot be properly rectified however, then direct observation data provides a context for consideration in the analysis of other data. Questionnaire data will be analyzed to reveal trends or tendencies that indicate the effectiveness of different aspects of the program in relation to stages in learning, such as activation of prior knowledge, elaboration, and restructuring. The way the students felt about the PBL process, and how they perceived the effectiveness of the overall learning task will be extrapolated from the focus group data. Following this, all three sources will be considered together to enable an interpretation of major themes and issues, and how these have either helped or hindered effective learning.

Results

This is an exploratory study that is in progress. Results from the trial will reveal a number of aspects relating to PBL as a method, and the use of instructional technology for delivery. As PBL is essentially a way of structuring a learning process, data relating to how students experience the process, and its effectiveness in promoting effective cognitive processes is important. The approach to analysis of the case study is designed to reveal this. It is important that the critical processes of PBL are identified, and more important that the processes in PBL with which students have difficulty with are identified. Too many inquiry-based technology-enhanced learning environments place students in information dense learning situations without appropriate cognitive supports or scaffolding. Our research agenda is to develop a suite of supports that students can use in such learning environments. We argue that the development of these sorts of supports and scaffolding must be based on empirical data, and that is what this research program is all about.

Abstract: This paper shows that ability grouping in the middle of a semester is effective for teaching computer literacy to freshmen who have a variety of skill levels. Three teachers including the authors have been teaching a computer literacy course to 150 students for about five years. In 1998 and 1999, we reorganized three 50-student classes based on an achievement exam in the middle of the semester. After the reorganization, we adjusted lectures according to the students' ability. Our statistical analysis shows that the exam scores were improved and the students' self-assessment scores of their own skills were upgraded in all classes. The effect was significant in the slow-learners class compared to the other two classes.

Introduction

In Japan, computer literacy education in colleges and universities is facing a problem of diversity of students' computer skill levels. The reason for this is twofold. One is that the computer literacy education is incorporated in very small number of high schools. The other is that as computer price is falling down the number of students is increasing who learn how to use computers by themselves at home. Besides the skill levels at the beginning of the class, there are differences between students how fast they get accustomed to computer operations in class. These were the problems to overcome for us to help students learn this subject in good quality.

Since 1994, the computer literacy education has been a required subject for all freshmen of Osaka University. Three teachers including the authors have been teaching a computer literacy course to over 150 freshmen majoring in Human Sciences for five years. The course consists of 15 sessions, and each session lasts 90 minutes, which includes demonstrations by a teacher and hands-on activities by students. Usually an assignment is also given which takes an hour or two to complete.

At the beginning of the course in 1995 and 1996, we organized three parallel 50-student classes according to the students' computer experience using a questionnaire survey. Other background variables (age, gender, future academic field) were not considered for this class organization. The organization method aimed at ability grouping, that would provide non-experienced students with a slower work pace and allow high-achieving students to be sufficiently challenged by more demanding lessons. In a few months, we realized that our approach was somewhat idealistic and did not work well. Nevertheless, six months after the semester had ended, we conducted a follow up study to see the students' attitudes toward computer use, and compared the log-on time and the number of mails sent when they were freshmen to those when they were sophomores. This result showed that the sophomores who took this course in their first year used computers more actively than when they were freshmen. There was, however, weak positive correlation between computer experience and log-on time or number of mails. This is because, we think, students' skills were not objectively grasped by the questionnaire and because experienced students are not necessarily diligent.

In 1997, we introduced a written examination in the middle of the semester in order to reorganize classes based on the exam score. This trial showed us that this class organization was not so effective because students' skills were not objectively grasped by questionnaire and written examination.

In 1998, we introduced hands-on work into the exam in the middle of spring semester, such as word document processing, looking into online dictionaries, and finding web sites using a web browser. Then we reorganized the three classes based on the exam score. At the end of the spring semester, we again gave them an exam that would
measure how they made progress. This ability grouping strategy brought us success. In 1999, we refined this method and compared the result of two years trial.

In this paper, we begin with related work and a brief explanation of our computer literacy course, followed by the methodology of class reorganization. Then, we give the statistical data analysis to show that both exam score and self-assessment score of low-ability class were significantly improved.

Related work

Although there has been much previous research on ability grouping, tracking, and class organization, they are mainly for K-12 school education, e.g. (Wiggins, 1993, Mills, 1998). Furthermore, as far as the authors know, there has not been any research on class reorganization in the middle of a semester for computer literacy education. The authors have tried class reorganization for years and presented its result in (Nakanishi & Harada, 1999). This paper includes the result in 1999 and completes our method.

Computer literacy education

Since the 1970s, the definition of computer literacy has evolved, and many researchers have discussed the courseware and teaching methodology of the computer literacy course, e.g. (Higdon, 1995), (Keizer, 1997), (Mills, 1998). The authors believe that to learn details of word processing and spread sheet application is not important but to grasp the concept and principal facilities of those applications is a key for students to become literate. Furthermore, the attitude to learn by himself or herself is also a key.

In the syllabus of the computer literary course in Osaka University, topics consist of two categories, 'Requisites' and 'Options'.

Requisite category consists of the following items.
- Login/logout, password, touch typing
- File system, file operation, floppy disks
- Word processing, kana-kanji conversion (for Japanese characters)
- Concept of the Internet, network etiquette
- Electronic mail, web
- Draw and/or paint software

Options are
- Net news
- LaTeX with graphics
- Spreadsheet
- Writing HTML
- Mathematica
- SAS
- Script languages (perl, awk, shell, etc.)
- Computer ethics, social problems
- Computability

Since one course session lasts 90 minutes and is held once a week, all topics of requisite category which authors think are the minimum competencies, are covered in about seven weeks. For the rest of one semester, teachers select some of the items from optional category depending on the students' majors. For example, LaTeX and Mathematica are chosen for students majoring in Physics and Mathematics, while spreadsheets and SAS for Economics.

Class reorganization Method

Reorganizing by a written exam

In April 1997, we started our three parallel classes with a questionnaire on computer experience. The class organization was based not on their computer experience, but on the enrollment order. The questionnaire showed 60% of the students had experience of word document processing using computers or word processors.

After we completed topics in requisite category, we conducted a written examination to reorganize classes based on students' competencies. The exam requested students to write computer operations, e.g., how to change fonts, how to cite the body of the mail to make a reply, why the login password is important, etc. A total of 150
#1 Change this plain text file to rich text format, then change the font of the marked words to Ryumin 12point, and place it in the center.
#2 Explain how to use Japanese Kana-Kanji translation and how to register your name in your own dictionary.
#3 Look up three words (omitted here) in the following dictionaries: English-Japanese, Japanese-English, and Webster.
#4 Draw a tiny picture and insert it into this page.
#5 Find URLs of the National Diet Library and two online book stores.
#6 Look into “/SharedLibrary/Literature/” and describe what's in it.
#7 What should be considered when deciding your password string?
#8 Find Akutagawa's books using Online Public Access Catalog (OPAC) of the University Library.
#9 What should you do if you find a nice picture of Madonna with a notice saying “copy free” and you would like to have its copy on your web page?
#10 Describe how to limit the line length to fewer than 65 characters in the body of an e-mail.

Table 1: Mid-term exam sample in 1998.

<tr>
<td>Canceling your printer job</td>
</tr>
</tbody>
</table>

Table 2: A questionnaire survey for self-assessment

Students in three classes were reorganized according to the exam score. In all reorganized classes, spreadsheets and HTML were selected from optional category. LaTeX was also selected in the two high-scored classes, while in the low-scored class word document processing was selected instead.

At the end of the semester, we again gave the students a written examination and a questionnaire, which asked whether the students were satisfied. The scores of the two written exams showed no remarkable difference between classes; however, most of the low-ability class students were satisfied with the class reorganization. There remained a problem that the student competencies were not so exactly evaluated by our written examination.

Reorganizing by a hands-on performance exam

In 1998 and 1999, we conducted a mid-term exam which demands hands-on work in an hour, in order to reorganize classes based on students' competencies (Table.1).

We included two questions, which had not been taught in detail in all classes, to see whether students could solve it using the online manual (question #3, #8).

We marked the examination papers out of 100 (each question of 10), and used the scores to reorganize classes. Because of the limit of PCs available in computer labs, each class could not exceed 60 students. So, 53 students who got more than 67 points were grouped to A-class. The threshold between B-class (50 students) and C-class (50 students) was 52 points. The average total score in 1999 was 60.3 (s=15.7).

The average scores of the new classes A, B, and C were 77 (7.4), 60 (3.9), 42 (7.5) points, respectively. The average score for A-class students was more than 5.5 for all ten questions, whereas the students who were grouped into C-class got only 2.2 and 2.3 for question #5 (web search) and #6 (file search), respectively, which were significantly lower than the other two classes. This tendency was very similar to the score of 1998.
Self-assessment by students

After the mid-term exam, a questionnaire survey paper was distributed to the students. The survey consisted of 10 questions, which would measure students' mastery of competencies taught by that time (Table 2).

The answers to these questions were collected on a 5-point scale. The scores of the collected questionnaire showed a positive correlation between the exam and the students' self-assessments. That is, A-class students felt good at the following competencies: inserting graphics into a document, operation of files/folders, and searching website, whereas C-class students answered that they had not mastered those topics. As for searching files from hierarchical file structure, C-class students perceived that they were good at it; however, its exam score is poor. This indicates that C-class students did not understand the file structure itself. Touch-typing and Email competencies were not statistically significant between three classes.

What and how should we teach after the class reorganization

The result of the exam and a questionnaire showed us what we should teach in the new classes after the class reorganization. We provided C-class students with a slower work pace and revisited those competencies which they were not good at. For A-class students, self-teaching of LaTeX was given as an assignment during summer vacation.

In order to allow them to have an active participation in the shaping and augmenting of their learning, we also took an independent study approach for teaching spreadsheets in all classes. That is, after a brief explanation given by a teacher, students follow tutorials on the teacher's web pages. Since graduate teaching assistants (two assistants per classroom) were also available to assist the students, we asked them to give students only hints not to give detailed step-by-step operations.

Statistical evaluations of exam and questionnaire

At the end of the course, we gave a final examination that included three questions similar to the mid-term exam and required hands-on work of about an hour. After the exam, self-assessment questionnaire survey was conducted. Here we begin with the analysis of the questionnaire.

Analysis of exams

The total score and the scores of three questions (use of online dictionaries, OPAC search, and limiting line length of Mail body), which are similar in two exams, were considered in a two-way ANOVA. As a result, these four items showed an "interaction" between the two exams and classes belonged to (p > 0.05).

Figure 1 shows a comparison of the average scores of two examinations. Note that Figure 1(a) shows the "ceiling effect", that is, the scores in A-class are distributed downward after the class reorganization.

Figure 1: Comparison of the average scores of two examinations
As for spreadsheets, two sessions (which means 180 minutes) were assigned for C-class and one session was assigned for A, B classes using self-learning web based text. But the score was is 8 points in A-class and 5 points in C-class. The score of writing HTML also supports this tendency. From this fact, it is proved that A-class students had higher ability in computer operations than other two class students.

Analysis of self-assessment questionnaire

As for the 27 items that were included both mid-term and term end questionnaires, the average term end exam scores were higher than mid-term scores in all classes in 1998 and in 1999. In Figure 2, the x-axis shows the midterm score, the y-axis shows term end score, and each scatter point in the graph represents the score of one item. Two years analysis shows same tendency.

We took the exam timing (mid-term or term end) and classes the students belonged to as the factors of the two-way analysis of variance (ANOVA). The following four items of the questionnaire shows that there is an "interaction" between exam timing and classes ($p > 0.05$).

- Creating a new folder (directory)
- Editing a word document
- Browsing web pages
- Searching web site

Figure 3 compares the average scores of these four items obtained through the questionnaire survey. From this figure, we conclude that C-class students perceived they were as self-confident in these items as the students in the other two classes.

Though the exam scores are not significantly correlated with students' self-assessments, the class reorganization was effective for slow learners class students.
Figure 3: Comparison of the average scores of these four items obtained through the questionnaire survey.

Conclusions

This paper described the efficiency of ability grouping strategy. Class reorganization in the middle of a term has enhanced learning outcomes in computer literacy classes. It is also a good tool for teachers to know the way to lead students to higher skill level.

We are planning to refine the examinations and questionnaire items so that we can more accurately measure the students' competencies and introduce RUBICS for assessment. In 2000, we will incorporate group work, discussion and presentation for high ability students after the class reorganization.

Mixed-Mode Delivery Models in First Year University

John C. Nesbit
Technical University of British Columbia
301 – 10334 152A Street
Surrey, BC, Canada
nesbit@techbc.ca

Abstract: A course delivery model is a framework promoting the scalable application of effective pedagogies and educational technologies. This paper describes how course delivery models were designed and implemented for the inaugural first year program at the Technical University of British Columbia (TechBC). In Fall 1999, ninety first year university students took 6 courses delivered through a central Course Management System (CMS) providing online conferencing, announcement posting, online quizzes, support for team-based learning, and course content in the form of web pages, streaming video, and animation. The courses, representing 5 distinct delivery models, differed substantially in their application of these features and in the use of face-to-face class time. A comparative analysis of questionnaire and web log data focusing on learner engagement and achievement with the delivery models will be presented at ED-MEDIA 2000.

In a widely publicized comparison of online and face-to-face teaching, Schutte (1997) attributed the higher achievement of the online group to “higher perceived peer contact and time spent on class work”. Schutte’s conclusion is compelling because, to no one’s surprise, time spent learning has long been confirmed (e.g., Carroll, 1963) as perhaps the most powerful determinant of learning achievement and, more interestingly, decades of research on cooperative learning (Slavin, 1995) have established structured, team-based learning as among the most effective educational methods.

In addition, research on metacognition and self-regulated learning (Butler & Winne, 1995) is revealing the critical role of these aspects of engagement in learner achievement. Thus, for the purposes of this paper, learner engagement is regarded as a combination of three inter-related factors: Time spent working on, metacognitive processing of, and social interaction in relation to, learning resources and tasks.

This paper describes the design and implementation of 5 course delivery models constructed from different combinations of educational technologies and teaching methods. In so doing it presents the groundwork for a study, to be presented at ED-MEDIA 2000, of how learner engagement varies across delivery models.

Institutional Goals for Educational Technology and Learning

The Technical University of British Columbia, Canada’s newest public university, welcomed its initial cohort of first-year students in August, 1999 with a curricular emphasis on Information Technology, Management & Technology, and Interactive Arts. The development of a strategy for the use of innovative pedagogy and educational technology began before, and extended throughout, the planning and development of the first year curriculum.

In the early institutional planning for educational technology and learning, four standards emerged with regard to the first year program:
• Most courses would emphasize collaborative learning with classes organized into teams.
• Averaged across the program, about half of learning contact time would occur online.
• Most courses would integrate online and face-to-face learning.
• All courses would include a substantial web-based component.

It was apparent that achieving these standards for the first set of courses and the small initial cohort of students would be easier than maintaining them as student enrollment and course offerings grew rapidly. To enable
scalability it was decided to design a relatively small set of delivery models consisting of appropriate combinations of learning methods and technologies. Each course is assigned to a delivery model so that technical and pedagogical support and planning can be organized around the delivery models rather than the unique requirements of each course. Having each of the delivery models represented in the initial set of course offerings also ensured that a variety of approaches would be explored and compared at the outset.

The TechBC Course Management System

Crucial to the successful implementation of course delivery models is the support for learner engagement provided by the course management system (CMS). After reviewing several commercially available systems it was decided to build a web-based CMS with core functionality written in XML/RPC, Dynamic HTML, and JavaScript. Specialized functions were provided by commercial products. For example, we used SoftArc’s FirstClass for online conferencing and QuestionMark’s Perception for online tests and quizzes.

Figure 1. The iSpace page provides a calendar, announcements, and links to courses.

To promote learner engagement, features of the TechBC CMS were designed to provide convenient access to course content and interaction with instructors and other learners:

- An entry page, was designed to support community building by providing general announcements, Java-based text chat serving as a virtual café or hallway, voting on community issues, and links to online conferences dealing with a variety of student concerns.
- A personal page (Figure 1) provides links to courses, email, a calendar, announcements, and personal file space on a university server.
- Each course has a syllabus page (Figure 2) providing links to learning objectives, presentations, online conferences, and descriptions of assignments and exams.
- Most courses have a teams page listing all class members by team. The teams page also provides access to team conferences.
- A navigation bar shown at the bottom of the Figure 1 is available throughout the CMS.

The course developers, faculty and teaching staff, were provided with preformatted web page templates specific to the delivery model for which they were working. Most developers were subject matter experts with little or no experience developing for the web. They entered text and graphic content into server files using Dreamweaver and
received support from educational technology staff for the creation and licensing of interactive and multimedia elements.

Figure 2. Example of a syllabus page in the TechBC course management system.

Many of the web page templates included interactive components. For example, a template in one delivery model included links to pre-study and post-study quizzes. A template in another model included a voting poll in which each student had one anonymous vote.

Some design goals intended to promote learner engagement were postponed to later versions of the CMS:

- Team management tools enabling instructors to easily assign learners to teams and evaluate team projects.
- Team participation tools assisting team members in collectively managing project work.
- Interactive features of the CMS interface further supporting self-monitoring and self-regulation of individual learning, such as meters or check lists showing progress through the objectives of the course.

Network Access Requirements and the Expansion of Broadband Service

Learners accessed the course management system from on-campus labs and from home. TechBC required that they have access to the internet through 3rd party ISPs at a minimum 56 kbps. In fact, learners’ home subscriptions and modem speeds ranged from 28.8kbps dial-up to cable modem and ADSL.

TechBC is located in the lower mainland of British Columbia, a region in which both ADSL and cable subscriptions are available for under $30 USD per month. Throughout the Fall of 1999 local cable companies were aggressively expanding internet subscriptions at a rate of about 300% per year.

As shown in Figure 3, there was a substantial increase in learners’ subscriptions to broadband internet services (ADSL and cable) in the early months of the term. By the 3rd week of classes in September, 46% of ISP accounts accessing the CMS were through broadband services. This figure had risen to 66% by mid-November.
Despite developers' attempts to optimize streaming video for 56 kbps, anecdotal reports from TechBC learners indicated that broadband access may be necessary to enable effective home use of streaming video presentations provided through the CMS. Some learners with dial-in connections report having to come to on-campus labs to effectively use streaming video.

When broadband access can be mandated for all learners, likely within a year or two, new delivery models using real-time, one-way video presentations with interactive components will become increasingly feasible.

The Course Delivery Models

A course delivery model is a combination of logistical, technological, and pedagogical features. Each model has implications for the scheduling of classrooms and labs, division of roles among teaching staff, course development time, demographic profile of learners, learners' hardware and network requirements, fit to curricula, and so on. Our design of logistical and technological components of the delivery models was influenced by, among others, Bates (1995) who discussed access, cost, teaching and learning, interactivity and user-friendliness, and organizational issues as key criteria for making decisions about educational technology and media.

The pedagogical components of the delivery models were influenced by theory, research and practice in asynchronous learning networks (e.g., Harasim, 1995), cooperative learning (e.g., Millis & Cotell, 1998) and instructional design (e.g., Diamond, 1998). The models were designed to shift one-way delivery of information out of lectures toward print or web media, or better yet, to replace one-way delivery with interactive approaches. Among the methods adopted were the use of explicit learning objectives, team-based learning in both face-to-face (F2F) and online settings, moderated discussions, primary trait analysis for assessment, and interactive simulations.

Curricular needs also influenced the design of the models. For example, a program focus on Interactive Arts led to the development of a Studio Lab model building on art school traditions. In fact, each of the models can be seen as a re-working of one or more traditional teaching models.

The following sections summarize the five delivery models used by TechBC's first year courses.

Presentational Cooperative (PC) Model

| Section size: | 48 learners |
| F2F cooperative learning: | 1.5 hours per week |
Study of web presentation: ~ 1.5 hours per week

Derived from the lecture-seminar method, this model replaces the lecture with a web presentation containing multimedia and interactive elements. During weekly face-to-face sessions students work in teams of 4 to 6 on structured cooperative learning tasks. An asynchronous online conference is provided for students to ask questions. Some courses may add open lab sessions where students come to receive help and work on assignments.

**Studio Lab (SL) Model**

Section size: 24 learners  
F2F studio session: 3 hours per week  
Study of web presentation: ~ 1.5 hours per week

This model bears some similarity to the PC model, but differs in the duration of required on-campus sessions, and in the learning activities carried out in those sessions. Studio sessions are held in a computer lab, and the learning activities tend to be project based. Although learners are pre-assigned to teams of 6, they are just as likely to be working individually as working within their teams. This model provides a weekly web presentation containing multimedia and interactive elements, and an asynchronous online conference for students to ask questions. Some courses may add open lab sessions where students can come to receive help and work on projects.

**Computer-Mediated Classroom (CMC) Model**

Section size: 24 learners  
On-campus activities: infrequent if any  
Online conferencing: ~ 3.0 hours per week

The CMC model is built on the tradition of asynchronous learning networks (Harasim et al., 1995) and makes heavy use of online conferencing. Every week, a section of 24 learners takes up a new topic in an online conference. Some web-based interactive and multimedia resources may be provided, but these are not expected to be extensive. The CMC model imposes a relatively low development cost, but the need to moderate and manage conferences results in high delivery costs. Students are pre-assigned to teams of six, with each team carrying out some of its work within its own conference.

**Flexible Study (FS) Model**

Section size: unlimited  
On-campus activities: optional open labs  
Study of web presentation: ~ 3.0 hours per week

Derived from the distance learning tradition, this is a self-paced model with no requirement to attend face-to-face sessions. The flexible study model demands the production or acquisition of high quality web-based and multimedia resources. Compared to other models described here, it imposes the greatest development costs but the least delivery costs. There are frequent self-diagnostic quizzes and less frequent formal examinations. An asynchronous online conference is provided for students to ask questions. To compensate for the absence of scheduled on-campus sessions, web-based conferences and contact support are provided to support the formation of informal study groups. Some courses may add open lab sessions where students visit campus to receive help and work on assignments.

**Threaded Process (TP) Model**

Section size: unlimited  
F2F integrated activity: 1.5 hours per week  
Study of web presentation: ~ 1.5 hours per week

This model arose from the curricular need to integrate the learning of communication, writing, team process, research and learning skills with other courses in the first year program. Thus the learning activities in this model tend to piggyback on the learning activities of other courses. For example, for a unit on concept mapping learners...
studied a web presentation on concept maps. Then later, in a PC class covering operating systems in a different course, they were asked to create a concept map to illustrate structures in a operating system. The concept map they created could be used in a portfolio to assess their learning of concept mapping.

**Implementation of Delivery Models**

Table 1 shows how courses were assigned to delivery models. Online components of the first term courses included a total of about 5000 web pages and 90 interactive or multimedia objects.

A few outcomes were apparent even during the early weeks of the term. First, delivery models placing more emphasis on online learning did not necessarily provoke greater activity in the CMS. Table 1 shows the mean number of hits to the course syllabus pages per learner during a fairly typical week in early December. In that week the delivery models with the greatest emphasis on f2f contact actually garnered the most syllabus hits. Second, the demanding schedule imposed by the 6 first-year courses inclined learners to assign low priority to the self-paced flexible study course. The model was subsequently adapted by introducing assignments and exams on a fixed schedule. Third, pressure to converge the delivery models emerged as instructors and learners requested features from other models and declined use of some features specific to the model assigned to their course.

SMILE: Giving Internet Instruction a Human Face

Matthew Nickerson
Gerald R. Sherratt Library
Southern Utah University
Cedar City, UT, 84720, USA
nickerson@suu.edu

Abstract: Southern Utah University has over five years of successful programming on the state’s closed circuit two-way video educational network. We have recently capitalized on this experience and expertise to create a unique web-based humanities course supported by video-on-demand lectures using RealNetworks® media streaming technology and SMIL (Synchronized Multimedia Integration Language).

Introduction

Streaming video technology is transforming multimedia content on the Internet and adding powerful new possibilities to on-line education. More powerful compression algorithms and broadening bandwidth capabilities make video delivery over the web more and more feasible for serious distance educators who want to maximize content delivery options.

Just as video-on-demand programs using VHS tapes added the power of video and moving images to “traditional” distance education programs now video streaming technologies make it possible to bring the power of video to web based courses as well. Mention of video as a possible ingredient in new on-line educational offerings began appearing in the literature as early as July 1999 (Thornton, 1999). Though relatively rare there are a few institutions using streaming video to support web based instruction. The majority of these programs are using in-house products developed by their institution to create Internet courses that include video and “electronic presentations” (Brusilovsky, 2000). At Southern Utah University (SUU) we have created a general education humanities course for delivery over the Internet that includes video-on-demand capability providing students with over 150 mini lectures in support of the content material. In seeking to create a new, exciting Internet offering we chose a general education humanities course as an ideal vehicle for testing the efficacy of multimedia streaming technology in Internet based university instruction. In short, we wanted to make our Humanities 1010 Internet course as human as possible.

The Course

The Humanities course selected is part of SUU’s growing distance education program and is taught yearly over live interactive TV as part of our concurrent enrollment program. Students across the state can take the course live via Utah’s closed circuit educational network, EDNET. The course was ideal for this project in that it is taught in a studio setting where a high quality recording of the lecture was possible. In addition, the instructor has designed the course to be delivered over TV so many of the instructional aids and projects have been optimized to the camera/TV environment adding quality to the video recording as well.

Lectures for the entire course were recorded digitally during Fall 1998 in preparation for developing the Internet course. Editing the recorded lectures into 5-10 minute mini lectures and securing still images to illustrate them all was a very time consuming process. The faculty instructor worked with a team of three student assistants to create the illustrated mini lectures. Development of the Internet course was funded in part with grants from the Utah Education Network (UEN) and the Higher Education Technology Initiative (HETI).
The Technology

The innovative structure and delivery of the course is made possible by a powerful WWW multimedia tool, SMIL, (Synchronized Multimedia Integration Language) pronounced, "smile." Recommended by the World Wide Web Consortium (W3C) it allows for the creation of time based multimedia delivery over the web (World Wide Web Consortium, 1998). Based on XML, it allows developers to mix many types of media together including, text, video, graphics, audio and vector based animation, and to synchronize them to a timeline. Specifically, SMIL provides Web users with:

- Easily defined basic timing relationships
- Fine-tuned synchronization
- Spatial layout
- Direct inclusion of non-text and non-image media
- Hyperlink support for time-based media
- Adaptability to varying user and system characteristics.

Our Humanities course for the Internet uses these capabilities to deliver video and still images to create an illustrated video lecture format unique to on-line instruction.

The simultaneous streaming of a variety of media is the key feature of SMIL that we use to create the "illustrated lecture" format of the class. We use RealNetworks® technology for our video encoding, streaming and player system. When we first envisioned video-on-demand support for a course delivered over the WWW RealNetworks® was the industry standard for streaming media on the Internet. Since beginning our program Apple, Microsoft and others have introduced streaming systems as well but we are pleased with our choice to use RealNetworks® and with the improvements they continue to make in their product and support. In addition, RealNetworks® was the first of the major streaming technologies to make their player SMIL compatible.

SMIL is a programming language similar in structure to html. Layout tags allow the player window to be customized, including the creation of multiple player regions, each capable of displaying a different media stream. Our mini lectures use a simple rectangular window divided into three separate regions: a video region, a menu region and a slide region (Fig. 1).

![Figure 1: General layout of player window](image)

The video and menu regions take up the left side of the window with the video region immediately above the menu region. The video region displays the instructor in a tight shot, as well as any visuals he used during the TV broadcast of the class. These visual supplements include such things as computer images, overheads and use of the white board. The menu region lies just below the video window and is a simple point and click menu for navigating through the current lesson.
The slide region is the largest window and lies to the right of the other two. The slide region displays still images that illustrate what the instructor is discussing. Standard video controls (play, stop, pause, fast forward, rewind) above the video window allow students to control the flow of the presentation (Fig. 2).

Figure 2: Screen capture of player window in operation

Another important SMIL feature beyond its layout capability is SMIL’s ability to create simultaneous streams of various media. This is the heart of the “narrated slide show” format of our class. SMIL allows the designer to synchronize various media streams to produce a multimedia product. Our design uses SMIL to “tie” a series of still images to the time line of the video so that they stream simultaneously with each graphic appearing in the image window “on cue” as the lecture progresses.

We initially demonstrated the video-on-demand courseware to a small number of students and were encouraged by their response. They found the video to be engaging and personal and they react very positively to the instructor’s excitement and enthusiasm for the subject matter. In fact, students tended to rely too much on the video which is meant to supplement and interact with the course reading assignments, not replace them.

One drawback of Internet-based multimedia is the fairly high bandwidth required for quality streaming. Our suggested minimum requirement for online students is a pentium class (or comparable Macintosh) computer, with 64K RAM, 300MHz processor and a true 56K Internet connection (or faster.) The high end technology does limit access to the course but we are confident that streaming video will be a major element in the future of web-based instruction and we feel it is necessary to begin working in this arena now. The necessary bandwidth and processor speeds for streaming video are already in place at most colleges and universities and at many public schools as well. With cable modems and other emerging technologies increasing the receiving capabilities of home users our early foray into this field will prepare us to better serve the needs of students in the future.

A Beginning

The course was officially opened winter 2000 with ten students. We are using this first course as a test of the program and pedagogy we have employed in creating it. All students will be expected to fill out a survey as part of the exit requirements for receiving credit for the course. The survey instrument will be distributed from a continuing education web site, unrelated to the course site, in hopes to encourage students to be frank and open in their response. The survey will focus on:

General
- Student demographics
- Satisfaction with course
- Satisfaction with the technology
- Satisfaction with student support
Specific
• Satisfaction and perceived value of the video lectures
• Satisfaction and perceived value of the streaming technology
• Satisfaction and perceived value of the on-line assignments and quizzes
• Satisfaction and perceived value of the student-teacher interaction

Conclusion
Overall, we are excited about what streaming video can bring to Internet instruction and look forward to implementing our first course using this new technology. We hope to have enrolled sufficient numbers by the fall of 2000 to be able to publish significant findings from our research into the operation, teaching effectiveness and student satisfaction related to streaming video-on-demand in support of Internet based college courses.

CoCoA2: Computer Supported Collaborative Language Learning Environment Based on Online Proofreading

Hiroaki Ogata  Yoshiaki Hada  Yoneo Yano
Department of Information Science and Intelligent Systems, Tokushima University
2-1, Minamijosanjima, Tokushima 770-8506, Japan
Email: ogata@is.tokushima-u.ac.jp

Abstract: CoCoA (Communicative Correction Assistant System) was developed for supporting students and teachers to exchange online marked-up documents via email. Its environment is very similar to a real one in which people use paper and pen. In order to effectively reuse marked-up digital documents created with CoCoA, this paper proposes a computer supported proofreading exercise environment called CoCoA2. CoCoA2 can reduce the overload of the teacher, and it can make composition learning more effective. CoCoA2 has been developed and used it experimentally.

Introduction

Recently, researchers in educational systems attempt to provide technological support for cooperative and collaborative learning advocated by educational theories (O'Malley, 1994). The explosive growth of networking, in particular, raises the possibility of widespread collaborative and open-ended learning activities (Harasim, et al., 1995). We have investigated technological support for open-ended and collaborative learning activities (Ogata, et al., 1996; 1997). In composition studies, coupled with the shift in writing pedagogy toward an open-ended and learner-centered approach, the theoretical view of learning has created a surge of interest in collaborative learning in such way as to prize conversation and interaction among students and among students and teachers.

In computer-based classrooms, writing teachers and students use various software tools based on some theories of writing. Writing compositions includes various sub-processes such as planning, transcribing, and revising, which do not need to occur in any fixed order (Scardamalia & Bereiter, 1986). Hence, it is very important for students to receive the instruction through the review. There are some asynchronous editing systems that support teachers to review and correct the students’ drafts with online mark-up. These systems adapt the traditional mark-up model to the computer screen. The symbols are both familiar and intuitive for editors and authors; for example, deletion, insertion, and move (Farkas & Poltrock, 1995). For instance, MATE (Hardock, Kurtecbach, & Buxton, 1993) allows the editors to use both online markup and comments. In this model, authors and editors can readily interpret the editor’s markings. Although there are many systems that employ markup that allows multiple users to correct an electronic document as if they were marking up a printed copy of the document, the systems do not provide a generalized format for exchanging the documents using Internet.

CoCoA (Communicative Correction Assistant system) has been developed for supporting foreigners and teachers to exchange marked-up documents by e-mail (Ogata et al., 1997). Its environment is very similar to a real one in which people use paper and pen. CoCoA allows teachers not only to correct the compositions sent from foreigners by E-mail, but also foreigners to see where and why the teacher had corrected them. CoCoA improves the opportunities that foreigners have for writing Japanese compositions and for receiving instructions from teachers. CCML (Communicative Correction Mark-up Language) (Ogata et al., 1998) has also been proposed for the representation of marked-up documents, which is based on SGML (Standard Generalized Mark-up Language) (Herwijnen, 1990). With CCML, teachers and students can exchange marked-up documents via e-mail (Ogata et al., 1999). In the experimental use of CoCoA, most of users commented that CoCoA was easy for them to understand the mistakes in documents because of the use of marks, and that the optional view of the original, marked or revised text was very useful.

This paper proposes an online markup based collaborative learning environment called CoCoA2, for Japanese language composition studies. In order to effectively re-use marked-up digital documents created with CoCoA, CoCoA2 reuses the documents in proofreading exercise for other learners. In CoCoA2, a learner sends a teacher an original text. The teacher then corrects the text with CoCoA2, and returns the learner the marked-
up text. The marked-up texts of all the learners are stored into a repository of the teacher. From the students in a networked writing classroom, CoCoA2 chooses an appropriate learner for proofreading exercise by analyzing writing errors in the CCML formatted documents repository. CoCoA2 presents the selected learner with an original text in which there are a number of errors that the learner has to find and correct. This exercise elevates error-correcting skills and self-monitoring skills in writing a composition (Coniam, 1997). After the learner finishes proofreading, CoCoA2 evaluates the result through comparing the correction of the learner with that of the teacher. CoCoA2 creates the opportunity of collaborative learning by connecting the proofreading learner and the learner who wrote the original text. The document can be improved through the collaboration. Because of the reuse of online marked-up digital documents, CoCoA2 can reduce the teacher's load, and it can make composition learning more effective.

Overview of CoCoA and CCML

CoCoA-Editor & CoCoA-Viewer

CoCoA system consists of CoCoA-Editor for a teacher and CoCoA-Viewer for a student. Figure 1 shows the interface of CoCoA. By selecting a mark from the mark palette shown in the window (A), a teacher can correct learners' documents. Moreover, the teacher can annotate in the document using the annotation palette, and he/she classifies the marks using a window which looks like (B). The "undo" button erases corrections. In figure 1, the teacher changes the words which means "attend", and determines the importance level of the correction is three. A learner obtains a marked text in a window (C). In this case, CoCoA-Viewer provides only the marks over the level two of importance. "?” denotes a question and "*" shows an explanation from the teacher. The system displays the contents of the annotation after clicking the mark. As shown in the message window, the learner can reply to the message and send it after revising the document.

![CoCoA-Viewer and CoCoA-Editor](image)

**Figure 1:** Screen snapshots of CoCoA-Viewer and CoCoA-Editor.

CCML

Japanese Industrial Standard (JIS) defines 20 marks and 18 sub-marks as the marks for proofreading (Shimano, 1986). A mark shows the spot of correction, e.g., text insertion. All the marks are not required in our situation because documents are inputted with a computer. Based on this standardization, seven marks were selected through our experiments. The seven marks for correction were selected; insert, replace, delete, separate, join, move and annotation. Based on SGML, CCML for exchanging marked-up documents has been proposed. SGML is an ISO standard (ISO 8879:1986) which supplies a formal notation for the definition of generalized mark-up languages. SGML is device-independent methods of representing texts in electronic form.
CCML document consists of three parts: header, body and close. A header part has an editor name, an author name, and the revision time. A close part shows the editor's comments. A body part consists of the six marks and the annotations. Every tag has an attribute “level” that a teacher gives a number from one to three; 1: weak correction, 2: normal correction, and 3: strong correction. It is very important for a teacher to annotate the marked text for instruction in composition. For example, PREP Editor (Neuwirth et al, 1996) is a word processor that allows writers and reviewers to create electronic margins, or columns, in which they can write and communicate through their annotations. In CCML, annotations are classified into three categories: explanation, question, and comment. The main characteristics of CCML are:

(1) Based on the experiment, CCML presents six marks and annotation CCML tags.
(2) The marks have three degrees of importance levels against respective corrections.
(3) Removing all the CCML tags generates the original text.
(4) The revised text is derived from the CCML document.
(5) Because CCML documents are text-formatted, it is easy to send them by e-mail.

Needless to say, CCML inherits its features from SGML.

CoCoA2: On-line Markup Based Collaborative Learning Environment

Learning process

Correcting exercise can help learners understand reasons for writing errors. Exercise materials can also transform the learning experience and enhance learner motivation. In making full use of every corrected document and writing errors data processed, in CoCoA, the correcting exercise method is suggested to assist learners for enhancing their writing ability. Figure 2 shows the method of providing learner with some similar documents for learner’s correcting exercises.

(1) Learner A writes an original text and sends it to a teacher by e-mail.
(2) The teacher corrects the text with CoCoA-Editor.
(3) The teacher sends learner A the marked-up text by e-mail.
(4) The teacher stores the marked-up text of learner A into the CCML document database.
(5) CoCoA2 selects a suitable document for proofreading exercises of learner B using the CCML document database. Analyzing the document database, the system recommends a candidate document containing similar errors to learner B’s errors. In figure 2, the system selects a learner A’s document for the exercise.
(6) Teacher sends learner B the CCML document of learner A.
(7) CoCoA generated the original document from the CCML text, and provides learner B the uncorrected document that includes similar writing errors of learner B. Then, learner B revises the text with CoCoA2.
(8) After learner B finishes correction, CoCoA2 evaluates it through the comparison between the correction of learner B and that of the teacher. Moreover, learner B can be helped to re-correct the document with some advice of learner A who received the corrected text by the teacher before.

In CoCoA2, it is very important how the system can support process 5 and 8. These designs are described in the following section.

Figure 2: Learning process of collaborative learning in CoCoA2.
Selecting a target document for proofreading exercise

In order to select an appropriate document for proofreading exercise, CoCoA2 analyzes the CCML document using natural language processing technologies (Feng, Ogata & Yano, 1998). Error words are identified by a morpheme analyzer called Chasen (Matsumoto, 1997). Statistical analysis of these errors can help the system to find a suitable document that includes similar types of errors to a target learner for the exercise. Using a TF-IDF vector space model (Salton et al., 1994), writing errors are classified. TF-IDF is one of the most successful and well-tested techniques in information retrieval. A document is represented as a vector of weighted terms. The computation of the weights reflects empirical observations regarding text. Terms that appear frequently in one document (TF = term frequency), but rarely on the outside (IDF = inverse document frequency), are more likely to be relevant to the topic of the document. Therefore, the TF-IDF weight of a term in one document is the product of its term-frequency (TF) and the inverse of its document frequency (IDF). In addition, to prevent longer documents from having a better chance of retrieval, the weighted term vectors are normalized to unit length. With this method, CoCoA2 compares the number of each morpheme of the learner's errors with that of other learners' errors, and CoCoA2 finds similar documents including the same errors as the target learner's errors.

Evaluation of learner's correction

The system evaluates learner's correction as follows:
1. Standardizing the corrected documents;
2. Comparing correction of the respective document;
3. Scoring a point on the learner's correction.
4. Advising the learner about the different correction.

The standardization is needed to make it easy to compare the two corrections, because the learner may correct the text with the different marks from the teacher. The standardization is based on the following two rules:
(1) Replacement rule: If there is an insert mark after delete mark, or if there is an delete mark after insert mark, then the two makes change one replacement mark.
(2) Union rule: If the two same marks adjoin, they are united. For instance, the delete mark and the neighboring delete mark are combined into one delete mark.

After the standardization, the system compares the correction of the learner with the model correction of the teacher. Correction marks of two standardized documents are classified into the following states:
1. Same correction: Learner completely corrected the same words/sentences as the teacher.
2. Different correction: The correction of learner is different from that of the teacher. For instance, corrected words are different, or learner was not aware of writing errors.

In order to make it easy for learner to understand the evaluation result, the system gives a score on the proofreading exercise. The point of same answer (X) is proposed as follows:

\[ X = \frac{\sum_{i=1}^{n} M_i}{C_i} \times 100(\%) \]

\( n \) is the total number of teacher's correction. \( M_i \) shows the correspondent number of correction between the learner and the teacher. \( C_i \) shows the number of the teacher's correction. The more similar to the teacher the correction of the learner is, the higher \( X \).

Implementation of CoCoA2

CoCoA2 consists of a server for a teacher and a client for a learner. With CoCoA-Server, teacher stores all of the learners' documents that the teacher has corrected with CoCoA-Editor and the teacher selects the document for proofreading exercise. CoCoA2-Client shows the proofreading learner the uncorrected document that is generated from the CCML document. After finishing correction, CoCoA2-Client evaluates it and connects the learner and the original writer.
CoCoA2-Server

Figure 3 shows an interface of the document selection function of CoCoA2-Server. Window A lists all of the learners' names. Teacher selects a learner for proofreading exercise from this list, e.g., Wang. Then, the system shows some files for proofreading in window B, comparing errors in all of Wang's documents and that of the other documents. Moreover a list of degree of similarity appears in window C. The degree shows the similarity between errors of Wang's documents and that of another documents. With this window, teacher can easily select a suitable document for the learner's proofreading exercise by referring the degree.

CoCoA2-Client

CoCoA2-Client is extended from CoCoA-Editor. Whenever a learner wants to study about compositions, s/he can start a proofreading exercise with CoCoA2 and correct a text with (A). The text is generated from the CCML document that the teacher sent to the learner. This system begins to evaluate the results of the learner's correction by pushing "evaluate" button. The results are shown in (B). The same answer rate is 53% in this case, comparing the learner's correction with the teacher's correction. "Show answer" button displays the teacher's correction as an answer. "Same answer" button shows only the same corrections of learner as teacher's correction. On the other hand, "different answer" button displays the different corrections of learner from teacher's corrections. "Advise" button shows helpful hints in (C), e.g. indicating the places to correct. "Collaboration" button creates a communication channel between the learner and the original writer of the document. The learner reviews and corrects in collaboration with the original writer. They can communicate with an online chat tool or email. If the original learner agrees with the learner's correction, the exercise will finish.
Conclusions

This paper proposed a computer supported proofreading exercise environment called CoCoA2 where a teacher and learners can exchange electronic marked-up documents. Although we tried to use CoCoA2 in Japanese language learning, CoCoA2 is independent of a language domain. Therefore, CoCoA2 will be able to be used for learning any language. In the future work, we will evaluate CoCoA2 in detail during long term, and we will also investigate how to support multi-lingual language learning in a cyber space. CoCoA2 have been implemented in Tcl/Tk on both Microsoft Windows 95/98/NT and Sun workstations. A Japanese version of this software is distributed to other researchers and developers for demonstration. For further information, our home page (http://www-yano.is.tokushima-u.ac.jp/research/cocoa/cocoa.html) is available. A commercial product of CoCoA that is called E-Correct is also download-able from the following URL:http://www3.apex.co.jp/~apex/correct/english/

A Case Study of Student Tool Use
During Hypermedia-Based Problem Solving

Kevin M. Oliver
Virginia Tech
Educational Technologies, #0232
Blacksburg, VA 24061
kmoliver@vt.edu

Abstract: During a qualitative case study in which middle school learners used computer tools to scaffold scientific problem solving, three research questions were addressed: how do students use technological tools to find, frame, and resolve open-ended problems; what is the nature of science learning in problem-based, Internet environments; and how do attitudes and environmental variables influence students' problem solving? While the students understood how to use most tools procedurally (i.e., collecting basic information), they lacked strategic understanding for why tool use was necessary (i.e., organizing, evaluating, justifying ideas). Students scored average to high on assessments of general content understanding, but developed artifacts suggesting their understanding of specific micro problems was naive and rife with misconceptions. Process understanding was also inconsistent, with some students describing basic problem solving processes, but most students unable to describe how tools could support open-ended inquiry. Personal barriers to effective problem solving included naive epistemologies, while environmental barriers included a lack of communication activities and training. In future studies, tools may support higher-order thinking by addressing study recommendations: training students procedurally and strategically, perhaps longitudinally; using students' personal problem models as an explicit part of instructional strategies; balancing students' epistemological comprehension of problem complexity with self-directed, self-management tactics; and employing the teacher as dialectic facilitator.

Introduction

National science standards call for increasing student exposure to inquiry and real-world problem solving (Hurd, 1997; National Academy of Sciences, 1995). Students can benefit from environments that stress the engagement of real problems and the development of thinking skills over the memorization of discrete facts. The Internet is an ideal vehicle for contextualizing problems with its seemingly endless supply of resources. Problems arise, however, since young students are developmentally ill-prepared to handle open-ended learning and have cognitive difficulties processing hypermedia. Computer tools were used to determine how they might support the process of solving open-ended problems. A preliminary hypothesis suggested students would solve open-ended problems more appropriately if they used tools in a manner consistent with higher-order critical and creative thinking.

Methods

Design and Participants

An embedded case study design was employed with an eighth grade science class. Multiple embedded units were analyzed: 12 individual participants who were grouped into 6 dyads that together represented the case or whole classroom.

Materials: Tools

The Knowledge Integration Environment (KIE) computer tools were chosen to scaffold student inquiry (Linn & Slotta, in press). The tools were designed to support students in developing advanced scientific understanding by...
integrating and reconciling scientific evidence on the Internet with individual scientific models. The KIE tools were of three primary types: processing, scaffolding, and communicating. The technical infrastructure of the research setting disallowed the use of communication tools for this research.

Processing tools seek to activate and model cognitive processes while extending the capacity of human memory (Kozma, 1987; 1992). KIE information processing tools included collecting tools to save web evidence into a conceptual framework, organizing tools to categorize evidence, and integrating tools to take notes and reflect on the data. Students in this study also used non-KIE information generating tools to develop sketches and web pages defending their ideas.

Researchers suggest scaffolding tools in particular are needed to assist learners who seek to process hypermedia effectively (Kinzie & Berdel, 1990; Lee & Lehman, 1993). Scaffolding tools are "engineered to assist learners in performing tasks for which they would otherwise be unprepared" (Laffey, Tupper, Musser, & Wedman, 1998, p. 75). They fall into three classifications: procedural, conceptual, and metacognitive (Hannafin, Land, & Oliver, in press; Iiyoshi & Hannafin, 1996). KIE tools allow for the embedding of procedural instructions suggesting how to go about tasks, conceptual prompts suggesting what topics were important to consider, and metacognitive advice suggesting strategies for resolving problems posed.

Materials: Curriculum Units

A theory comparison unit was employed in a pilot study, asking students to examine then choose and defend either the uniform or catastrophic theory of earth formation. A design unit was employed for the research study, asking students to find and frame various earthquake engineering problems, then resolve them with an original, evidence-based solution.

Data Sources

Data sources included artifacts, interviews, field notes, and tests. Eight artifacts collected included such items as student research questions, notes, argument graphs, and web pages. Field notes were taken daily during the four-week study. Each of six dyads was interviewed three separate times as the study progressed about their use of tools, their scientific understanding, and their attitudes toward inquiry-based learning. The teacher participant was interviewed twice regarding the same student outcomes. Individual students were interviewed after the study to clarify their understanding of the open-ended problem solving process. A content test and ordered tree instrument (Naveh-Benjamin, McKeachie, Lin, & Tucker, 1986) were used to determine conceptual understanding.

Procedures

Students were trained on tool use by means of a 2-day mini-project and a 3-week pilot study, during which they were explicitly instructed how and when to use specific tools. In the research study, however, students were given the choice of using or not using the tools to accurately depict "intentional" tool use. They were not told which tools to use in response to their tasks, but were provided with procedural scaffolding describing how to use tools if they forgot.

Data Analysis

As recommended by Yin (1994), data analysis sought evidence confirming or disproving a theoretical proposition: young students who use computer tools to manipulate hypermedia resources in higher-order creative and critical ways (e.g., organize, annotate, represent) will effectively solve open-ended problems. Hypothesis refinement situated this research within the analytic induction tradition—beginning with theory in mind and building to more focused theory (Merriam, 1998). Data analysis consisted of coding and reduction, then display and pattern seeking (Miles & Huberman, 1994). The data were reduced by coding against typological frameworks of critical and creative thinking to address tool use. Further codes were developed openly by seeking instances of learning, attitudes, and environmental factors in the data that would directly inform the theory-built research questions. A lengthy aggregated text and partially-ordered checklist matrices were developed from codes to seek categorical evidence of students thinking with tools, learning science, or displaying attitudes and behaviors (Creswell, 1998; Miles & Huberman, 1994; Stake, 1995) (see Figure 1). Matrices illustrated the thinking skills exhibited by each
Asterisks indicated a tool was used, but ideal or expected thinking did not occur (e.g., students created a web page to describe their solution, but did not justify their idea with web evidence). Categories were generated by studying the matrices for commonalities in thinking (e.g., "the first dyad rarely used metacognitive scaffolding, did the second, did the third, ... ?"). The process was consistent with "...discriminant sampling" suggested by Lincoln & Guba (1985). Categories were then related by studying their "semantic" relationships (e.g., X is a kind of Y, X is a cause of why) (Spradley, 1979). Shared relationships suggested themes that were developed into an "analytic text" of findings (Miles & Huberman, 1994). For example, one tool use theme noted was students organize information, but rarely use their frameworks as the basis for decision making or integration of further evidence.

![Figure 1. Checklist matrix partially ordered across three study dimensions.](image)

**Findings**

**On Tool Use**

Students did not use tools strategically, as evidenced by three underlying themes. First, students used processing tools more appropriately when scaffolded and when provided with limited resource sets. During the initial problem finding stage, students were provided with 13 web pages and conceptual scaffolding in the form of question prompts in their note-taking tool. Students answered prompts explicitly, identifying underlying premises, conclusions, and restrictions, but neglected to describe patterns across and personal reactions about the information. During a problem framing stage, students were provided with 65 web pages and no conceptual scaffolding. Students identified less information overall, and skimmed resources by searching for keywords related to their problems.

Second, students did not attribute strategic values to the tools, using most infrequently and often inappropriately. For instance, some students did not effectively use their organization tool to seek patterns in the web evidence by generating problem-specific categories. Only 1 of 12 participants made use of a system function to integrate additional web information as "evidence" for a specific category or problem. Further, few students used print-based documents to evaluate resources or their own solution ideas with criteria, and most did not use information generation tools to argue for and justify their ideas (e.g., making hyperlinks on web pages to supporting evidence).
Finally, students relied heavily upon explicit procedural scaffolding, but neglected to use metacognitive guidance suggesting appropriate inquiry strategies.

On Learning

Three types of learning were evident in the study: problem, content, and process. Students identified basic problem information and used that to generate some original solutions. Students based these ideas on limited evidence, however, so many of the original ideas were flawed in design. For example, one dyad suggested an hourglass-shaped structure with external bracing. External bracing was a suggested technique found in the web evidence, but the odd-shaped hourglass design contradicted further evidence showing the structural failure of asymmetrical structures. Another dyad created an alternative design for building columns, employing layers of discs that could slide or pop-out during an earthquake instead of a single column that was shown to buckle and collapse. The solution was both original and relevant, but would not likely support an overhead load. The ability of students to test and revise their ideas within a lab or computerized simulation might have helped them move beyond partial understanding and misconception.

Beyond student understanding of specific self-selected earthquake engineering problems, most students acquired basic content understanding about general earthquake engineering constructs. Only one-half of the participants, however, demonstrated process understanding for open-ended problem solving following the study. Most were able to list steps in the process during post-study interviews, but few could describe the strategic value of tools to support that process.

On Student and Environmental Factors

Student and environmental themes suggested some possible causes for inadequate tool use. First, students exhibited characteristics of a naive epistemology: evaluating ideas summatively rather than formatively, infrequently revising and updating ideas on the basis of evidence, perceiving open-ended problem solving as non-complex, and seeking help from others rather than the system in a self-directed manner. Further, they managed resources and time improperly: skimming evidence, neglecting to use non-electronic resources, and rushing through activities. In terms of environmental factors, some students needed additional procedural training on tool use. Almost all students needed explicit training on strategic tool use, or at least more direction from the facilitators regarding which tools to use for strategic purposes. Finally, when student activities involved communicating with peers and facilitators, students' thinking reached high levels never managed by tool use alone (e.g., evaluation and justification of ideas). More communication activity during the study would have supported better inquiry and thinking.

Interpretations and Recommendations

Support Tool Use through Extended Training and Improved Interfaces

Students did not understand the value of their tools in this study. Myers (1993, p. 75) found students using hypermedia to solve open-ended problems needed time to learn to process that information in higher-order ways, "...perhaps a semester or school year." Such implicit, longitudinal training will eventually lead students to more appropriate tool use, or a more proactive technique would involve teachers explicitly training students on the strategic value of specific tools.

Students will tend to use scaffolding tools when they are conveniently located. Tool designers should embed scaffolding, particularly metacognitive, within information processing tools. These tools should not be far removed from the processes they seek to support. Further, tool-based scaffolding by itself is insufficient to support open-ended problem solving. Myers (1993) found teachers are also required to prompt students into appropriate action.

Support Learning with More Facilitation and Feedback Mechanisms

Students lacked endogenous models of earthquake engineering from which to interpret the evidence presented (Bruning, Schraw, & Ronning, 1995). In such situations, dialectical scaffolding is called for whereby peers and teachers with prerequisite facts and skills help students to reach proper levels of task engagement with selective help. Other techniques include the provision of manipulation tools which can promote personal theory development
(Land, 1995), or the provision of ongoing feedback from the teacher regarding student progress and performance. Finally, students should be required to state a prediction or hypothesis early in their inquiries, constantly reflecting on their stated assumptions as they encounter new evidence and revising their understanding when appropriate.

Encourage Student Intentions Strategically

Some students in this study exhibited characteristics of a naive epistemology which may simply be age-related or a function of the traditional school environment. While the problems provided to students in this study were open-ended, the KIE activity structure itself was rather explicit, structuring a series of activities for students. Students did not learn to apply processes, but gathered and learned basic information as one might expect from traditional learning environments. It seems likely that open-ended environments need to support students more implicitly in learning to handle the complexities of ill-defined problems. Laffey et al. (1998) designed tools that allow students to set their own goals and objectives, plan responsibilities, and allocate work to specific periods of time. To help students overcome their naive epistemologies, tool sets should strive to support processes implicitly rather than activities explicitly.

Implications and Conclusion

This research has implications for tool and instructional designers who can learn to design better open-ended systems and activities. Further implications apply to administrators and science teachers who seek to appropriately implement such curriculum reform. Authentic scientific inquiry is a model of learning that is far from prevalent in today’s classroom. It stresses the development of lifelong metacognitive and strategic skills (Duffield & Grabinger, 1997; O’Reilly, 1991). Realistically, open-ended activities take more time to develop and implement, also limiting the number of topics that can be taught (O’Reilly, 1991). However, educators will better prepare students for the scientific community if they cover fewer topics in more depth and stress the development of strategic thinking processes (Linn, 1987; Norris, 1988, p. 219; O’Reilly, 1991).

The study hypothesis was neither supported or refuted. Students did not exhibit higher-order thinking, nor did they use tools effectively. If students had used tools with strategic intent, it is still possible they would have thought critically and creatively about their resources to generate elaborate, original solutions. Future research can build upon the study recommendations to improve tool use and develop better process understanding. Longitudinal studies of students learning to strategically use tools over time are highly recommended.

Abstract: This paper reports on a study undertaken in Australia where the practice and development of generic skills was studied in the context of a Web-based learning environment. The results showed that students perceived the learning environment provided many opportunities for them to practice the generic skills being explored. Furthermore the results showed high levels of student perception of development of these generic skills. We conclude that Web-based learning environments offer many opportunities for teachers wishing to develop students' generic skills and this is yet another advantage of using this technology for program delivery.

Introduction

Education is often viewed by teachers and students as collections of courses and units, with units being comprised of learning objectives linked to domain specific outcomes. Increasingly we are becoming aware that effective university teaching and learning extends far beyond the development of skills and knowledge in specific subject domains (eg. Dearing Report, 1997). An holistic view of education suggest other forms of skills and knowledge that are important outcomes of university education. These holistic skills are often common to all courses and units irrespective of their subject domain and are often referred to as generic or key skills. The generic skills are those that students need, to become successful learners and successful practitioners in their fields of study and work and in other aspects of their life. In a society where change is rapid and where knowledge and information are now marketable commodities, this extended set of outcomes in curriculum and teaching are gaining prominence in all sectors of education.

One of the main factors causing the emergence of generic skills as a required outcome of formal education is the growing use of technology in all facets of life. Many of the generic skills that are defined and described relate to students' abilities to make meaningful use of technology. The influence of technology as the subject of generic skills coupled with emerging opportunities for students learning with technology appears to create a powerful synergy for generic skills development. The use of technology in teaching and learning already has been shown to provide many opportunities to teachers and learners. These opportunities include among other things, increased access to learning, increased flexibility for learners and enhanced learning outcomes in domain specific knowledge outcomes. If it can be shown that particular forms of technology use can also provide opportunities for learners' generic skills development, teachers and institutions can be guided by these findings into modifications and changes to their technology-based learning environments to provide even greater returns on their investments and efforts.

Defining Key Skills and Competencies

Defining the full range of generic and transferable skills that are useful (or essential) for university students is an exhaustive process. It is as almost as exhaustive as finding agreement in the terms which might best be used to describe the set. In the context of this paper we use the term generic skills to describe the full range of domain independent skills that are considered to be essential life skills for people both in and out of the workforce. There has been interest in key skills as outcomes of education for many years now. In
different countries, different sets of skills are listed, all with similarity and consistency to each other. The 1993 New Zealand Curriculum Framework, for example, proposed 8 essential skills as important outcomes of New Zealand Schooling. These were: communication skills; information skills; self-management and competitive skills; physical skills; numeracy skills; problem solving skills and co-operative skills, work and study skills. In the United Kingdom, The Qualifications and Curriculum Authority have developed a set of key skills that the government and much of industry consider as essential for successful lifelong learning and a flexible workforce. The QCA key skills comprised 6 areas; communication; information technology; application of number; working with others; improving learning and performance and problem solving.

The conceptualisation of generic skills is problematic in many ways. Bennett, Dunne & Carre (1999) describe a number of synonyms including personal, transferable, generic, common, work and employment related skills. Are they skills or are they competencies, capabilities or learning outcomes? The skills that are reported as important outcomes of schooling tend to be broad and extensive. In university teaching, the skills set is often narrowed to focus on those that are not, or cannot, be taught as discrete components of coursework. At the same time, the generic skills sought by university education assume learners are numerate and literate as a consequence of the requirements of university entrance. The key skills included in the mission statements of most universities tend to include higher level aims relating to critical thinking, inquiry and a capacity for lifelong learning. Typical generic skills described for graduates include:

- skills that students need to develop to becoming successful and self-sufficient learners. For example, information literacy, metacognitive skills (eg. Candy, 1994);
- intellectual and imaginative powers, understanding and judgement, problem solving and critical thinking skills and an ability to see relationships (eg. Squires, 1990; Ramsden, 1992);
- personal and interpersonal skills needed for communication, cooperative and collaborative teamwork, and leadership (eg. Ashcroft & Foreman-Peck, 1994; Gibbs et al. 1994).
- skills required for successful work practices including time management, task management leadership and self evaluation (eg. Gibbs et al. 1992; Blumhof et al. 1996).
Management of Self
- Manage time effectively
- Set objectives, priorities and standards
- Take responsibility for own learning
- Listen actively with purpose
- Use a range of academic skills
- Develop and adapt learning strategies
- Show intellectual flexibility
- Use learning in new or different situations
- Plan/work towards long-term goals
- Purposefully reflect on own learning
- Clarify with criticism constructively
- Cope with stress

Management of Others
- Carry out agreed tasks
- Respect the views and values of others
- Work productively in a cooperative context
- Adapt to the needs of the group
- Defend/justify views and actions
- Take initiative and lead others
- Delegate and stand back
- Negotiate
- Offer constructive criticism
- Take the role of chairperson
- Learn in a collaborative context
- Assist/support others in learning

Management of Information
- Use appropriate sources of information
- Use appropriate technologies
- Use appropriate media
- Handle large amounts of information
- Use appropriate language and form
- Interpret a variety of information forms
- Present information competently
- Respond to different purposes/contexts and audiences
- Use information critically
- Use information in innovative and creative ways

Management of Task
- Identify key features
- Conceptualise ideas
- Set and maintain priorities
- Identify strategic options
- Plan/implement a course of action
- Organise sub-tasks
- Use and develop appropriate strategies
- Assess outcomes

Table 1: A framework for the development of key skills (Bennett, Dunne & Carre, 1999)
Bennett, Dunne & Carre (1999) offer an elegant model (Table 1.) to conceptualise key skills in the higher education sector by suggesting a framework comprising 4 broad managerial skills. These authors argue that the important key skills are fundamentally those associated with being able to manage self, others, information & task. They contend that the bulk of all generic skills can be embraced within the four categories of this framework and they propose that this model can be applied “to any discipline, to any course and to the workplace and indeed to any other context “ (p. 77).

Developing Keys Skills
The provision of generic skills and competencies can be undertaken through a variety of forms. Traditionally it has been attempted through 3 main types of learning activity: integrated approaches, stand alone approaches or approaches where key skills are developed in parallel with the conventional curriculum. (eg Drummond et al. 1997 cited in Bennett, Dunne & Carre, 1999). Many writers question whether it is really possible for the learning taking place in university settings to be transferable to vocations and the work place. One school of thought suggests that through situating learning in meaningful contexts, this transfer can be facilitated (eg. Brown, Collins & Duguid, 1989). Contemporary thinking is that university learning can be significantly strengthened through workplace-based practica and applications (eg. Seagraves, Kemp & Osborne, 1996).

On-line problem-based learning
We have been using the WWW in our university teaching for several years now and recognise that one of the major benefits of the use of this technology is the facility it provides to incorporate learning activities which help to develop students' generic and transferable skills (eg. Herrington & Oliver, 1997; Oliver, Omari & Stoney, 1999). In the introductory multimedia course in our undergraduate program, we have embraced a Web-supported problem-based learning environment with which the students engage and interact with the course content. The system involves learners working in collaborative groups to explore...
the solutions to open ended and ill-defined problems. From these activities we have sensed learners developing a raft of generic skills through their interactions and activities in the Web-based course.

The on-line system we have been using is a database driven Web-based learning system designed to support a form of problem-based learning. The database elements enable the system to record, manage and support the interactions of a large number of students and a large number of tutors. The system supports problem-based learning by providing a means for students to collaborate on set problems, to share resources, to post solutions and to compare and review answers from other groups. The system was designed with a degree of flexibility in mind to enable it to be used in a variety of ways in a variety of units and courses. Typical use of the system in a course of study is expected to revolve around the following activities which were characteristic of our initial implementations and trials. The system is Web-based and all the following activities are undertaken using on-line technologies:

- Each week a problem is presented to students, the purpose of which is to contextualise and authenticate the weekly content of the course.
- Students are required to work within groups of 3 or 4 to explore the topic, locate relevant information and resources, consider the various options and outcomes and to create a response which is informed and well argued.
- The group post this solution to the bulletin board, an action which then reveals to them the solutions of the other groups in their cohort. Each group is asked to review the solutions of the others and through their feedback, the solutions are given a peer-assessed grade. Each tutor also reads the solutions and gives a mark which is added to the peer-assessed grade to give an overall mark for the solution.
- Students are able to view the marks achieved each week in a number of ways and this mark accumulates throughout the semester as each new problem is solved.

The nature of the learning involves high degrees of self-regulation on the part of the students. There is very little support or help provided and students have to judge when and where their research will stop and when and where their summarising and reviewing will stop. At first glance, this learning environment appears to provide many opportunities for students to practice and develop their generic skills. It was our impression from observing the students' learning activities and levels of engagement in the problem solving tasks that students had many opportunities to practice a large number of the generic skills shown in Table 1. What was not clear though was the extent to which these skills were being practised and the influence of this practice on actually developing and extending students' existing levels of these skills. The aim of this study became to explore the generic skills which the problem-based learning environment caused learners to practise and the extent to which this developed, or had the potential to develop, the particular skills.

**Method**

The learning environment was implemented in a first year university course with an enrolment of 90 students. The theoretical component of the course was well suited to problem-based learning and the system was used to support students' problem solving activities through weekly problems for 10 weeks of the course. A questionnaire was administered to students in the 8th week of the course after they had completed 7 problem solving activities. The questionnaire provided students with a list of the generic skills described by Bennett, Dunne & Carre (1999) and students were asked to reflect on:

1. the level of practice that the problem-based learning environment encouraged; and
2. the extent to which this practice contributed to their development of the discrete skills.

The instrument used a Likert Scale to enable learners to show their responses. The questionnaire took 15 minutes to administer and was completed by the students in their class settings. After the questionnaire had been given, a small number of students were interviewed to gather some first hand data on the strategies employed in the problem solving processes. It was clear that students were using a range of different approaches in creating their weekly problem solutions and the different strategies were likely to influence their practice and development of the generic skills.

**Results**

a. Practising Generic Skills

To explore the level of practice encouraged by the problem-based learning environment, the questionnaire showed each of the generic skills listed in Table 1 and asked students: *How often did you practise the
following during the problem solving activities? Responses were made using a Likert scale with the options: never, a little and regularly. Table 2 below shows the students responses as a percentage of the options chosen. A weighted index was calculated to determine the relative amount of practice each skill received on a scale from 0 to 2, with 0 representing no practice and 2 representing regular practice.

Table 2: Students' Perceptions of the Relative Levels of Practice of Generic Skills

The striking outcome from this first dataset was the extent to which students perceived the learning environment encouraged them to practise the generic skills. There is insufficient space to show the discrete scores achieved for the 40 individual skills listed in the table but the summary data conveys the overall information quite clearly. For example, in terms of practising generic skills associated with self-management, the sample of students perceived that they failed to practise any the listed generic skills only 3% of the time. In the sample of 32 students, there were only 10 instances when students felt that their learning activities did not practise one of the 12 generic skills listed for self-management.

The summary data shows that students perceived that overall their learning activities involved a little practice of the generic skills 50% of the time and regular practice of the generic skills 44% of the time. Among the 4 categories, the one category that seemed to be least practised was that of management of others. When we say least practised, there were more instances in this category than the others where students perceived they were practising these skills least but the overall practice level still remained quite high. The skills in this category related to working with others and practising the skills associated with delegation, negotiation, collaboration etc. It was clear that the way we had structured the approach limited students' opportunities to continually practise some of these skills. The students remained in the same group throughout the semester and from one week to the next, some members assumed roles within the group and this led to a lessening of their practise of such tasks as delegation, chairmanship, etc. The category that students appeared to practise the most was that of information management. The use of the Internet and WWW as a resource base was a fundamental component of the Web-based activity and each of the problems involved many skills associated with access, reading, reflecting and using information. It is difficult to imagine another learning environment where more practice was possible.

b. Development of Generic Skills
The study also sought to establish students' perceptions on how much skills development was associated with the practice they were doing. Although we often associate practise with skills development, it is useful to explore whether this is the students' perception and to explore whether or not students feel that their skills are being developed through their learning activities. Table 3 shows the results of students' responses to the question: How much did the problem solving tasks help you to develop these skills? against each of the 4 generic skills categories. To explore this area in more detail, students were given a 5 point Likert scale on which to record their results, the scale ranging from not at all, through to very much.

Once again, the results were very positive and showed that the students perceived that the learning environment helped them in more than minor ways to develop the various generic skills. There were only a small number of instances where students felt that the learning environment did not contribute to the development of particular generic skills. The value of 6%, as an average of those perceiving no learning at all, in Table 3 is indicative of a very small number of students and an even smaller number of discrete skills. The perceived levels of skills development correlate highly with students perceived levels of practice and if we assume that students can tell when they are developing skills, then the amount of practice
is a metric which can be used to reflect skills development. Interviews with the students tended to support this assumption. In interviews, the students gave examples of their increased abilities to seek and use information, to work with others and to manage open-ended tasks, all examples of the skills in Table 1.

</tbody>
</table>

Table 3: Students’ Perceptions of the Relative Levels of Generic Skills Development

Table 3 provides an indication of the relative levels of skills development between the 4 categories and once again, the weighted index provides a measure by which this can be compared. Once again students perceived the management of others to be the skills which developed to the least extent and the management of information to the skill which they developed the most. In all cases however, both the results and the student interviews suggested that the students felt that had developed skills across all 4 categories. The weighted indices were all equal or greater than 2.00, the middle value of the scale. Once again, the discrete data for each of the 40 skills provides some interesting material for discussion and highlights particular skills which a small minority of students felt were less developed than others.

Summary and Conclusions

The results from this study have provided strong confirmation of our expectations that the Web-based learning environment helps students to practise and develop their generic skills. The study shows that the students’ perceptions are that there were few generic skills in the framework described by Bennett, Dunne & Carre (1999) that were not practised in the process of learning through the Web-based learning environment which we had developed. Likewise, the results showed that the students found few instances where their learning activities did not also contribute to the development of the generic skills listed. While there were some small differences observed in the perceived levels of practice and development across the 4 categories, the results were very positive for them all.

It is our intention now to create our own set of generic skills based on the needs and demands of our course and programs and to use the data from this study to see which skills might need to be intentionally considered in modifications we will make to the learning environment. We sense that it will be possible to modify the learning environment in a number of ways to address those skills which we are particularly interested in developing and to reduce the levels of practice of students in skills which are of lesser importance. One limitation with this paper has been its reliance on student perceptions as its measure of the amount of practice and level of skills development. For the purpose of this exploration, we feel that our results still have validity and we base this feeling on substantiating evidence from student interviews and the consistency of the data that was gathered. We suspect that in our future work we will need to explore ways in which we might find more empirical measures on which to base assumptions about generic skills development and plan to make this an integral part of our future work.

Note: An earlier version of this paper was presented at ASCILITE’99 held in December, 1999 in Brisbane, Australia.

Abstract: This paper describes a project undertaken in Australia where national flexible learning materials were developed. The paper describes the rationale and background of the project and the processes by which a set of Toolboxes were developed for widespread use in the Australian context. The paper discusses issues that arose out of the project and provides information and ideas for others who are looking at ways to create scalable and sustainable technology-based resources for education.

Introduction
On-line technologies such as the Internet and World Wide Web hold considerable promise for improving accessibility and quality of education and training programs. In the context of the vocational, education and training (VET) sector, these technologies have particular relevance. In the Australian setting, many authorities within the VET sector are using and promoting flexible learning as a preferred delivery form for their courses and programs (eg. ANTA, 1996). Within the VET sector, flexible delivery can support a wide array of learning settings including open learning and work-based learning. On-line learning materials are seen to be fundamental for increasing flexibility. However, the move to on-line learning among these groups, while desirable from many perspectives, has been slow and fragmented.

There has been considerable interest paid from all sectors in recent years to strategies that can support and encourage efficiencies and economies in both the development and delivery of on-line teaching and learning. Much of the early development of materials has been conducted by individuals or small teams for local and restricted use (Collis & Oliver, 1999). Whereas with CD-ROMs, people often planned large projects with big budgets and gained returns on their investment through widespread use of the product, the same cannot be said for the majority of developments of on-line learning materials. National and state authorities responsible for VET within Australia have recognised that developing online materials is expensive and best achieved through a collaborative approach (EdNa VET Advisory Group 1999). It was this challenge that prompted the Australian National Training Authority (ANTA) to consider strategies that could motivate and support registered training organisations (RTOs) to embrace modes of flexible delivery for their students. A resource strategy was formulated by which sets of generic and customisable materials could be developed and applied widely throughout the training sector. The intention was to create efficiency and economies of scale though large scale production of learning materials capable of wide acceptance and use. This plan became the ANTA Flexible Toolbox Project and is further described in this paper.

Vocational Education and Training in Australia
In Australia, the mission of ANTA is to "ensure that the skills of the Australian labour force are sufficient to support internationally competitive commerce and industry and to provide individuals with opportunity to maximise their
potential” (ANTA, 1998a). ANTA’s agenda has been “to deliver training more responsively and efficiently and to a wider catchment area” (ANTA, 1998). The Authority recognises that technological advances have been the catalyst for new forms of educational and training communication systems and that the demand for, and supply of vocational education and training is globalising. Consequently it has enacted and sponsored strategies to encourage the VET providers to provide more flexible, technological-based, delivery for domestic and international markets. ANTA recognised that implications of technology advances and globalisation required “new ways of creating and customising training material” (Eccles, 1998). The Toolbox initiative was one of ANTA’s strategies to encourage development and delivery of more flexible learning materials for the training market – particularly for online learning. In 1998-1999 ANTA invested $3.8 million in “toolboxes” with the aim of producing a “smorgasbord of multimedia resources from which providers can pick and choose in designing online training programs” (Eccles, 1998).

The setting of a national framework with many discretionary elements provided a perfect opportunity for the Australian National Training Authority to explore the concept of Flexible Toolboxes to support learning. In the first instance, any products developed in this setting would have widespread application providing significant economies of scale. Secondly the use of on-line technologies appeared to provide and promote the many forms of flexibility associated with the delivery of the Training Packages in the national setting.

Flexible Toolboxes

The concept of a Toolbox as a building block for flexible delivery and open learning is relatively common in education. The concept imbues the notion of a set of tools that can be implemented by teachers and trainers to create and implement on-line and computer-based learning environments. The concept is a powerful strategy as a means to create sustainable and scalable materials for technology-based teaching and learning (eg. Hanley, Schneebeck & Zweier, 1998). Where a Toolbox creates unique and innovative opportunities is through the provision of alternative options to the creative teacher. Furthermore a Toolbox is intended to facilitate its use through its ability to stand-alone and to be employed through customisation and adaptation. Given these inherent characteristics, Toolboxes are often chosen as productive solutions to the development and delivery of flexible and on-line courses (eg. Oliver, Omari & Herrington, 1998).

Toolboxes come in varying shapes and forms and the term itself is quite flexible in the way in which it is applied. The single most important characteristic of the Toolbox concept is its flexibility of use and, in the various interpretations that have been made of the concept, this characteristic is extremely variable. Figure 1 shows a continuum describing flexibility of use as it can be applied to toolboxes used for on-line learning. Across the continuum, it is possible to identify discrete forms of toolbox applications. Consideration of the discrete forms shows that there are opportunities across each for open and flexible materials development. At the same time, each of the forms carries limitations and pitfalls that can act to impede their application and use.

Because of the impetus to create resources for Training Packages, ANTA deliberately sought to develop Toolboxes that were towards the “restricted” end of the continuum. It was recognised that it would be an advantage if the materials that were developed could be implemented in their immediate form. While a number of providers of VET courses have substantial information technology resources, many are not in a position to make major changes to on-line materials. Providing online materials which demanded high levels of input was not seen as desirable. At the same time, it was considered important for the materials to have the capacity to support user customisation, and thus an important component of the initial design brief was to require that any materials developed for the project had a capacity for customisation by the teachers and training providers.

| restricted flexibility of use total |
| --- | --- |
| curriculum packages | course modules | generic tools |
| on-line courses | Java Applets | content-free applications |
| complete programs | course resources | construction templates |
| course exemplars | curriculum materials | construction shells |

Figure 1: A flexibility continuum describing Toolboxes for on-line learning
Therefore, in the context of this project, a Toolbox was defined as “a set of multimedia resources that provides a framework for the development of training programs for online delivery to meet the requirements of Training Packages. As discussed, a key feature of the Toolbox was that providers could customise the contents to meet the needs of learners and enterprises. The toolbox was required to constitute two essential components (1) a completed multimedia program designed to satisfy specific training competencies and (2) a range of tools and functions which provide access to the program’s components and resources. The building blocks that could come together to form the multimedia package were conceived to be available as separate resources. Each toolbox was expected to utilise a wide range of the building blocks. For example:

- Packages of generic resources in a variety of media;
- Developer’s notes, guidelines, supporting documentation and technical guidance to facilitate online provision;
- Learning materials ‘translated’ from the Training Package and combined with authoring software to facilitate the development of further, customised materials;
- Assessment instruments which meet the assessment guidelines contained in the Training Package and combined with authoring software to facilitate the development of further, customised materials;
- Interactive tutorial packages on researching through the internet, including directory services, and WWW with simulated search examples, search tasks;
- Generic case studies, and interactive simulation games,
- Guidelines for communication functions (e.g. email, web forums and chat) and student management systems;
- Tips, hints, ideas for student friendly, student ‘grabbing’ instructional design;
- Web sites with email for comments, support and feedback on material developed as part of the Toolbox and
- Listings of publicly accessible Web sites relevant to the content of the targeted Training Package.

The Development Project

A detailed specification was developed and applications were called nationally for parties interested in developing Flexible Toolboxes. Over 100 expressions of interest were received and after an exhaustive selection process, twelve were finally selected for funding. In all instances the Toolboxes represented cohesive sets of course materials for various qualifications comprising around 12 areas of study, each with many defined competencies. The various Toolboxes covered a cross-section of training areas and qualification levels. Their proposed construction included a range of authoring tools and included CD-ROM, LAN and Web as intended delivery media. Portability, the capability of the software to run on a range of hardware systems, differed across the Toolboxes. Some Toolboxes were designed to be platform independent whereas others required the purchase or access to proprietary delivery systems, eg WebCT. Similarly the ease of customisation (sequencing learning events, adding/deleting/modifying resources and content, changing text/graphics) varied considerably across a range of dimensions (user skill levels, pre-requisite software and hardware). An additional project called the ‘Toolbox Central’ was established to provide an on-line professional development and quality systems to support the implementation and application of the Toolboxes once they had been developed. The Toolboxes covered a variety of training areas including Hospitality and Tourism, Metal and Engineering, Community Services, Agriculture, Information Technology, Workplace Training and Assessment, Printing and Graphic Arts, Rural Business Management and Agriculture.

The Evaluation Team

The Toolboxes were developed over an eight-month period and were completed by the middle of 1999. ANTA recognised that this was rather a bold and innovative project and contracted an external team to evaluate and monitor the development of the individual Toolboxes and to provide a mentoring facility for the developers to assist with the timely completion of a quality product. The Evaluation Team established close contact with all the developers and created channels of communication between them to create a sense of community and a sharing of knowledge. Communication and contact between the various teams was facilitated by a Web-based Communication Hub that was built for the project with a range of communication facilities (Figure 2). The Evaluation Team monitored all stages of the development process and provided constructive feedback in such areas as project management strategies, instructional design and system architecture. It was the intention of ANTA to use this project as a learning experience to inform and guide subsequent projects of this nature.

It was interesting but not surprising to find that the various development teams, while anxiously pursuing best practice in all aspects of the design and development, were generally reticent and reluctant to work in the collaborative ways which the evaluation team was seeking. The teams tended to have tight and fixed timeframes
with firm development ideas and tended to know what they wanted to produce and the best approaches to be used. For these sorts of reasons, the planned high levels of communication and interaction planned for the teams were not achieved nor was collaboration and cooperative sharing. The Communication Hub did however provide a vehicle for enabling public scrutiny of the project and its various components and it served well as a distribution centre for project information and document delivery.

![Diagram of the Communication Hub](image)

**Figure 2: The Components of the Communication Hub**

**Project Outcomes**

On completion of the project, the development teams had produced multimedia resources for nine Training Packages. Each development team created resources for ten to fifteen units of competency, each representing approximately 40 hours of independent study. The set of Toolboxes represented an enormous collection of new and exciting technology-based resources for the Australian VET sector. An on-line distribution system was established to enable institutions and training providers to view selections of the available resources and to order them for their own use. All of the Toolboxes were made available to any Registered Training Organisation for the cost of the media and distribution. In practice, this meant people could buy $A3.5 million dollars worth of teaching and learning resources for about $A2500. In most instances though, RTOs would buy only those Toolboxes appropriate to their own training areas.

Despite the broad range of subject areas involved and the range of industries represented, there were many patterns and consistencies identified by the evaluation team between the learning materials. Some comparisons and descriptions of the various toolboxes in terms of teaching and learning processes functionality, flexibility and utility are given below. There were many indicators by which the success of this project could be measured. Some of the more important indicators of success included:

- The timely completion of the Toolboxes;
- Extent of completion to the agreed technical and functional specifications;
- The quality of the learning materials within such functional criteria as: scope, flexibility, and portability; and
- The quality of the learning materials from an instructional perspective.

Despite the array of hurdles and obstacles that faced the teams embarking on new projects and working in areas and ways which were distinctly different from previous experience, timely completion was met by most and completion to the technical and functional specifications was generally achieved. The evaluation team observed an array of issues associated with large scale project development and many recommendations and new strategies were fed back to the organising panel as guides for future projects. Perhaps the most pressing item that emerged from the evaluation was the need for detailed specifications to guide all aspects of the design and the development processes. While developers were given strong indicators at the commencement of the project as to the intended audience and the need for flexibility in their development approaches, the resulting products differed broadly. The differences occurred across a number of areas and it became evident that the varying interpretations placed by developers on the stated requirements and product utility had the capacity to limit aspects of the projects’ intentions.
**Technical Requirements** The requirements for utility as defined in the project brief included such technical requirements as multiple platform capability, modularity in structure, and consistent file organisation and directory structures. The large variations in approaches that were ultimately used created a number of challenges for determining how the products would be stored and distributed. Across the 12 Toolboxes, there ended up being many Gigabytes of information to store and distribute. While the various Toolboxes each represented independent entities, they still needed forms of consistency to ensure maximum scope for use among the various users and students.

**Performance** The specifications that the developers followed indicated that the Toolboxes needed to provide minimum levels of functionality in terms of progress tracking, privacy safeguards and ability to be customised to meet the needs of the users. Once again, providing descriptions of the functional requirements alone resulted in a range of different approaches and the extent of the differences proved to be a factor that had the prospect to limit application.

**Flexibility** Developers were required to provide flexibility in the form of an easily customisable set of resources with a range of customisable features. The end-products tended to meet the specified requirements but developers had chosen different approaches and solutions. The majority of the customisable elements and strategies appeared at the screen level and involved a high overhead time to implement. Once again, the extent of the variations gave rise to the feeling among the evaluators that these specifications needed expansion for the best outcomes to be achieved.

The second area of inquiry and guidance for the evaluation team related to the quality of the products from a teaching and learning perspective and as with the functional elements, large differences emerged in this area as the following sections demonstrate.

**Content** Developing multimedia learning materials is different in many respects to developing conventional learning materials. One major difference exists in terms of the content that can be used. The various Toolboxes differed considerably in the scope and extent of the media elements used. It became clear that some developers were using design and development processes more suited to development of print-based materials and were quite limited in their thinking and resourcing. On the other hand, the best examples from the project provide evidence of outstanding uses of the media and content to support learning. Developing guidelines which create more consistency in terms of the media applications among products was seen as an important future activity.

**Learning Strategies** As with the content, many differences were observed in the forms of learning strategies employed by the instructional designers across the various projects. As might be predicted when conventional design processes are being employed, many of the learning settings appeared as electronic forms of paper-based materials. Across the various Toolboxes there were many strong examples of effective design for electronic and interactive learning and many examples of learning strategies designed to take advantage of the best features of technology-based learning. For example, use of video and sound files in case-study settings, interactive modules to engage the learners and activities using the Web to facilitate cooperation and communication. Some development teams were constrained by the content provided and the view of their content experts and industry expectations in terms of how a learning package should appear.

**Assessment** The challenge for developers of technology and Web-learning environments is to creatively use the facilities to create assessment strategies and activities that enhance the learning experience as well as measuring achievement. All of the Toolboxes were required to provide activities for learners to self-assess their competency. While there were some sound examples among the various Toolboxes that could guide future developments, assessment tasks tended to measure learning outcomes through conventional processes such as objective tasks and multiple choice quizzes.

**Media Usage** One of the major criticisms of education and schooling in the past is that it is abstract and removed from reality. Multimedia and on-line learning can reduce the abstractness of education by providing learners with access to real life settings, realistic environments and authentic information and cases. Several Toolbox development teams used the opportunity provided by this project to create information and content that reflected this real world use. They used examples drawn from real life and presented cases rather than abstracted descriptions. These types of Toolboxes contrasted sharply with those that tended to present text descriptions instead of videos or
pictures to portray real life settings; and subject matter experts talking about processes in place of videos showing the process studio re-enactments in place of real life footage. It was clear to the Evaluation Team that there were many opportunities where Toolbox projects could have made better use of the technologies from a teaching and learning perspective. However, it should be noted that there were many constraints on the designers in terms of expectations from teachers and industry about the forms they perceived the learning materials should take. It was clear that a process of education was needed to move thinking along the path to more student-centred and active learning settings. The first set of Toolboxes contained many fine examples for people to follow and these were seen as a good way to start and support this learning process.

Summary and Conclusions
This was a very large multimedia development project by any standards. The budget for the project exceeded $A3.5 million dollars and the completed Toolboxes contained on-line and technology-based learning resources for over 150 competencies, each a discrete, self-contained online learning program. ANTA purposely used the 1998 project as a pilot and as a learning exercise for future policy and resource emphasis. It was an intentional strategy to provide flexibility to the developers to encourage and stimulate creativity and innovation. The Evaluation Team was established as a means to gather data and to provide feedback which could inform future practice. The main findings of the Evaluation Team related to the forms of specification and prescription needed to be given to developers to provide consistency between the completed products in relation to their technical and instructional characteristics. In essence these specifications could provide consistent forms of quality between the Toolboxes in all the important areas.

As this paper was being written, the second stage of the project was in its early stages with an increased budget and the benefit of hindsight influencing the procedures and policies being used. An evaluation is planned that includes investigating the use and application of the first set of Toolboxes. At the same time, the second project has concentrated on developing effective environments for on-line learning and exploring ways to encourage developers and designers to use the technologies to promote students’ knowledge and understanding. Feedback from the first project has been used extensively to guide and inform the second development round.

There were many things learned through the development and evaluation processes associated with the ANTA Toolbox project. The process was designed not only to produce learning materials but also to develop sustainable strategies and processes for these endeavours. As this project drew to an end and a follow-on project commenced, it was heartening to see the many lessons that had been learned by the stakeholders in this initial project being reflected on and used in meaningful ways in the follow-up project.

Abstract: The growing use of information and communications technologies in commerce and industry is once again encouraging debate and questioning of the development of students' skills and knowledge in this domain. Whereas in the past, the debate has centred on school education, questions about ICT literacy are now being raised in the context of post-compulsory education. Post-compulsory education sits ahead of employment and ICT literacy in the population and workforce is seen as an important component of a nation's competitiveness and advancement. This paper explores the concept ICT literacy in the light of new technologies and suggests factors that are currently seen to limit and impede its attainment.

Introduction
In the early days of computers in schools, a common rationale for the investment in hardware and software was the notion of computer awareness. This concept was premised on the view that schools had a responsibility to introduce students to this emerging technology and to prepare them for the fact that one day computers might have a role to play in their daily living. As time went on, and the impact of computers in society grew, the notion of computer awareness evolved to computer literacy, not only knowing about computers but being able to use them. Throughout the 1980s the relevant literature abounds with descriptions and comment on both the rationale for such programs and evaluations of their success (eg. McCormick, 1992).

In the past ten years, computer technologies have diffused into many aspects of everyday life and in recent years this diffusion has been accelerated and exaggerated by the convergence of computer and communication technologies. The place of computer technologies in schools has evolved from objects of study or specialist applications to tools for teaching, learning and administration. Computer literacy disappeared from main gaze and focus of attention as the stand alone computer lost its novelty. But today, the concept is regaining attention as the new technologies once again gain novelty and public attention through the next phase of their development. This renewed interest appears to be fuelled by Internet and communication technologies, which are causing yet another revolution their use and growing influence of life and society.

The renewed interest in computer literacy appears to be driven not only by those in education and industry but also by governments looking to maintain or to upgrade their world competitiveness through leadership in an activity set to dominate the trade and corporate world in the new millennium. Whether it is the place of schools to expose students to computers and information technology (IT) for vocational purposes, or simply for personal needs, remains a much argued point. It is clear that many in government perceive the development of IT skills in schools as an economic and vocational imperative. This view is not shared by all and we are frequently reminded that the role of education is:
“Not so much to closely align to the ephemeral demands of industry but to equip students with the more fundamental, expansive skills of being able to critique and reflect on the changes taking place in their society” (Watkins, 1986, p. 85)

The concept of computer literacy appears now to have moved beyond schools to the post-compulsory education institutions that prepare graduates for employment. The purpose of this paper is to explore this renewed interest in computer literacy and to establish the growing implications for the post-compulsory education sector.

Defining Computer Literacy

There have been many studies over the past two decades into both the concept and attainment of computer literacy. These have focussed on many different aspects of the perception of computer literacy. Much effort has been put into defining set of skills, which adequately describe a computer literate person. Other efforts have focussed on devising assessment tools to measure levels of these skills, a difficult task in such a multi-faceted and complex area. Further studies have compared computer literacy levels and attitudes towards computers with different groups of people, based on gender, ethnicity or socio-economic factors.

Through the 1980s, computer literacy tended to be considered a grab-bag of different skills and attributes. A widely accepted definition of computer literacy is that of Simonson, Maurer, Montag-Torardi & Whitaker (1987) who define computer literacy as:

"An understanding of computer characteristics, capabilities and applications, as well as an ability to implement this knowledge in the skilful and productive use of computer applications suitable to the individual roles in society. (p. 232)"

In this definition, the knowledge and skills of a computer literate person were divided into four components comprising computer attitudes, computer applications, computer systems and computer programming. While this is now a dated definition and classification, it has been used and modified in subsequent studies (e.g. Smith & Necessary , 1996) and the concepts broadened to be independent of a given time frame. The essential elements of this form of definition still hold currency today.

The Evolution to ICT Literacy

The rapid developments in communications technologies which have occurred over the past ten years has seen a broadening in the range of skills that are considered to be imperative to the constantly evolving notion of computer literacy. We now see a spectrum of differing expressions and terms which relate to computer literacy. For example, information technology literacy, Net literacy, digital literacy or on-line literacy (eg. Gilster, 1997). Overwhelmingly however more recent references in the literature still often use computer literacy as an appropriate keyword for reference listings. Definitions of computer literacy have varied in their breadth over time and with the rapid changes in technology are evolving accordingly.

Where once “basic” computer literacy was narrowly defined and could be used to easily differentiate students that were deficient. Such students could be directed to specific “context free” courses to build their computer literacy. Over the past decade, the notion of “basic” is too obscure when considering the myriad of potential contextually driven applications of computers in contemporary society. Increasingly there appear to be diverse cohorts of students, each with different bundles of computer skills, knowledge and attitudes. Students could be considered literate in one setting but illiterate in another. For example, many school leavers have the ability to confidently browse and use the WWW but may have little or no file management or word processing skills. Similarly, there are a large number of mature aged students who have had no prior computer experience.

The move toward the broader term of information and communication technology (ICT) literacy has at its roots the need to involve the acquiring and advantageous use of information through the use of technology. Use of a range of communication tools such as the Internet, e-mail and the World Wide Web (WWW) for the location of information and dissemination are now considered to be components of ICT literacy and yet not necessarily that of computer literacy. In addition, many of the skills, which had previously been associated with those that an individual would need to have acquired in order to be considered computer literate, are now commonly seen to be components of the more encompassing term of ICT literacy. Many authors describe the place of computer literacy as a component of a more encompassing list of ICT skills (eg. Eisenburg & Johnson, 1996; Shapiro & Hughes, 1996; Bruce; 1998).
Generic Skills
The notion of computer literacy is tending to be considered a component of a larger set of key skills that have been identified as important outcomes of schooling outside the domain of traditional curriculum areas. These generic skills include such elements as reading and writing literacy, communication skills, numeracy, critical thinking and people skills (e.g., Gibbs et al., 1994; Harvard, Hughes & Clark, 1998). An emerging trend is the perception that ICT literacy forms part of a generic skill set, with implications for teaching and learning in the schools, as well as for life-long learning and just-in-time learning. The American Library Association, for example, recognizes the need for ICT skills in the form of information literacy skills as necessary for America’s continuing success in the information age. The ALA (1999) discusses the future role of the teacher moving from textbook lecturer, to coach and that an effective information literacy (IL) curriculum moves away from learning traditional library location skills taught in isolation to one of learning IL skills which have been embedded in the curriculum. The desired outcomes are for people who are prepared for lifelong learning, because they can always find the information needed for any task or decision at hand.

The role of ICT skills as being fundamental to general work place literacy is reiterated by Mikulecky and Kirkley (1998) and Tomei (1999). The implications of this for post-secondary education are that there appears to be a significant shift to providing a range of generic skills that allow the learner to prepare for a life where learning is an ongoing process. The need for appropriate and sustainable ICT skills is implicit in these types of recommendations.

Operationalising ICT Literacy
The net result of the incorporation of ICT literacy into the realm of generic skills has seen a move away from its definition as a discrete series of skills and attitude and knowledge components to a more competency-based description. ICT literacy is increasingly being seen as a capacity for purposeful and effective use of ICT technologies in one’s own setting and this creates different needs for different people. In the context of schooling and education, it is now recognised that ICT literacy describes a range of personal competencies that are in many cases distinct from ICT components specific to the needs of individual subject disciplines and domains. It is interesting to note that there is now a perception of ICT literacy specific to being a successful student and across all sectors of education, discrete and appropriate ICT skills are being suggested.

For example, Collis (1999) argues that post-compulsory students today need, at a minimum, skills and competency in the use of appropriate presentation systems such as word processors, electronic display systems. Students need to be able to use e-mail to send and receive communications and need to be able to use Web browsers to access and retrieve information from this source. When one deconstructs exactly what levels of computer skills and use underpin these forms of competency, this level of specification necessarily includes an array of associated skills including competence, confidence and efficiency in the use of hardware, software and operating systems associated with personal computers, networked computers and the Internet.

Yet another component of the ICT literacy issue which is gaining prominence among teachers and educators is the impact of these technologies on the basic forms of reading and writing literacy. There are a number of writers who have demonstrated that computers and the Internet are changing the ways in which many people communicate through the written word (e.g., Warschauer, 1999; Orlikowski & Yates, 1994). The Internet in particular is changing the way many people write and the screen-based technologies are impacting on the way many people read. Researchers are arguing that given the rapid uptake of ICT technologies, these changes will soon need to be recognised in the way literacy is taught and developed in schools and universities (e.g., Bruce and Candy, 1994).

The use of Internet and communication technologies in the delivery of both information and instruction for learners has seen in recent years a significant lifting of the perceived baseline level of ICT literacy deemed necessary for post-compulsory students. Trends suggest that this list of competencies will likely grow in the near future as ICT technologies continue to develop and have application to teaching and learning. The increasing use of computers in all aspects of life seems set to bring about even more changes to our perceptions of what actually constitutes ICT literacy. The research suggests that different disciplines within education are now recognising the
impact of ICT on their core business and are creating strategies to deal with it, for example, linguists and language teachers and teachers of writing and reading literacy, information skills, and teachers of training (eg. Victorian University of Technology, 1998).

With growing use of ICT in the workplace, demands for literacy have now heightened with growing emphasis on reading, comprehension and information literacy, and on the ability to gather information from multiple sources and to use the information meaningfully and critically. This is leading (in many low and middle-level jobs), to a more complex understanding of literacy that includes making critical judgements about the accuracy, current relevance, and unexpressed messages implicit in information (eg. Mikulecky & Kirkley, 1998).

The concept of 'just in time learning' is diminishing in many instances the need for the general resources employees must bring to an occupation. Technology can now manage many of the operations in a job by sending exactly the right information to exactly the right terminal at the right time (eg., Talbot, 1999; Flew, 1998; Tomei, 1999). The scenario appears to exist for future workers to go to a workplace without the specific skills to operate in that particular environment but with the technology skills and abilities to rapidly adapt to the potentially changing requirements of the job. The rapidly changing nature of the workplace can mean that given the appropriate information the worker has the skills needed to seek out information, as it required.

Achieving Computer Literacy

There are formal programs now in many countries to encourage and support the development of IT skills in schools. The results of these programs and activities ensure that many students entering post-compulsory education have some level of ICT literacy although all too often, students demonstrate largely varying levels of skills and knowledge. There is evidence that many post-compulsory institutions are moving positively to address the need for ICT literacy among students. Some require prospective students to undertake ICT literacy tests and to take bridging courses prior to commencing their studies. A survey by the American Association of State Colleges and Universities in 1995 reported that 22% of American State Colleges and Universities require computer literacy of their students (Davis, 1999). Many of these have initiated computer survey courses to redress the lack which was reported at this time. In addition a number of universities worldwide require that students purchase their own computers to use in their learning programs (eg. Davis, 1999).

Increasingly students at all levels of education are gaining ICT skills at home as home ownership of PCs increases to almost saturation levels. In Australia, for example a recent survey of student Internet users in school, vocational education and universities, revealed that for 96% of them, the primary point of access for students was through a home computer. Sixty seven percent of those surveyed indicated that the educational institution was their secondary point of access (White, 1999). In Australia in 1999, 96% of the educational institutions had access to on-line services. Recent studies among school students have clearly indicated the strong influence of home use on skills development. The students with the highest levels of ICT literacy are frequently those with home access to computers and Internet technologies.

Achieving ICT skills going forward into the next century is becoming increasingly complicated as education authorities move toward embedding a whole raft of ICT skills into the general curriculum. Models of different approaches are:

- to either include intensive courses in ICT at the commencement of enrolment or at periods throughout an individuals life
- to present individual modules which occur at the precise time when the skills and tools are required by the learner to satisfy other learning objectives.

Tomei (1999) describes these models with respect to adult learners who were reported to prefer the second model. This 'infusion' approach differs from the more traditional approach of delivering a single intensive course at a less appropriate but probably at more convenient times, the 'concentration' approach.

Whilst both approaches have benefits and disadvantages educational institutions at all levels may find that a hybrid of these two models may be desirable. Certainly there are often subject specific components of ICT which have to be dealt with in an 'infusion context as they are required whereas more generic ICT skills outcomes can be achieved by the 'concentration' approach. But in the long run, most appropriate forms of skills development are
those where the skills are practised and developed from relevant experience. Karsten & Roth (1998) report results from their study that suggest that it is the relevance rather than the quantity of computer experience that students bring to class that is the most predictive of performance. The results also suggested that although a wide variety of computer experiences enhance student perceptions of their computer competencies, only those experiences that develop or enhance the specific computer skills defined to comprise computer literacy in a particular context are likely to have an impact on computer-dependent course performance.

There is a growing awareness in all circles of education of the need for context and relevance in the teaching and learning processes especially those associated with ICT literacy. For both adolescents and adults, the most likely path to success lies in integrating the new technologies into the activities of everyday learning. Computer simulations, tutorial programs, the Internet, and information-processing and electronic communication tools can be used to address these learning goals. These goals are (a) learning to think critically while solving problems, (b) becoming familiar with the use of technology tools for processing information, (c) expanding the breadth of materials encountered by learners, and (d) developing habits of mind suitable for lifelong learning (Tomei, 1999).

ICT In Post-Compulsory Education

For the majority of students post-compulsory education sits between schools and workplace. It is in this setting that many believe ICT literacy is most importantly dealt with. Studies have revealed differences in ICT literacy between minority groups and discipline areas (eg. Smith & Necessary, 1996). Institutions with active social justice views and policies are now stipulating benchmark levels of generic graduate skills for the workplace among which ICT literacy in its various forms can be found. In most studies where ICT literacy has been explored, an important indicator of students’ skills development has always been the extent to which students have been exposed to the new technologies in their courses and programs. And research in this field has always demonstrated that this is heavily influenced by the ICT literacy of the teaching staff (eg. Carr, 1998). Students who learn in technology-enriched learning environments develop practical experience in the use of ICT technologies as a matter of course (eg. Davis, 1999). This practice becomes problematic when it is common, students across education sectors to frequently demonstrate higher levels of ICT literacy than their teachers. Consequently, many writers now express the view that an efficient way to improve the ICT literacy levels of students and school leavers is to firstly address the ICT literacy levels of the teaching staff.

It is clear that the ICT literacy levels of students is very much influenced by the level of ICT use in their educational programs and this in turn is influenced by the degree of confidence and competence of their teachers to appropriately integrate ICT applications within learning experiences. Across all sectors large differences exist in the use of IT in educational programs. The use of ICT technologies has long been seen (and proven) as a way to create enhanced learning outcomes in subject domains (Davis, 1999). Its capacity to provide important and useful generic skills for students’ working and private lives is yet another reason supporting ICT technology use as a teaching and learning tool. The use of the ICT technologies in teaching provides a means to create meaningful learning experiences which can develop a range of generic and transferable skills, among which are those associated with ICT literacy (eg. Oliver & McLoughlin, 1999).

Summary And Conclusions

A reading of the extant literature in relation to computer and ICT literacy reveals that this topic is still an important issue for many stakeholders in the education process but that its scope is often underestimated by policy makers and education and training providers. As a consequence of the burgeoning use of the Internet and Web, ICT technologies are becoming integral parts of all facets of life, from education to work. We are seeing governments and industry pushing for graduates to demonstrate appropriate skills and knowledge in this area to enable them to retain and push their competitive edge in commerce and trade. And we are seeing learning enhanced through applications of ICT technologies as information and learning tools. We are seeing new ways of learning and new ways of communicating through these technologies. Among all this, however, there are examples of vastly differing levels of ICT literacy among students and graduates.

It is clear that ICT literacy is most effectively developed through relevant and contextual use of ICT technologies. Students with home computers regularly show higher levels of ICT literacies than their counterparts whose only access and use is through school and education. The key to improving ICT literacy levels would appear to be through an increased and targeted use of technologies in teaching and learning programs appropriately modelled
by teachers. Impediments to this are the levels of available infrastructure and the capacity of teachers to make meaningful use of the technologies in their programs. There is a growing body of evidence which suggests that the rate determining step in moving along the path of ICT literacy is the general low levels of ICT usage in educational courses brought about by low levels of ICT literacy among teachers in general. The way ahead in all of this is clearly through the promotion of ICT literacy among teaching staff and by immersing students in technology rich and stimulating learning environments where information and computer literacy is both a learning enabler and a learning outcome.

ASSESSMENT OF ONLINE INTERACTION: HELPING OR HINDERING THE GOALS OF EDUCATORS AND LEARNERS?

Meg O'Reilly
Teaching and Learning Centre
Southern Cross University, Australia
moreilly@scu.edu.au

Abstract: This paper considers new approaches to assessment in the online environment. Increased use of computer-mediated communications for teaching and learning is affecting assessment strategies across disciplines. Initial investigations are equivocal and point to the need for more questions regarding whether assessment of online interaction in a variety of formats is helping or hindering the goals of educators and learners. Data was collected in 1998 via interview and email questionnaire to discover the goals of educators in their approaches to assessing online interaction. Responses were received from nine educators across four continents – Australia, South Africa, Canada and the United Kingdom. Initial results demonstrate that the conditions for effective use of assessable online interaction rely upon matching educators’ goals with their approaches to assessment. Questions around student responses to assessable online interaction were explored through the literature, yet further research is needed for a fuller picture.

Background

Over the past decade, discussions have proliferated on the educational use and effectiveness of computer-based technologies such as the World Wide Web and email. Most questions have focused on the nature and purpose of online communications; possibilities of this medium for education in general and learning outcomes in particular; opportunities for development of new teaching and learning strategies; and implications for changing roles of educators, learners, experts and novices.

Broad-ranging as these questions are, we can take some heart from recent reports on the effectiveness of online strategies for teaching and learning and the concomitant staff development responses (e.g. McNaught, 1995; Allen and Otto, 1996; Ellis, O’Reilly and Debreceny, 1998; Sherry, 1998). In regards to assessment, the online environment has promised to bring greater support to learners and educators alike through immediacy of feedback and availability of a collaborative learning community (Jonassen, 1995; Parry and Dunn, 1999; O’Reilly and Morgan, 1999).

When used effectively, online interaction has the potential to build communities of learners, foster the development of meaningful collaboration and support deeper levels of learning (Mason, 1990; Harasim, 1992; Yeoman, 1996; Holt el al, 1998). Coupled with assessment, online interaction is now being shown to be affecting individual student approaches to learning, students’ motivation to collaborate and provide mutual support to peers, as well as influencing both group and individual learning outcomes (Rimmington, 1998; Thorpe, 1998). For example, Parry and Dunn (1999) found that:

...while collaboration can foster “deep” or “meaning” approaches to learning, it is important that meaning approaches to learning tasks are valued in the assessment regime; students are unlikely to invest much time and effort in any activity that is not rewarded by an assessment grade, and this applies equally to learning ‘how to learn’ strategies [in the online environment].

Methodology

Interviews were conducted in early 1998 with educational designers across seven Universities in Australia to determine the location and activities of educators who were experimenting with dialogue and assessment in the
online environment. Similar questions were posted to four international email discussion lists seeking introductions to educators identified as innovative in their adoption of the online environment for student assessment. Approximately 30 contacts were made, though several of these proved to be 'blind alleys', where the online interaction of learners was not ultimately assessed. Through this 'snowballing' method of contacts (Roberts and Taylor, 1998), a small sample of educators reported to be using online interaction as a component of assessment was identified and surveyed by email questionnaire.

Nine educators from a total of four continents provided responses – six from Australia, one each from South Africa, Canada and the United Kingdom. The results of these surveys were processed according to a mixture of qualitative and quantitative approaches to the data. Responses to survey questions were viewed by frequency and specific comments were collated with the help of computer software to assist in the sorting processes. Making sense of the responses on email questionnaire – the verbal categorical data – was the crux of the task, since each of the responses were in respect to different discipline areas and reflected somewhat different objectives and strategies.

The principle question for investigation concerned the ways in which technologies helped or hindered the meeting of educators’ goals. Further investigations are needed to complete the picture from students’ perspectives as to whether assessment of online interaction is seen to help or hinder their own goals and learning outcomes.

**Features of online interaction and assessment**

Since commencement of this project, adoption of online technologies in teaching and learning has grown exponentially. Although the most common uses of online technologies are for communication and assignment submission via email or web-pages, there is an increasing adoption of structured online assessment processes. These include group discussion to support individual assignment preparation, collaboration on a common project or presentation, peer-review and self-review, and problem-based approaches to cases, scenarios and consultancies, to name just a few.

This paper considers only those features exemplified by respondents to the questionnaire and the resultant roles emerging for both educators and learners. Before moving onto the formal results section, let’s take a brief look at the individual cases reported and their unique features.

**Teaching and Learning Strategies for Interaction**

(a) **Group support for individual product** – both formal and informal structures can provide learners with opportunities for discussion without full dependence on each other for a grade. For example, listserv discussions can provide collegial practice in developing professional discourse in a supported environment such as in “Discrimination and the Law” (Macquarie University, Australia). In this case students are required to (1) submit weekly critiques of a specified article to the group, drawing out the legal argument (2) participate in informal discussion with peers concerning these critiques, the evidence of legal argument or assumptions, and (3) continue to actively participate in online interaction.

(b) **Collaboration for common product** – students are asked to work together in teams to coordinate development of a conference and website (“Science and Communication” University of Melbourne, Australia) or a professional co-authored paper for publication (“Environmental Psychology”, University of Pretoria, South Africa; “Nursing Honours”, Curtin University of Technology, Australia). Development of skills includes teamwork, collaboration, negotiation, presentation, a shared sense of achievement and academic standing in the field.

The products in these examples each demonstrate elements of professional standards. Specifically, “Science and Communication” students experience the organisation and participation in a conference of professional standing where discipline based experts participate as keynote speakers, and these first year students present their own work to a mixed audience of peers, staff, experts in the field and family supporters. “Environmental Psychology” students publish a co-authored paper of suitable quality to submit for refereeing by professional journals. “Nursing Honours” students publish a refereed online nursing journal for access by peers and professionals alike.
Peer review plus self-review – having worked together towards a common goal, students may then be asked to assess their own progress and to evaluate the contribution of their peers. This may be an assessment of group processes or the final product, but must be according to given or previously-negotiated criteria.

The projects for “Science and Communication” University of Melbourne; “Environmental Psychology”, University of Pretoria; and “Nursing Honours”, Curtin University of Technology have all been briefly described above. Students in these subjects follow up their project work with specific activities which lead to self and peer assessment. In another example from Curtin University of Technology, “Foundations and Issues in Science, Mathematics and Technology Education”, students are acknowledged as co-professionals. As qualified teachers themselves, students have a rich resource in their own daily classroom experiences from which to draw upon in reflective exercises. The choice of a social constructivist approach to learning in this subject therefore readily lends itself to critical reflection, and assessment includes the journal-based input of students regarding their own learning-in-action as well as that of their peers.

(d) Debate – students may form teams and through negotiation select a topic and their position on the debating team. Following a given preparation period where work may be collegial, a debate can take place according to established protocols. A very sophisticated example of online debate is the international collaboration called “Communication and the Media” conducted between University of South Australia; Governors State University, Chicago; and University of Technology, Sydney.

In this instance, the debate is a particularly authentic genre of expression in such a subject. For students to formally research and develop a more-or-less provocative position, and then to challenge the arguments of members on opposite sides, is highly applicable in the vocational contexts of a range of media. Debating topics concerned with globalisation and the media, and to further be engaging in debate across cultural differences significantly enhanced students’ learning, sometimes in the most poignant experiential ways.

New Roles

New roles for educators which can be gleaned from these examples include facilitation, moderation and the orchestration of a distributed community of learners. We have already seen how the educators involved with “Communication and Media”, UniSA/UTS/GSU; “Science and Communication” University of Melbourne; and “Discrimination and the Law”, Macquarie University, had the work of coordinating and facilitating students’ activities in novel, applied and appropriate ways.

Another example is the subject “Designing Training for the Internet” from Open University, UK. Here students do just that, they are required to develop training materials in the web environment for their own organisation’s purposes, using templates and asynchronous text based support from teaching staff. The resulting outcomes from this subject not only provide students with useful resources which they may implement in their workplace, but also provide the educators with new resources and a range of authentic approaches to build upon in future iterations of delivery and for future cohorts of students.

Additional online assessment methods illustrated in this study include the use of automated quizzes and exams (“Business Finance”, University of Technology, Sydney; and “Microeconomics”, University of New Brunswick, Canada). In these cases, the interaction demanded of students while online is their response to assessable questions presented within formative and summative activities. The new role of the instructor in these instances includes development of assessment tasks which support knowledge testing and reduce the likelihood of, or desire for cheating.

Learners now also find themselves developing a range of new skills simultaneously with their development of subject specific knowledge. These skills include – research and critical review of resources found online; experience in the formation of virtual groups, where dependence on non-verbal cues is unreliable or even impossible; publishing web pages; collaboration in either synchronous or asynchronous modes which take place across times zones and cultural contexts; and the review of peers which though anonymous must be ethical and constructive.
Results

Results show effective use of assessable online interaction where such interaction is an inherent objective and thus supports the educators' goals. Examples include areas which value development of communication skills, collaborative activities such as problem-solving and peer review. Figure 1 summarises (a) the technologies used in the nine case studies to facilitate interaction and (b) the educators' reflections on the impact of these technologies upon their teaching strategies and their goals as educators. It can be seen from this summary that in many cases educators are using both the capacity for dialogue and speed of the technology as well as the capability of students themselves to engage and support group and individual student learning.

Questions around student responses to assessable online interaction were explored through the literature, yet further research is needed relating students' perspectives of assessable online interaction to their own learning goals. A small glimpse of the student perspective is revealed in Figure 1 through feedback quoted by educators.

Online assessment approaches were identified as hindrances where the technology failed to be transparent and presented obstacles to learning. In some cases, for example the international debate between USA and Australia, breakdowns in technology were treated as inevitable and students were not penalised nor ultimately prevented from carrying out their assessment activities. Rather, students' motivation to collaborate and provide mutual support in the face of technical problems revealed approaches to learning which move away from an entirely competitive culture.

Hindrances were identified in the form of escalating workloads arising from the very appealing opportunities for dialogue. These hindrances were not however a fundamental drawback of the educators' goals but point to the need for careful design of teamwork, discussion and support for collaboration. Of note is the problem of keeping up with the changing environment of educational technology, identified when the study was conducted in 1998 and which continues today. Students' objections to mandatory dialogue and dependence upon fellow learners for assessable activities further challenges notions of flexibility and independence boasted by traditional print-based distance education.

Conclusions

Research such as this, which principally considers educators' goals, must further consider learners' goals. Hindrances identified in this study suggest appropriate educational design for teaching with reliable, robust technologies and through purposeful dialogue will ensure rich and rewarding teaching and learning experiences.

The study reinforces the work of John Biggs (1996) in identifying the need for a constructive alignment between objectives, teaching and learning strategies, and assessment as being fundamental to successful online teaching and assessment. Such a matching of goals with assessment is not only critical from the educator's perspective but is also essential to an effective learning experience by reflecting the process of learning in the strategies for assessing the outcomes of learning.

Used with care and consideration, it seems that assessment of online interaction can enhance group and individual learning outcomes and precipitate motivations.

<table>
<thead>
<tr>
<th>&quot;Interactive&quot; Technologies Used</th>
<th>Helping or Hindering Educators' Goals</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. • Computer conference with tutors and trainees&lt;br&gt;• Email&lt;br&gt;• Javascript self-tests</td>
<td>Technologies defined the educators' goals.</td>
</tr>
<tr>
<td>2. • Listsever</td>
<td>It appears as though goals were achieved, students benefited</td>
</tr>
</tbody>
</table>
• Personal email contact
• Individual feedback on assignments

significantly from this course, switching from being taught to becoming independent learners.

3. • Notice board discussion
   • Small group discussion
   • Formal debate

Technology helped a great deal in actualising much of the content e.g. cultural diversity (Australian students interacted with US students); ‘new technologies’ (subject considers impact of new technologies on the nature of communication).

Only hindered by limits of the technology [organisational policy] e.g. no provision made by IT dept. for real time chat.

4. • Asynchronous conference
   • Journal for submissions
   • Email

WWW facilitated learning about information literacy in addition to enhancing learning in regards to objectives of the subject.

5. • MCQ self-assessment
   • Timed online exams
   • Email and group conference

Students appreciate one-to-one responses to email questions. On-screen graphics help illustrate key concepts and elucidate verbal arguments. Auto grading for tests and exams ensure immediate feedback, fundamental to successful learning.

6. • One-to-one and group email
   • Collaborative web publishing
   • Database searches on CDROM

We are moving quickly each year and the learning curve for revisions is always a problem. For example, electronic conferencing [systems] were at our disposal but simply no time to learn to use [them] effectively. Battle to find productivity tools e.g. drag-and drop web authoring packages that are affordable, always a dilemma. Extra instruction is needed to overcome the deficiencies of what we can afford.

7. • Email (tutor-student, student-student)
   • Discussion Room or Notice Board
   • Course Materials on WWW

Our goals are about social constructivism and connected learning, so the older forms of distance education were very frustrating for us. It is so much more powerful for our (practicing teacher) students to be able to share ideas and experiences, tell ‘war stories’ from their school context and know one another (and us) as struggling co-professionals.

8. • Online Q&A discussion with 24 hour turnaround from staff
   • Self-assessment quizzes, auto graded
   • Package of CBL scenarios

[Online technologies] help to:
- deliver opportunities for conversation
- arrange relevant learning, practical and non-cheatable assessment tasks
- reduce time spent answering repetitive questions and providing feedback
- communicate in a caring and consistent manner to a very large and diverse student population (~1100 students)

9. • Assessable critique of article by each student
   • Assessable informal discussion among peers
   • Constant discussion with tutors on the listserv

The combination of printed study materials and listserv discussions enabled the students to learn with each other and from each other. Some students found the weekly contributions a bit much but it also meant that they studied regularly rather than in bursts.

This panel will discuss the role of Internet advertising in higher education. Advertising on college and university campuses has long existed through sporting events, soft drinks, magazines, newspapers and bookstores and more. Yet with the introduction of the Internet in recent years, the impact and prevalence of ads on college and university campuses has changed. Computer savvy Generation Y is demanding schools provide costly Internet tools and resources and some universities are struggling to find ways to offer these tools to stay competitive. Collegiate Web sites offering these tools and resources are extending themselves to Universities free of charge with the condition that the schools allow the sites to present ads. Universities are now faced with a tough decision. Do they accept the free resources Internet companies are offering with advertising or do they try to create a comparable Internet offering or their own?

Abstract. Telelearning research conducted in our research centre in the last five years has resulted in a Virtual Learning Centre (VLC) model and an implementation for Web-based training called Explora. This system is now in operation at Télé-université, in three professional corporations and in a company. Our VLC model focuses on the interaction spaces between five theoretical actors: the learner, the informer (content expert), the trainer, the manager and the designer. The Explora implementation supports learners and the other actors in their interactions. Each actor has a specific environment enabling him/her to manage his/her activities, consult and produce information, engage in collaboration and receive assistance from different sources. We will finally present a reengineering process that has been applied to transform a traditional distance education course into a web-based course within the Explora environment.

1. An Open Virtual Campus Model

In our societies, individuals and organisations are coping with an exponential growth of information and the knowledge management challenge. The rapidly evolving availability of multimedia telecommunication is an answer to this challenge but it has to be mastered, to mature, not mainly technologically but in the way people use it, in the way it is integrated to practice, conceptions and attitudes.

Behind terms like “distance education”, “on-line learning”, “telelearning” and “multimedia training”, is a multifaceted reality from which we can identify many paradigms. High-tech classrooms, virtual classrooms (Hiltz, 1990), multimedia Web-based training, on-line learning communities (Harasim, 1990 and Ricciardi-Rigault et Henri, 1994) and electronic performance support systems (EPSS) (see Gery, 1997) are all modalities that can be integrated in a truly open virtual campus. Such a virtual campus will enable individuals and organisations to manage transitions from the predominant classroom presentation to fully interactive telelearning.

We see a telelearning system as a society of agents, to use Marvin Minski’s term, some of them providing information and explanations, others constructing new information, still others fostering collaboration between agents or providing assistance to the other agents on content, pedagogical process or organisation of activities.

A Virtual Learning Centre (VLC) is the central part of a Virtual Campus where instructional resources, learning events as well as technological and organisational infrastructure are created and assembled to forward the delivery of telelearning systems. Our VLC model (Paquette, 1997) emphasises the concept of a process-based learning scenario coupled with assistance resources. Basically, the learner proceeds to a scenario, a network of learning activities, using different kinds of information resources to help her achieve the tasks and produce some outcome: a problem solution or new information that can be used in other activities. The assistance resources for each task are also defined during design process. The assistance can be distributed among many agents: trainers interacting through e-mail or teleconferencing, other learners, contextual help or intelligent advisors.
2. The Explora Model: Actors, Roles and Agents

We have described elsewhere (Paquette et al., 1993 and Paquette et al., 1997) how we have built an object-oriented model of a Virtual Campus. In our Virtual Learning Centre architecture, we identify five actors, each personified by different persons or media agents.

The Learner transforms information into personal knowledge. "Knowledge" means the information that has been integrated by a cognitive entity into its own cognitive system, in a situated context and use. The learner achieves knowledge acquisition and construction by managing a learning environment planned by another actor, the designer, through collaboration with other learner agents, consulting and producing information, receiving assistance from other actors.

The Informer (the content expert) makes the information available to the learner. It may be a person or a group of persons presenting information, but also a book, a video, a software or any other material or media. Conversely, the learner will also produce information that can be made available to others through an informer agent, as a result of his/her production activities.

The Designer is the actor planning, adapting and sustaining a telelearning system (TLS) that integrates information sources (human informers or learning materials), and also self-management, assistance and collaboration tools for the other actors.

The Trainer provides pedagogical assistance by giving advice to the learner about his individual process and the interactions that may be useful to him based on the learning scenarios defined by the designer.

Finally, the Manager provides organisational assistance to the learner (and other actors) by managing actors and events, for example creating groups or making tele-services available in order to ensure the success of the learning process, based on the scenarios defined by the designer.

![Figure 1 - Actors and interaction spaces](image-url)
Figure 1 shows the five theoretical actors and their interactions with the learner. In our VLC model, there are five interaction spaces: management, consultation, production, collaboration and assistance, each giving access to a number of resources.

3. The Delivery System: the Hyperguide and the Explora Environments

At delivery time, the learner and the other actors interact within a computer-based learning environment called the Virtual Learning Centre. The Explora implementation of such a system is a web-based server that helps designers build a learning environment for each actor, adapted to their role in a certain course or telelearning event. Then the other actors can use their own Explora environment to intervene in relation to the course web site.

Each course can be any web site we called the Hyperguide. This web site describes the course structure, down to learning scenarios and learning activities distributed into modules or learning units. Each scenario gives access to specific resources to be consulted or productions to make.

Figure 2 shows such a HyperGuide for an introductory course in artificial intelligence. The main window here is one of the Hyperguide pages showing the scenario for module 3. Each oval shape represents a learning activity. A click on it brings the description of the learning activity: goal and type of the activity, expected duration, resources to consult, productions to make, proposed assignment steps.

The rectangular shapes give access to the input resources: a text to read, a video to watch, a CBT or a multimedia simulation to interact with. They also give access to output resources storing the learner’s production for future use in other activities, exchange with other learners or submission to a trainer for evaluation.
Different actors need different points of view on the host system in each interaction space. For example, in the information space, a learner will need different input resources such as a list of related web sites, videos from a server, or didactic software on AI content. In the same information space, a trainer needs other information resources: traces of the learners activities for diagnosis, information on the group of learners and on learner productions and annotation tools to identify and organise information for assistance.

These resources are made available through an external palette as shown in the floating window of figure 2. This is what we call an *Explora environment*. It is an actor's set of resources for a course or program supported by the Virtual learning centre. It groups resources into five interaction spaces (self-management, information, production, collaboration and assistance) according to an actor's role and course specifics. In the example here, if we open any one of the five menus in the Explora window, we can gain access to the following resources.

Table 1. Example of the distribution of resources in an Explora Environment

These resources are all external to the web course. There are three types of resources:

- Java applets that we have developed mainly to exploit the learner's trace in the web course, to build individual progress reports, group profiles, advice generation or support to peer collaboration tools;
- Executables downloaded or resident on the user's workstation, that trigger CBTs, simulations, or generic software shared by the group so that file exchange is facilitated; this is particularly needed for some communication tools wherein the use of different software will simply not work.
- HTML generic services that sometimes have to be sometime adapted to the course content; examples of these are course evaluation questionnaires through which learners and trainers will give feedback to designers to improve the course, and also the webography which is a structured list of commented web sites.
4. Reengineering a course for a Virtual Learning Centre

We will now focus on four major steps in a process through which a distance learning course can be re-engineered into a HyperGuide within Explora environments. In the example above, we started from a distance course at Téléuniversité based on a package containing printed documents, a 500 page book, a study guide describing the course and its learning activities and a technical guide for the software material. The package also contained 8 small software on 3 diskettes to illustrate IA concepts and 8 videos on VHS cassettes for a total of 4 hours' viewing time.

1- Engineering the telelearning system. We have re-designed this course with MISA (Paquette et al 1997). The MISA method presents the ID processes and tasks according to an engineering perspective analogous to software engineering. This method innovates by using cognitive modelling techniques to represent knowledge, as well as pedagogical scenarios, learning materials specs and delivery plans. In this process, we have made all the fundamental decisions, separating the components specific to the AI content that must be integrated in the HyperGuide web site and the generic resources (documents, tools, services) that will be useful for this course in an Explora environment.

2- Building the HyperGuide web site. This second step was rather straightforward, based on the MISA models that provided precise orientations to the development team. They could then focus on the ergonomics of the web site and the presentations of the pages with very little interaction needed from the designers. Three other courses have been rapidly constructed afterward on the same model.

3- Selecting actors and resources. This task was achieved in parallel to the previous one, based on the MISA models. At this point, we have decided to have only two actors at delivery time: learners and trainers (called tutors here). An informer actor was not necessary, since all the content had been mediated. A manager actor may be added in the future. The learner’s and the trainer’s environments are quite similar but specific tools for the trainer have been designed to give them access to a more synthetic group progress profile, to maintain a FAQ, to animate teleconferences and to integrate their evaluation into the learner’s progress results.

Linking a course HyperGuide and the Explora environments. This last step has been presented recently with more details in (Girard et al, 1999). Essentially, the designer is here using some of the Explora designer’s tools to define progress levels for each learning activity or knowledge unit. Then these progress levels are updated according to the learner’s actions in the HyperGuide web site by the system, according to conditions defined by the designer, or by the learner’s direct action in a viewing interface. These progress levels form a user model employed by the system to give feedback and support to the learner. Support is given using help messages, avatars demonstrations, but also adapting the interface with graphical cues to guide the learner to aspects of his task or to resources that may be useful to him. This aspect is being developed in a new graphic adaptive interface described in (Dufresne et al, 1999).

Conclusion

There are many advantages to the open architecture that has been presented here. The Virtual Learning Centre is at the learning organisation’s level, thus avoiding duplication and facilitating evolution and reuse of resources from one course to another. It also speeds up the design process because each individual web-course (the Hyperguide) is freed from all the generic resources and the information management load between different actors. Furthermore, each course can have a very different content, structure and presentation. In fact, it can be any web site, regardless of the software used to produce it. On the other hand, all of the Explora environments are similarly structured, thus facilitating their use in different courses by learners, trainers or managers. From an organisation’s viewpoint, this architecture facilitates management through standardisation of resources, without constraining the design teams in a particular authoring software.

Multiple Representations in Interactive Learning Environments: Two Case Studies

Alan P. Parkes, Constantinos Drakakis, & George Marselos,
Computing Department
Lancaster University
Lancaster LA1 4YR, UK
app@comp.lancs.ac.uk

Abstract: This paper discusses two systems that exploit multiple representations to facilitate learning. The Programming Tutor facilitates the acquisition of fundamental programming concepts through interaction with textual descriptions and flowchart simulations of program behavior. The Electricity Laws Tutor supports understanding of some of the basic laws of electricity through the use of co-operating representations: text, formulas, simulated circuits, and animated metaphors. Dimensions of multiple representations are discussed, as are their potential advantages and disadvantages. The paper discusses the evaluation of the two systems, and concludes with a brief discussion of the problems arising in attempting to evaluate multiple representations for learning.

Introduction

Most forms of learning involve information that is encoded into different representations. We can have "paraphrases" of information expressed in the same medium (e.g., a textual explanation of a corresponding mathematical formula, for example). Alternatively, we may find representations of some aspects of given information expressed in different media (a flowchart and a fragment of programming code representing the same algorithm, for example). Certain representations may be chosen in preference to others because they make otherwise abstract or hidden features and processes concrete and visible. Concepts that are usually formally expressed and can be difficult to conceptualize may benefit from being expressed in an alternative form. An obvious application of this is the drawing of metaphorical representations, such as rope and pulley diagrams, to capture salient details of an abstract notion such as force (Larkin & Simon 1987).

It is often the case that different representations exploit and express different properties of the represented thing. The diagrams used to express geometry problems are excellent for expressing the relationship between lines. There are conventions for indicating that two lines are parallel, for example. However, reasoning must also be applied to solve problems, observational evidence alone is insufficient. The incorporation of multiple representations into interactive multimedia learning environments presents exciting opportunities to support and enrich the learning experience, in three main ways. Firstly, representations can be animated. Secondly, the representation can be manipulable so the learner can control and explore the effects of changes to the representations. Thirdly, representations can co-operate, in the sense that the effects of changes in one representation can be seen in terms of corresponding changes in the other representations.

This paper describes the evaluation of two interactive learning environments. Both embody one or more of the above three dimensions of animation, manipulability, and co-operation. The domains featured are in one case, the learning of basic laws of electricity, and the other, the acquisition of basic programming concepts.

The structure of the paper is as follows. The next section outlines certain dimensions of multiple representations, and the advantages and disadvantages of multiple representations for learning. Section 3 briefly describes the two systems. Section 4 discusses their evaluation and the results obtained. The paper concludes with a brief general discussion of the evaluation of co-operating multimedia representations.

Multiple Representations in Learning Environments

This section considers some useful properties that can be use to analyze and categorize multiple representations, and then discusses the potential advantages and disadvantages of multiple representations.
Dimensions of Multiple Representations

The key dimensions of multiple representations have been identified as perspective, precision, modality, specificity, and complexity (van Someren et al. 1998).

The perspective taken by a representation may be functional, behavioral or physical, or some combination of these. A functional perspective of a program may describe its major components and the interface between them. A flowchart represents one possible behavioral perspective on the program. The code of the program itself represents, to some extent, a physical perspective.

The precision of a representation is the level of accuracy with which it represents the target entity. A representation may be precise in some ways and not in others. Consider a diagram of an electrical circuit showing the components (battery, lamp, etc.). The diagram precisely defines the relative placing of the components in the circuit, but the depictions may bear little or no resemblance to the components themselves.

The modality of a representation refers to its predominant form (text, graphics, video, and so on).

The specificity of a representation refers to its informational economy. Representations have computational properties (Larkin & Simon 1987). The computational properties of a representation refer to its support for tasks such as inference and search. For example, it is much easier to locate a component of a software system in a structure diagram than by scanning the code.

The final dimension of multiple representations, according to van Someren et al., is complexity. Consider a flowchart for a program and the corresponding program code. Many of the same features are present in both representations (e.g., a given Boolean test), albeit in different forms (a loop, visually represented in the flowchart, may appear in the program as a “WHILE” loop). In this sense, there is some redundancy in the representational scheme, which enables each representation to offer a unique viewpoint on the salient details.

In multiple representation schemes, the different representations are usually conceptually linked. However, they could also be physically linked, in the sense that operations in any of the representations result in the corresponding operation being carried out automatically, where appropriate, in the other representations. Such “co-operative” multiple representations have been considered in (Cox & Brna 1996), (Parkes 1991), (Parkes 1992), (Parkes 1994a), and (Parkes 1994b).

Advantages and Disadvantages of Multiple Representations

As indicated by the preceding discussion, to represent all of the salient details of the topic, several complementary representations may be necessary. Text may provide a detailed description, but an accompanying diagram may be indispensable in orientating the learner to the key elements to which the text refers. Moreover, for a complex domain, it is possible to separate key details out into different representations, which avoids overloading the learner with a single all-encompassing and highly complex representation.

Expertise in a given domain is often, at least in part, related to the ability to use several different representations as and when needed, and to be able to translate concepts into, and between, such representations as necessary. Co-operating multiple representations can support the learner in the task of integrating the different representations into a conceptual whole, as learning progresses. Such schemes can also help the learner to pace the learning process. In the initial stages, the learner focuses on one or more of the simpler representations (e.g., a circuit diagram). As knowledge and confidence increases, the learner can devote more attention to the more complex or abstract representations (the formula for Ohm’s law, for example).

The redundancy present in multiple representation schemes reinforces the encoding of information in long term memory, by providing the opportunity for rehearsal of that information in different forms. Moreover, the fact that the redundant information can be acquired through several forms may provide several “memory traces” for that information, thus ensuring that the information is more likely to be retrievable from long term memory in the future. Multiple representations can provide a learner with access to a preferred representation. Learners can choose which representation to attend to. In a single representation system, a learner who encounters problems in understanding the sole representation must seek alternative representations outside of the learning environment in question.

A potential problem with the use of multiple representations is that each representation may be, in some senses, a statement in a different “language”, and a learner may need to acquire its syntax and semantics, which may obstruct the learning of the target domain itself. Co-operative representations may help here: the user can observe the corresponding outcomes in several representations. The user will be able to learn about the unfamiliar
representation by observing the translation of changes between an understood representation and an unfamiliar one. However, while such positive transfer of knowledge can take place, there is always the possibility that misconceptions about one representation may propagate misunderstandings throughout all of the representations.

A final potential disadvantage of multiple representations concerns development cost. Each representation is essentially an interface in itself, and must be designed, implemented and evaluated as such. Moreover, if the representations are co-operative, each representation must have an associated set of controls to manipulate it. As designers, we intend each representation to be effective and necessary. The provision of a representation that benefits no learner is a pointless exercise. This point is discussed further in the concluding section of this paper.

The preceding discussion suggests that the potential advantages of the use of multiple representations for learning outweigh the disadvantages. We now describe case studies involving two interactive learning environments, both of which feature co-operating multiple representations.

Two Interactive Learning Environments

The systems described here were developed by the second and third authors as students on Lancaster’s MSc in Distributed Interactive Systems (Drakakis 1999), (Marselos 1999). The target domains of the systems were, in one case, fundamental programming concepts and, in the other, basic laws and formulas of electrical circuits.

We now briefly describe the two systems, before considering their evaluation.

The Programming Concept Tutor

This system (Fig. 1) facilitates the acquisition by complete novices of basic programming concepts, such as input, output, assignment, simple arithmetic expressions, conditional expressions, and loops. The tutor uses animated flowcharts to express the programming concepts.

The learner can proceed through the lessons in a suggested order, but also has direct access to any lesson at any time. Interactive exercises are provided for each topic, as described later.

Each lesson occupies one complete screen. At the left of the screen is a textual description of the concept. In the center of the screen is a picture of the flowchart construct that represents the lesson topic. On the right of the screen is a flowchart representing a complete program featuring the lesson concept. This flowchart can be animated, so the user can watch the execution of the flowchart (continuously or via single stepping). Along the bottom of the lesson screen are other representations, such as a textual description of the current statement, and a small “display screen” showing output from the animated “program” as it executes. Clicking on any flowchart symbol anywhere in the system results in information about that symbol being presented to the learner.

The exercises involve the learner in identifying the errors in example flowcharts. They are answered by clicking on appropriate flowchart segments, which are then placed into the appropriate part of the flowchart, replacing the erroneous part. Explanations are provided for both correct and incorrect answers.

The Electricity Laws Tutor

The aim of this system (Fig. 2) was to facilitate an understanding of the basic concepts of electricity, and formulas for Ohm’s Law, Power (Wattage), Serial and Parallel Resistors, etc.

A main screen provides direct access to each lesson, and a suggested, but not enforced, order is given. Interactive exercises are provided for each topic, as described later.

Each lesson occupies one complete screen. A screen features a textual explanation of the law or concept, the actual formula of interest, an animated circuit diagram and a metaphorical animation exemplifying the topic concept. There are a number of (+ and -) buttons that are used to increase or decrease the values of one of the relevant properties (e.g., voltage). Typical examples of the metaphors used are water pipes with changing diameter to represent resistance, and a lorry carrying a varying size of load to represent electrical load.

When the buttons are used to change the values, the circuit diagrams, any dependent button values (according to the calculation of the formula) and the metaphorical animation, undergo corresponding changes.

All exercises involve the application of the lesson formula when one value is missing. The given values are randomly generated. Each exercise screen consists of a circuit diagram showing the problem, with the missing property indicated. The answer is chosen from a list of “radio button” options.
Figure 1: Part of a screen from the Programming Tutor, paused while a flowchart simulation is in progress.

Figure 2: Part of a screen from the Electricity Tutor, showing the various co-operating representations involved.

**Evaluation of the Two Systems**

This section provides an overview of the evaluation trials conducted for the *Programming Concepts Tutor* and the *Electricity Laws Tutor* described in the preceding section. First, the evaluation methodologies are outlined, following which the outcomes of the evaluation trials are discussed.
The Evaluation Methodologies

Each system was empirically evaluated with a small number of adult users who were deliberately chosen for their lack of knowledge of the target domains. Eight subjects took part in the evaluation of the programming concept tutor. The electricity tutor was evaluated in trials using six subjects. We acknowledge the small scale of these trials. At this stage, our aim is qualitative analysis only.

In each case, subjects were presented with a pre-session questionnaire to establish their backgrounds and experience. Following their session with the system, subjects completed a post-session questionnaire. The post-session questionnaire featured questions on all aspects of the interaction with the system, such as usability, navigability, understandability, interactivity, enjoyment of use, and so on.

Each user's session with the respective system was video-recorded. The experimenter also observed the sessions and took notes. Subjects were encouraged to think aloud as they interacted with the system. Considerable effort was expended to ensure that subjects were relaxed and not intimidated by the evaluation process.

The rationale for the combined use of three evaluation methods was to attempt to exploit the effectiveness of each while overcoming its potential drawbacks. Direct observation is a simple and cost effective method, but notes taken by an observer may be incomplete, while video recordings are a permanent record that can be studied many times, and thus aspects missed by direct observation may be subsequently revealed. On the other hand video recording (unless done using many cameras from different angles) does not capture all aspects of the interaction (it may record the subject's body language, at the expense of what is actually happening on screen at the time - 'aloud protocols' can be useful in indicating what the subject thinks they are trying to do. However, attempting to verbalize a complex task while actually trying to learn how to carry it out can actually interfere with the learning of that task. Similarly, interventions by the experimenter to ensure continued verbalization by the subject when a challenging task is being attempted would also impede effective learning. That a session is recorded in several forms makes it unnecessary for an unwilling subject to constantly verbalize. A more thorough discussion of evaluation issues can be found in (Preece et al. 1994).

With each system, a typical end-user session took around 1 hour 15 minutes.

For the programming concept tutor, subjects were also given a post-session test. This is discussed later.

Outcomes of the Evaluation

For both systems, evaluation results were very encouraging. Subjects performed very well in the in-system tests. For the electricity tutor, more than 90% of the first answers given were correct, while for the programming concept tutor, the corresponding figure was greater than 95%.

For the electricity tutor, the animated graphical circuit was the favored representation for all subjects. It should nevertheless be observed that learning the corresponding formula could only take place if the subject used that representation in conjunction with the formula description. The circuit diagram provides an advance organizer that facilitates the learning of the formula. The extent to which the metaphorical animation was effective is not so readily determined. Given that this representation has the highest cost in terms of design and development time and effort, the question of its effectiveness is highly significant. However, the users did state that the metaphor was useful in encouraging comprehension of the more abstract material.

As stated above, a specific post-test was undertaken by the subjects of the programming concept tutor. In this test, the subjects were first asked to define each of the programming concepts in their own words. Then the subjects were asked to solve four programming exercises, expressing their solution as a flowchart. The subjects did not have access to the training materials while taking the test. The four exercises were of increasing difficulty, the final exercise requiring a nested loop construct. Though only one subject answered all four exercises correctly, the errors made by the others were mostly of an extremely trivial nature (e.g. correctly represented logic, but expressed using the wrong flowchart symbol). This is impressive, given that no subject had previous programming or flowcharting experience. Moreover, the fact that they were able to define the programming concepts in their own words indicates that more than superficial acquisition of the concepts was fostered by exposure to the system. These results relate to Parke's assertion (Parke 1992) that an effective learning environment must do more than facilitate the acquisition of skills and techniques that can only be applied in the environment in which they are acquired.
Conclusions

The case studies described above lend some support to the hypothesis that co-operative multiple representations can be an effective facilitator of learning. In creating learning environments of the type described above, we would like to be confident that each representation is playing its part in providing enjoyable and effective learning. However, evaluating any of the representations in isolation may yield misleading results. The system exploits the interaction between the representations, and therefore results applying to a representation considered individually may differ from those pertaining to that representation when it is located in the multi-representational scheme. On the other hand, a representation within the scheme may not be realizing its potential if it is poorly designed, but the roles played by the other representations in the scheme may obscure the effects of this. Truly effective methods for evaluating the effectiveness of co-operative multiple representations for learning have yet to be devised. This is an important aim. Learning environments need to be multi-representational, because knowledge, skills and expertise are multi-representational. Co-operative multiple representation schemes provide the potential to reify the computational processes involved in expertise, so that learners can explore and subsequently acquire these processes as part of an engaging and effective learning experience.

Abstract: This paper presents findings from a research project that examined students' behaviors during mass lectures that utilized interactive multimedia. Students' engagement behaviors and disengagement behaviors during the computer-assisted mass lectures were influenced by three types of lecture elements: interactive multimedia (IMM), the lecturer, and student-idiosyncratic factors. The significance of these lecture elements and factors that triggered the student's behaviors are categorized and discussed. Being able to understand what influences students' behaviors and attention in computer-assisted mass lectures can provide guidelines for promoting effective learning in computer-assisted mass lectures.

Introduction

There is increasing use of interactive multimedia (IMM) in university lectures for teaching and learning. Yet IMM does not guarantee better content learning than do traditional instruction methods. Studies report that IMM is most effective when learners work with IMM individually or, better still, in pairs or small groups (Park and Hannafin, 1993; Simpson, 1994). However, in a mass lecture, the IMM is controlled by the lecturer. Learners play a passive-receiver role. As they do not have direct access to control the IMM, what do they do during lectures? What triggers their attention? What causes their behaviors? Are they focused on the content?

There is still too little research concerning how students engage with the new computer mediated technologies, particularly the increasingly popular use of PowerPoint and IMM in mass lectures. Most research on the increasingly popular use of IMM in lectures has focused on "how-to-tips" and critiques (for example, Broughton, 1997; Paldy, 1997; Seaman, 1998). There were few qualitative or empirical research studies. One by Nowaczyk, Santos, and Patton (1998) examined student perceptions of various characteristics of multiple media such as color transparencies, video, and IMM in the undergraduate classroom, mainly in terms of gaining and holding attention. Others (Jackson, 1997; Van-Meter, 1994) sought student perceptions of the effectiveness of PowerPoint presentations rather than IMM presentations to support note taking, interest, attention, and clarity of content organization. Faraday and Sutcliffe's (1996) empirical study tracked eye movement and ascertained memorization of content during a short medical IMM presentation. Research by Putt, Henderson, Patching (1996) and Henderson, Putt, Ainge, and Coombs (1997) examined teachers' thinking processes about the academic content of IMM and WWW courseware, respectively. However, these did not focus on a mass lecture context. None investigated students' behaviors triggered by a combination of the features of IMM and the lecturer in mass lectures.

Heeding current literature in the field, the study does not aim to ascertain whether learning with the new technologies produces better learning or test outcomes than traditional lectures. Rather, it utilizes qualitative methodologies to ascertain the students' behaviors as they learned in the authentic context of a lecture theatre. Thus the study sought to identify, categorize, and analyze the engagement and disengagement behaviors that were reported by the students.

Methodology

The research context and methodology capitalize on authenticity. The students' behaviors were
obtained in realistic, ecologically-valid situations as the data were collected from students working in their regular mass lecture environment, a medical school setting. The research was conducted with a physiology class in a mass lecture theatre, Faculty of Medicine Siriraj hospital, Mahidol University, Bangkok, Thailand. The lecturer used A.D.A.M. (A.D.A.M. Software, Inc., 1995) in two one hour lectures. The lecture sessions were video recorded. Six students volunteered to participate in stimulated-recall interviews. There were four males and two females with ages ranging from 17 to 19 years. They were in the third semester of a six-year medical degree. The six participants self selected into 2 male pairs and 1 female pair. The first male pair was interviewed after the first lecture session; the others after the second lecture session. The content of both lectures was the same topic and used the same IMM application. All six participants attended both lectures.

Data Collection

The participants were interviewed using the stimulated recall technique that follows strict guidelines (Putt, Henderson, & Patching, 1996). The interviews were conducted with one pair at a time. The interviewer and each pair of participants together viewed a videotape of the lecture and a synchronized computer screen showing the IMM that was used in the lecture. The video picture included the lecturer’s verbal and nonverbal behaviors and the content of the computer-assisted lecture. The computer screen showed the IMM (A.D.A.M.) content which appeared on the videotape. Both videotape and computer screen facilitated the participant’s recall and verbalization of their thinking and behaviors during the lecture. The three stimulated recall interviews, one hour duration for each interview, were conducted immediately after the lecture sessions and were audio taped for later transcription and analysis.

Results

From the interview transcripts of the students' stimulated recall interviews, their behaviors were jointly identified and categorized on the first transcript by the researchers. The remaining transcripts were analyzed individually and the data from each researcher were compared and discussed. Consensus was achieved when disagreement occurred. The behaviors reported by the participants were classified as those that involved their engagement with the content and those that indicated disengagement with the content. These two major categories were then subdivided according to what influenced their engagement and disengagement: the "IMM" product (A.D.A.M), "The Lecturer", and "Student-Idiosyncratic Factors" that were not specifically triggered by either A.D.A.M. or the lecturer (see Table 1).

The frequencies for each of these types of behaviors were tallied. A total of 203 reported behaviors were identified from the transcripts. The engagement behaviors were reported 158 times (78%) while the disengagement behaviors were reported 45 times (22%). For the factors of engagement, students' behaviors influenced by the IMM, the lecturer, and student-idosyncratic factors were 68%, 23%, and 9% of the total reported behaviors, respectively. For the factors of disengagement, students' behaviors influenced by the IMM, the lecturer, and student-idosyncratic factors were 47%, 15%, and 38% of the total reported behaviors, respectively. Each of the mass lecture elements, IMM, the lecturer, and student-idosyncratic factors, that triggered each of the behaviors are tabulated in Table 1. Features of the IMM influenced the highest number of engagement behaviors. However, it influenced the highest number of disengagement behaviors as well.

Discussion

Engagement

Interactive multimedia (IMM)

Because IMM played a major role in the computer-assisted mass lectures, it is not surprising that IMM is the factor that most influenced students' engagement and disengagement behaviors. From students' reports, IMM influenced 68% of their engagement behaviors and 47% of their disengagement behaviors.

(a) Focusing
Focusing on the IMM presentation was the highest reported engagement behavior during the computer-assisted mass lecture. These behaviors were influenced by animations, pictures, text, sound effects, voice-overs, graphs, and color changes. The findings show animation was the feature to which students paid most attention. "Animation has a strong effect on attention" (Faraday & Sutcliffe, 1996, p.270) because it simultaneously contains pictures, sound, and movement concerning the concept being explained (Hillstrom & Yantis, 1994). Because the animations were replayed immediately, the students paid more attention to the detail during the second or third time it was shown. The benefit is that all students received the correct information. They might have had different understandings if they had had to imagine the animations by themselves as they would have had to do, if the graph or picture was on an OHT or if the lecturers' verbal explanations had been the medium of delivery.

Text was the second highest ranked IMM feature that influenced students' attention. The reason for this finding is text is readable and notable data, that is, it lends itself to note taking. Graphs were the third highest ranked IMM feature that influenced students' engagement behavior. The graphs contained statistical data that helped explain the content. However, the findings show graphs were reported less than text. This could be that graphs were presented on screen less than text. It is interesting that pictures were the fourth highest ranked IMM feature that influenced students' attention even though they had been used many times during the lecture. According to Levie (1987), a possible explanation is that students have to spend more time decoding information from animations and text compared with pictures. Therefore, they paid more attention to those features than pictures.

(b) Note taking

Note taking is the second highest ranked (17.7%) engagement behavior influenced by IMM. Note taking is one thing that students would do to record information for review, especially for the exams. However, note-taking behaviors were reported less than focusing on the IMM presentation. A possible explanation is that students may learn by remembering the combined features of IMM such as animation, pictures, and sound without the need for note taking. In other words, the animations made the information more memorable and understandable (Nowaczyk, Santos, & Patton, 1998) and, therefore, students may not need written "evidence" (notes) that help them recall the content. Also it is not easy to take notes of animations and pictures. Students reported they took notes from computer-assisted mass lectures less than traditional lectures and lectures that used OHTs and PowerPoint. Less note taking could help students focus more on the content and not worry about writing. They may engage with the content more by learning with computer-assisted mass lectures.

(c) Anticipating

Anticipating includes predicting, looking forward to, and speculating about, the likelihood of encountering problems, types of content, and features of the medium. Anticipation is also the second highest ranked engagement behavior. A possible explanation for this finding is that the lecturer or the IMM was the only person who controlled the IMM, thus the students anticipated and predicted what the lecturer would present. Students' anticipations concerned animations, graphs, pictures, text, color, and sound in descending order of reported occurrences. Predicting what would happen next in the animation influenced 47% of the reported anticipating behaviors. A possible reason for the high percentage for animations is that the animations provided information that showed, for example, how the muscles contracted and expanded and how this affected the rest of the body, and students therefore attempted to guess the consequences of subsequent animations.

(d) Linking

"Linking" is a mental activity in which students associate or bring together two or more ideas, topics, contexts, personal experiences, etc. It is the third highest ranked engagement behavior. Students reported linking from pictures and graphs to their past experiences with the content of the lecture, such as experiments in the laboratory. However, linking behaviors were reported as disengagement behaviors as well. Students, sometimes, linked pictures and graphs to objects and images that were outside the content, for example, the movie, "Titanic".

(e) Understanding

"Understanding" is the fourth ranked engagement behavior. Students may have understood more than the six reported comments suggest; however, given the number of reported engagement-with-the-content behaviors, it seems that students distinguished between understanding (6 reports) and focussing (39 reports). Research in this area could be worthwhile. Students reported that some of their understanding was influenced by pictures, animations, and color changes. The possible explanation for this finding is that pictures, animations, and color indicating changed the points that the lecturer or the IMM voice-over was discussing.
and thus highlighted aspects of the concept, for example, by changing the color of the text or graph.

Generating, using textbook, and not sleeping

"Generating", "using the textbook", and "not sleeping" have the same frequency. There are several reports of using the textbook during the lectures. The students reported that they wanted to follow the lecturer's explanations in the textbook. This was also a reason given for not taking notes of what the lecturer was saying. The A.D.A.M. IMM software that was used in the lecture had a beneficial effect in terms of maintaining students' engagement. Students reported not sleeping during the lectures. Their reason was that the IMM was an exciting, fun, and interesting medium. The males also reported that they did sleep more during lectures that used OHTs or traditional lectures. Their reasons point to the advantage of using IMM in mass lectures.

The Lecturer

The lecturer influenced engagement behaviors as well. From the students' reports, the lecturer influenced their listening, replying to whole class questions, following his explanations, note taking, imaging, anticipating, focusing, understanding, and "not sleeping" behaviors. Most of these behaviors were triggering by the lecturer's explanations. Listening was reported 3 times as being influenced by IMM but was reported 10 times as being influenced by the lecturer. The reason for this finding is that the lecturer provided verbal information in Thai whilst A.D.A.M. had English voice over explanations. Therefore, the students chose to listen to the lecturer rather than IMM voice over. Generally, engaging with the lecturer's explanations was also because he explained and clarified the content being shown in A.D.A.M. Because the students reported that they might not be able to comprehend the information from IMM, partly because they had no control over pacing or reviewing, they therefore focused on the lecturer's explanations in order to understand the content. Their "not sleeping" behavior was triggering by the lecturer's voice as well.

Student-idiosyncratic factors

Beside IMM features and the lecturer, there were other factors that influenced engagement behaviors. The most frequent factor that influenced engagement behaviors was content. Students reported that some generating, waiting, reviewing, focusing, and understanding behaviors were influenced by the content itself (rather than the IMM or the lecturer). Engagement with the content naturally depends on the individual. Students who perform well would engage with the content without the IMM. However, engagement with the content that was not triggered by IMM or the lecturer's keying devices (for example, "note this" statements) represented just 9% of the students' idiosyncratic behaviors. Compared with the percentage of engagement behaviors influenced by IMM (68%), IMM was a significant factor helping students engage with the content.

Disengagement
Interactive multimedia (IMM)

IMM also triggered student disengagement behaviors that were reported 21 times. This number is higher than disengagement behaviors that were influenced by the lecturer (7 times) and student-idiosyncratic factors (17 times). Not looking at the IMM software projected on the screen was the highest ranked disengagement behavior. Small text was the main factor that made students decide not to look at information on the screen. This finding shows the significance of presenting readable text data on the screen in mass lecture situations. Moreover, readability problems could affect note-taking behaviors as well.

Lecturer

The findings show that students did not focus while the lecturer was searching for the information and paid less attention when the lecturer stopped interacting with the computer and adopted the traditional lecture style of talking to the students. This also caused students' sleeping behaviors; this was confirmed from the authors' observations of the students during the mass lectures. Therefore, the lecturer's explanations were the triggering factor that most influenced listening behaviors yet it also caused disengagement behaviors as well, particularly when the students had become used to the combination of IMM and lecturer explanation.

Student-Idiosyncratic factors
The "student-idiosyncratic factors" influenced disengagement behaviors more than the lecturer did. Student-idiosyncratic factors that triggered disengagement behaviors were varied. Not focusing on the content, in terms of being absent-minded and thinking about something else, was the first ranked disengagement behavior. This relies on individual differences that could be dependent on attitudes toward content and motivation to learn (Reeves, 1998).

Conclusion

According to the findings, IMM features triggered students' engagement with the content more than the lecturer and other features did. However, most engagement behaviors influenced by IMM were triggered by visual effects. The first ranked IMM feature that triggered engagement behaviors, animation, has a strong effect on engagement (Hillstrom & Yantis, 1994). Students' attention will be locked when processing the animations (Faraday & Sutcliffe, 1996). The replay function of the animation feature gains more students' attention. Color changes indicate the important points. It can shift students' attention to other elements on the screen that the lecturer wanted to emphasize. Changing screens also create movement on the screen, thereby influencing students to refocus on the content. Leaving the information on one screen for a long time may cause disengagement behavior such as daydreaming. Sound effects may focus students' attention but they might not be able to provide better understanding (Bradey, 1997). Students paid most of their audio attention to the lecturer's explanations. At this point, this research shows that, in a computer-assisted mass lecture environment, the students' engagement could be triggered by IMM visual effects and the lecturer's instruction (Paivio, 1990). The "collaboration" between IMM and the lecturer in computer-assisted mass lectures should encourage engagement behaviors. However, inappropriate visual information may trigger disengagement behaviors. Small text is an example in this study. This may lead to difficulties in comprehension (Faraday & Sutcliffe, 1996).

Even though this study cannot be generalized, the results should help lecturers and IMM designers understand some of the factors that influence engagement and disengagement behaviors during learning with computer-assisted mass lectures.

The Essen Learning Model – a Multi-Level Development Model

Jan M. Pawlowski
Information Systems for Production and Operations Management
University of Essen, Germany
jan.pawlowski@wi-inf.uni-essen.de

Abstract: The Essen Learning Model is a generic development model supporting development processes on three levels: development of curricula, learning sequences, and learning units. We focus on finding an adequate combination of didactical methods and educational technologies. Secondly, we focus on interoperability, reusability, and ease of use, using standards on the modeling level (ARIS), architecture level (LTSA, IMS), and implementation level (XML). The approach will enable educators, project managers, and authors to efficiently develop and implement Computer Supported Learning Environments.

Introduction
The Essen Learning Model is a development model to ensure the overall quality of the development process of learning environments on different levels. New technologies in the educational sector require a well planned and controlled development process. Our experience has shown weaknesses of current development models for the utilization of new technologies in the educational sector.

The use of new technologies is often seen as a universal solution to all problems and challenges in the educational sector. Educational concepts like Virtual University, Multimedia, or Edutainment have gained an increased attention. Despite of extensive research efforts, many immature and unsuitable products and concepts can be found. Quality management is not yet a natural part of educational projects.

The use of development models, originating from the field of software engineering, is a first step towards quality management and assurance. Nevertheless, several restrictions remain: software development models do not include didactical concepts adequately. Specific models for the development of hypermedia systems or CBT-systems require the selection of didactical methods before the start of the project. To overcome those weaknesses of most development models, a multilevel development model was designed, supporting educational processes on three levels: the design and implementation of curricula, learning sequences, and learning units.

I present basic concepts of learning environments and the Learning Technology Systems Architecture which is the base for the development of learning environments. By following this standard architecture, systems implemented using the Essen Learning Model can easily be integrated and coupled with other systems, reducing the development effort significantly. Thereafter, I describe design principles and the levels of the Essen Learning Model together with a sample implementation for the development of a learning sequence on “Simulation”.

Computer Supported Learning Environments
Our development model is based on the Learning Technology Systems Architecture. I will briefly describe this standard and our implementation.

Classification of CSLE
According to (Euler, 1992), Computer Supported Learning Environments might be classified into five classes: Drill & Practice Systems, Intelligent Tutoring Systems, Hypermedia Systems, Cognitive tools, and Simulations/Micro Worlds. Those criteria only describe trends of developments. They cannot be used for evaluating or selecting a certain learning environment. In contrast, the Essen Learning Model uses a detailed multi-dimensional classification including attributes like learning objectives, strategies, learning contents, temporal aspects, location, interaction, and users.

Architectures of CSLE
Concepts like the Virtual University or distance learning are based on the exchange and combination of courses and learning contents distributed world-wide. Unfortunately, the majority of learning environments and authoring systems do not use standardized methods in order to support exchange of materials or courses. This leads to an enormous number of isolated systems, not utilizing and being utilized by other systems. To overcome
those weaknesses, several standardization projects have been started. The Essen Learning Model uses an implementation of the proposed standard architecture by the Learning Technology Standards Committee of IEEE.

The Learning Technology Systems Architecture (LTSA) is an abstract model describing the architecture of learning environments (Fig. 1). It contains the following components: Processes describe the main subsystems of learning processes: Learner, Delivery, Evaluation, System Coach. Flows describe in- and outputs of the processes: Behavior, Assessment, Performance, Query Index, Content Index, Locator Index, Learning Content, Multimedia, Learning Style. Finally Stores store relevant information: Records Database, Knowledge Library.

Furthermore, the LTSA defines formats for the communication and interaction of systems. The implementation of ELM (Fig. 2) uses the standards of the LTSA specification in order to combine and integrate different learning environments.

The main element of a CSLE is a Learning Engine for the steering, control, and co-ordination of the components. The Knowledge Base contains learning objectives and contents used by the CSLE. The Methods Base of a Learning Environment contains different didactical methods and concepts, supporting authors and educators. A User Model is designed in the development phase. This model contains attributes, characteristics, and knowledge of a user. In collaborative learning environments, additional information about the group and the group process is modeled (Kinshuk, Patel, 1997). The Presentation Component allows the generation and presentation of learning contents in different ways. The Communication Component determines the level of interactivity of a Learning Environment. It contains methods for communication, co-operation, and its technical realization. Communication between learner, teacher, and system is to be co-ordinated in different forms (Heeren, 1996). The Evaluation Component determines the performance of the learner, providing tests or ratings.

**Development Models in Software Engineering**

The main function of a software engineering model is to establish the phases in which major tasks are performed within a project, and to establish the transition criteria for proceeding from one task to the next. A software development process model supports the implementation of software projects together with the planning, scheduling, and controlling of time and budget constraints. According to (Balzert, 1998), a development model specifies the following issues: Processes (scope, activities, work breakdown structure, schedule, prioritization), Organization (competencies, responsibilities, roles, budget), General Issues (standards, guidelines, methods, techniques, tools, reporting). There are various software development models, following different strategies. For many years the Waterfall model (Royce, 1970) was the most popular process model. It is a highly structured approach, breaking down the development process into multiple phases. Each phase creates a result which triggers the next phase after approval. If the result is rejected, the performed phase is repeated. Backtracking is limited to successive stages due to complexity reasons and to minimize expensive re-work. In general, the model is transparent and easy to understand, however, there are essential disadvantages. Requirement changes during the development are hard to handle because of the limited backtracking mechanism. Involvement of the users is only provided during the requirement specification in a very early phase. Especially for learning environments, the lack of motivational factors leads to acceptance problems. Due to the sequential approach, concurrent activities are not supported, hence extending the duration of a project. 

Prototyping (Balzert, 1998) is a popular method to provide „user friendly“ software. It is based on the development of executable models and patterns, defining software characteristics and requirements successively during the development process. These basic steps are repeated until all requirements are well defined. The
prototype itself is discarded and the real system is build, based on the prototype. In comparison to the Waterfall model, the development effort is higher due to the additional development of prototypes. The main advantage of Prototyping is early user involvement. Because of this important advantage, the Essen Learning Model incorporates prototypes into the development process.

The Spiral model (Boehm, 1986) combines positive aspects of the Waterfall model and the Prototyping approach. It can be used for rapid development of incremental versions. The definition of the software product and software process is elaborated in a series of repetitive steps. These steps are represented as a spiral progression through a project. Each cycle of the spiral elaborates product and process objectives and constraints, alternative product and process solutions, identifying and resolving major risks. The disadvantages are concerns about the high level of control and negotiation difficulties caused by the amount of control. High expertise in risk management is required. Advantages are the match of changing requirements in the whole development process, and the consideration of risks at all stages of the development. Especially for learning environments these characteristics are significant: therefore this approach was chosen for the Essen Learning Model.

Development Models for CSLE
There are various models specifically designed for the development of CSLE. Major approaches are:
models based on Didactical Frameworks, e.g., on the „Berliner Modell“ (Heimann, Schulz, Otto, 1965). They do not consider to use technical innovations. Therefore, they can be used for didactical planning but not be applied to new methods and technologies. Specific CSLE models for certain instances, e.g., CBT development (Steppi, 1997) or Hypermedia Development Model (Garzotto, Paolini, Schwabe, 1993). The weaknesses of these models are obvious because didactical decisions must be made before the selection of the CSLE. Instructional Design models (Issing, 1997) describe the structured development process of the educational systems, courses, and teaching products. They fulfill the requirements much better than the above described models, however, they support authors and teachers only insufficiently because the conceptual phase lacks flexibility.

As a conclusion, all the above mentioned models do not consider technological and didactical aspects sufficiently. Either they lack flexibility, or developers and users are highly restricted in their creativity. The Essen Learning Model is an approach which integrates and improves positive aspects of different development models.

The Essen Learning Model
The Essen Learning Model was developed at the University of Essen. It is currently being evaluated to be used in several departments of our university. I will describe the design principles and the general flow of the approach.

The Essen Learning Model (Fig. 3) is a multi-level development model. The complex development process is divided into modules supporting both, the development process and the use of the system on different levels. The support of curriculum development and design (C-level), planning and implementation of learning sequences (D-level), and the design and implementation of learning units (E-level).
We distinguish three abstraction levels: The development model provides generic knowledge for a variety of contexts. This generic model is customized depending on the user's needs and preferences, and transformed into a specific process model for each project. The process model provides a framework for educational technology projects, specifying the timeline of the project, involved participants, and information technologies. It supports conceptual and implementation decisions. Furthermore, it can be used to integrate learning processes and business processes to close the traditional gap between education and every-day-work (Adelsberger, Körner, Pawlowski, 1998). The third level is the result of the development process, resulting in certain implementations on each level. The result of ELM-C is a detailed network of learning objectives and goals. The structure and relations of learning sequences (courses) are determined. Based on these results, learning sequences are developed in ELM-D. The focus of this phase is to find an adequate didactical method including the right technology depending on learning objectives and the user group. Single learning units are designed and implemented in ELM-E.

ELM follows the approach of the spiral model. By using this approach, changes concerning the needs, requirements, and wishes of the project participants can be integrated dynamically. Furthermore the user is involved in the development process, evaluating prototypes and contributing actively to the development. By using this approach we ensure the quality of the product from the beginning to the final implementation.

One of the most important goals is the interoperability with other systems. The architecture of the learning environment is consistent to the Learning Technology Systems Architecture of the Learning Technology Standards Committee of IEEE and to the specifications of the Instructional Management Systems Project (EDUCAUSE, 1999). Furthermore, we used standard tools and formats for both, the development and the implementation. The learning processes are modeled in ARIS, a process modeling tool (Scheer, 1998). Our approach is not limited to this tool, process definitions in IDEF (Adelsberger, Körner, 1995), UML (Booch, Jacobson, Rumbaugh, 1998), or object oriented modeling languages can be integrated easily. We have implemented a web based learning environment in XML. XML (Extensible Markup Language) is a text-based language, describing, exchanging, and presenting structured data objects (e.g., data, applications) (W3C, 1999). Using this approach, web based learning environments can be combined and integrated with other resources.

In the following I present the modules of ELM in detail and a successful implementation: a learning environment for students of Business Computing at the University of Essen. A learning sequence on "Simulation" was implemented and is being evaluated.

ELM-C - Curriculum Development

The ELM-C module starts with an analysis of the context. Educational and structural aspects are investigated in this phase. First of all, overall policies and strategies are investigated. This is necessary to determine the role of education for a specific company or institution. Then existing educational concepts and the corresponding business processes are analyzed. To acquire knowledge about the future users, the organizational structure is investigated, determining roles, stereotypes, and responsibilities of the users. As another important aspect, the structure of existing technologies has to be analyzed. This leads to conclusions about which resources can be utilized for learning processes. Furthermore, potential changes of the existing structure are identified.

After this first phase, the generic development model is customized, resulting in a specific process model for the development process. The actual project planning, including team building, scheduling, and guidelines are determined. Furthermore, the main processes for the design, implementation, and evaluation of the curriculum (Fig. 4) are included into the process model.

In the design phase, learning goals are determined. Documents gathered during the analysis phase, business processes, and external sources (such as reports on domain trends) are examined. Educators and domain experts are questioned, both formally and in creativity sessions. The results are mapped into a scheme, which is a matrix of the learning goal dimension (Bloom, 1956, Krathwohl et al., 1964, Simpson, 1966) and the abstraction level, represented in an ARIS data model. Furthermore, relations between the learning goals, such as prerequisites and conceptual similarities, are modeled. As mentioned before, a learning sequence on "Simulation" has been developed based on our approach. Fig. 5 shows a simplified excerpt of a network of learning goals. Based on the network of learning goals, a possible structure of learning sequences (courses) is determined, serving as a prototype for user evaluation and as input for ELM-D.
ELM-D – Development of Learning Sequences
The focus of ELM-D is the development and implementation of learning sequences. Based on the specified learning goals from ELM-C, the most important concepts of a certain topic are specified in the phase “knowledge acquisition”. Those concepts are modeled as a data model in ARIS (or the chosen modeling tool). Furthermore a user model describes the proposed group of users. It contains personal and job related data (role, competencies), learning preferences, characteristics, and a history of learning activities. This data is also modeled in ARIS and used for an individual adaptation of learning sequences.

ELM-E – Development of Learning Units
Finally, single learning units are designed and implemented in ELM-E. A pattern for the unit is generated, not limiting the user in the sense of Drill & Practice approaches, but serving as a guideline. Depending on the learning content, user group, and the selected method, structures for presentation and interaction/communication are suggested and implemented.
A process model of each unit is generated, serving as an orientation for the author and the users. Furthermore, this model can be integrated in other systems or, as suggested in (Adelsberger, Körner, Pawlowski, 1998) combined with business processes. The author is responsible for the consistency and final evaluation. Finally, the CSLE is implemented using standard authoring tools, or, in our university, in XML.

**Conclusion**

The multi-level approach of the Essen Learning Model leads to a variety of supporting features for both, developer and user. All phases of the development process are supported, using standard methods and formats (ARIS, LTSA, XML). This approach leads to several synergy effects: reusability, integration, and coupling with other resources. These effects are essential for future developments in the educational sector, helping project managers, designers, and authors of cooperative educational programs. The use of a development model will ensure the quality of educational technologies, helping companies and institutions becoming learning organizations and meeting the requirements of the future.

A Constructivist Framework for WWW-based Learning Environments that Combine Streaming Media and WWW functionalities

Oscar Peters and Betty Collis
Faculty of Educational Science and Technology, University of Twente,
P.O. Box 217, 7500 AE Enschede, The Netherlands
o.peters@edte.utwente.nl

Abstract: Technical developments in the compression and streaming of audio and video over networks commonly available to instructors is leading to a new cycle of interest in the educational applications of audio and video. In this new cycle, the traditional benefits of audio and video are given a wider audience through their access via WWW browsers, but also more forms of learning resources and activities are emerging. In this paper we first discuss some of the educational possibilities that come from the combination of synchronous audio/video and WWW functionalities, particularly with respect to a constructivist learning context. Secondly, we discuss a theoretical framework based on a constructivist learning approach for the use of asynchronous audio and video in WWW-based learning environments. Following this we illustrate how these sort of environments have been realised in the course Tele-Learning at the University of Twente.

WWW-Based Learning Environments and Streaming Audio and Video

WWW-based learning environments allow the integration of hyperlinked information systems, databases, interactive learning resources, communication tools, publication tools, and tools to support collaborative and individualised learning. Each of these types of activities can be supported in a variety of modalities, including text, images, animations, audio, and video. New technical developments in WWW-based technologies allow the use of video and audio on demand (as opposed to the two-way video and audio communication streams that occur in conferencing situations). These developments mean that asynchronous digital video and audio sequences, even of considerable size, can now be integrated into WWW-based learning environments, and used, in whatever segments that are wished and whenever desired, for appropriate learning goals (Collis & Peters, 1999). The technical advances that allow video and audio to be integrated within WWW environments and to be available on demand to learners are of educational consequence if they lead to learning experiences that are perceived as valuable and appropriate for particular learners, subject areas, and learning conditions.

In particular, with the integration of asynchronous audio and video in an WWW-based learning environment different types of constructivist learning activities can take place. Simons (1998) describes constructivist learning environments as environments where students are being challenged to learn actively together, with a clear focus on the functionality of learning and the learning content. Within such environments the learning is situated in a concrete context where the authenticity of that context is as high as possible. For example, a didactical model based on principles of situational cognition (Brown & Duguid, 1994) could be realised through the capacity of video and audio learning resources to connect a learning task with a realistic context. A didactic approach based on anchored instruction (Ward, 1998) could offer information-rich simulations and case studies with which the learner could interact. A didactic model reflecting principles of cognitive apprenticeship (Collins, Brown, & Newman, 1989) could be facilitated by presenting groups of learners a variety of information-rich resources that show an expert in action in related problem areas. A didactic approach representing crisscrossing landscapes (Simons, 1998) could be enriched by making available a large variety of audio and visual views of a problem domain. A didactic approach reflecting reciprocal teaching (Scardamalia & Bereiter, 1989) could be supported by students creating their own audio and video resources and making them available as learning materials for their peers.

In each of these approaches, students are expected to steer and control their learning as independently as possible. The teacher is more a coach and guide than a transmitter of information.
Audiovisual and simulated realities offer the student the possibility to come closer to the concrete reality and thus to learn in a practical and experiences-centered perspective. We believe that these learning approaches can be attractively supported in WWW environments that combine the strengths of streaming video with the capabilities of the WWW to support communication, offer links to associated resources, and allow re-use of video segments in other learning contexts. In Table 1 we indicate five forms of learning activities which can reflect constructivist approaches and the possibilities that come from the combination of asynchronous audio and video with WWW functionalities in those learning contexts. Following Table 1, each of these forms will be further discussed and their relationship to constructivist learning illustrated.

Table 1: New forms of learning activities, related to video aspects and WWW functionalities (Collis & Peters, 1999)

Capturing & re-using a presentation

There are many examples now of how a classroom or lecture-hall presentation can be captured as it is delivered (usually digitally), stored as digital video on a video server, and then made available for re-view or re-use via a WWW site. The intended users include: students and non-students who could not be present at the actual presentation and students who were present but wish to review portions of the presentation. The presentation may be made available in linear form (with a controller to slide forward or backward within the video sequence), but most usually is also synchronised with slides or presented along with an index relating to different portions in the video sequence, so that the user can jump immediately to the portion desired. While the captured sequences can be planned and executed by the instructor, they can also be captured in less-formal communication settings, such as when students discuss different points of view relating to an issue or articulate their ideas and reactions to a complex learning situation. Students can easily do such capturing themselves with a digital video camera. These reflections can then be revisited, commented upon, and extended in asynchronous print communications and added to course resources available via a course WWW site for reuse, such as in Categories 4 and 5 in Table 1 (see examples to follow).

Giving access and depth to real events
There are many examples of WWW sites which focus on particular real events, as they are happening or extended in time before or after they happen, in which video segments play a major role. One example is the site of America's Health Network (http://ahn.com/liveevents/default.asp), aimed primarily at health professionals or medical students, but also for the layman with a particular medical interest. At regularly scheduled intervals, via real-time video streaming, users can watch an operation as it is occurring and hear the comments being made by the medical team as they carry out the operation. Following this, the operation segments in edited form are available as asynchronous streaming video segments via the WWW site, as well as other video segments including interviews with the patients and their doctors, discussions among medical specialists, and interviews. Any event can be captured as a digital video stream, and then used as basis for students to add elaborative materials and reflective comments via a WWW page. Such a page can start as a template that students then fill with appropriate extension resources, or students can construct such a page themselves with an html editor.

Supporting a learning process

When the focus of a learning activity is a process, rather than the learning of pre-defined content, WWW sites integrated with video segments can play a major role in learning support. An example is the site Biological Timing Online Science Experiment (http://www.cbt.virginia.edu/Oh/Oh/exp.html) from the University of Virginia. This site is designed to help students in the process of carrying out scientific experiments by showing them, when they have need of the information, (via video fragments) many examples of aspects of an experiment, including aspects relating to the reasons for carrying out the process and aspects relating to the setting up and conducting of experiments.

Developing and accessing a library of cases or units of learning material (ULMs)

The site Learn & Live (http://www.glef.org/learnlive/toolkit/clearview.html) is an example of how a collection of video segments, with voice overlay, can serve as cases, or units of learning materials, related to a particular theme or context. In the Learn & Live context, the target group is teachers and the focus is on how 4th- and 5th-grade students conduct a research project when they have the opportunity to work collaboratively with university scientists. In each of the cases linked to the site, a video segment showing the children carrying out various learning activities is available, with voice-over comments by either the teacher or the scientists. The intention of the site is that others (teachers, teachers-in-training, scientists, and those who design such special collaborative projects) can see what actually occurs in the classroom during such an interaction.

Constructing and sharing one's own video & WWW resources

From a constructivist perspective in which learning by doing is emphasised, the possibilities for learners to create their own video segments as well as the surrounding WWW environments through which those segments are available, can be an example of a new type of collaborative learning activity. Such creation can relate to any and all of the other four categories of learning activities in Table 1. In the next section, an illustration is given of how all five of these types of learning activities have been realised in the course Tele-Learning at the University of Twente.

Illustration: The course Tele-Learning at the University of Twente

The course Tele-Learning in the Faculty of Educational Science and Technology (see http://education2.edte.utwente.nl/98193524.nsf/framesform?readform) at the University of Twente in The Netherlands is a senior-level elective course focusing on the educational use of network applications. A major way in which the learning takes place in this course is through the students working together in groups on a project for a real context and audience and in response to a real need of that audience. In the 1999 cycle of the course, the audience was instructors in our own faculty and the context was to help them become aware of opportunities in their own classes (all of which make use of a WWW-based course-support system, called TeleTOP, http://telestop.edte.utwente.nl) in which
video integrated with their WWW sites could bring added value to their courses. Each of four groups of students in the class had to develop a different WWW-based performance-support site for the instructors, in which a form of streaming video use integrated within an educational WWW site was illustrated and described and defended from an educational perspective. The forms chosen by the groups included video as part of WWW-based tutorials for various learning processes and video used for action with commentary to help students work together to handle a particular problem situation. Thus the students themselves participated in a learning experience as indicated in the fifth row of Table 1 (constructing their own uses of video), but with a focus on showing examples of the third and fourth rows in the table (video to supporting a process, and video to illustrate examples from practice). In addition, during the final meeting of course, each group of students presented their WWW sites and reflected upon their own impressions of the educational value of video integrated in WWW environments and were captured on digital video during the presentation. These captured presentations (Category 1 in Table 1) will add to the meaningfulness of the performance-support sites for the instructors who subsequently use the sites. The students captured their own video sequences rather than using professionally prepared video, using only a handheld digital video camera and simple video-editing software. They learned the html necessary to insert a streaming video segment into a WWW page and were responsible for the design and construction of the overall WWW-based performance-support environment.

A video-illustrated case as part of WWW-based tutorials

An example of one of the performance-support sites made by the groups of students in the Tele-Learning course for instructors in their faculty is shown in Figure 1. This group of students chose to develop a video-illustrated case study as part of WWW-based tutorial. They developed a WWW-based tutorial with video that combines the benefits of video, self-study activities, and the WWW. The tutorial mode of instruction guides the learner throughout the material, the video adds visualisation, and the WWW environment allows more flexibility in time, place, sequence, and pace of learning as well as adding communication support relating to the content of the video. The site has the following generic structure that all the four groups in the class used: (a) a hyperlinked set of pages containing the instructional example itself - in this case, the example of a WWW-based tutorial integrated with streaming video; (b) educational issues - an essay on learning-related issues surrounding the use of this sort of WWW environment for situated learning, anchored instruction, and other forms of constructivist-oriented learning as well as instructivist learning; (c) design issues - a discussion of guidelines for designing a WWW site that uses video in a WWW-based tutorial; (e) technical procedures - steps to be taken when making video for the WWW; (f) external examples - links to other, external, examples of WWW-based tutorials with video; and (g) group members - information about the students that worked on the project. The topic used for illustration purposes of the performance-support site shown in Figure 1 was 'Shooting a good video!' The students designed an environment that contained resources for learners to explore the characteristics of video, as well as, how to take these characteristics into account when creating good educational videos for the WWW. The study materials include an option, called "Common problems" where instructors can find out what students usually don't like about educational videos. A second option is a case study where instructors are prompted to think about how to shoot a good video for the WWW, followed by a presentation where the instructors have the chance to study the lesson materials and a quiz to test themselves. Other options available are links to resources for further learning and a forum where instructors can share their ideas about making video for the web.

Action with commentary

An another example of a performance-support site made by the groups of students in the Tele-Learning course for instructors in their faculty is shown in Figure 2. This group of students developed a WWW environment with asynchronous video to show how such an environment can assist students learning to handle a complex learning task. In this case, the illustration chosen of such a task was the experiences of a foreign student coming to study at the University of Twente. The environment includes the audio of a moderator, who gives comments about the most important things that foreign students have to know about the campus in order to handle problems that arise when the student first has to negotiate using the library, the computing center, the system for using swipe cards to get in and out of buildings, etc.
The purpose of the embedded video segments in the site is to help students learn about various complex situations by having a voice-over commentary guide the student through visualizations of those situations. Links are available for additional information, campus maps, contact names and email addresses, and other resources to help the student in the problem situations. As four of the five members of the group were in fact foreign students for whom the Tele-Learning course was their first course at the University of Twente, they had a personal context for the problem situation. The video in this case captured the information that had to be communicated to the learner in a practical and illustrative way. In their reflections, the students indicated that they believed that this type of learning resource involves a number of educational benefits for the learner. The first scene of the video generates interest and motivation. The video supports a situated-learning environment that includes several complex themes: the arrival, procedures for using food and drink automates, the computer lab, the cafeteria, and some general information about the faculty. The video and WWW site combined facilitates the possibility of exploratory learning. The use of knowledge is increased by the different contexts. The students also felt that the process of making the site themselves was a valuable learning experience for them as well as being of potential value for others.

In addition to designing and producing their own WWW-sites integrated with video as examples for instructors, the students in the Tele-Learning course also made use of video in many other ways within the course. Video integrated within educational WWW sites was the content of the course as well as a medium for the content of the course; thus the students used the course WWW environment as a framework in which to place their links to examples of external WWW sites making good educational use of video (in all of the categories in Table 1); their evaluative and reflective comments about the use of video in WWW sites for learning purposes; and for the study of captured presentations of the students in the previous cycle of the course. These presentations captured the students during the final class session of the 1998 cycle, and made these comments available to the 1999 students as asynchronous video synchronised with presentation slides made by the students related to different aspects of the course. The students in the 1999 cycle of the course could thus see and hear their peers in the 1998 cycle comment on their own work (the work was also available to the students in the 1999 cycle as learning resources, another example of re-use of video segments). During the last session of the 1999 cycle, this same process of capturing on video the presentations and reflections of the students and making these immediately available for re-view and re-use was continued.
Conclusion

Many of the new technological developments in education involve convergences: of the learner as both consumer and producer of his or her own learning resources; of linear and interactive media in a single WWW environment; of communication, collaboration, and learning within contexts that integrate theory and realistic applications. These trends can be seen in the uses of asynchronous video within WWW environments that are now emerging, particularly when the video is developed or captured by the learners themselves as a study resource and used, on demand in an interactive manner by other learners. These sorts of learner-captured video resources are now becoming easily available with advances in desktop video technologies and the WWW; what is only just emerging is an assessment of their educational potential. The promising technical developments are creating a strong technology push, which needs to be confronted by an even stronger educational rationale.

Abstract: In this paper we describe an effective way to create a web-based self assessment tool. Our approach uses an exercise applet that reads and extracts questions from their descriptions in XML format and presents them to the students depending on students’ preferences. A simple authoring tool is used for adding questions and corresponding hints to the exercise environment. Questions can be accompanied by additional media such as video, picture, sound or animation applets.

Introduction

In the past, distance education has always suffered from a lack of opportunities for hands-on experimentation and access to physical objects, models, simulations and instruments in computer and engineering labs. Today, computers in education and networked learning environments offer new ways of discovery learning through some unique forms of interaction with virtual objects, online laboratories at home, learner-directed animation of realistic processes, and lightweight software tools. In networked learning environments interactivity allows students to manipulate input data, parameters and thresholds of real-time simulations or animations. Learners may also influence the progress and output of process or algorithm visualizations. The project group at FernUniversität Hagen is exploiting some of these possibilities with the development of a series of exercise environments (Mogey 1997) that let students apply and experience what they have learned to predefined problems or problems of their choice. Thereby we expect to raise the attractiveness of the learning material and enhance the students’ motivation, especially that of distance learners. In the design of these environments we have attempted to associate learning objectives with appropriate multimedia solutions (Williams 1997) with respect to different teaching functions such as motivation, presentation of new structures, practicing new behavior, modeling, exploration by trial use and error, or application of new techniques. To achieve a high degree of platform independence, ease of use and portability and to remain independent from proprietary formats, it was decided to rely on HTML, XML (Harold 1998, Idris 1999) and Java (Horstmann 1998, Sun 1998) as core technologies for implementation of the exercise labs.

Since the introduction of Java programming language we can see the use of applets in traditional hypertext systems as well as in an Intelligent Tutoring Systems. Java applets are employed very often to explain complex processes to deepen the understanding of difficult parts of educational documents. However, the use of Java applets does not have to be restricted to simulations or visualizations of specific problems. Many examples show that applets can be used for exercises and tests and therefore offer more flexibility than common media. Another advantage of applets is the possibility to accept parameters so that they can be tailored to different learner types. It should be possible to find common learning oriented descriptions for different users of the exercise applet and to make the exercise applet itself adaptable to specific needs. That way only one version of the applet would be necessary for many different kinds of users.

A Generic Exercise Environment

After having developed several exercise environments by hand, we realized that we need many more exercises for the students to make the self assessment effective. Developing an exercise applet for each specific topic was
not very effective if we want to generate a lot of questions for different topics. Another possibility is to create HTML based questions with applets as companion, which are often found in web-based exercises. The downside of these HTML questions is that they are static, which means each time the exercise is restarted the students will receive the same set of questions. What we were looking for is the ability to create a dynamic exercise environment, that can pick a random set of questions from a question pool, adapt to the student’s preferences and that is easy to use for the tutors creating the questions. This approach would also separate the questions from the applets and use the applets in conjunction with the questions in an exercise environment. The applets should show an animation or a simulation of a certain topic, and the question can be asked in relation not only to an applet but can also relate to other media such as video, picture, sound. We chose to develop an XML based exercise environment since XML is ideal to describe the question structure, the exercise structure and the structure of a student’s profile. The idea was to describe each question in XML and let those questions be parsed by the exercise environment applet and be presented in an appropriate format depending on the question type and companion media during the exercise. That way a large amount of question pool can be generated more easily. The configuration of an exercise, such as how many sections or how many questions, what kind of question, etc. is also described in XML and parsed into an exercise specification object used by the exercise environment applet at the beginning of an exercise. The exercise environment covers both formative and summative assessment types (Bull 1996, Williams 1997). This approach provides flexibility to authors, since any applets that the authors find useful for the exercise can be added any time to the applets pool as a companion to the questions. The same rules apply to pictures and video clips. With this flexibility comes a big task of putting a lot of questions into the exercise environment. To give a picture of it let’s take an example of an exercise for one topic with one difficulty level, five question types (true/false, multiple choice, text gap, set ordering, matching) with five questions for each type. That will result in at least 25 question files and 50 picture files and not to forget the hints and explanations for errors and companion applets. In order for the exercise environment to select a different set of questions each time the students restart the exercise, more than 25 questions have to be provided to enable a random pick out of the question pool. As soon as enough questions are available, the exercise environment can give the students an adaptive and interesting platform to do self assessment. Currently for evaluation purposes we have created about 150 question files, 150 pictures, a VRML scene, some companion applets and JavaScript animations for 6 topics, which in turn consists of several subtopics.

The exercise environment consists of 3 modules or applications:

a) Question generator
A Java application with forms to create a question. Five of the most common question types in Computer Based Training (CBT) can be generated such as: true/false, multiple choice, fill text, matching and set ordering. An XML Document Type Definition (DTD) was defined to describe the structure of questions. Important parts in a question description include:

- Domain: defines to which domain or topic the question belongs.
- Create: defines the date of creation.
- Level: defines the difficulty level of the question. 5 levels are currently supported.
- Language: defines the language for the question.
- Subtopic: defines the subtopic or subchapter of a question.
- Question type: defines the question type which has to be one of the 5 described above.
- Question: defines the elements that describe a question such as
  - Problem statement: defines the question asked.
  - Answer options: defines the answer options in question types multiple choice, matching.
  - Keys: defines the answers to the question.
  - Hints: defines the hints, each hint is related to an answer option and the hints consist of 3 levels, starting from a general hint to a detailed hint. The exercise environment will show the hints depending on the selected difficulty level. All 3 levels of hints will be shown for exercises in the first 2 lower difficulty levels, 2 levels of hints will be shown to those in the medium difficulty level and 1 hint will be shown to those in the last 2 higher difficulty levels. Hints are only available in formative mode of the exercise. If the student chooses to do the exercises in exam mode (summative), no hints will be shown.
Example of a question description:

```xml
<?xml version="1.0"?>
<DOCTYPE QUESTIONSPEC SYSTEM "questionspec.dtd">
<QUESTIONSPEC>

      <PICTFILE>test/pictures/fddi5.gif</PICTFILE>
    </PICTLIST>
  </QUESTION>
</QUESTIONSPEC>
```

b) Exercise generator

A Java application for creating the overall exercise specification. The exercise is described using the following fields:

- Domain: defines the topic of exercise.
- Level: defines the difficulty level of the exercise.
Number of sections: defines the number of sections in the exercise, 5 is the maximum since there are only 5 question types available.

Section Description: specifies each section by defining:
- Section type: defines the question type of this section.
- Number of question: defines the number of questions in this section.
- Total question: defines the number of available questions in the question pool. If the number of questions needed in an exercise section is smaller than the available questions in the question pool, the exercise tool will select the questions randomly from the question pool. The exercise is less predictable and becomes more challenging since the students do not get the same questions each time they start the exercise.

Description of test mode:
- Maximum error in relation to minimum solved questions. These 2 numbers are needed to define the maximum error rate allowed to pass the exercise in exam mode.
- Time limit can be defined for exam mode.

e) Exercise environment applet

A Java applet which is the environment (Fig. 1) that the students will work with. A student profile is loaded by the applet at the beginning of the exercise. The student’s profile gives the information of selected exercise topic, subtopics, language and difficulty level. The applet then loads the selected exercise scenario and parses it using the IBM XML parser. Using the extracted information about the exercise, the applet prepares the exercise and loads the defined questions one after another. The exercise environment creates a random number for each question category in order to provide variation each time the exercise is restarted. In order to create a correct random number, the exercise environment checks the number of available questions on the server. If the number of available questions is less than requested in the exercise specification, then the exercise environment adjusts the question number for this exercise by reducing it to the number of available questions. Thus preventing the error of creating a random number of a non-existent question. The XML file describing the exercise will not be modified, since more questions can be added to the question pool in the future, so next time the exercise is started, there could be more questions available than requested in the specification. After all random numbers for each question category have been calculated, each question is loaded, parsed and shown when the student arrives at the specific question. There are two methods to navigate in the exercise: sequential navigation using the forward and backward buttons and free navigation by using the navigation tree. The navigation tree gives more freedom to jump from one question to any other question in the exercise. If a certain media is related to a question such as an applet showing an animation or a simulation, a video clip, an audio file or a picture, then it is shown together with the question. Questions can either be answered or skipped. Skipped questions are counted as unanswered errors. Hints are also provided and can be called during the exercise. Each possible answer option has 3 levels of hints starting from a general one to a more detailed one. The number of hints that can be shown to the student depends on the difficulty level of the exercise. No hints are available in exam mode. In exam mode a time limit can be activated which limits the time given to the student to finish the exercise. When the time is up the exercise will automatically end and no further answers will be accepted. Students can submit the exercise any time and get the result of the exercise. The result of the exercise has an HTML format and is shown in a separate window. Student’s answers are listed together with the correct answer. If the question author provides the question with reason, in case of error, this reason text will be shown. A summary is provided at the end the result report showing error rate and achieved points. Each question number on the result window is linked to the exercise environment applet through an interface. That way students can reload the corresponding question by clicking on the question number in the result window, instructing the exercise environment applet to reload and parse that particular question. A log file is created at the end of the exercise and the student’s profile is also updated. This profile shows how many exercises a student has done and how well.

Example of a student’s profile:
<?xml version="1.0"?>
<!DOCTYPE STUDENTPROFILE SYSTEM "studentprofile.dtd">
Weisen Sie die entsprechende FDDI-Komponente dem jeweiligen Bild zu. Eine größere Darstellung erhalten Sie durch Anklicken des entsprechenden Bildes.
Conclusion and outlook

In this paper we described an XML based exercise environment applet, a simple question generator tool and an exercise specification generator tool to create interactive web based exercises for self assessment. Our approach extends the usual static HTML-based exercises and provides more variation and a higher number of questions in an easy and efficient way. At the moment the exercise environment is being integrated into a CD-ROM based multimedia technology lessons. This material will be distributed to buyers of the book and students of the course Multimedia-Technologie (Steinmetz 1998) and will be evaluated for usability and learning effectiveness.

Abstract: This paper describes some design principles, main actors and functions of an open learning environment called A&O. A&O is an open learning environment which can be used via computer networks, especially over the Internet. It supports both self-paced and collaborative learning. A&O is open to various learners and different contents and it offers an opportunity to study independently of time and place. The main goal of the A&O environment is to be both pedagogically appropriate and technically functional. It is designed on the basis of modern learning theories that emphasise the construction of new knowledge on the basis of previous knowledge, the learners' active role and collaborative learning. In addition to these, learner's intentions, meaningful contexts, transfer and reflection play an essential role. The system architecture of A&O consists of data management facilities including data acquisition tools, tools for communication and collaboration, course-dependent cognitive tools and authoring tools for producing hypermedia courseware. In this paper the first learning experiment in Matrix Algebra with A&O-learning environment is reported.

1 Introduction

The purpose of this article is to present the design principles, implementation and evaluation of the hypermedia-based A&O learning environment (see also Pohjolainen, Ala-Rantala, Nykänen & Ruokamo 1999). The design of the learning environment is based on the exploitation of the broadband information networks' characteristics, on hypermedia-based learning materials and modern learning theories (see Ruokamo-Saari & Pohjolainen 1997; Ruokamo & Pohjolainen 1998, 1999). In order to achieve optimal exploitation of the possibilities provided by modern information technology, theories of learning must be incorporated into planning of the learning environment. In the research on technology-based learning environments constructivism has gained ascendancy among theories. According to constructivist theory learning is a constructive process in which the learner has an active role and learning is based on the learner's own cognitive activity. Students construct new knowledge on the basis of previous knowledge, on their own activity in constant interaction with the surrounding reality. The A&O learning environment was planned to be applicable to different students and different content fields and to be used independent of time and place. Such an open learning environment supports lifelong learning. Open and distance learning (ODL) based on the information networks and on hypermedia can be utilised in schools and universities, in organisations offering education and in entrepreneurial education - from childhood to mature students. This article presents the objectives and design premises of the research and development work of the A&O environment. The article describes the A&O spaces, actors and tools, and partly its technical realisation. Finally the first learning experiment in A&O environment is described and the results are presented.

2 Objectives

The A&O open learning environment refers here to a hypermedia-based environment which can be used via the information networks, especially the Internet, and which supports self-directed and collaborative learning. The learning environment is open to different students and different content areas. It moreover provides the opportunity for study via the information networks, independent of time and place and for lifelong learning. In the learning
environment an attempt has been made to cater for mental, physical and social activity and it is intended to be both pedagogically appropriate and technically functional.

3 Premises in Planning an Open Learning Environment

This section presents the basic structure of A&O: actors, spaces and tools and offers a description of the functions of the Office and Study.

3.1 Actors

In planning A&O an effort was made to cater for all those actors who operate in a conventional learning environment. Thus it is possible to ensure that the environment enables and supports the contribution of the various actors in the learning process. The main actors in the open learning environment are: the student, the student tutor, the teacher, the teacher tutor, the expert, the content provider, the director or rector, the secretary, the researcher, the system administrator and the visitor. The role of the student is to function as a learner on the courses. S/he is a main actor in the learning environment and is also responsible for his/her own learning. The role of the teacher and other actors is to support the student in his/her learning process. The teacher on the course functions as the teacher responsible, as supervisor and in the role of evaluator. The student tutor is a student who has already completed the course in question. S/he may counsel the students and advise them in matters pertaining both to study and practical problems. The teacher tutor is an assistant teacher whose function is to assist the teacher responsible for the course and to supervise, and further to support and guide the student in his/her studies. The expert is a person who has particular knowledge or skills related to the content area of the course. The task of the expert may be to offer advice, to participate in discussion groups, to propose subjects for project work or to give special supervision for doing these. The researcher is a person possibly along on the course who examines the students' learning and learning processes. The content provider is a person who produces hypermedia-based learning materials for the learning environment. In principle a person external to the A&O environment may also act as a content provider. The administrative personnel of the learning environment includes the director/rector and the secretary. They are responsible for decision-making and practical measures related to the courses of the open learning environment, eligibility to study, registration, and entering credit points in the academic record. The person maintaining the system is a person who is responsible for maintenance and the updating of the system and for administration at system level. There may also be visitors to the learning environment: a visitor may be anyone using the Internet who has browsing access and can get to know the courses at a certain level.

3.2 Spaces

The A&O learning environment structure is based on a space model comprising four spaces. These are 1) Office, 2) Study) 3) Media Centre and 4) Gallery. Figure 1 presents the front page of the learning environment. There is a noticeboard on the front page of the A&O learning environment where Internet users can obtain information about the courses included in the environment. All matters pertaining to administration of studies are taken care of through the A&O Office. When beginning and ending their studies students are in contact with the Office, where they enrol on courses and have entries made for courses completed. The Study is a working space for students, teachers, tutors and experts. Its functions vary depending on the role of the actor. Via the Study students can study courses independently or collaboratively with other students: they can obtain supervision from teachers, tutors or other students and experts and also feedback. The students' log data accumulated in the A&O environment is accessible to the student, the teacher and possibly also to the researcher for the duration of the course. Via the Study all actors can collaborate with one another. The Media Centre serves all actors in the learning environment. In addition to courses this also contains materials related to study. The material in the Media Centre may, for example, include text, sound, image, video and animation material. In future it will be possible to locate video-on-demand services in the Media Centre, too. The implementation of the Media Centre is comparable to a database, which makes structural access possible. There is also a Gallery in the A&O environment, and here the practical assignments and final projects of the students are displayed complete with evaluations. The Gallery is to have an option to vote such that Internet users will be able to elect their own favourite. The technical realisation of the Gallery is also as in a database.
3.3 Tools

The actors in the A&O learning environment have tools at their disposal for the creation of content, cognitive tools for each course, communication tools, tools to support collaborative learning and management tools. The tools for creating content are important, as course content is primarily created using these. The course material may include hypertext-based material, images, animations, video, links to external sources and ready-made programmes and elements supporting self-evaluation. The structure of the course material to be produced is an important delineating factor in learning, its effects extending to the organisation of the A&O communication and collaboration tools. Naturally the tools for creating content are also available for students’ use as in the open learning environment students, too, are producers of content. Constructing knowledge is accomplished through the cognitive tools among others. Such cognitive tools include various tools for information seeking and ordering, navigation tools, question-making tools, problem-solving tools, and special tools for use on certain courses. The present article describes the Maple program in the field of symbolic mathematics as a cognitive tool. The A&O communication tools comprise e-mail, discussion groups and real-time discussion. E-mail can be used by the actors to send information in the form of correspondence in their own words. The discussion groups render possible supervised discussion group by group. The real-time discussion supports collaboration between students on the course at the time of studying. The administrative tools are used to administrate the environment. Administrative measures include the granting of the right to study, acceptance as an actor, acceptance of the course and entering the course or parts of it in the academic register.

3.4 Functions

Students enrol as actors in the A&O learning environment through the Office. The Office noticeboard carries general information on courses and details of all actors on the courses. A system-specific ID card is made for every student, teacher, tutor and expert. This ID card contains personal details, role on the course, contact information, photograph, link to the individual’s homepage and an open space for the individual to introduce him/herself and his/her hobbies to other participants. The aim of the ID cards is to help course participants to get to know each other and to support collaborative activity. The Office also has course curricula, which include course objectives, schedules, contents, information on course materials, teaching methods, evaluation, teachers, tutors, experts and researchers possibly involved with the course. In A&O all these actors have their own Study. Figure 2 presents such
a student Study. It contains the course to be studied and also a whole lot of tools for planning studies, study management, communication, constructing knowledge, monitoring studies and resource management.

Figure 2: A student Study and part of its functions

In A&O the student may participate in several courses, and the selection of each of these is made in the Study. The Study has a noticeboard for the course and a curriculum on the basis of which students can make their own personal curricula. The A&O learning environment also collects log data about students' activities in the course of study. This data can be utilised in students' self-evaluation, in teachers' evaluation work and as a support for researchers' analyses. A student can take a look at the matters to be dealt with on the course in a given week. This information is obtained from the noticeboard and the course discussion group. S/he selects a subject for his/her practical exercise and seeks for further information in the Media Centre. The selection of the subject can be narrowed down by e-mailing the teacher. After selecting the subject s/he forms a workgroup. For this purpose s/he goes through the ID cards and puts a notice on the course noticeboard. The workgroup presents the plan for the practical exercise to the teacher in a public discussion group, accomplishes the work using as aids the e-mail, the real-time discussion group, the discussion group set up for the workgroup. Finally the workgroup submits the work to the teacher by e-mail and comments and further develops it as necessary. At the end of the course some of the group work may be displayed in the Gallery.

4 A Learning Experiment on Matrix Algebra in A&O

In order to test the A&O learning environment a learning experiment was organised at Tampere University of Technology. The students studied using A&O environment an introductory part of the course of Matrix Algebra at TUT during three weeks in September 1999. The A&O-learning environment contained: Introduction to Matrix Algebra as hypertext, interactive exercises generated and checked by the symbolic algebra program Maple, noticeboard, internal E-mail, real time discussion (chat).

In the beginning all the students filled in their ID-cards. The theory to be studied as well as weekly exercises were announced weekly on noticeboard. The students were asked to study the theory, to study the interactive exercises, to solve easier theoretical exercises by themselves, and to solve more demanding problems in groups. The results of group work were presented in the weekly noticeboard so that other students could study them. As all the proposed solutions were not correct, it turned out that some students started to make comments about weaknesses in the proofs and to present ideas how to improve the solutions. This was interesting to the teachers, as they had not
planned to use noticeboards as a media to constructing the correct solutions. At the end of the experiment the students' opinions about the learning experiment were collected. The feedback consisted about pedagogical, content-based and technical matters. Part of the results is shown in Table 1.

Pedagogical parts of the learning experiment emphasized self-directed learning and the learner's own activity. That is partly because teachers chose consciously the passive role in the students learning processes. In the results the students seemed to be motivated to take responsibility for their own learning. They preferred the A&O learning environment because it gave freedom to learning for example by delivering course from timetables and from the structures of the course material. The students were responsible for setting the goals to their learning process and also for achieving them.

Students felt that A&O made self-directedness in learning possible by providing cognitive tools needed in learning processes. Learning environment supported contextuality by offering exercises helping to understand the theory. Examples given in A&O helped students to apply the theory into practice. Partly caused by the teachers' passive role in the students' learning processes, interaction between the participants of the learning environment wasn't too active. Only few students actively participated in discussions in the noticeboards. That is why students felt that the learning environment supported only slightly collaboration between them. Students followed noticeboards actively, but they seldom commented conversations.

One main problem which arose in results is that there are still conservative attitudes concerning studying. Students are used to conventional, teacher oriented learning and also this was seen in results. Students preferred conventional lectures to self-directed learning. Many of them told that they studied mainly using printed lecture notes.

Table 1: The students feedback from pedagogical and technical issues from the learning experiment. The scale was 1 = strongly disagree, 2 = disagree, 3 = do not know, 4 = agree, and 5 = strongly agree.

From the technical point of view the results of the experiment were good. The server program didn't break down during the experiment. The server's performance was a bottleneck, but it will be significantly boosted by fine tuning the program code. Users liked the graphics of the environment. The placement of functions was considered to be fine and the user interface of utilities was thought to be acceptable too. Altogether, the design of the user interface was good, but there's still need to improve it. The performance and the reliability of the client were known to be problematic since thorough testing of the environment wasn't done in forehand. The results of the test confirmed some of our doubts although the problems weren't too bad. The environment was updated three times during the
The updates improved performance and reliability. The performance in general is not bad but some functions are bit too slow (e.g. drawing the tree structure of noticeboards). As a result, the problematic functions have been pinpointed. They will be improved to an acceptable speed. Reliability has already been improved much, thanks to the feedback from the students during experiment.

5 Conclusions

The present article presented the A&O learning environment. The open learning environment is based on a space model which is divided into Office, Study, Media Centre, and Gallery. The article presented the main actors of the learning environment, the functions and the production of content for the open learning environment. The planning and realisation of the A&O learning environment proved to be a very challenging task, considering the learning theories and rapid development in the field of information technology. In the learning environment the student is the most important actor learning is the most important process - every effort has been made to take this into account in the planning and realisation of the A&O learning environment. However, there is so far no empirical knowledge available as to how well the open learning environment, the structure of the learning material and the tools developed do in practice support learning and the activity of the learners, their collaboration and objectives, contextuality, transfer and reflectivity. The first learning experiment in Matrix Algebra, was carried out and the results were presented. Further experiments and data collection during the ongoing Open Learning Environment research project will be performed.

Abstract: Models of multimedia communication attempt to classify the numerous types of media objects available, and to provide a basis for unambiguous terminology in a new and expanding field. Many of these models are products of theory, rather than practical investigation, and few have been empirically studied to assess suitability. This paper reports on an experiment which investigated the understandability of a recently proposed multimedia model, TOMUS. The experiment entailed subjects classifying various media objects according to the TOMUS model. Error and perceived difficulty data were collected; analysis revealed which of the categories are the most difficult to comprehend. Suggestions are made as to the causes of these difficulties, and recommendations as to how the model might be correspondingly altered are proposed.

Introduction

The concept of "multimedia" suffers from inadequate standardisation of terminology, and the lack of commonly agreed definitions results in much ambiguity both within and between articles written on the topic. Recognising this lack of consistency, many authors have provided classifications, definitions and models, attempting to create a theoretical basis for the study of multimedia communication. The fine-grained model proposed by Arens et al (1993) is based on the characteristics of perceiver, producer, information and media, and has a set of rules associated with it which determine matchings between information and media. The taxonomy used by Heller and Martin (1995) is based around common (potentially ambiguous) terms "text", "graphics", "sound" and "motion". Its aim is to enhance students' understanding of the range of possible media types in their production and evaluation of multimedia software. Vetere's model (1997) includes the notion of interaction, relating to the goals of the user and the goals of the system, and uses 3D vectors to represent complex media types. Bernsen's (1995) input and output modalities define forty-eight low-level "unimodalities" in a hierarchical model.

Empirical studies are rare in the area of multimedia definition: the afore-mentioned models are products of thought, rather than practical experiment. Lohse's model (1994) is based on data taken from subjects' grouping of objects, but only in the visual domain. While Heller and Martin (1995) tested their model by observing its use in student projects, the outcomes were as much indicative of student skill as of model suitability. Theoretical multimedia models need to be empirically tested for their suitability. This suitability may be with respect to suitability for use for a particular multimedia task, ease of understanding of the model definition, or correspondence between the model and human cognition and perception. The aim of this paper is to present the results of an empirical investigation of the TOMUS multimedia model (Purchase, 1998), from the perspective of its understandability. A theoretical model that is based on definitions that are difficult to understand is not useful for any task.

The TOMUS model

The TOMUS model was devised as an attempt to categorise the many types of simple media objects that may comprise multimedia texts. Its intention was to provide an unambiguous theoretical model that could be used to avoid vague and
inconsistent terminology: it offers a means for producing a consistent definition of the terms associated with multimedia communication (multimodality, hypermedia, etc.).

This paper presents results of an investigation into the understandability of the TOMUS dimensions. The aim of this paper is not to present the TOMUS model in detail, nor to propose an unambiguous definition of multimedia communication: this has been done more completely elsewhere (Purchase, 1998).

The TOMUS model consists of three dimensions: sign, syntax, and modality.

The sign dimension determines the nature of objects used in multimedia communication, and is based on semiotic categories of sign: symbol and icon (Bruner, 1966). (The enactive category included by Bruner does not form part of the TOMUS model, as it is concerned with physical movement, rather than communication.) An iconic object is perceptually similar to the concept it represents (e.g. a “no smoking” sign), while a symbolic object has no perceivable similarity to the concept it represents (e.g. the Olympic rings). In the TOMUS model, the iconic category is divided into two: concrete-iconic (the object is perceptually identical to the represented concept, as in a photograph), and abstract-iconic (the object is perceptually similar to the represented concept, as in a cartoon character). This distinction follows Arnheim’s proposal of a continuum of abstraction for visual signs (Arnheim, 1969). The sign dimension thus has three values: concrete-iconic, abstract-iconic and symbolic.

The syntax dimension determines the manner in which single media objects may be arranged in a multimedia document. There are five syntax categories in the basic TOMUS model: individual, augmented, temporal, linear and schematic. (The complete TOMUS model includes a network syntax value, used in order to distinguish between multimedia and hypermedia; its inclusion in this TOMUS description is beyond the scope of this paper.)

- The individual syntax describes documents comprising a single object in a single moment of time (e.g. a road sign).
- The augmented syntax describes documents that comprise a single object, where the object is augmented with additional information (e.g. colour or font) essential to its interpretation (e.g. a red traffic light).
- The temporal syntax describes documents where the same object is repeated over time, and only a single concept is represented (e.g. a fire alarm, a pendulum). The concept cannot be comprehended without transmission over time.
- The linear syntax describes documents which, like the temporal syntax, are transmitted over time. Unlike the temporal syntax, the concepts change over time, as part of a narrative (e.g. a novel, a film).
- The schematic syntax describes documents where the relationship of the objects to each other in an additional spatial dimension is important (e.g. a map or graph, a family tree). In the aural dimension, this additional dimension is the frequency dimension, representing complexity of sound.

The modality dimension distinguishes between the senses used for perceiving the multimedia document. Currently, this dimension has two values: visual and aural.

Within these three dimensions, thirty different media objects can be classified (Figure 1).

An important attribute of the TOMUS dimensions is that they are all defined independently of technology, and are based on the nature of the text, rather than the device that communicates it. This approach recognises that linking the model to technology may mean that it will soon be out of date, and acknowledges that multimedia need not be the exclusive domain of the computer. This technology-free approach sets TOMUS apart from other multimedia classifications.
Empirical investigation

While TOMUS was primarily intended to provide unambiguous terminology, it also aimed to be a useful model for multimedia tasks, by clearly defining the range of multimedia objects. However, it is a purely theoretical model, the product of thought rather than practical investigation. While the sign dimension is based on semiotic definitions, and the modality dimension is based on the senses, the syntax dimension is merely based on the experiences of TOMUS’ designer. There is no guarantee that the model will be easily comprehensible to other people. It was therefore important that the model be evaluated empirically, to determine its understandability, and to dictate any essential changes.

To this end, an experiment was conducted where twenty subjects, having knowledge of TOMUS, were each presented with a single example of each of the TOMUS categories, and were asked to identify the correct TOMUS category. The aim was to determine whether there were any categories that subjects were having particular difficulty understanding.

The research questions

A desirable property of a theoretical model of multimedia, is that the dimensions, and the values on the dimensions, are easy to understand. Subjects were asked to identify the TOMUS category of each of thirty different media objects. Two types of understandability were measured in terms of misclassification of given media objects:

- **Dimension understandability**: the extent of correct classification of media objects according to their value on each dimension. Thus, if the [concrete,linear,aural] object were classified as [concrete,schematic,aural], a linear-dimension error would be counted, but not a concrete-dimension error nor an aural-dimension error.
- **Composite understandability**: the extent of correct classification of media objects within their values on each dimension. Thus, if the [concrete,linear,aural] object were classified as [concrete,schematic,aural], a linear-composite error, a concrete-composite error and an aural-composite error would all be counted.

In addition, the “perceived difficulty” of the values along each dimension was collected by way of a questionnaire. Three questions were therefore considered for each of the three TOMUS dimensions (sign, syntax and modality):

- Are the values along the three dimensions equally easy to understand? (dimension errors)
- Are the values along the three dimensions equally easy to classify within? (composite errors)
- Are the values along the three dimensions perceived as equally as difficult to understand? (perceived difficulty)

Methodology

The subjects interacted with an online system, the display of which comprised buttons labelled with the values of each of the thirty TOMUS categories, and a display area. For each of thirty media objects that were presented, subjects were required to indicate to which TOMUS category the object belonged.

A within-subject experimental design was used, with all subjects being shown all thirty media objects. To reduce any learning effect, the order of presentation of the objects was randomised for each subject, and six “practise objects” were presented at the start of each session: the subjects were not aware that these six initial objects were not experimental.

The online system recorded the TOMUS categories selected by the subjects for each media object, and identified misclassifications. The independent variable for the experiment was the TOMUS category; the dependent variable was errors. Twenty third year computer science students participated voluntarily.

After the classification task, subjects completed a questionnaire. For each TOMUS dimension they were asked to “rate the difficulty [they] had in deciding the [sign/syntax/modality] of the examples”, 1 representing the most difficult value on each dimension. This data was collected in the form of rankings.

The media objects

Each media object was accompanied by a sentence defining its meaning (Figure 2). These concept definitions were necessary in providing a context for the categorisation: without a context, the TOMUS category of an object may be ambiguous. For example, a picture of a lightbulb might mean “lightbulbs” (abstract-iconic) if seen on a packing box, but may mean “an idea” (symbolic) if seen in a cartoon.
Figure 2: The experimental media objects. The first column is the TOMUS category: sign (Concrete-iconic, Abstract-iconic, Symbolic), syntax (Individual, Augmented, Temporal, Linear, Schematic), and modality (Visual, Aural).

Data Analysis

The error data was analysed using a standard ANOVA test based on critical values of the F distribution; in the case of significance, a Tukey pairwise analysis was performed, to determine which values on the dimensions proved most difficult. The perceived difficulty data was collected by way of ranks; thus, a non-parametric statistical analysis was required. The Friedman analysis of variance test was used; in the case of significance, the Kruskal-Wallis test identified where the differences lay. Figure 3 shows the outcome of this statistical analysis, and figures 4, 5 and 6 show graphs of the average dimension errors, composite errors and perceived difficulty rankings. Figure 7 shows where pairwise differences lay. (NS indicates a non-significant result.)

Discussion

The sign dimension

The data is significant for all three tests, and the pairwise analysis shows significant differences between abstract and the other two categories in almost all cases.

The abstract-iconic category was added on to Bruner’s semiotic definitions (Bruner, 1966). It produces a “grey area” that the subjects may have had difficulty distinguishing. Informal preparatory experiments revealed that symbolic objects tend to be classified with respect to function (e.g. # has the function of sharpening a note in music) while concrete-iconic objects tend to be classified according to form (e.g. a photograph of a pie on a menu merely shows
what the pie looks like, and is therefore classified according to its visual form as a pie.) On the other hand, many abstract-iconic objects may be classified according to function or form, depending on their context, and thus may have ambiguous TOMUS classification. For example, a diagram of a pair of scissors may represent scissors in a pictorial representation of items to be included in a first aid kit, but may mean “cut here” if found on a dress pattern. It is this ambiguity that requires the association of concept definitions with media objects when they are categorised within TOMUS. And it is perhaps for this reason that the abstract-iconic category produced the worst performance.

The aural distinction between concrete and abstract is awkward (as the difference between synthesised sounds and real recordings), making it a less useful distinction than in the visual modality. Further analysis of the data may reveal whether a significant number of abstract errors were made within the aural category.

Following Arnheim (1969), we believe that a continuum between symbolic and iconic is necessary, particularly in multimedia texts where photographs (which are concrete-iconic) are used extensively. Removal of the abstract-iconic category due to bad performance is not appropriate. A more suitable proposal would be for the definition of abstract-iconic to be clarified, or for a form/function distinction to be introduced.

The syntax dimension

The data is significant for all three tests, with best performance in the individual and temporal categories. The pairwise analysis confirms that, for the error tests, augmented, linear and schematic are more difficult than individual, and that linear and schematic are more difficult than temporal.

It is not surprising that individual and temporal are easy to understand and distinguish, as they both represent only a single concept. But it is a surprise that the linear category proved difficult, as the notion of narrative is common. The TOMUS stated definition of this category needs to be reassessed, and clearly distinguished from temporal.

The schematic category is awkward in the aural modality: more tests are required to see whether most schematic errors were aural. Most surprising is the fact that the subjects did not perceive the schematic category to be difficult, despite their poor performance. The subjects seemed to understand the concept of schematic, but were less sure when to apply it. The schematic definition needs to be reassessed so that it more closely relates to its use in the model.
The augmented syntax is concerned with comparisons: the font or colour of an augmented object is only important when compared with a different font or colour. This comparative property of augmented objects adds to the complexity of their TOMUS definition, and to their classification. It is recommended that the augmented category be removed from the model. The process of adding extra information (e.g. font, colour) to a media object can be acknowledged, but can be applied outside the TOMUS model categories, in a separate part of the multimedia process.

The modality dimension

There is no significance for dimension errors: the subjects understood the visual/aural distinction. The composite error data is highly significant, indicating that classifying within the aural domain was difficult: subjects had less difficulty understanding the other dimensions in the visual domain than in the aural domain. This is not surprising, as our visual sense dominates the others.

What is surprising is that subjects thought it more difficult to determine whether something was aural than visual: we would have expected this data not to be significant. It is possible that the students were projecting their difficulty in classifying within the aural dimension onto their response to this question.

There is no reason why this dimension should be altered: a predictable extension would be a tactile category.

Conclusion

The problem with this model, is the assumption of equal priority for each of the classification cells. No consideration is made for the fact that some types of media objects may be more common or more important for multimedia tasks. For example, redefining “schematic” so that it better relates to the aural modality assumes an equal priority of [schematic-visual] objects with [schematic-aural] objects. It does not acknowledge that the [schematic-aural] category may not be useful, nor that [schematic-aural] objects may be rare in practice.

This observation does not mean that it is irrelevant if less important or less common categories are less easy to understand, but it does suggest that tweaking model definitions to force media objects to unambiguously fit one category may not be a useful process.

We anticipate that a well balanced model, with equal priority for each value on each dimension, would be difficult to propose, and may not be any more useful in practice than TOMUS as it stands. While investigating TOMUS understandability has been a useful start in assessing its worth, it is more important that its practical use be investigated: how useful are these classifications to designers and evaluators of multimedia texts? Assessing practical use will avoid issues regarding the relative priority or frequency of occurrence of the values on the dimensions, and will rather focus on the benefits of models like TOMUS in action.

Abstract: This paper features a study on the use of electronic catalogs and retail storefronts as a concrete collaborative class project for the Electronic Commerce Course in the Business curriculum and a survey of the MBA students that undertook this project in response to the course requirements. The survey results provide positive indications for the achievement of the goals of collaborative inquiry, team-based and active learning, constructivist pedagogical approach, and learning by doing. The technical details of the project are also described in the study.

Introduction

The Internet is providing an extraordinary environment for designing teaching and learning experiences. This paper will focus on how the World Wide Web (WWW) could be utilized for teaching Electronic Commerce (E-Commerce) in Management Information Systems (MIS) program of the Business curriculum. The opening of the Internet to businesses in the early nineties initiated the E-Commerce phenomena that has not only revolutionized the conduct of business online but also overhauled the way E-Commerce-related business courses need to be taught. The unusual aspect of these courses is that the WWW is primarily the environment in which online establishments also conduct their business. This means students can actually simulate the conduct of business via the same environment where their learning takes place. Not only that—the instructional setting can also take advantage of web hosting services used to support online businesses to supplement if not entirely replace inadequate university information technology infrastructure that needs to undergird the activities of electronic merchants.

This paper reports the experiences of the MBA students at the School of Business, Montclair State University, in building electronic storefronts using Merchandizer software, which is a requirement in their Management Information Systems course that has an E-Commerce theme. Using the survey technique, student feedback was gathered from two MBA classes that took the course during the summer and fall 1999. Data was conducted to measure students’ perceptions of the quality of their overall learning experience and their ability to gain collaborative team work skills, discipline-specific skills in building an electronic storefront and catalog, skills in using the Merchandizer software, and various forms of thinking skills.

The E-Commerce course could be taught by combining the pedagogical principles that surround a number of appropriate teaching strategies: cooperative learning, constructivist approach, active learning, and learning by doing. These strategies can be used to structure and coordinate electronic learning spaces. In a cooperative learning environment, the instructor organizes content and topical activities around tasks, problems, and projects that student teams with a balanced mix of abilities and backgrounds are designed to undertake (Adams and Hamm, 1996). Cooperative learning also provides valuable opportunities for students to work together across gender and ethnic lines as long as communication skills, prior achievement, expectations, friendships, and group status are factored in (Chizhik, 1999). A meta-analysis of university-level and adult-learning courses found that use of collaborative
learning concepts promoted higher achievement, higher-level reasoning, more frequent generation of ideas and solutions, and greater transfer of learning than did individualistic or competitive learning strategies (Johnson et al., 1991). Team members' social skills, also called "interpersonal intelligence" according to Howard Gardner, encompassing interpersonal communication, task management, group interaction, and conflict resolution are constantly honed throughout the process.

The constructivist pedagogical approach invites students to build personal meanings out of the material taught and encourages them to reflect on how new knowledge builds on their previous base of understanding (Pankratius and Young, 1995). In a group setting, the constructivist approach could lead to the social creation of knowledge as a basis of learning.

"The yeast of knowledge, openness, and enterprise raises the need for a multiplicity of learning media and technological tools "(Adams and Hamm, 1996). The very wealth of Web site building tools that is now available allows students to experiment and "play" through "learning by doing" activities and significantly changes the whole instructional experience. Students have more control over the end product via the software tools and they assume greater responsibility over their learning process (Adams and Hamm, 1996). MIS instructors are strongly encouraged to move towards the "learning by doing" mode which is, by far, the most effective way of teaching students "how to" skills. While this is clear to most teachers, it is not easy to do unless certain prerequisites are in place: professional development, teacher preparation, technological infrastructure support (hardware, software, and helpline service), an appropriate incentive system that will reward the countless hours that will go into a more technologically-oriented class (as opposed to a traditional lecture-style one), and above all, an overarching plan that clearly defines the role of technology in the pedagogical process (Adams and Hamm, 1995).

Merchandizer Software Features

Students are asked to build an electronic retail storefront for either consumer-to-business or business-to-business commerce. What this means is that the store can sell a product that individual consumers may be interested in buying such as an Amazon.com for books or a CdNow.com for musical CD-ROMs. Or, the storefront could be an electronic catalog for firms interested in buying materials they need in running their business such as office supplies, for instance---staplers, bond paper, paper clips, etc.---in other words, these will be businesses buying from another business. The product used in the project is Merchandizer Software, which is an online solution that allows users to build and manage an electronic storefront with just a browser software such as Netscape Communicator or Microsoft Internet Explorer and an Internet connection which an Internet Service Provider (ISP) or web hosting service can provide for a fee. In designing the site, students could either enter all product information using a step-by-step wizard or they could work directly with hypertext markup language (HTML) forms to both make and modify their sites. In building the electronic catalog itself, students either enter information manually using the wizard templates or they may import extensive information using Microsoft Access database tables which are loaded onto the servers.

Merchandizer software makes use of frames or windows appearing within the browser's display area, each of which displays the contents of a different HTML file (Carey, 1998). The software also allows storebuilders to divide their product lines in a hierarchical fashion, first into groups, then, into subgroups, and finally, into catalog items. The group and subgroup headers become navigational links in one frame, displaying product pages or other HTML pages or entire web sites altogether created by the students. The frame concept facilitates the navigation of the customer through the storefront.

Once groups, subgroups, and catalog items have been defined, students enter product information either of two ways. They can enter the information using simple electronic forms that allow them to submit information like product name, code, description, and price. Alternatively, they could use preformatted Microsoft Access tables that essentially mimic the wizard online templates. These tables are more convenient to fill out when merchants have hundreds or even thousands of product items to enter. Since students are building only prototype stores with a limited product line, they end of using the forms, although the use of the Access table is demonstrated to them should they be interested in trying it.

Merchandizer has features like a search function that will allow hypothetical customers to search the storefront using any word or phrase related to the products on sale. Merchandizer also incorporates a shipping table for UPS directly into the software so that the students do not have to be concerned with this. They need to specify the appropriate sales tax, though. Merchandizer keeps track of all sales transactions, customers, and prospects (those who visit but do not buy). A report generating facility gives students information on the most saleable products, customers who buy most from the store, aggregate sales figures for the week or the month, and areas of
interest of prospects, among other things. The software can also autogenerate email messages to prospects about special promotional activities the store is conducting.

Version 3.0 of Merchandizer offers students a wide range of features to play with to simulate a real online store even more realistically: easy translation of the website into any language; ability to insert forms with special buying instructions before the shopper checks out; offer global coupon numbers to shoppers so that they can accumulate their purchases and eventually received discounts on items; ability to submit the store site to top search engines; more managerial report forms that can be generated from the sales transaction data; a personalization field for each catalog item for shopper input that will be carried over to the order tables; ease of uploading and downloading Access tables, among other more advanced features.

HipHip software, the company behind the Merchandizer storefront building tool, is also a web hosting service. A merchant that does not have networking facilities to support the store could subscribe to this service and pay a one-time setup fee and monthly maintenance fees that vary depending on the number of catalog items supported in the store. HipHip software offers educational pricing for universities interested in using their hosting services for the purpose of instruction. This arrangement is a boon for universities and colleges that do not have adequate information technology infrastructure to allow E-Commerce instructors to mount interesting student projects.

The web hosting service is important because of the backend office component of the online store. Sales transaction information submitted by customers and personal information keyed in by interested prospects who do not purchase during their visit to the store need to be stored in web servers so that the order could be processed and sales prospects could be reached through promotional email messages in the future. Backend office processing requires the availability of web servers that can store order transaction data in databases that can later be accessed using some form of structured query language so that reports and statistics could be generated for managerial decision making. The extensive requirements of the storefront make the storefront project too challenging for the normal capabilities of a typical university's academic technology support group. It is far better to sign up with the web hosting service—if reasonable fees could be negotiated with the company—and have their technical support staff provide the services necessary for optimizing all functionalities and features of the storefront.

Methodology

This study used the survey technique using a written questionnaire, which was administered to two classes of the MIS 503, Management Information Systems course at the MBA level. Data was gathered during the Summer and Fall of 1999. Both classes had the theme of "Electronic Commerce" and the project assigned to the students was the construction of an online retail storefront for either consumer-to-business or business-to-business commerce. Students were assigned in teams of four to five students. Each team was in charge of a storefront web site, which was maintained and supported by HipHip Software. The technical support staff that advises the students and oversees the web servers that host the software and product information entered by the students is located in Miami, Florida. Survey data was analyzed using descriptive statistics, correlations, and simple regressions among key variables.

Findings

The sample size consists of 43 students in the MBA program of the School of Business, Montclair State University, who all took the INFO 503 class in Management Information Systems, with special emphasis on Electronic Commerce. The students were at various stages in the MBA program and majority of them hold full-time jobs in industry.

Students were asked to respond to a five-point Likert scale for different items where 1=Strongly disagree, 2=Disagree to some extent, 3=Uncertain, 4=Agree to some extent, and 5=Strongly agree. Most of the students felt that the retail storefront project was an important learning experience overall (mean=4.44). Students found the project instructive in terms of teaching them new ways of doing business over the World Wide Web (mean=4.35). They also thought that the project taught them skills they could use after the completion of the course, particularly the setting up of an online Web site for a product or service (mean=4.30). They also felt the project gave them a chance to create Web site content that was meaningful to the entire team (mean=4.30). In the construction of the storefront site, they thought that they learned the following specific skill sets in decreasing order of importance: design issues for creating an online catalog (mean=4.30); overall planning issues for preparing an online retail web
site (mean=4.14); web site product information and content issues (mean=4.07); advertising (mean=3.84); and product/service promotional activities (mean=3.74).

The next important set of findings relate to the students' perceptions of how this project enhanced their ability to collaborate with peers in a team setting. Most students found the project a good venue for encouraging collaborative teamwork (mean=4.40). Communication skills were paramount in getting the work done (mean=4.33). While standards for personal accountability were set within the team setting (mean=4.30), members made sure they also helped each other out (mean=4.28). The project clearly taught the students a variety of group process skills: (a) looking out for the best interest of all concerned over and above one's own personal interests (mean=4.26); (b) arriving at mutually acceptable solutions (mean=4.26); (c) dividing the work equitably among members (mean=4.23); (d) practising interpersonal social skills (mean=4.21); (e) learning from members' different ways of thinking (mean=4.21); (f) learning positive interdependence (mean=4.21); (g) respecting a diversity of opinions (mean=4.16); and (h) striving for goals as a team rather than as individuals (mean=4.12).

They gained a better understanding E-Commerce as a subarea of Management Information Systems (MIS) in the School of Business curriculum (mean=4.07). The storefront project, which is a natural cross-over between marketing and MIS, made them more aware of the interdisciplinary connections within the business curriculum (mean=3.95). They perceived the project as a venue for learning about E-Commerce vendors of hardware and software (mean=4.28), consulting services (mean=4.12), professional associations (mean=3.79), and job openings (mean=3.63).

It is very likely that the positive experiences reported, thus far would not have been possible if the Merchandizer storefront software itself was difficult to use. Most students found learning the software a fairly easy task (mean=4.19) and that they found it was a reachable goal to be skillful in the use of it (mean=4.14). The Merchandizer software templates were easy to understand (mean=4.07) so that students were able to learn them on their own without extensive instruction (mean=4.05).

Two important attributes of students in the sample were measured: frequency of computer use and length of time spent working with the computer. In a simple regression procedure, it was found that frequency of computer use significantly predicts students' perception of the ease of learning the Merchandizer software at the significance level of p<.10 (F=3.24284; p=0.0791). In two other simple regression runs, it was found that the students' perception of the project as having enhanced collaborative team work predicts their perception of the storefront as being an important learning experience overall (F=11.42868; p=0.0016) and their ability to create a web site with content that is meaningful to the entire team (F=3.59981; p=0.0648). Then, students' perception of Merchandizer as an application software that was easy to use predicted their organizing skills in arranging web site information so that the site could be presented more effectively (F=12.27518; p=0.0011).

When taken together as two independent variables in a regression equation, both the students' perception of the project as having enhanced collaborative team work and their perception of Merchandizer as an application software that was easy to use predicted a number of dependent variables. Significance levels were tightest for their organizing skills in arranging web site information so that the site could be presented more effectively (F=7.28378; p=0.0020) and their perception of the storefront as being an important learning experience overall (F=7.14604; p=0.0022). Both independent variables in a regression equation also significantly predicted student's perception that the storefront project encouraged creative thinking (F=4.12591; p=0.0235), their perception that the project enhanced their integrating skills or their ability to put information or content together (F=3.40767; p=0.0430), and their perception that the project developed useful skills in web site development they could use even after the course was over (F=2.62482; p=0.0849).

The association among selected variables using Pearson's correlation values was also investigated. Only those variables that bonded very strongly at the significance level of p<0.001 are shown here.

Learning important lessons in determining web site product information and content issues correlated strongly with the following seven variables: learning positive interdependence in the team (.4999); learning different ways of thinking in the team (.5271); achieving the goals as a team (.5511); considering the storefront project an important learning experience overall (.5193); creating web site content meaningful to the team (.4843); developing skills usable even after the course such as building a web site (.6225); learning overall planning issues in a storefront (.6854).

Learning how to achieve goals as a team correlated strongly with five other variables: perceiving the project as encouraging collaborative team work (.7380); learning to communicate with team members (.7264); learning positive interdependence (.8872); learning interpersonal social skills (.8041); and learning how to achieve goals as a team (.9168).

Learning design issues for creating an online catalog correlated strongly with the following four variables: perceiving the project as encouraging collaborative team work (.5269); learning to communicate with team
members (.5038); learning different ways of thinking in the team (.5784); and learning how to achieve goals as a team (.5380).

Learning different ways of thinking in the team correlated strongly with four other variables: perceiving the project as encouraging collaborative team work (.7333); learning to communicate with team members (.7026); learning positive interdependence in the team (.8792); and learning interpersonal social skills (.8245).

Conclusion

This paper has shown concrete data supporting the promise of the use of the WWW for instructional purposes in the area of E-Commerce in the business curriculum. Not only does the WWW provide an environment that perfectly simulates the subject of the course itself, but the web hosting service arrangement also provides information technology infrastructure support to universities that are resource poor or unable to afford the hardware, software, and manpower requirements of mounting E-Commerce projects. The survey results provide positive indications for the achievement of the goals of collaborative inquiry, team-based and active learning, constructivist pedagogical approach, and learning by doing.

Didactical Activities and Strategies in the Use of WWW-based Course-Support Environments: Design Guidelines for Instructors

Elka Remmers and Betty Collis
Faculty of Educational Science and Technology, University of Twente, Enschede, The Netherlands
e.remmers@edte.utwente.nl, collis@edte.utwente.nl

Abstract: New developments in educational technology at the University of Twente are providing instructors with a set of tools and templates for WWW-based course-support environments. Those templates can be used by the instructors to fill in learning activities and study material for all students, both local and at a distance. The task for the instructional designer is to create these general templates and make them suitable for different kinds of teaching situations. To guide the instructors in how to use those tools and templates, a series of design guidelines for the use of the WWW have emerged for each of the following didactical activities: face-to-face sessions, self-study activities, assignments, monitoring and feedback. Those guidelines are based on the experience of the Faculty of Educational Science and Technology at the University of Twente with the implementation of approximately 44 courses supported by WWW-based environments in the context of the TeleTOP Project (http://teletop.edte.utwente.nl/) as well as on instructional principles that predate WWW use. The paper concludes by noting the need for a course (re-)design model which combines the guidelines into an overall perspective.

A new role for instructional designers.

New developments in educational technology as well as new insights in the experiences of instructional design and information and communication technologies are stimulating new roles for instructional designers. Their major tasks are not to transmit the educational content, but to design activities; not to design hyperlinked learning materials, but to design and develop templates which can be used in multiple situations in which students are active and using WWW tools and environments to support and manage that activity. Their task is to design those tools and functionalities, so that instructors in turn can design their own activities and study material with those tools.

At the Faculty of Educational Science and Technology a WWW-based course-management system has been developed in which tools and functionalities are collected in a database which serves as a general base of templates (This system is called TeleTOP; see Collis & De Boer, 1998; see http://teletop.edte.utwente.nl). The instructor chooses the templates or functions he or she desires to support the course, and only has to type into various types of fill-in forms to organize the notes and other material that is to be put into the WWW environment. If a template is not available that meets the instructor's needs, the TeleTOP team creates it.

As the instructors are confronted with the task of choosing tools and functionalities for their courses, they express a need for educational and didactical guidance (Evaluatie werkgroep TeleTOP en C@mpus+, 1999). In response to this growing need, the new-generation instructional designers of the TeleTOP team have created a set of design guidelines for instructors (Remmers, 1998). Those guidelines can be sorted around five general types of didactical activities which focus on a direct learning process: face-to-face sessions, self-study activities, assignments, monitoring and feedback (Collis, 1997). Communication is a major aspect within all the activities. For each didactical activity a variety of different types of (WWW-based) applications can be used. In Table 1 an overview of a sample of such applications is listed for each activity, as well as the numbers of the guidelines that are related to those activity-application combinations (the numbered guidelines are elaborated later in this paper).

In the next sections the didactical activities are discussed in more detail. Every section discusses the following: (a) background information; (b) the manner by which TeleTOP supports the activity and what tools are available for the TeleTOP instructors; and (c) guidelines derived from practice and theory.
Face-to-face sessions and the WWW environment

Face-to-face contact between the instructor and the student as well as between students are still not-to-be neglected instructional activities even when the WWW is extensively used. "It is to the learner's advantage to occasionally come to a face-to-face setting interacting directly with the instructor and peers. Some learning experiences, plus the more-intangible aspects of developing as an intellectual (called in Dutch, academisch vorming), are more than the sum of reading books and completing assignments from the convenience of one's home" (Carree & Collis, 1998). Moreover certain skills as, for example, applying statistical formulas are sometimes only learned by the active discourse between instructor and student, at least for some students.

During the contact session: For students who live at a long distance from the educational institution, the amount of face-to-face sessions must be kept to a minimum because of time and money issues. Therefore, the face-to-face sessions should be used to address only the most important subject matter or activities (see Guideline 1 and Figure 1). The evaluation study of TeleTOP concluded that part-time students, students who carry out a profession elsewhere and study part-time, and students with a part-time job particularly wish to have elaborations of the study material in the face-to-face sessions, not to have the time filled up with listening to organisational aspects of the course, which they can read in the WWW-based course environment (Evaluatiewerkgroep TeleTOP en C@mpus+. 1999). Thus, Guideline 1:

1. Use face-to-face sessions:
   - to provide the context of the course and the subject matter
   - to show relations between topics in the learning material
   - to explain difficult and essential issues
   - to show (good) examples of applications or assignments
   - to make the students enthusiastic and inspire them
   - to let the students interact and have discussions with one another
   - to reflect upon submitted work
   - to invite expert guest speakers on the subject matter

   Do not use the face-to-face sessions:
   - to provide organisational aspects of the course
   - to repeat what students can read

   Figure 1 reflects Guideline 1, showing how a face-to-face session was used in the course "Tele-Learning", not as a lecture, but for a variety of activities, capitalising on the presence of a guest visitor from another institution whose work relates to the study material for the week.

   Figure 1: Example of the topics discussed during a face-to-face session in the context of a course which is given partly at a distance. Telelearning course. 1999.

   Also, it is necessary to prepare a contact session so that students who were not able to be physically present (especially part-time working students) can also participate, either at the same time or at a later time. This typically has three aspects: (a) any content material to be elaborated in the contact session by the instructor is prepared in note form in advance and made available on the WWW environment for students who will not be present; (b) an interactive activity (a discussion, a short analysis task, a problem to work out, etc.) is devised that can involve the students attending the contact session at the same time (and perhaps some of them in different locations) so that the students are actively engaged in some sort of articulation and collaborative learning; (c) support materials to guide this interactive work, plus to be used by the students to report on their work, are created and put in the WWW course environment (see Guideline 2).

2. Prepare the face-to-face session so that students not physically present can also participate (synchronously or asynchronously), by providing the content material to be elaborated, an interactive activity, and support materials to guide this interactivity.

Students' preparation before the session: For the students to carry out an assignment during a face-to-face session, to have discussions, and to reflect on assignments it is necessary for them to have a basic understanding of the subject matter before they come to the session. For this reason the TeleTOP team has designed a specific kind of matrix-like structure called a roster, containing self-study activities to be carried out before the session (see Guideline 3 and Figure 2) that are integrated (via being in the same row) with notes and activities for the face-to-face sessions.
3. To provide students with the necessary basic understanding of the subject matter, give them self-study activities before the session, integrated in the WWW environment.

Figure 2: Example of the roster of a WWW-based course-support environment in which the students have to study certain literature before the class session: Principles of Learning and Instructional Design CC3. 1999

Follow-up after the session: After the session a follow-up activity to structure students' reflections on the contact session and how it integrates with their self-study materials and their other course activities can be planned. The instructions for this activity and the reporting form for the students to use are entered into the WWW environment before the contact session. A cut-off time should be indicated for the submission of the follow-up activities from the students, and after this time, the instructor should look at their submitted comments and post a feedback response in the WWW environment or by email (for example, a different comment may be appropriate to the part-time students than to the local students). See Guideline 4.

4. To structure students' reflection on the contact session and to relate it to the study-materials, provide students with a follow-up activity and a WWW-based template through which they submit their work relating to this activity, and indicate a cut-off time for this submission.

Self-study activities
The profile of the ideal professional practitioner requires that students should possess a solid knowledge base with regard to the profession (Verhagen et al. 1999). In general, self-study could be used for rehearsal of knowledge and for reflection on this knowledge. Reflection is oriented towards realising learning tasks: to process and to refine insight and understanding (De Jong, 1995).

Self-study activities are mostly used in TeleTOP as a preparation for face-to-face sessions and assignments and for the replacement of face-to-face sessions if necessary. For self-study activities, as well as for assignments, it is very important that they are not a stand-alone and independent activity. They should be implemented in the course WWW environment with for example an explanation of the relevant issues of the self-study activity, the active involvement of the learner, feedback from the instructor and repetition (Westera, 1999, see Guideline 5); otherwise students will not feel much value in the activity.

5. For self-study activities to be more effective, provide students with the relevant issues to interpret in terms of the study materials, provide WWW-based templates for the students that structure their active involvement, feedback and repetition.

The following applications could be used in TeleTOP for self-study activities: study guides, quizzes, simulations, and asynchronous audio and video. Quizzes will be discussed later in this paper.

Asynchronous audio and video: For students who were not participating in the contact session as it occurred, the instructor has the possibility to capture via digitised audio and/or video anything needed to make the notes more effective for those students who will study the materials later. In this way the communication event is captured and can be re-used (Peters & Collis, 1999). Other reasons for using asynchronous video are described in more detail in Peters and Collis (1999) and are summarized in Guideline 6.

6. Use asynchronous audio and video:
- to capture presentations or lectures
- to give access and depth to real events
- to support the learning process in situations involving procedures or social situations
- to develop a library of cases or units of learning material
- to capture and share one's own video materials

Self-study activities are primarily oriented around the acquiring, rehearsal, and reflective consideration of knowledge, whereas assignments are more focussed on the application of the students' knowledge base and insights into practice (see the next section).

Assignments
It is generally accepted that if you "put students to work" they learn more (De Jong, 1995; Collis, 1998). For this, the term action learning is used. Meyers and Jones (1993) identify four major elements associated with action learning which students use to create new mental structures: speaking, listening, reading, and writing and reflecting. Those elements refer to cognitive activities which enable students to clearly investigate, consolidate, and acquire new knowledge. For example, when conducting a discussion, the process of telling clears the thoughts of students, whereas listeners have the possibility to reflect on alternatives to one's own perspectives (Peters, 1998)
Within TeleTOP there are several ways to put the students to action: small assignments (before, during, after or in-between contact sessions), working on case studies, making contributions to the course study material, developing their own research questions and discussions, and contributing materials that can be used as model answers or help resources. For assignments to be effective some of the issues mentioned in Guideline 5 are also important for the implementation of assignments. These are summarized in Guideline 7.

7. To help make assignments be more effective, provide students with relevant issues relating to the topics to be studied, use WWW-based templates that help structure and manage the active involvement of the students and that integrate feedback with the assignments: when possible, use student submissions as a basis for study and reflection in the course itself.

Small assignments: One of the major orientations of the TeleTOP method is to reduce the number of lectures and increase the number of "in-between assignments", relatively small assignments to which feedback is quickly given. The process for handling this is supported within the Roster of the course-support environment (see Figure 2). The trick is to make the management of this process as automatic as possible, while still maintaining instructor contact when useful. This becomes the major task of the instructor: to think of these assignments, and of how they can be carried out efficiently and effectively (i.e., both instructor and student getting regular insights into how the learning process is going on). In TeleTOP the instructors have the possibility to let the students submit their work on (small) assignments in the WWW environment during a face-to-face session, but also before or after a session. Before the session, to help the students become familiar with the subject matter. After the session, to let the students reflect on the presentation of the instructor, on the answers to the assignments, or on ideas that emerged during the face-to-face session, etc. However, assignments need to be assessed or else students tend not to do them and the learning potential is not realized. "Although students appreciated the follow-up assignments, they often did not have time to carry them out if they were not given points but only offered on a voluntary basis" (Dijkstra, Collis & Eseryel, 1999).

Students' contributions to study material: Another major orientation of TeleTOP is that students can contribute study resources to the course-support environment. This can occur in many ways: for example, through adding to a FAQ (frequently asked questions) collection, adding to a database of examples, supplying model answers, adding links to external resources, adding definitions to a course glossary, and constructing and sharing one's own video & WWW resources (Collis, 1998). The most important function of the students contributing to the course study material is to stimulate a more-active learning process among the students, by providing valuable exercises and letting them participate in building the course environment by finding or creating resources and sharing them with others (Dijkstra, Collis & Eseryel, 1999). For example, "Students appreciated being able to read the contributions of other students in the shared workspace" Dijkstra, Collis & Eseryel (1999).

Working together on case studies: If correctly applied, case studies are suitable for developing skills for problem-solving, for critical thinking, and for creativity (Romiszowski, 1995). For part-time students who carry out a profession as well follow a study, exercises with case studies can be done by placing the case study in the contexts of their work. The TeleTOP system allows different assignments to be described for different groups of students: the students only see the descriptions for the groups to which they belong.

For both the students' contributions to study material and for the case studies, TeleTOP offers the tools workspace and presentation. At the workspace students can work together on certain assignments and only the group members can enter the group workspace. They can work for example in an on-going way on their case-study exercises or their self-developed study material (see Figure 3). To make the workspace not too complicated, overly filled with files and comments, the students can present their final work in the section presentation. This function could present in a well-organised overview the final products of the groups for all students to access (see Guideline 8).

8. To let the students actively learn or develop skills for problem-solving, critical thinking and creativity, use students' contributions to study material and case study exercises as resources in the course WWW environment:
   - Let the students work together in a shared workspace and present their final products in a separate part of the course environment.
   - For part-time students use the context of their work experiences for their case studies.

Figure 3: Students working together in the Workspace (in Dutch: Werkplaats). ICT-project 2000 course, 1999.

Monitoring and feedback
One of the reasons for monitoring which Dodman and Coxhead (1994) have put forward is: monitoring students and groups of students to see which parts the students do not master and which they do not master very well. In classical situations
monitoring takes place on the basis of the experience and knowledge of the expert, the instructor (Winnips, 1998). In telelearning situations the instructor may not always be present physically, which could result in limited feedback on the progress of the individual students or on a group of students. By applying monitoring strategies, this progress can be made clear and actions can be undertaken if problems should occur.

TeleTOP offers the instructors a number of tools which could make the monitoring of students and group of students easier (see Guideline 9). Quizzes (with multiple-choice questions, short answers, true-false, etc.) and clear overviews of the submitted work of students are all being used by the instructors of the faculty of Educational Science and Technology. In the beginning of August 1999 the faculty initiated a digital portfolio project (see Guideline 9):

**Guideline 9.** To monitor the work and progress of the students, use WWW-based quizzes, overviews via the WWW-site of the submitted work of students, and digital portfolios accesible via the WWW-site.

**Quizzes:** When using quizzes in his or her course, the instructor can get a glance at the understanding of the students relating to the topics which are covered in the quizzes (see Guideline 10 and Figure 4). The answers to the questions in the quiz are sent to the instructor and if a student answered (several) incorrect answers, the instructor could take action and give appropriate feedback to the student. Students can also submit quiz questions themselves, as small assignments during the course.

**Guideline 10.** Use WWW-based quizzes to monitor the understanding of the students of the subject matter. Let the answers be sent to you via the WWW-site. Consider the strategy of having students contribute quiz questions via the WWW-site as an assignment, which are then used by all the students for self-study.

![Figure 4: Questions created by the instructor in the course Instructional Theory 1, 1999](image)

**Overview of submitted work:** As the instructor has chosen that the students will submit assignments through the roster, the instructor is able to get an overview of each item of submitted work of each student and can give the student immediate feedback or remedial help and perhaps a mark or some number of points (see Guideline 11 and Figure 5). If the instructor decides to give the students points for the assignments, the overview will also show the total amount of points per student at each moment in time. The instructor should keep track of the student's submissions, and send a message to students who did not submit to find out if they are having particular problems (this message can be pre-structured, so the time and effort needed to send it can be small).

**Guideline 11.** To monitor the comprehension of the students as to how to apply their recently acquired knowledge into practice, use an overview of the submitted work of students in which direct links are available to the work of the student, the submitted date, the feedback to the students, the points given; all ordered by student.

![Figure 5: Overview of the submitted work of the students and of the given feedback (checkmarks) and points. Telelearning course. 1999.](image)

**Feedback:** When feedback is needed, as a consequence of monitoring or as a reflection on the work of students, the instructor has the possibility to (a) provide individual feedback via the course environment (this feedback can only be seen by the instructor and the particular student), (b) provide public feedback (feedback that is meant for one student, but can be read by all students), (c) provide feedback to a group of students, (d) give one key-answer to all students, and/or (e) let students give feedback to themselves and each other (self- and peer evaluation). See Guideline 12.
Digital portfolios: As a current development for the Faculty of Educational Science and Technology, the students’ overall progress within all their courses is being monitored by the use of students’ digital portfolios. Individual assessment will still take place by the instructors of the particular courses, but overall monitoring and support will be done by faculty members serving as mentors. This type of support is designed to stimulate the professional growth of the student by examining his or her added products and documentary evidence relating to his or her work.

How to re-design your course for the use of a WWW-based course support environment?
The above-mentioned guidelines and applications are a handle for the instructors when they are (re-)designing their courses to make them suitable for WWW-based course support or tele-learning purposes. Although the instructional principles underlying the guidelines may not be new in themselves, what is new are increased possibilities for putting these principles into practice through the support of WWW-based tools and environments. Also, WWW tools and environments are being used by many instructors (i.e., in technical faculties) who are not familiar with instructional design theories. The guidelines are written in a practical way to steer the use of the WWW for good pedagogical practice.
The set of guidelines can be elaborated with new experiences of instructors and students, as well as with new developments in educational concepts. On a regular basis, new guidelines are being added to the set of guidelines that we now have. However, there is also a need to put the guidelines in a broader perspective in such a manner that instructors will know when to choose certain applications in certain didactical situations (especially important for novices). This could result in an instructional (re)design model for WWW-based course-support environments.

References

Abstract: New search tools and techniques that can improve the efficiency and effectiveness of web searches are highlighted, including metasearch tools, improving search relevance with search engines (backward searching and other advanced search features), and searching the "invisible web".

Comprehensive Searching with Metasearch Tools

A recent article in Nature (July 8, 1999) by Steve Lawrence and C. Lee Giles received wide attention in the press. Lawrence and Giles examined the World Wide Web in February 1999 and found that publicly indexed web pages had increased to 800 million (up from an estimated 320 million in December 1997). Their article analyzed how well eleven search engines/directories performed in accessing the information contained in those 800 million pages. Lawrence and Giles estimated that the combined coverage of the 11 tools was only 42% of the total web and that the overlap among the search engines was surprisingly low. This research implies that using multiple search engines is a necessity today. Metasearch tools allow us to do just that -- quickly and effectively. Popular metasearch tools include ProFusion (http://www.profusion.com), Metacrawler (http://www.metacrawler.com) and SavvySearch (http://www.savvysearch.com).

Improving Search Relevance with Search Engines
Most of us probably have a favorite search tool, such as Yahoo!, Infoseek, or Excite, and there is certainly something to be said for developing a high degree of familiarity with the search features of a single search engine or directory. However, in the rapidly changing world of the web, it is important to be aware of new search tools and the features that they use to try to improve the relevance of results. New search algorithms are developed regularly, usually in conjunction with a new search service.

Google (http://www.google.com) is one of the most exciting search tools available today. Google's search algorithm is based on an approach called PageRank. The FAQ states that, "PageRank capitalizes on the uniquely democratic characteristic of the web by using its vast link structure as an organizational tool. In essence, Google interprets a link from page A to page B as a vote, by page A, for page B. Google assesses a page's importance by the votes it receives. But Google looks at more than sheer volume of votes, or links; it also analyzes the page that casts the vote. Votes cast by pages that are themselves "important" weigh more heavily and help to make other pages "important" (available online at http://www.google.com/why_use.html). Google allows users to capitalize on this by choosing an "I'm feeling lucky" button. When this button is chosen the user is directly linked to the page Google identifies as the most relevant. A search limited to United States government sites is also available through Google. A recent addition to Google is a directory, featuring a hierarchical list of sites organized by category. Unlike the more familiar Yahoo directory, the Google directory is based on the same page ranking algorithm used by the search engine.

Oingo (http://www.ingo.com/) suggests that it is the first meaning-based search engine. When a search term or phrase is entered, Oingo returns with one or more dialog boxes that allow the user to specify the exact meaning of the word or phrase in the context of the search. For example, when the search string "travel to Montreal" is entered, Oingo asks the searchers to specify the meaning of two terms, travel and Montreal. For travel, the user is asked to choose between several shades of meaning (from commercial travel to locomotion) and for Montreal, the searcher is asked to specify one of several different locations for towns or cities named Montreal. After the meanings are predefined the search is narrowed and results are presented. Results include categories (from Oingo) and individual web sites (from Alta Vista). Those results that match the predefined meanings are indicated using a lightbulb icon. Another interesting feature of Oingo is that it asks for feedback from the searcher.

While Surf Fast (http://www.surffast.com) isn't based on a new searching algorithm, it does provide "one stop shopping" for web searchers. This well organized page provides keyword searching for all of the major search engines, plus quick access to major news organizations and other useful web resources such as Mapquest and Travelocity. Surf Fast shows how important it is to match the kind of information needed to the search tool. Making this match is crucial in improving search relevance.

Chris Sherman suggests the term "backward searching" for the technique of using the "link" operator to identify pages linked to the URL that you have entered (http://websearch.about.com/library/weekly/aa082499.htm). The basic idea here is that people only add links to sites that they consider highly relevant, although searchers still need to determine whether or not popularity actually equals quality. Backward searching is done using a link operator. Queries are usually structured like this: +link:URL. To assess quality, look over the list of "linking" URLs. Are all of the links from individual pages or are the links from well respected sites like Kathy Schrock's Guide for Educators (http://school.discovery.com/schrockguide/index.html) or the Librarian's Index to the Internet (http://sunsite.berkeley.edu/InternetIndex/)? If you find a promising page and you follow these "backward" links, you get a sense of whether others find the page so useful that they link to it. Backward searching is just one of the many advanced search features included in different search engines. Unfortunately it can be a challenge to locate information about using advanced search features. At Infoseek you have to choose advanced search then choose help before you come to this information (http://infoseek.go.com/find?pg=advanced www.html&ud9=advanced www).

Searching the "Invisible Web"
Many useful and relevant resources cannot be retrieved using standard web search tools. ERIC, online library catalogs, and archival resources are examples of resources that are simply not retrieved by the spiders and bots used to build search engine databases. If you have ever spent hours fruitlessly searching for information you’re sure is accessible electronically, the information is probably “hidden” on the invisible web. And if students tell you that they couldn’t find even one article on a common topic, they have probably been doing a web search, not searching in a specialized database. Students often do not understand the difference between information on web pages and information found in databases and indexes. Identifying places to search for these “invisible” resources is one step toward developing this understanding.

Direct Search (http://gwis2.circ.gwu.edu/~gprice/direct.htm) is a comprehensive index maintained by Gary Price at George Washington University. Direct Search provides links to a variety of education specific resources, plus general interest resources including Your Nation (which uses data from the CIA World Fact Book to create customized, comparative statistical profiles for different countries), Termium Plus (billed as the definitive French-English dictionary), and the Writer’s Guidelines Database. Lycos provides access to over 300 searchable education databases at http://dir.lycos.com/Reference/Searchable_Databases/Education/. Infomine (http://infomine.ucr.edu/) permits multiple database searching, which is a significant time saver, and it also has two long lists of instructional resources databases (for K-12 and for higher education). The Invisible Web (http://www.invisibleweb.com/) includes both quick and advanced search features. Like Direct Search, The Invisible Web was specifically designed to provide a well organized interface between end-users and information on the invisible web. Categories listed under “education” range from “Alumni and Reunions” to “Distance Learning” but the category structure is simple to follow and provides an excellent approach to each topic. A Hot List of commonly searched topics is clearly presented. Currently the only search enhancements available through advanced search are Boolean and phrase searching.

Research by Hertzberg and Rudner (1999; “The Quality of Researchers’ Searches of the ERIC Database”, available online at http://epaa.asu.edu/epaa/v7n25.html)) indicates that even experienced web searchers rarely use advanced searching techniques to improve the quality of their searching. Citing results from a study of users of the ERIC database, Hertzberg and Rudner conclude that “Patrons are not using effective search strategies and cannot possibly find the best and most relevant articles in the database being searched. We have reason to believe that most end-users are satisfied with any somewhat-relevant hit.” (p. 8) If this is the case in a controlled searching environment like ERIC, it is even more of an issue on the web, where search tools and techniques are much less obvious to end-users. Web searching is a complex activity that requires a considerable amount of knowledge, critical thinking, and practice. The good news is that it is a skill that can be perfected, but the bad news is that the strategies and tools available change daily. A recent visit to the Search Engine Guide (http://www.searchenginenguide.com/) found a categorized listing of over 3200 search tools, which implies that there is a specialized search tool available to meet virtually any information need. Useful resources for keeping up with the latest trends in searching include the Search Engine Showdown (http://www.notess.com/search/) and Search Engine Watch (http://searchenginewatch.com/). Both sites specialize in providing current news about web searching and both also include critical evaluations and comparisons of search tools.
Moving an Australian Dual Mode University to the Online Environment: A Case Study

Abstract: This paper discusses an educational initiative, USQOnline which has enabled the University of Southern Queensland (USQ), Australia, to deliver multiple courses via the Internet to students worldwide. The paper briefly outlines the underlying structure and philosophy of distance education at USQ and then describes how the online initiative has evolved from this existing distance education infrastructure. The paper reflects on the conceptualisation and initiation of the USQOnline project and the consequences of an apparent shift in the pattern of teaching and learning in a higher education institution following the introduction of online teaching. An interim evaluation conducted by the authors makes the following recommendations: open communication, consultation and collaboration should form the basis of such a major institutional initiative; roles and responsibilities of all stakeholders should be clearly defined; synergies and alliances with strong partners are essential; and there should be sound technological support at all levels.

Background

In recent years, higher education worldwide has been faced with significant change which has been in response to a number of influences (Armstrong et al., 1997, Askew & Carnell, 1998). These influences have been the greater emphasis on lifelong learning and the advent of the Information Age, resulting in globalisation and a move to a knowledge society. Also, economic rationalism has required universities to enter the commercial arena (Coaldrake & Stedman, 1999; Dearing, 1997). Student cohorts have also made further demands on universities for greater flexibility in the ways they are able to access programs and services. The adoption of flexible learning methodology has been a key initiative in many institutions in an attempt to adapt to this changing environment. In addition, information and communication technologies have created new educational opportunities and challenges, which impact upon distance education models and theory and challenge the traditional roles of teachers and learners. The paper will now examine the impact of these changes within the context of an Australian institution of higher education.

USQ is an internationally recognised leader in the provision of flexible learning opportunities and has a well-established Distance Education Centre. In 1999, the Executive Committee of the International Council for Open and Distance Education (ICDE), based in Oslo, Norway, awarded its inaugural Prize of Excellence to USQ in recognition of the University's significant contribution to providing global education. In 1967, USQ was first established as a face-to-face Institute of Advanced Education, moving to full university status in 1992. In 1977, it presented itself as a viable alternative to traditional universities by offering distance education. Distance education has been defined according to several characteristics: separation of teacher and learner; the existence and influence of an educational institution; use of various media; provision of two-way communication; and an absence of group learning with the focus on independent learning (Keegan, 1986; Rumble, 1986). In Australia, a typical distance
education learning package consists of print-based materials supported by audio, video and computer-based resources and is designed to enable learners to interact independently with the materials.

USQ delivered distance education while continuing with classroom-based teaching, earning it a 'dual mode' label. This experience in dual mode delivery has strategically positioned USQ to take advantage of possibilities created by the advent of information and communication technologies and the move to online delivery. The university services over 14,000 distance students from every state in Australia, and many overseas countries. It also provides on-campus, face-to-face delivery for 5,000 Australian and international students. USQ is a regional university with an international mission. Almost seventy-five percent of the students studying with USQ are off-campus and more students study offshore through flexible learning modes at USQ than with any other Australian university. Providing learning experiences at a distance using an electronic delivery mechanism presents further challenges but also opens up a whole new world of opportunities and possibilities. For one, the approach questions the traditional definition of distance education as having an independent learning focus and lacking in group interaction.

USQ delivered its first course solely online in 1997. In 1999, a major online initiative called USQOnline (http://www.usqonline.com.au) was introduced. This initiative enables the delivery of multiple courses via the Internet to students worldwide. USQOnline presently offers 29 award courses and has involved all six Faculties within the university and approximately one quarter of the 400 academic staff. It involves a contractual arrangement with an independent commercial provider, a company in which USQ is a shareholder. Aiming at a mass global market, it provides a complete delivery package - the administrative structures (including enrolment), delivery platform, and mirror sites around Australia, Asia and North America.

Change in Higher Education

The introduction of the online initiative has caused major cultural and administrative change within USQ. The institution has responded to the current influences and demands and has made some substantial changes to the way it offers its programs and services. Many of the institutional systems have had to undergo major reform and the pedagogical framework of "traditional" distance education has been challenged by the unique possibilities of online delivery. There has also been quite significant organisational restructuring to enable the implementation of a more corporate approach to management at the University. Teaching online has had an enormous impact on academic staff roles and workloads, and on the conceptualisation of models of online teaching and learning.

The literature supports the belief that the most critical barriers to change in educational processes are "personal" ones. Kefford (1980) maintain that the most decisive factor in ensuring the success of change in educational organisations is the positive reaction and commitment of the personnel affected by that change. According to Waugh and Punch (1987), there are basic generalisations common to all educational change and these can be incorporated into ideal-type models for implementing change. Waugh and Punch have extracted general variables that should be included in such models, identifying the variables as:

- overall feelings and attitudes towards the previous system, particularly so with regard to teachers who have been in the system for a long period of time. They may not be receptive to change that challenges their traditional values and those of the organisation and previous system;
- the extent of alleviation of fears and uncertainties associated with the change. The lack of knowledge about the proposed change may hinder receptivity to that change and teachers should be encouraged to be actively involved in the decision making process;
- the practicality and importance of the new education system; and
- the personal cost appraisal for the change. Teachers will tend to appraise the value of the proposed change in terms of the amount of incentive and support received to implement change; the amount of energy, time and difficulty involved in having to learn new skills; and the effects on students, on home life, and on personal satisfaction.

Coaldrake and Stedman (1999) observe, "universities more so than most organisations are built on a culture of individualism and academic personal autonomy" (p. 1). The roles of staff and students in the traditional tertiary education framework have been established over hundreds of years. The traditional academic culture has been labelled a "person" culture by Handy (1993, in Laurillard & Margetson 1997), with an emphasis on individualism for both staff and learners. In this culture, academics work autonomously on the preparation of face-to-face teaching
materials. It is very much an individual task, with the control of content an individual responsibility. The Distance Education Centre at USQ was established to facilitate design, production and delivery of material for students separated from a tertiary institution by distance, creating what Laurillard & Margetson (1997, p. 3) call a "role culture" or industrial model of education. The introduction of distance education caused considerable tension between the "person" culture and the emerging "role" culture. The role culture of traditional distance delivery means that course material is delivered in print, is therefore available for peer scrutiny and usually prepared in a team environment. The team approach is deemed essential because there is no one person who can design and deliver the teaching/learning programs that are epitomised by distance education, suggesting that perhaps "educators...must...drop the arrogance of academic isolation" (Limerick et al. 1998, p.11) within this culture.

The Study

In order to reflect on the initiation and conceptualisation of the USQOnline project within the context of organisational change, the authors conducted an interim evaluation with a representative group of academic staff at the university. This was a preliminary investigation and the authors are not suggesting that the initiative has only affected academic staff. Through an analysis of data collected from interviews, the authors were able to reflect on the staff perceptions of the online initiative. The interviews were conducted over a one week period with staff from a cross-section of Faculties and levels. This was to gain a snapshot view of the perceptions of the initiative, its conceptualisation, initiation and its communication to the university community. The interviewees were sent the questions (see appendix 1, Interview Questions) prior to the interview to allow time for consideration. The structure of the interview was followed closely to give consistency in the data collection, although the opportunity for extended exploration of the themes and more free-ranging discussion was available within the interview context. As a result of analysis of the interview data, the paper identifies key challenges and experiences that have emerged and offers proposals from which others interested in institutional change and transformation might benefit.

Findings and Recommendations

Communication, Consultation and Collaboration

According to the interview data, there was a concerted attempt to inform and consult with staff about the online initiative in a structured way through a variety of channels. Communication occurred via written means and verbal presentations such as university-wide assemblies (including the "launch"), demonstrations, meetings within Faculties, focus groups, and through small committees (see appendix 2 for a diagram of the USQOnline management structure). Throughout the interviews, a persistent recommendation was the need for open and ongoing communication involving all stakeholders during the process of conceptualising and communicating of such a major initiative. Interviewees articulated that lack of consultation and free exchange of information can cause feelings of disempowerment and stressed that the implementation process, and the following impact at grassroots level needs to be made very explicit. One recommendation was that an outside consultant could facilitate focus group processes to ensure a professional, unbiased approach with a free and fair exchange of information. It was also articulated that academics have much to offer in the way of educational and management expertise, and that they should contribute to both the conceptualisation and implementation of such an initiative. A consensus of opinion from the interview data indicated a need for shared "vision" and consultation and collaboration at all stages of the developmental process in order to facilitate shared meaning and a sense of ownership of the decision-making process amongst those who have to implement the project.

The literature supports the findings of the interim evaluation. Dolence and Norris (1995) observe: "Campus leadership must find ways to stimulate discussion, debate, and dialogue on the need for a transformation vision. Existing processes and/or initiatives can be reshaped as agents of transformation. Given the ethos of Academe, the development of shared values must be a process of co-creation, consultation and testing of ideas" (pp. 87-8). This supports one of the main variables discussed by Waugh and Punch (1987) – that a lack of knowledge about a proposed change may hinder receptivity to that change. Yukl (1999) emphasises the importance of empowerment and discusses how "resistance can be a source of energy that enables people to collectively make better decisions about what type of change is needed" (p.40. These points were strongly supported by all interviewees in the study.
Roles, Responsibilities and Workload Implications

As previously mentioned, there have been some significant changes at USQ in the way the members of the academic community perform the tasks required to develop and implement flexible learning programs and services. A key pedagogical feature of the online teaching/learning environment is that the technology facilitates interaction through electronic means (discussion groups, email, virtual chats). This capability impacts on the design and delivery of course material and has caused a significant shift from the independent learner mode of traditional distance education courses to interaction between participants in online courses. Distance education also has meant staff have a larger, more varied cohort of students to service and track. Furthermore, teaching online has had a significant impact on student learning and staff workloads, as technology allows opportunity for increased online communication, changes in traditional teaching roles, and changes in the way information is published and resourced. A more commercial emphasis, changes in course design and delivery and a shift to a greater client focus (giving learners what they want, when and where they want it) has meant that courses are now being offered throughout the year, and in multiple modes. Students have been provided with opportunities to extend or shorten the time taken to complete particular units of work. University administrative systems have been put in place to accommodate this added flexibility but staff workload issues remain a major concern. One interviewee observed that "for a long time the university has operated on the goodwill of its staff, but when a job grows from that which is manageable to just another ten percent, things get a bit fractious about the edges". Several of the interviewees observed that USQ staff have already undergone role changes as a result of distance education initiatives so perhaps it is considered by management that staff are ready to undergo a further evolutionary move building on this history of organisational change.

Interview responses provided suggestions for ways to assist the workload situation. These include a reduction in course offerings with a focus on particular disciplines or courses that have already proved popular to learners. Reward/award systems might be established as an incentive for staff having to do the additional work involved which is often on top of existing workloads. However, the conflict still exists in institutions of higher education as to what is considered worthy of reward - research, teaching or a combination of both. The cost-saving benefits of major online initiatives are also still to be proven. An investigation conducted by the University of Illinois (1999) states: “Because high quality online teaching is time and labour intensive, it is not likely to be the income source envisioned by some administrators” (p. 1).

Loosely Coupled Networks/ Synergies and Alliances

One of the key themes emerging in the literature is the need for an organisation to enter into loosely coupled networks or strategic alliances in order to operate within the emerging global environment. Alliances with other knowledge producers, such as a partnership with an independent commercial provider in the case of USQ has been a strategy aimed at capitalising on the strengths of both partners and increasing student access to higher education. Kanter (1989) argues that “a major component of post-entrepreneurial strategy involves developing close working relationships with other organizations, extending the company’s reach without increasing its size. Strategic alliances and partnerships are a potent way to do more with less” (p. 347). One interviewee observed that the online initiative at USQ “builds on existing expertise, positions USQ as an initiator and leader in full-scale, online delivery, draws on the capabilities of a commercial partner and also enables opportunities for joint partnerships with other academic institutions”. The alliance enables USQ to offer its students global access by using the technology network. According to Higgins and Vincze (1989, in Limerick et al., 1998), "corporations with ambitions must turn to a new strategy of agreements, alliances, and mergers with other companies if they hope to survive" (p. 78). However, as raised in the interview data, the importance of a clear allocation of roles and responsibilities and a clear understanding of the capabilities of each partner is essential and there is also a need to choose strong partners, as synergies do not come out of combined weaknesses.

Technological Difficulties

An important consideration in the use of electronic delivery and communication systems is that of technical support. The interview data revealed that people who are unfamiliar with using technology spend a large amount of time coming to grips with it. Staff skills in using the Internet vary immensely, as do their learning styles. A Staff and Student Support (SSS) Focus Group has emerged out of the new committee structure. This group has been charged
with the responsibility of developing interactive, online education and training materials for staff. The group has also established a Staff Development Gateway web site which contains links to other courses available, Help Desk facilities, multiple resources, exemplary materials, teaching and learning advice and peer mentoring support. All interviewees acknowledged that these developments have been well received by staff. However, it was evident from the responses that there is still a need for face-to-face education and training support which is also managed by the SSS Focus Group. It was also acknowledged that this preparation may not be enough to alleviate all the concerns of academic staff and will have to be closely monitored and addressed. The advice through the interviews has been to slow the developmental process down in order to reflect on events and evaluate the initiative and make sure the operational components of the system are working well. It was observed that there is always more to be done but there is still a need for time out and reflection.

Conclusion

The use of an electronic environment such as USQOnline to provide learning experiences opens up new challenges in terms of teaching and learning. The interim evaluation conducted by the authors at USQ makes the following recommendations: open communication, consultation and collaboration should form the basis of all stages of such a major institutional initiative; roles and responsibilities of all stakeholders should be clearly defined; synergies and alliances with strong partners are essential; and there should be sound technological support at all levels. The key to organisational change and sustainability is shared vision, shared values and shared decision making. The trends in and impacts of the use of communication and information technologies in the higher education sector mean that change is an ongoing factor of tertiary education. This is not necessarily something to be feared as it also promises to offer some exciting challenges. As Eckel et al. (1999) observe, change is "an ongoing, organic process" and "there is no point in time at which everyone can declare a victory and go back to normal life" (p. 1). The challenge facing all education providers in the 21st century is to meet the needs of lifelong learners in the Information Age and distance education providers are uniquely positioned to service the needs of these learners.

Abstract: The Computer Aided Information Navigation (CAIN) project provides a new method of adaptive navigation support that aims to increase the World Wide Web's value as a pedagogical tool. To examine whether the system's approach improves comprehension under specific conditions, an experiment compared CAIN with conventional web tools on three measures of performance: comprehension scores, task completion times and user satisfaction. Results revealed that comprehension scores were 30% greater with CAIN than with the conventional tools and indicated that task completion times can also be reduced without compromising user satisfaction.

Introduction

The Computer Aided Information Navigation project (CAIN) aims to provide adaptive navigation support as a way of increasing the Web's value as a pedagogical tool. CAIN's approach is a reactive one as it seeks to provide a way of dealing with the vast amount of useful information available on the Web as it currently exists rather than trying to improve or alter the Web's infrastructure.

In order to help users reach their goals, CAIN provides direct guidance navigation support as a form of non-obtrusive weak hypertext linearization enabling the user to follow a context specific ranked sequence of selected Web pages without ever needing to perform any search or follow any link if they do not wish to. This approach does not seek to prevent goal-oriented exploration but rather to provide a sound thread or guideline to help users to retain their focus.

The system's representation of the Web, crucial to the success of its adaptive features, builds on the Dublin Core (Weibel & Lagoze 1997) and on the Resource Description Framework (Lassila & Swick 1998).

The users' representation combines three user modeling techniques resulting in a hybrid solution that uses stereotypes, overlays and attribute-value pairs (Benyon & Murray 1993; Brusilovsky 1996).

Navigation support is accomplished by a basic route-finding heuristic which selects context specific Web model items, sorts them using associated qualitative ratings, and presents them to the user, one at the time, based on the attributes of the user's model (Lamas 1998).

This paper presents and discusses the results of an experiment which examined whether the directed Web navigation guidance provided by CAIN can improve the performance of Web users under appropriate conditions. Section 2 describes the methodology used and section 3 presents and discusses the results. Section 4 discusses related empirical work and section 5 evaluates the current study and suggests directions for future research.

Method

It was hypothesised that contextualized direct guidance of the information available on the World Wide Web may improve comprehension under the specific conditions that:

- Users are either inexperienced in Web use or have little expertise in the target subject topic, or both.
Users use the system pursuing learning or initial research goals. For this purpose a standard task was devised in which volunteers were required to use the WWW to learn as much as they could about two given subject topics — cryptography and poetry — using either CAIN or alternative tools that the users chose to employ. The experiment compared the use of CAIN with conventional tools on three dependent measures of performance:

- **Comprehension** as measured by a multiple-choice comprehension questionnaire;
- **Time taken** to complete the tasks; and
- **System usage appreciation** assessed by a like/dislike rating completed at the end of each task.

Performance was examined as function of the following independent variables:

- **Tool used**, either CAIN or Free;
- **Web expertise**, the Web experience of the users, either Low or High; and
- **Subject expertise**, the users' expertise in the target subject areas, either Low or High.

In order to implement the experiment, volunteers were recruited from the university's population, specialist help was required to build the domain model and to provide the subject abstracts and questionnaires and a specially designed environment was prepared to implement the experiment.

**Design and procedure**

The devised task consisted of carrying out two learning assignments performed in sequence and assessed at each one's completion. The task could be accomplished using either CAIN or any other Web navigation tool. Forty volunteers were used as test subjects, 20 of whom performed the test using CAIN while the remaining 20 performed the task using the tools of their choice. To control for order effects, the CAIN and non CAIN groups were each divided into two sub-groups of 10 subjects so that the learning assignments were counterbalanced between groups. Each sub-group was assigned to a task permutation, either CAIN AB, CAIN BA, Free AB or Free BA.

- **Before the test began** — Self-assessment of Web expertise along a scale of 1 to 7 was provided by each participant.
- **Before each of the learning tasks began** — Self-assessment of expertise in the subject area of 1 to 7 was provided by each participant.
- **Following completion of each of the learning tasks** — A ten question multiple choice comprehension questionnaire was completed by each participant together with a 7 point rating of system satisfaction.

Participants were required to complete the tasks within time boundaries and each participant's actual completion time was recorded with a resolution of 1 minute².

Volunteers undertook the tasks in a specially prepared and isolated environment.

**Materials and apparatus**

In order to provide valid learning assignments and comprehension questions, two specialists in the domains provided all relevant data from CAIN's domain model to the assignment descriptions and the comprehension assessment multiple choice questionnaires.

The questionnaires

Task scripts, learning assignment descriptions and the various questions were specially prepared to cater for each of the four task variations. Everything was written in Portuguese as the experiment was conducted in Portugal. Apart from ensuring the specific multiple choice questionnaires, the subject specialists also provided marking grids so that data could be gathered as soon as the tests were accomplished.

The test site

The test site was designed so that volunteers could enjoy suitable silence and isolation. A pilot experiment was run before the main with four volunteers to establish the appropriate experimental parameters such as the time boundaries, the learning assignment descriptions, the number of MCQ questions.

Participants

An opportunity sample of 40 volunteers was used in the experiment. All volunteers were members of the university and were the first 40 who responded to the call for volunteers broadcast throughout the university. The sample consisted of 24 undergraduate students, 12 postgraduate students and 4 staff members. There were 28 males and 12 females in the sample.

---

1 Universidade Fernando Pessoa, Porto, Portugal
2 these are the Time A and Time B variables
3 professors Estela Pinto Ribeiro Lamas and Feliz Ribeiro Gouveia, both from Universidade Fernando Pessoa
All had English reading skills. No financial inducements were offered and written consent was obtained from each of the volunteers.

**Results and discussion**

The participants were grouped to produce three independent variables as described below.

- Given that the design of the experiment was counterbalanced, the four permutations, CAIN AB, CAIN CA, Free AB and Free BA, results in the Tool grouping variable with two levels, CAIN and Free.
- In order to class volunteers as either High or Low in Web expertise, a mean was taken of overall self-assessed Web expertise. Volunteers who scored above the mean were assigned to the high Web expertise group and volunteers who scored below the mean were assigned to the low Web expertise group resulting in the Web expertise grouping variable.
- The same was done with subject (i.e. domain) expertise resulting in the Subject expertise (High/Low) grouping variable.

Finally, comprehension assessment scores were collapsed across subject A and subject B multiple choice questionnaires scores resulting in a mean comprehension score dependent measure. The same technique was applied to the time taken to accomplish the learning assignments and to the system appreciation/satisfaction ratings producing two further dependent measures: mean completion time and mean user satisfaction.

The new variables meanings and usage conventions are explained in table 1.

<table>
<thead>

<td>The volunteer's self assessed Web expertise classified as either Low or High</td>
</tr>
<tr>
<td>Subject expertise</td>
<td>The volunteer's self assessed subject (domain) expertise classified as either Low or High</td>
</tr>
<tr>
<td>Mean score</td>
<td>Average comprehension score achieved by a volunteer after completing a learning task ranging from 0 — minimum — to 10 — maximum</td>
</tr>
<tr>
<td>Mean time</td>
<td>Average time taken by a volunteer to complete a learning task measured in minutes</td>
</tr>
<tr>
<td>Mean system</td>
<td>Average used system appreciation by volunteer rated from 1 — minimum — to 7 — maximum</td>
</tr>
</tbody>
</table>

**Table 1: Definition of the independent and dependent variables used in the experiment**

Comprehension

The results of the self assessments conducted before each learning task began showed that subject expertise was equivalent for the CAIN and Free groups ($t(38) = 0.276, p = 0.784$), a difference of only 2.5% (approximately). Therefore a meaningful comparison between the comprehension performance of the CAIN and Free groups following a Web learning session was possible.

Following Web learning, a t-test comparing comprehension scores showed that comprehension was significantly greater in the CAIN group than in the Free group ($t(38) = 2.9, p = 0.006$).

The comprehension score group statistics presented in table 2 together with the mean subject expertise ratings presented in table 3, indicate that CAIN produces an improvement in comprehension scores of nearly 30% compared with the other methods used by the volunteers.

**Table 3: Mean subject expertise and comprehension score contrast**

In order to explore these results further, an analysis of variance of comprehension scores, with Subject expertise, Tool and Web expertise as the three independent factors, was conducted.

The analysis showed a significant main effect of Tool such that comprehension scores were higher after completing a learning assignment with CAIN than after completing a learning assignment with Free ($F(1,32) = 4.85, p = 0.035$).
This repeats the result from the test and in this case, no other variable or interaction between variables has enough statistical significance (all $p > 0.05$) to be regarded as influential.

Separate analyses of variance were conducted on comprehension scores for subjects $A$ and $B$ which revealed that the main effect of Tool was highly significant on comprehension scores for subject $B$ ($F (1,32) = 8.554, p = 0.006$) but not for subject $A$ ($F (1,32) = 0.709, p > 0.05$).

Subject $A$ was cryptography and subject $B$ topic was poetry. These results may reflect the fact that cryptography Web sites have better structure or are easier to find and use than poetry Web sites and so benefit little from the use of CAIN.

The separate analysis of variance also revealed a significant main effect of Web expertise for subject $A$ ($F (1,32) = 5.979, p = 0.020$) and subject $B$ ($F(1,32) = 5.353, p = 0.027$) which did not appear in analysis of variance collapsed across domain.

This situation results from a crossover interaction between Web expertise and domain (subjects $A/B$) (see table 4).

<table>

</tr>
</tbody>
</table>

Table 4: Comprehension scores means by Web expertise level

Although unexpected, these results suggest that the subject topics used — cryptography and poetry — are at opposite ends of a qualitative range for Web sites and that by using them both, this experiment neutralised their differences and provided a fair testing environment.

Finally, table 5 provides a straightforward comparison between the mean comprehension scores under every condition combination.

Table 5: Web expertise X Tool X Subject expertise comprehension scores.

**Time taken**

Next, an analysis of variance of completion time performance was conducted with the same Subject expertise, Tool and Web expertise independent variables.

Although overall learning assignment completion times are quicker with CAIN than with Free, this difference is not statistically significant ($F(1,32) = 2.05, p > 0.05$).

Nevertheless, several interesting remarks can be made:

- There is a significant main effect of Web expertise such that highly experienced Web users performed faster than the low experienced Web users ($F(1,32)=9.02, p=0.05$). As all of the experiment was conducted over the Web, it is not surprising that highly experienced Web users performed faster.

- There is an interesting 3 Way interaction between Subject expertise, Tool and Web expertise ($F(1,32) = 4.61, p = 0.039$).

Table 6 illustrate this last result highlighting the fact that CAIN produces faster performance than Free under all combinations of levels of the independent variables except when the volunteer has High Web expertise and High subject expertise, i.e. it suggests that:

- Time taken may be slower with CAIN when the user is a highly experienced Web user and an expert in the learning assignment field, but;

- CAIN is faster when users are inexperienced Web users and inexperienced in the study subject or inexperienced in the Web and experienced in the subject.

<table>

<td>75.76</td>
</tr>
</tbody>
</table>

Table 6: Web expertise X Tool X Subject expertise performance times contrast

Note that Web expertise alone does not slow performance when using CAIN. In fact, highly experienced Web users performances are slightly faster under CAIN than Free.
It is the particular combination of High Web expertise and High subject expertise that slows performance using CAIN compared to using other tools on the World Wide Web. Further analyses of variance, conducted separately on time performances for subjects A and B, revealed that the main effect of Tool was specially significant for subject B ($F(1,32) = 5.783, p = 0.022$) but not significant for subject A ($F(1,32) = 0.017, p > 0.05$). These results provide further evidence that cryptography Web sites may differ in quality or quantity from poetry Web sites and that CAIN may be more effective when addressing topics whose Web sites have characteristics similar to those of poetry Web sites (i.e. less well organised).

The same analysis of variance confirmed the significance of the main effect of Web expertise on both subject A ($F(1,32) = 4.819, p = 0.036$) and subject B ($F(1,32) = 5.362, p = 0.027$) performance times. This only indicates that although CAIN improves time performance in general, Web expertise still plays an important role as novice Web users spent more time than experienced Web users. This does not come as a surprise since CAIN is itself Web based and it does not replace existing navigation tools, it merely provides non-obtrusive navigation support.

**System usage appreciation/user satisfaction**

The t-test for system usage appreciation does not show any significant difference between the CAIN and the Free groups ($t(38) = 0.698, p = 0.489$).

In fact, table 7 shows that CAIN rated 5.7 out of 7 while Free rated 5.475 out of 7. This is only a 4% increase.

</tr>
</tbody>
</table>

**Table 8: Web expertise X Tool X Subject expertise system usage appreciation contrast**

As shown, satisfaction was higher for CAIN under almost every condition combination except for users ranking low in both Web and subject expertise. This was probably due to the extra effort required to cope with new systems, the Web and CAIN, and a new subject at the same time.

Finally, in this case there was no significant difference between the independent analysis of system usage appreciation for subjects A and B.

**Related empirical evidence**

Although to date empirical studies on the value of adaptivity in hypertext based learning environments are limited, they are critically important to validate the different approaches in this research area. Although most of the existing empirical evidence reviewed by Eklund and Brusilovsky (1998) fails to show if adaptive hypertext navigation contributes at all to improve the student's or researcher's performance, it hints that adaptive navigation could be valuable under appropriate conditions.

Nevertheless, in experiments measuring the number of hypertext nodes used to accomplish some predefined goal, existing empirical evidence favours adaptive curriculum sequencing\(^4\) versus adaptive link annotation over a closed information corpus. Although not directly related to CAIN, these results do not contradict this project's approach. Further, on the InterBook\(^5\) experiment reported in the same review, apart from other results, it is also stressed that the direct guidance mechanism was chosen by test subjects in over 90% of the transactions. Again, this system relies on a closed information corpus but nonetheless, the experiment's results provide added support to CAIN's approach.

This is however an under-investigated area and there is clearly a need for continued studies on the value of adaptivity in hypertext based learning environments.

---

\(^4\) a direct guidance approach
\(^5\) an adaptive hypertext system supporting adaptive link annotation and direct guidance in the form of a continue link
Final Remarks
The experiment herein examined the nature of the interaction between the users' Web expertise, Subject expertise and the used tool and its results show that CAIN, as specified and implemented, does indeed improve user's comprehension by 30% when supporting learning or initial research tasks performed over the World Wide Web. This is probably due to the way CAIN guides the user through a sequence of previously selected and relevant Web resources.

Though not in a very significant way, the experiment's results also suggest that the time taken to accomplish such tasks can also be reduced when using CAIN except in circumstances in which it is redundant, i.e. when the user is already an expert using the World Wide Web and an expert in the subject domain.

As far as enjoying the system, the results do not show any significant difference between using CAIN or any other approach to navigate the World Wide Web. In fact, the results show that users in general enjoy using the Web with whatever tools they use.

Although encouraging, this experiment's results are not sufficient to understand all the implications of a system like CAIN and further studies need to be undertaken. In fact, the current investigation only measures the adaptive guidance support leaving untouched issues related to all the other relevant areas brought together in this work such as:

- The adequacy of the metadata records and associated rating strategy;
- The soundness of the implicit co-operation model;
- The reliability of the relevance feedback mechanism; and
- The validity of adaptivity itself.

Specifically, it fails to understand other success factors such as:

- How relevant is the order in which Web resources are presented to the user?
- How do users cope with the domain building process?
- Are the rating criteria adequate and easy to apply?
- Is such Web representation successful for all its users?
- How does the system cope with long term users?
- How does physical distance affect the system's collaborative nature?

This is an under-researched area and there is clearly a need for continued studies on the value of adaptivity in hypertext based learning environments.

In conclusion, the Computer Aided Information Navigation system appears to be moving in the right direction and research will continue in order to achieve this collaborative environment's long term goals: To guide the user while learning, understanding, memorising and forgetting material in order to increase motivation, concentration and comprehension, reducing the environment's noise and improving the knowledge acquisition process.

Abstract: Many industries, including aerospace, automotive, agricultural and marine, use Fluid Power systems for power transmission. The design of these systems is a skilful and complex task requiring significant practical experience and heuristic knowledge gained over many years. With few formal Fluid Power design courses being taught in further and higher education, both academia and industry are seeking new methods of delivering this specialist knowledge. The Internet opens up low-cost, low-risk training opportunities for Small-to-Medium Enterprises that may not be able to afford the cost of residential courses, and also for employees seeking career development within the context of lifelong learning. This paper describes the early stages of a project to develop an open, domain-independent, Java-based framework for the delivery of multimedia training. This framework forms part of a Performance Support System for trainees and professionals involved in Fluid Power systems design. Also described is a formative evaluation of the framework.

Introduction

The need for lifelong learning is driven by the swiftly changing nature of global commerce which requires unprecedented levels of flexibility from a highly competitive employment market. The term itself refers to the continuous renewing, upgrading and updating of existing personal skills and expertise required - in addition to the acquisition of new capabilities - if individuals are to remain in gainful employment [Davies 1998]. Holt and Radcliffe [1991] state that the quality of engineering design is largely determined by the quality of the learning processes that are central to the design experience. From this, it is apparent that, in order to remain competitive, enterprises within engineering must become pro-active partners with education providers in the lifelong training of their employees [Berkley 1991]. Despite this, many Small-to-Medium Enterprises (SMEs) often find themselves unable to afford traditional training courses either in terms of the financial outlay or the time lost through personnel being absent for extended periods.

The term "Fluid Power" is used to denote systems where mechanical power is transmitted from one point to another by means of a fluid such as hydraulic oil. Examples are to be found on aircraft, ships, industrial plant and mobile equipment. The teaching of Fluid Power Systems Design poses particular problems, principally due
to the complex nature of the task which often requires extensive heuristic knowledge and many years of practical experience for a professional to become proficient. In the context of lifelong learning, an overhead such as this may become prohibitive for many individuals. It is argued that by using hypermedia to facilitate the learning process within the context of an overall Web-based Performance Support System for Fluid Power Systems Design, the cost of Fluid Power training to industry in general and SMEs in particular can be reduced to acceptable levels, and the problem of learning overhead for individuals can also be overcome. It is also argued that the developed methods and techniques would bring potential benefits to other domains.

One drawback with delivering training material over the WWW is the very loose integration of the Web itself. In order to co-ordinate lessons and gather feedback from trainees a somewhat tighter integration is required which is nevertheless flexible enough to accommodate changing content, changing users and changing styles of learning. One approach is to use server-side scripting to generate HTML pages and forms on the fly. Three systems currently seeking to improve integration of WWW learning frameworks are Interbook [Brusilovsky et al. 1996], IDEALS-MTS [Graf & Schmaider 1996] and KBS-HYPERBOOK [Frölich et al. 1998]. One disadvantage of a server-centric approach is that the resulting content can be rather static or slow in its interaction due to being bound to the server, while making little use of the ever-increasing client-side power and multimedia capabilities of modern computers. The framework under development aims to provide an optimum balance between integration, flexibility and interactivity by linking generic client-side Java navigational tools and multimedia renderers with server-side tracking, feedback and dynamic content-generation capabilities. Schank and Cleary [1994] describe eight principles for designing educational software, which, they argue, also pertain to teaching in general. These provide a checklist of desired tasks and outcomes for computerised teaching tools. The need to relate any given information to real-life examples and problems is crucial, with preferably simulation offered to enable trial and error analysis. Software should be adaptable to the students' needs and a good design will enable self-assessment and monitoring of progress. The framework under development seeks to satisfy these principles by providing real-life examples via multimedia elements such as 2-D and 3-D interactive graphics, sound and video, and supporting user experimentation via simulation. Each framework element is discussed below with reference to a prototype being developed at the University of Bath.

**Feasibility Study**

Richards et al. [1999] describe a feasibility study into the applicability of Java technologies for delivery of multimedia over the Internet. Multimedia examples from the domain of Fluid Power were developed as animations, 2D and 3D interactive simulations, and digital video. Navigational tools were also created to provide a "clickable" table of contents (TOC) and the facility to search a remote database. Java technologies were used,
including "Swing", Java Media Framework, Java 3D, Java Database Connectivity (JDBC) and Remote Method Invocation (RMI). [Fig. 1] shows the general screen layout of the framework. The prototype multimedia modules were tested on a mixture of PCs and SUN Workstations. The conclusion was that the Java technologies tested had reached a sufficient level of maturity and breadth of functionality to satisfy the requirements for the system. Java was therefore selected as the authoring language, with version 1.2 taken as the project baseline.

Client / Server Architecture

At the beginning of each session, user data is read from a client-side "cookie" by the TOC applet and passed to the server. The server creates a new session, retrieves the corresponding user object from the previous session (or creates a new one), and returns the URL of the last page visited, enabling the TOC to load the corresponding page in the Content Panel and update the TOC node elements accordingly. The appearance of the nodes indicates which sections have been consulted and (where applicable) successfully completed. The tree structure of the TOC itself provides one suggested path through the course material, but additional guidance will be provided by modifying the structure and appearance of the nodes according to user actions through integration of the JESS [Friedman-Hill 1999] inference engine on the server side. Java RMI is used for client/server interaction because it offers the possibility of passing true Java objects between client and server. The architecture also lends itself to the provision of expert design guidance as part of the overall Performance Support System.

Re-Usability of Software Components

In order to allow users to construct circuits and observe their behaviour via simulation, Fluid Power Components have been modelled as JavaBeans, which can be loaded dynamically and discover each other at run-time. The JavaBeans Event Model enables components to be aware of flow, pressure and demand signal changes within the circuit and react accordingly. Circuits built up in this way can be saved and re-used as courseware using the generic multimedia renderer applet (see below). The user can choose to view each component in the form of a realistic (and, where appropriate, animated) diagram or as an internationally-recognised symbol. Component pop-up menus contain embedded search hyperlinks that trigger searches in a remote multimedia database. The results of a search can be browsed by the user in a separate window using a generic multimedia viewer. This viewer provides a single container into which the system can plug different renderers on the fly, depending on the type of multimedia content to be displayed. The same generic viewer can also be embedded as an applet in an HTML page, maximising software re-use and simplifying the work of the courseware author.

User Testing of Prototype

Selection of Test Users, Equipment and Courseware

The test users were attendees of a Fluid Power course run by the Centre for Power Transmission and Motion Control at the University of Bath. The course was entry-level in terms of its Fluid Power content and was administered using traditional teaching methods. The delegates were divided into four groups with 6 trainees per group. The allocation of groups was carried out by the course organisers on a random basis. The experiment was conducted on four PCs, each running either Windows95 or NT4.0, ranging from a 200MHz Pentium MMX laptop to a 400MHz Pentium II. Installed RAM was between 64 and 160 MB, but available RAM dropped to between -9 and 44 MB with both the operating system and web browser running. The web browser used was Netscape Navigator, though the framework has also been used successfully with Microsoft Internet Explorer. In addition, each test PC was set up with the Java Plug-In (version 1.2.2, using Java Runtime Environment version 1.2), Java Media Framework 1.1 for video rendering and Java3D 1.1.1 (DirectX for Win95, OpenGL for NT) in conjunction with the Java3D VRML 97 loader for rendering of 3D content. The existing course notes were converted into individual HTML pages, each page corresponding to a section within a chapter. The formatting was adapted to on-line viewing using Cascading Style Sheets and by the inclusion of multimedia elements where it was thought that this would enhance comprehension.
Test Procedure and Method of Evaluation

Each test session lasted 35 minutes. A short introduction to the system was given in which the objectives and procedure of the experiment were explained. It was left to the users to organise themselves between the available workstations. In general, the less experienced computer users tended to work together. The users were allowed to proceed at their own pace through the chapters of the test courseware. A questionnaire was used to evaluate the users' reactions, which was divided into four sections. The first section, consisting of 14 questions, concentrated on the generic features of the system, such as navigational means, screen layout, and feedback given to the user by the system. The second section (three questions) focussed on the users' estimation of the suitability of the system and multimedia in general to future training needs. The third section (10 questions) asked users to assess the effectiveness of the multimedia elements used and also give personal preferences for relative levels of differing types of multimedia in future. The fourth and final section collected data on the users' individual levels of experience. All questions used sets of bipolar semantically anchored items, on a scale from 1 to 5, except for the questions on personal experience where a scale of 1 to 10 was used in order to provide users with greater freedom. Due to the practical constraints of having to operate within the framework of the external course, it was not possible to administer pre- and post-tests or to divide the users into control and test groups.

![Figure 2: Evaluation of generic features of system](image)

![Figure 3: Evaluation of effectiveness of multimedia content](image)

Test Results

There was a broad range in the users' experience with both Fluid Power and the Internet, but in general the users could be said to have "average" experience of these domains. In contrast, theyed themselves above average in terms of their computer skills. As can be seen from [Fig. 2] the generic features of the system such as TOC, search facility, navigation, screen layout and overall impression were felt to be mostly "Good" or "Very
"Good". Comments made indicated that users liked the ability to simultaneously view the content and browse to another topic via the navigational tools. The screen layout was thought to be clear and uncluttered. The ability to increase the size of the content panel by selectively hiding and revealing the navigational panel was welcomed.

[Fig. 3] shows a high appreciation by the users of the effectiveness of the multimedia elements used in the tutorial, particularly the 2D and 3D simulations. Comments made indicated that the 3D axial piston pump simulation in particular [Fig. 4] was a good example of interactive multimedia techniques enabling users to visualise a Fluid Power concept which is extremely difficult to teach and visualise with traditional methods. In the context of what form of training users would generally prefer, however, [Fig. 5] reveals a relatively low preference for multimedia-based instruction over traditional methods. This particular question generated the most comments by far. Many users emphasised the value of human interaction - both with tutors and other trainees - which is absent in self-paced individual multimedia learning, and proposed the adoption of some kind of hybrid approach. Notwithstanding this, the users were very enthusiastic about the possibility of future multimedia courses being offered and the suitability of the system when fully developed for meeting future Fluid Power training needs.

![Interactive 3D simulation of axial piston pump](image)

**Figure 4**: Interactive 3D simulation of axial piston pump

![Suitability of system for meeting future Fluid Power training needs](image)

**Figure 5**: Suitability of system for meeting future Fluid Power training needs
Conclusions

The Java-based hypermedia framework described in this paper has been implemented in prototype form within the context of an overall Performance Support System for Fluid Power Systems Design. The content used was drawn from the domain of Fluid Power Systems, and formative testing of the framework as an educational tool was carried out with Fluid Power Systems trainees. The results showed a high level of appreciation of the navigation and search facilities, the multimedia elements used and the overall functionality. The application of 3D techniques to provide visualisation of complex concepts was particularly valued. The possibility of future multimedia-based courses was welcomed, and it was felt that the system would ultimately be well suited for the future training needs of the Fluid Power industry. In future, summative testing will be carried out to evaluate the framework's educational effectiveness. Its use as a design support tool, complementing the educational role, will also be investigated. Although the content itself, together with a number of the prototype's interactive elements, was specific to Fluid Power Systems Design, the overall framework is by no means limited to this one domain, but lends itself to application in many other fields. In the next stage of development, the adoption of XML for content storage and encoding will further enhance its cross-domain applicability.

Abstract: This is a report on a case study, which was carried out by applying the qualities of meaningful learning based on constructivist theory to the evaluation of the distance learning environment. As a part of the Web University pilot, the evaluation was directed to the lecture series “Web Publishing Today and Tomorrow” by Håkon Lie, organized at CERN (European Organization for Nuclear Research), in Geneva, Switzerland. Web University distributed the lectures to distance audiences in Finland over a high-speed network and recorded them on a server. Originally, the lectures have been planned for face to face learning but modified suitable for distance learning by using learning tasks of the distance students. The distance learning environment, delivery technology complemented by distance tasks, has been evaluated by analyzing how the qualities of meaningful learning appear. The results of the case study lend support to assumptions that delivery technology could be complemented by the student project work and obtain the qualities of meaningful learning.

Introduction

Web University (Rinta-Filppula 1999) is the international pilot of the Finnish distance learning project “Open Learning Environment” (1999-2002). Web University is based on the concept of virtual university where distance participants communicate over the network by using applications such as multicast interactive videoconferencing, video-on-demand, World Wide Web (Web), email and mailing lists. The project uses national research networks and European wide high speed Internet connections.

Distance learners can update their knowledge by participating in CERN seminars from their personal workstations or conference rooms over the real-time broadband network based on ATM (Asynchronous Transfer Mode) and Internet technology. Teaching is interactive and it is in principle targeting researchers and postgraduate students, but some courses in physics and information technology have been additionally offered to undergraduate students and special groups, such as journalists and general public.

The latest scientific knowledge of the researchers can be applied straight and immediately even to undergraduate student studies. The technology enables to attend the lectures and update knowledge, no matter the physical location of the learner.

The aim of this case study is to evaluate a realization of the vision how CERN lectures could be integrated in local studies of distance students by using the qualities of meaningful learning based on constructivist theory (Rinta-Filppula 1999). The evaluation has been carried out analyzing the learning tasks and the recorded transmissions. The selected case is the lecture series “Web Publishing Today and Tomorrow” given by Håkon Lie from the World Wide Web Consortium in March 1999 at CERN and a local implementation of distance student tasks in Tampere University of Technology in Finland.

The Qualities of Meaningful Learning
The evaluation was realized by reflecting the qualities of meaningful learning over distance learning environment. The content of the lectures was not included in the analysis. The aim of the study was to analyze how the qualities appear in real-time sessions, recorded transmissions and learning tasks. Two alternative learning tasks – learning diary and project work with student evaluation reports – were connected to the lectures in Tampere University of Technology, where the distance students participated in real-time lectures.

Theoretical background of this evaluation lies on the theory of constructivism. Based on the assumptions of constructivist perspective Jonassen has proposed a list of qualities of meaningful learning (Jonassen 1995). Ruokamo & Pohjolainen (1998, 293-294; 1999, 7; 1999, 924) have merged conversational and collaborative qualities in Jonassen’s list into one and added the quality of transfer into the list. On the basis of Jonassen and Ruokamo & Pohjolainen, seven qualities will be presented as follows:

Active – Learners have an active role during the mindful processing of information and they are responsible for the result.

Constructive – Learners construct new knowledge by accommodating new ideas into prior knowledge.

Collaborative – Learners cooperate in building new knowledge together exploiting each other’s skills and providing social support.

Intentional – Learners attempt actively and willingly to achieve a cognitive object.

Contextual – Learning tasks are situated in a meaningful real world tasks or they are introduced through case-based or problem-based real life examples.

Transfer – Learners are able to transfer learning from situations and contexts, where learning has taken place and use their knowledge in other situations.

Reflective – Learners articulate what they have learned and reflect on the processes and decisions entailed by the process.

**Distance Learning Environment**

**Interactive and Real-time Videoconferencing**

The CERN lectures were transmitted real-time and interactive over the high-speed network and recorded digitally on CERN server at the same time. The recordings were transferred to FUNET (Finnish University and Research Network) server daily after the real-time session. This gives an opportunity for distance participants to study distributed lectures in case a temporary network problem in a real-time learning session.

The lecturer and the distance audiences in Finland were introduced at the beginning of CERN’s face to face lecture series. The lecturer Håkon Lie welcomed all the participants at CERN and in Finland (Espoo, Pori and Tampere) and the distance learners were taken notice and accepted to attend the lectures as local audience.

The lecturer gave the distance audiences an opportunity to ask questions during the lecture, not only at the end of each lecture. Some questions were asked during the lectures. When a distance learner wanted to ask a question, he/she showed the question sign whereafter the lecturer gave him/her the floor. The learner then took a microphone and asked. The lecturer and all the participants at CERN and in Finland heard the question and saw the speaker.

Real-time interaction between the lecturer and the distance learners functioned well. The learners and the lecturer were active, the situation was authentic and the audio was clear and comprehensible. Only movements of video images were a little bit slow because of 256 kbit/s limitation of the software used for transmissions. In spring 2000, the limitation has been risen up to 1 Mbit/s.

**Video-on-demand Service**

The whole transmission including the distance audiences has been recorded on a server. Successful studying of the recordings requires PC, Linux or Unix workstation with network connection, soundcard and loud speakers.

Studying the recorded transmission presupposes an active role from the learner. The control of the recorded lecture is on the learner’s hands. From the control panel of the recorder, the learner is able to see how long the lecture is still going on. It is also possible to return to a chosen point of the lecture again, e.g. to check some information. The learner can study the recordings from his/her own workstation at his/her convenience. He/she can study the recorded lectures together with other local learners and/or a tutor or professor whenever necessary.
The interaction between the lecturer and the learner who studies the recordings is possible by using applications such as e-mail or mailing list. The benefit of the recorded transmissions is that they are available when the students have time to study.

The quality of the real-time session is as good as the quality of digital recording taken that the real-time network functions without any problems. This has been usually the case: the sound has been excellent, the video colored, clear and bright and the images of the lecturer and the distance audiences in Finland all visible and recorded. Actually, the whole transmission has been recorded. It is also possible just to listen to the recordings without observing the video.

Learning Tasks

The students in Tampere University of Technology included the CERN lectures to their studies and accumulated credits. In addition to attending the interactive and real-time videoconference, their professor Seppo Pohjolainen integrated alternative learning tasks to the lectures. The students should write individual learning diaries or prepare project works in small groups and write down student evaluation reports about their work and learning experiences. Moreover, the professor asked all students to add own opinions and criticism with arguments.

The professor requested the students to describe in their dairies the content of the lectures as well as the topics they had found interesting. Furthermore, the students were asked to analyze the way the lectures were accomplished and suggest how the lectures should be improved.

The students who chose to write the diaries got one study credit, whereas the students participating in the lectures and the project work in a small group could get three. The project work was realized, as follows: a team was asked to name the project work after an interesting topic presented by the lecturer. In addition, the students should deepen the chosen topic by examining their notes and looking for material from the library and Web. The team was required to publish their project work on the Web and study other team project works. The teamwork also consisted of an individual contribution of each student. Finally, the team was asked to present their work in a virtual seminar and prepare questions about other team project works. The professor also wanted the team to analyze the project working itself and both the personal and team learning process. Nearly twenty students with their professor participated in the real-time lectures in Tampere University of Technology. Ten of them made distance tasks and passed the course, six students wrote diaries and four students formed a group.

Evaluation of the Learning Tasks

Both learning tasks supported the student learning as a process, where the knowledge is constructed through a personal and active participation. It presupposes not only an active participation in the lectures but also successful activation of the students to follow the lectures intensively. The abstract of the lectures published on the Web beforehand facilitated the student orientation to the content – it activated the prior knowledge of the learners. This might also encourage the learner to search information on the topics independently.

Learning Diaries

Each learner writing a diary had to react to the information with a critical attitude and present his/her personal opinions about the topics. This presupposes that the student understands the content and facilitates calling in question in the knowledge. In addition, it activates the student to modify prior knowledge with new one and requires him/her to give arguments for own understanding and ideas. The conversation with another learners is seen to improve the student social skills, collaboration and argumentation.

Writing a diary strengthens the student as an active, responsible and self-directed learner. The fact that the students were additionally asked to write about the topics that interested them personally supports the student as an intentional learner.

The students were asked to comment on not only the content of the lectures but also the way the lectures were realized in practice. The feedback showed that they were satisfied with the lecturer and technology, which functioned even surprisingly well. The audio was very clear but the images of the video could have had a higher speed. The content of the lectures was considered interesting and useful. Some students requested to have more this kind of expert lectures.
When writing a learning diary the student reflection is internal if he/she has neither experience nor practice in process writing. The student could naturally reflect his/her own ideas with the professor who gave the credits. The interaction with the other students would probably have deepened the learning process because the learning and knowledge construction are also collaborative and socially interactive.

Project Work

Technical help was available for the student throughout the learning period. This is important when using new technology. The project work organized and created in a small group required both active individual and collaborative learning. The team had to select a jointly interesting topic and divide the work itself into individual tasks. The group should select work tools and make a timetable and a plan to ensure that all-essential information would be included. Furthermore, the request for additional material to the project work encouraged each student to take an active role in his/her own and group learning process. It also deepened the understanding and knowledge of the learner.

The learning process engages the students in analyzing information through the project work. Each individual student is responsible for the whole team success by contributing his/her own activity, knowledge and skills for the good of the project. The team was also asked to report on the division of labor of the group. This makes possible to evaluate the activity of an individual member and ensures that the student is willing to take responsibility for his/her own objectives of the teamwork. The fact that the group made their project work about the topic that interested personally and published it on the Web gave some additional support to intentional learning.

The content of the lectures was implemented by asking the team to publish their project work on the Web. This means that the learners are able to transfer their knowledge to a new situation and use it. The technology and the content of the lectures offered a fine learning environment not only by providing the lectures but also by operating as a context of knowledge performing. The title of the project work carried out is Style Sheets. Some students who wrote the diaries had asked additional information on and examples of the style sheets. Now they and others who will later study Web publishing have all necessary available on the Web.

The project work enabled the student collaboration. The team members had a common goal and they constructed new knowledge together. The seminar at the end of the project work supported collaboration as well as the development of social skills and reflection. As only one group was formed, the team reflected their own project work with their professor in the face-to-face seminar. The learners used e-mail and organized four face-to-face meetings during the project because they all worked in the same office.

In addition to the project work, the team was asked to report their learning experiences by writing down what they had learned individually and jointly. The student work and learning evaluation report enable to analyze the learning process as a whole. The students articulated the matters they had learned about the topics. It was probably too difficult to describe the learning process itself if they had no previous experience in it. More detailed questions about the student learning process could support the process.

The students also gave statements about execution of the course and proposed e.g. how to improve it. This means that the students were accepted to participate in the development work. The students gave affirmative feedback about the lecturer, the lectures and very well functioned technology. In addition, they expressed a wish that the slides would be published in advance on the Web. In order to help the students to concentrate on making their own notes and comments to the copies instead of wasting time for copying the slides. The distance learners evaluated very carefully the technology used for transmissions. They even noticed that the audience at CERN heard distance questions better than the lecturer.

Conclusions

In this case of distance education, the qualities of meaningful learning were realized at least partially throughout the process. The real-time interactive videoconferencing enabled interaction between the distance students and the experts. The digital recordings and the material on the Web supported the student flexible learning process and encouraged the individual and group activity. In addition, the means and methods mentioned above offered the students an opportunity to reflect their prior knowledge and notes taken when constructing and deepening the knowledge by doing the tasks. This kind of distance education gave the students even a possibility to include the latest research results to their studies and reflect their own ideas with the well-known experts. This all took place thanks to well-functioned technology.
The learning tasks, learning diaries and project work together with the student evaluation report indicated the qualities of meaningful learning but on a different level of student learning process. Both tasks were based on the student activity and self-learning. The intentional learning was realized through writing the topics and selecting the project work topic that interested the students. The learning context, knowledge construction, transfer and reflection were achieved by creating and publishing the project work about Web publishing on the Web and by writing the student learning evaluation report. The student knowledge construction and reflection seemed to happen by writing the learning diary. These were internal processes for the student and more superficial in comparison with the other learning task.

Jonassen underlines (1995) that the most productive and meaningful uses of technology engage learners in knowledge construction, conversation, articulation, collaboration and reflection. Technology used in this case was delivery technology complemented by learning tasks. The results of the case study lend support to assumptions that delivery technology could be complemented by the student project work and could thus obtain the qualities of meaningful learning.

Abstract: Graphics-dependent industries such as advertising and the print and electronic media, as well as institutions which undertake in-house and on-line publishing, require computer professionals skilled in electronic image manipulation, however, employers often overlook the need for staff to apply high ethical standards in the practice of their technical skills. Computer technology allows 'seamless' alteration of photographs and other images, but these technical advances have made possible visual misrepresentation with intent to deceive, as well as difficulty in establishing copyright for original images. The challenge for educators in teaching techniques of image manipulation is to instil in students an ethical basis for their practice as computer professionals. This paper describes the image/ethics interface in a higher education multimedia program.

Introduction

A 1999 television advertisement on behalf of an Australian Cancer Research Foundation is 'spoken' by the late actor Steve McQueen, who died of lung cancer some twenty years ago. He begins his message by saying, 'I died in 1980. There wasn't a cure for cancer then and there isn't now, but...' and he goes on to solicit donations to assist cancer research. This advertisement demonstrates state-of-the-art computerised imaging, but also brings into sharp relief ethical questions related to image manipulation.

On investigation, no ethical problem is created by this particular advertisement, as was explained in a television interview (Kirwan 1999) when a spokesman for the Sydney advertising agency which produced the video clip described its technical dimensions, and, more significantly, how its graphic effects were accomplished ethically. Kirwan told how his advertising agency gained prior approval from the executors of Steve McQueen's estate for the use of a clip from McQueen's film The Cincinnati Kid, in which the actor spoke directly to the camera. To create the impression that McQueen was 'speaking' twenty years after his death in support of cancer research required the use of an actor with a McQueen look-alike mouth, and another with a McQueen sound-alike voice, and these physical features were 'seamlessly dubbed into the old film clip, using similar imaging techniques to those which created the 'talking' pig and other animals in the Australian film, Babe.

From its beginning, the McQueen project was ethically beyond reproach, from the worthiness of its intent, the seeking permission to use the actor's image, the involvement of the McQueen executors during the advertisement's production, and their approval of its final outcome. However, the print and electronic media do not always display such ethical behaviour in respect of the computer manipulation of photographic images. For example, in Australia, on the day following the tourist shootings at Port Arthur, in Tasmania, a photograph of the alleged gunman's face appeared on the front page of some Australian newspapers with his eyes 're-touched' to create a sinister facial expression. This unacknowledged 're-touching' was evident when the same (but untouched) photograph of the suspect appeared in other newspapers.

Similarly, in the United States, at the time of the O.J. Simpson trial, a cover of Time magazine featured a computer-retouched police 'mug shot' of the former football star and then alleged murderer. When challenged that the photographic manipulation was misleading, racist, and potentially prejudicial, the editor argued that the photographic image had been 'subtly smoothed and shaped into an icon of tragedy' (Wheeler & Gleason 1995: 8), however, under further pressure, the editor did in fact apologise to his readers for this photographic manipulation. During this same period, Kobre (1995: 14) describes a National Enquirer photograph under the banner headline 'Battered Nicole: Photos taken by her sister show how O.J. beat her up', which gave, at first
impression, a photograph of Nicole Simpson's bloodied and swollen face, until a statement in small type under the photograph was noticed, 'Sister describes photos seized by cops - computer re-creation'.

In the face of such blatant, misleading manipulation, Kobre makes a case for greater photographic access to all situations and a wider distribution of photographs, so that fakes may be countered with the truth. He argues that had the media had access to the pictures tendered at the trial of the beaten Nicole Simpson, which were even more horrendous than the Enquirer's fictional image, then the fake would not have been necessary, or it would, at least, have been countered by the authentic images. Unfortunately for Kobre's argument, the control of visual news information increasingly rests with a powerful few (Reaves 1995), and photographic manipulation has a long history. Thus there appears little chance that greater photographic access will control this misrepresentation by skilfully altered photographs unless the ethics of its practice are challenged.

Photographic manipulation's long history of deception

The manipulation of photographs dates back to the early nineteenth century, when photography, while basing its validity on its technical capability for making representations of reality, was always a 'combination of artistic, technical, theatrical and entrepreneurial achievement' (Slater 1995: 218-219). Thus, from its inception the concept of photography as truth has been set alongside artforms such as photomontage, where photographic manipulation was used for caricature (Evans & Gohl 1986), but in these early days, this practice most often stopped short at retouching to remove unflattering facial characteristics such as wrinkles and pox marks in middle class portraiture, which was popular at the time (Lester 1991; Kobre 1995).

Later there was more serious manipulation with obvious intent to deceive, and this may be seen in historical war and political photography, where the deceptions were not detected until much later. For example, some photographic manipulations from the American Civil War were discovered only when similar photographs were set alongside each other and comparisons revealed, for example, the rearrangement of 'corpses' in different photographs of the same scene. Even the famous portrait of Abraham Lincoln was a composite of the body of a Southern statesman, with Lincoln's head sandwiched atop. (The same technique has been used recently to set Oprah Winfrey's head on the body of actress Ann-Margret on a TV Guide magazine cover.)

In Making People Disappear, Jaubert (1986) (cited by Lester 1991: 101) chronicled numerous photographic abuses by totalitarian regimes which involved using retouching and effacement techniques to doctor the historical record to reflect a political leader's version of the truth. And, in more recent times, charges of manipulation cloud famous historic photographs. Lester (ibid.: 117) recounts the 'unrelenting ethical controversy' surrounding Rosenthal's Pulitzer Prize photograph involving the US marines' flag-raising at Iwo Jima in World War II. Subsequently it was revealed there were at least four photographs taken at the time, three by Rosenthal and another by a Naval photographer, which suggests the occasion of the famous photograph was staged, and it was not the eye-witness representation of the historical event as was first believed.

What is significant about this historical record of photographic manipulation is not that it happened, but that it was so easily discovered. Detection was easy then because the clumsy techniques of the time allowed the discovery of alterations. As well, these earlier techniques took painstaking work which was expensive and time consuming, and this deterred the practice from becoming more common. On both counts, this is no longer the case, for the application of computer technology now allows photographs to be modified seamlessly, that is, with little or no evidence of alteration, and with an ease and speed which encourages the practice.

Modern computerized photographic techniques also allow the quick synthesis of artificial images which are not based on reality. When a photograph is taken with a digital camera, or scanned and converted to digital information, the entire image can be modified in many ways, that is, its colour, brightness and focus can be changed, and elements of the image (such as a background, or persons) can be replicated or removed in a process which takes only minutes and is almost impossible to detect. In some cases, these techniques are revealed intentionally to warn readers of the potential for deception, as in a Science 84 cover (cited in Ritchin, 1991: 32) which used three major imaging techniques to create a 'realistic' image from scratch, that is, a simulated reality. The editor did not set out to deceive his readers, in fact the cover carried a caption 'This Picture is a Fake'.

In addition to issues of misrepresentation, photographic manipulation raises questions of both copyright and ownership with respect to the original photograph. Should the original photographer and the photographic manipulator share the reward for the new image? How might a manipulated photograph be traced back to its source? Whereas a book or painting may be seen as a whole, and the copying of all or part may be reasonably detectable, the easy, and most often undetectable, manipulation of photographs and other images (including clip art) renders the ownership of this artwork difficult, if not impossible, to protect (Mitchell 1994: 51).
Ethical problems related to photographic manipulation arise not only in respect of photojournalism, but also in using photographs as evidence in legal cases and for other documentary purposes such as the compilation of social and cultural histories. And wider still are the ethical considerations which relate to the rights of subjects in photographs, and the visual persuasion and deception which is evident in the advertising industry.

**Moral rights of subjects in photographs**

Abuse of the moral rights of subjects in print media photographs, television and film has been identified by Gross et al. (1988) and Lester (1991, 1995 & 1996). One case was the use by the large corporation, Benetton, of the harrowing picture of a dying AIDS patient in an advertisement of its products (Lester 1995: 78-79, 98-99). Other examples of the intrusiveness and inappropriateness of photographic reporting of tragic and often grisly events are reported in Lester (1991 & 1995) and in his 1996 text, in which he has examined the use of photographs in perpetuating the stereotyping of minority groups.

The struggles for protection of the privacy of personalities from the intrusion of media photographers have been reported comprehensively, but Powell (1998: 93) suggests the privacy of ordinary individuals is also now under threat with developments in satellite technology which fast outstrip the development of ethical protocols which might guide its use. He reminds us that in earlier days of U-2 spy planes and Sputnik, ethical issues centred on military secrecy and national boundaries, while at the end of the nineties it is satellite use, high-powered lenses, infra-red sensory devices, instant high-resolution image transmission, and the capacity for global observation which magnify communication ethics issues.

As satellite images reveal military forces, conventional warfare becomes obsolete, but civilian privacy has changed dramatically as well, as ‘backyard sunbathers, naturalists, couples, speeding vehicles, and naked paramours seen through bedroom windows can all be identified, photographed, and publicized without their awareness or permission’, (Powell ibid.: 94).

Powell suggests that as the capacities of space photography increases in parallel with its potential commercialism (already vendors in many countries routinely sell space imagery to media outlets), then communication ethicists must consider, firstly in journalism, the decisions of editors and producers regarding the publishing of invasive photographs, and secondly, in new media ethics, who it is who ‘employs, duplicates, regulates, as well as who sells and buys satellite imagery’, (Powell ibid.: 95).

**Visual Persuasion in Advertising**

Ethical issues regarding visual persuasion in advertising have been raised by Mitchell (1994) and Messaris (1997). Advertisements which use images to make false claims or to sell harmful products can be readily judged as unethical, but a different form of advertising uses images in a more subtly unethical manner. For example, Messaris (1997: 267-8) points to images which focus on the discrepancy between an idealized vision of life and the needs and abilities of real people, for advertisements which use sex or status for their appeal may create a source of dissatisfaction in people’s lives, such as with their body shape, thereby creating an anxiety which may be linked to eating disorders.

But, Messaris (ibid.: 271) suggests ethical judgements on specific advertisements may not always be clearcut, and cites a 1990 Volvo TV commercial in which a monster truck flattens other cars, but fails to squash a Volvo 240, in a scene staged with a car which had been strengthened. As the advertisement was based on a real-life incident in 1988 in which a Volvo had withstood a monster truck’s weight, why was it necessary to reinforce a similar car for filming the commercial? An industry spokesman’s defence was that the car was reinforced because of the need for repeated ‘takes’, but Messaris questions whether this explanation justified the advertising’s staging, or whether the addition of a ‘dramatization’ tag would be sufficient to excuse the commercial’s creators.

And graphics-based advertising may allow sellers to express ideas they might be unwilling to put into words, lest the advertiser’s claims be challenged legally. Messaris (ibid.: 273-4) cites an example of the promotion of nutritional supplements for bodybuilders. Scientific evidence had shown that these were no better at inducing muscle growth than an ordinary balanced diet, and, in fact the commercial did not claim that they did, verbally. Instead its message relied on a visual ‘cause-effect juxtaposition: that is, on one hand, an image of the product; on the other, an image of a champion body-builder’. When challenged, a spokesman argued the company could not be held responsible for what individual viewers concluded from these images, however, the intent here was obvious, that is, persuasion by inference.
Towards a Protocol for Graphics Ethics

Wheeler & Gleason (1995) suggest that, in respect of the digital manipulation of photographs, an ethical protocol should be established which would identify (by the use of a system of icons) altered and unaltered photographs, thus enabling a reader or consumer to ascertain whether or not the graphic had been modified. However, whilst a system of labelling of photographs and other artwork is commendable, there is need for a more encompassing protocol for image ethics in view of the myriad of new communications technologies developed in the late 1990s, and others which are anticipated.

These technologies (which include satellites, the Internet and virtual reality), each bring with them social effects and ethical issues which arise before society has begun to assimilate these rapid developments in technology. Documents and photographs can now be altered from a distance without detection, and realistic, yet artificial, images can be quickly synthesized. Theoretically, as Cooper (1998: 74) suggests, 'a presidential candidate may now be computer-generated, credentialled online, and elected without ever being publicly seen (other than via a human stand-in)'. In similar vein, Powell (1994) predicts totally synthetic news events.

When invasion of privacy occurs with old technologies such as a camera with telephoto lens, such invasion has very different qualities than 'cyvacy', (computer privacy invasion) (Powell 1998: 93). This new invasion of privacy is remote, undetectable and impersonal and amplifies existing problems such as obscenity and indecency 'by making controversial and criminal (in many cultures) images available to much larger, different, and younger audiences' (Powell ibid.: 94).

A protocol for image ethics thus must encompass the issues outlined above and be proactive rather than reactive to the ethical problems created by the unique features of the new technologies, which are exacerbated by their rapid rate of invention and implementation.

Image Ethics in a Higher Education Multimedia Program

In higher education the teaching of ethics is most often left to philosophers or to specially designated courses. This is a missed opportunity, for research shows that integrating ethics in discipline-appropriate ways embellishes the study of ethics (Roberts 1994 & 1995; Lisman 1996). This view supports the integration of image ethics in the multimedia program of a Bachelor of Arts award in an Australian university.

The image ethics program relies on the model of ethical decision-making developed by Rest & Narvaez (1994; 23-24) which involves a continuum of four distinctive stages, that is, moral sensitivity, moral judgement, moral motivation, and moral character. This model is particularly useful in the context of the university’s ‘Graduate Qualities’ which are a set of personal and professional qualities which the university anticipates as outcomes for its graduates, and which underpin its educational programs. One Graduate Quality involves the development of the graduate as an ethical citizen and professional.

The Image Ethics program commences in a foundation (mandatory) introductory computing subject in the first semester of the Bachelor award. Its pedagogy (described in Roberts 1994 & 1995) aims to establish a moral sensitivity to a range of issues in Computer Ethics, which includes, amongst others, an examination of computer crime, ‘hacking’, privacy, computers in critical systems, and the use of imaging techniques, with the intent to deceive. Some 650 students undertake this subject. For some of these, this will represent their only exposure to considerations of the social and ethical implications of computing, but as users and citizens, this first encounter with Computer Ethics may provide them with the opportunity to make better informed choices, and as consumers, they are more likely to influence the design and direction of new technologies (Pool 1998).

For other students who will extend their studies to the computing major in Multimedia Studies, in subjects which have as their main focus visual arts and communication, these will engage in the construction and manipulation of graphics. Each subject in the major includes an image ethics component, appropriate to the particular level of study and its technical content, and the students are encouraged to develop moral judgement in their creation and use of images in the artwork which they design, in a manner similar to their judgement in the use of text, with respect to copyright and the intellectual property of others.

As students spend hours of painstaking work in creating their own artwork, their natural concern for their own rights to claim intellectual property for their products is a timely and practical reminder of their responsibility also to protect the rights of other artisans, and to encourage their peers to do likewise. It is gratifying to see examples of this growth in moral motivation which is a cornerstone of the moral character required of the computing professional.
In these laboratory sessions, the integration of discussions of ethical issues in image creation and manipulation is combined with practical work to produce a natural interface between ethics and computing, which avoids creating a dichotomy of an abstract philosophical theorizing of ethical principles in computing, and the ‘hands-on’ work of the computing practitioner.

The overall aim of this ethics program then is that students establish a personal protocol for image ethics which they will apply in their academic, personal and professional lives. This protocol may be briefly summarised as follows:

- An image should be identified as ‘original’ or ‘altered’ and labelled accordingly;
- An image should not infringe copyright or another’s intellectual property;
- An image should not be used to deceive or persuade;
- An image should not infringe the moral rights of its subject(s) in relation to privacy and stereotyping;
- An image should not breach ethical and legal standards in relation to obscenity and decency;
- A computing professional should anticipate that new communication technologies may carry with them unpredictable and unwanted effects for society, be prepared to research and debate these effects, and work towards society’s control of technology;
- A computing professional has an individual responsibility for vigilance and action to defend the visual truth of information.

Conclusion

Too often ethical issues in computing are studied only after serious problems have arisen. With the benefit of hindsight it can now be anticipated that each new technology will bring both benefit and disturbance to society, and that in order for society to gain control over technology and to be able to influence its effects, evaluations of technologies must include not only the performance of their technical properties, but their potential effects on organizations, societies and individuals.

Such is the case in the teaching of imaging techniques to users and future industry practitioners who will work in a variety of contexts which use graphics to enhance communication. There is a vital task here for all educators to prompt awareness of the scope of ethical issues which arise from the use of this technology, and the need for moral responsibility in its use.

How do we get these budding professionals to look beyond the seductive power of computer technology and the aesthetic appeal of working with graphics? The skills/ethics interface is all important in this task, an interface which requires that at the same time that students learn the skills of image manipulation, they are also made aware of the ethical dimensions of these skills.

Students are now fully aware of the issues of plagiarism of text in their academic work, and universities have policies in place which require students to acknowledge the intellectual property rights of authors, by procedures for referencing quotations and ideas from original work. The same respect for the artwork and photographs of visual artisans has been ignored, and a similar system of referencing which applies to a scholarly essay should be applied to the production of graphics in a student’s multimedia projects.

But the wider issue of an ethical approach to the presentation of visual information has great importance for a society which turns increasingly to a reliance on pictorial communication. For as Ritchin (1991: 37) warns:

As readers we must remain vigilant. Otherwise, what as a society, and among societies, are we going to be left with as a form of communication that can be trusted? What information will people be able to rely upon to make decisions? Or most precisely, what will the role of the press in a democracy be worth? ... Undoubtedly, we will all be told that what has happened is the computer’s fault, and we will then be even more isolated in our own media bubbles than ever before.

Kirwan, P. (1999.) Interview, Today Show, Channel 9 Television, Australia, July.

Abstract. Metadata and interoperability standards are essential to support the educational and commercial effectiveness of learning technology. A number of related and cooperating organizations are working to develop such standards. This paper briefly explains why such standards are important, who is involved in their development, and what standards are being developed. The penultimate section discusses the standards process in general and points out that learning technology standards are attempting to create new infrastructure rather than codify or standardize existing practice.

Introduction

This paper reports on activities in two areas: metadata and interoperability standards. Its purpose is to give a snapshot of the players and recent developments in these areas and to make some general comments on the standardization process. Its focus is work being done by the IEEE Learning Technology Standards Committee (LTSC, 2000) and related efforts.

Metadata and Interoperability Standards

Metadata is data about data. In this paper metadata refers specifically to relatively small amounts of descriptive data that capture essential aspects of a learning resource. An example from the print world is the information in a library card catalogue. The title, author, publisher, publication data, copyright, subject classification, and call number are metadata that cover important aspects of a book or document, although pedagogical information is largely missing. The most prominent examples of metadata standards in the educational arena are Dublin Core metadata and the Learning Object Metadata (LOM) that is being developed by the IEEE learning technology standards committee. Dublin Core metadata consists of fifteen core elements that as yet do not address educational issues. This paper will concentrate on developments in LOM and standards related to it.

Interoperability standards are standards that permit different systems or different parts of the same system to work together. Protocols such as Internet Protocol (IP) and standards such as Postscript may be thought of as interoperability standards. IP allows diverse systems to exchange information by standardizing its encoding for transmission. Postscript provides an abstract and device-independent language for describing two-dimensional print and graphics; documents described in Postscript can be rendered on any device that can interpret the language. An analogous effort in learning technology is a standardized scheme for describing the quizzes and tests commonly used by learning management systems and other online testing software. A quiz described in this fashion could be exported and imported by any compliant systems.

Metadata can in many instances play the role of interoperability standards. The MIME type (Hood, 1998) is a piece of metadata associated with data delivered over the Internet that tells the recipient the general nature of the data and what software is needed to process it. As such, the MIME type enables interoperability. Descriptions of the subject matter, intended grade level, student learning outcomes, and other educationally relevant data associated with a learning resource also serve as interoperability standards since they can potentially assist in assembling a collection of resources into a single cohesive unit such as a lesson or course.
Organizations Involved in Learning Technology Standards

A number of organizations are involved in producing metadata and interoperability standards specifically for instructional technology. A list of the major ones includes:

- **ADL**: The *Advanced Distributed Learning Network* was formed in 1997 by the United States Department of Defense and the White House Office of Science and Technology Policy to enable anywhere/anytime access to quality learning.

- **AICC**: The *Airline Industry CBT Consortium* was formed in 1988 to standardize hardware used for training in the airline industry. Since that time it moved into the standardization of Learning Management Systems as well. (AICC, 2000)

- **ARIADNE**: The *Alliance for Remote Instructional and Authoring and Distribution Networks for Europe* started in January of 1996 and focuses on the development of tools and protocols that support the production, storage, delivery, and reuse of curricular components used in educational training (ARIADNE, 2000).

- **CEN/ISSS WS-LT**: The CEN (European commission for standardization) *Information Society Standardization System* started a *Learning Technologies Workshop* in March, 1999, with the goal of supporting the learning technology market and ultimately the European information society with standards-oriented services and products (CEN/ISSS, 2000).

- **DUBLIN CORE**: The Dublin Core metadata initiative began in May, 1995, as a metadata workshop sponsored by the Online Computer Library Center (OCLC) and the National Center for Supercomputing Applications (NCSA) in Dublin, Ohio (Weibel et. al., 1995). The Dublin core has produced a stable set of 15 elements that support the storage and retrieval of general online resources. An education working group was started in August, 1999, to investigate extensions for pedagogic resources (Dublin Core, 2000).

- **GESTALT**: *Getting Educational Systems Talking Across Leading Edge Technologies* is a European Community project involving eight academic and corporate partners. Projects include metadata and architectures for learning technologies.

- **IEEE LTSC**: The *Learning Technology Standards Committee* of the IEEE was formed in 1996 and is in the process of developing standards for a variety of aspects of learning technology divided into five groups: General, Learner-related, Content-related, Data and Metadata, and Management Systems and Applications. Participation is open to any individual or organization.

- **IMS**: The IMS project is a coalition of corporate, academic, and government partners that grew out of the EduCom *National Learning Infrastructure Initiative* in 1997. Originally entitled the “Instructional Management System project,” IMS has the vision of creating a comprehensive open architecture and infrastructure for learning technologies (IMS, 2000).

- **ISO/IEC JTC1/SC36**: The *International Standards Organization and International Engineering Consortium Joint Technology Committee* (ISO/IEC JTC1) has started a Standards Committee (SC36) on Information Technology for Learning, Education, and Training. The first plenary session was held in March 2000 (JTC1/SC36, 2000).

- **PROMETEUS**: The PROMETEUS (*PRomoting Multimedia Access to Education and Training in European Society*) initiative was started in late 1998 to assert Europe’s role in learning technologies and also to protect educational and multicultural values central to the European culture. PROMETEUS members sign a Memorandum of Understanding committing to the goals of PROMETEUS, among which is interoperability. PROMETEUS supports several study groups on metadata an interoperability standards. Members of PROMETEUS include a range of corporate and academic institutions.
Learning Object Metadata

Learning object metadata is important for the discovery and re-use of educational objects. One of the exciting developments of the last year and a half is the agreement among many groups developing learning object metadata (IMS, ARIADNE, GESTALT, AICC) that they would use the IEEE LTSC as the vehicle for standardization. All four of these organizations have actively participated in the development of LOM, as the IEEE LTSC metadata standard is called. Conversely, IMS meta-data Version 1.0 is based on LOM 3.5, which was the IEEE metadata working group document prior to September 1999, and similar statements apply to metadata implementations by ARIADNE and GESTALT.

The LOM Data Model

The approach being taken to LOM is based on an extensible structured data model. Mathematically, this model is a tree. The object being described is the root. The leaves contain data. Every other node is labeled as an element. At any node in the tree, the path from the root to that node determines what is being described and the entire sub-tree descending from that node is the description.

For example, in Figure I the path to the node [Contribute] proceeds from the root object through the path LifeCycle - Create - Contribute. This means that the node is describing a contribution to the creation of the object being described. The sub-tree emanating from Contribute has two elements, Person and Role and terminates in leaves containing the data Judy Jones and Author. Together (but not separately!) these specify that the contribution being described is that of an author named Judy Jones.

LOM Bindings

As it stands, LOM specifies three things:

- A set of metadata elements and their meanings (semantics)
- Relationships among the elements (structure)
- The type and size of data permissible in each leaf (data types)

This is abstract and does not dictate how LOM should be implemented in a real learning environment or digital library. To do this, one needs a binding of LOM, meaning a concrete data structure that meets the LOM specifications. When existing projects, such as ARIADNE, GESTALT, or CMU Online (CMU, 2000) use learning object metadata, they must store, transmit, and receive the metadata. In doing so, they create bindings of LOM in the form of XML DTD’s or database designs. These bindings are not unique, which makes the bindings themselves candidates for standardization. A recent move on the part of the IEEE LTSC was to separate LOM as defined by the three bullet points above from any of its bindings and to view bindings as separate projects.
Interoperability Standards

From an interoperability perspective, it is important to have a standardized definition of the components and architecture of learning systems, as well as standardized interfaces among them. Having this would address at least three major frustrations:

- Content developed for one Learning Management System is not usable in another except to the extent that raw text, HTML, graphics, or applets can be extracted and uploaded.
- Large consumers of training and educational materials (e.g., the Department of Defense) are limited in their ability to specify compliance for procurement purposes.
- If content can be developed once and used many times, its value is greatly enhanced. This increases the incentive to develop educationally effective and professional quality learning materials and is a precondition for a thriving market—a precondition that has been lacking and that has contributed to the reluctance of content producers to commit large development budgets to online educational materials.

Work on interoperability standards is being done by the IEEE LTSC, the IMS project, ADL, the AICC, and various European groups. Many of the people and organizations involved are active in two or more organizations. Each group is really part of a larger community effort but has its own emphasis. The AICC is focused on a single industry. The ADL is focused on broad applications and early on designated the IMS project as the means through which at least metadata specifications would be developed. The ADL has also set up a “CO-lab” program and is working closely with corporate and academic institutions. The IEEE LTSC is working towards official standardization, which is a difficult and often political process about which more will be said later. The ISO/IEC SC36 that has just started will also work towards standardization, while the various ARIADNE is focused on creating and maintaining a knowledge pool of learner resources, PROMETEUS is concerned with European social and political issues, GESTALT has developed a working implementation, and CEN/ISSS is concerned with standardization and dissemination in Europe.

Specific Interoperability Projects

Among the many pieces that comprise interoperability, the potentially easiest to handle is that for questions and tests. The IMS project has released a first version of a Question and Test Interoperability structure, together with XML binding. The AICC has done a LTSC work on Computer Managed Instruction as well as SCORM—Shareable Courseware Object Reference Model—released on January 31, 2000, by the ADL. The people responsible for SCORM are from the DOD, the AICC, the IMS, and the IEEE LTSC Computer Managed Instruction working group. The press release (SCORM, 2000) indicates that the University of Wisconsin System, Wisconsin Technical College System and Carnegie Mellon University are academic partners.

Another area in which progress is being made is that of learner profiling. This includes not only personal information about the user of a learning technology but might also reference competencies that a learner has demonstrated or that accrue to the learner as the result of a particular experience. Learner profiling is educationally important in that it is necessary to implement any sort of situated learning. In other words, the background, context, and goals of the learner can and should influence the choice and method of learning experience. Learner profiles also include electronic transcripts (Roberts & Robson, 1997). But learner profiling touches on numerous institutions external to technology and education—such as privacy protection and legal access to information. Identifying the learner in a typical academic or corporate training setting also begs for interoperability with information systems that handle student/employee data and records.

Schools Interoperability Framework

The combination of these external influences makes the standardization of learner profiling a high stakes and non-trivial matter. To underscore this, Microsoft Corporation started an initiative called the Schools
Interoperability Framework (SIF) that has been taken over by the Software and Information Industry Association (SIIA, 2000) and is being developed there as an open standard. The SIF Web Page (SIF, 2000) explains SIF as

The Schools Interoperability Framework (SIF) is an industry initiative to develop an open specification for ensuring that K-12 instructional and administrative software applications work together more effectively. SIF is not a product, but rather an industry-supported technical blueprint for K-12 software that will enable diverse applications to interact and share data seamlessly; now and in the future.

The version 1.0 specification was released at the end of March 2000. Although SIF is intended for K-12 use only, it should be observed that it is in some sense in competition with the work being done by IMS, of which Microsoft is a member. SIF is an XML application but is educationally very conservative and primarily codifies an American K-12 system based on letter grades and seat time, not content standards or outcomes. SIF also goes beyond the work of being discussed in this paper since it includes specifications for the food service, HR/financials, and transportation.

Comments on Standardization

Until now an emphasis has been placed on what is to be gained by standardization. However, there are some negative sides as well.

The industrial standardization process has traditionally been one of fossilization whereby established (and possibly competing) industry practices were made uniform. As the pace of change in technology has picked up, the time lag between the establishment and the institutionalization of practice through the standards process has perhaps lessened, but the standardization process has remained driven by that which exists as opposed to that which is envisioned. The process can be highly charged since choices made by standards bodies can pick winners and losers and affect billions of dollars worth of commerce, but having standards is also a condition for accelerated growth of an industry sector (Shapiro & Varian, 1998).

In the educational arena, content standards have traditional been instruments of social change. This was true of Carnegie units and standardized tests and remains true of the current educational reform movement. Educational standards are typically developed in response to failures of existing institutions and in the hopes that the new institutions introduced by the standards will be meet with more success. Thus it may be said that educational and technology standards live on opposite sides of the line between fossilization and innovation.

Learning technology standards have purposefully crossed over the line from fossilization to innovation. The goal of the IMS project, and indeed its parent, the National Learning Infrastructure Initiative, was to develop non-existent infrastructure that its architects envisioned as being needed in the near future. The same applies to ADL. Although the IEEE LTSC is more constrained, its standards also have an anticipatory quality. This choice of modus operandi was made quite intentionally at the beginning of the work.

Learning technology standards are consequently a bold experiment in creating standards. The World Wide Web Consortium (W3C, 2000) has done much the same thing with the development of its recommendations (the equivalent of standards), but W3C recommendations operate for the most part on the level of communication protocols as opposed to applications. A clear danger with developing anticipatory standards for learning technology is that premature standardization can cut off desirable future development paths. If, for example, the model of learning systems being promoted by SCORM dictates industry practice, then new models will be harder to develop. Since pedagogic innovation is slower paced and much less of a science than technological innovation, premature standardization could lead to the tragic result that truly better ways to teach and learn are nipped in the bud because they were not anticipated.

Another difficulty with the approach being taken by the standards community in learning technology is one illustrated by the emergence of SIF and the exaggerated claims made by academically oriented Learning Management System companies. In practice, formal standards do not carry as much weight as de facto standards, and the information industry is not in the habit of waiting for formal standards. However, for sales and marketing purposes it is often convenient, if not necessary, to claim conformance to formal standards. The learning management system vendors have been claiming IMS compliance for well over a year, despite the fact that there is no clear definition of what this compliance means. If this situation persists, it could devalue all formal learning technology standards and leave the industry with a set of competing de facto standards. The result would be a lack of interoperability and a lot of finger pointing.
Conclusion

Only time will adjudicate the success of learning technology standards. It seems clear that they are badly needed and that there is a hard-working community making good progress on their development. Anyone interested in developing learning technologies, especially online and networked learning technologies, should pay close attention and, if possible, participate in this process. This paper lists a number of references to relevant organizations and is meant to be a starting point for this type of involvement.

It remains to be seen whether the attempt to use the standardization process as a means to anticipate and jump-start the learning technology industry will be successful. It could spur growth yet not find acceptance for the standards currently being produced and thus succeed by failing. But given the participation of the major technology companies, government agencies, and academic institutions, there is a good chance that the combination of the partners listed earlier will succeed in creating accepted standards and that the ultimate question will be how to adjust and revise these in response to innovative products and pedagogy.

Abstract: The purpose of this paper is to introduce a project whose goal is to design and develop a productivity tool which helps academic instructors in their course preparation. This tool will be composed of a number of "instructional design agents", which combine techniques in human-computer interaction, artificial intelligence and educational theory. The first of these agents is based on Bloom's Taxonomy, and a brief overview of this work in progress is presented.

Introduction

In today's rapidly changing academic environment, the role of university professors is also increasing in complexity. While the three core areas of faculty evaluation are still typically teaching, service and professional development/research, in reality, there are many additional responsibilities that are embedded in these core areas. For example, faculty are not only responsible for the more traditional tasks of preparation and delivery of course materials, but they are also expected to devise and choreograph appropriate "active learning" activities, to incorporate new technologies such as multimedia and the Internet, and to participate in seemingly endless cycles of self- and program assessment and evaluation, to name just a few. In addition to the conduct of their own professional lives, it appears that faculty are also to be held accountable for students' learning, even though increasing class sizes and shrinking resources make it harder and harder to monitor and adjust in such an individualized manner. It is becoming more and more difficult to lead a "scholarly" life, particularly at institutions where teaching is the primary activity. In fact, even there, it is almost impossible to find the time to devote to thorough a priori course design, development and improvement. Traditionally, university faculty are trained to be highly skilled content experts in the process of obtaining a Ph.D. Training for job duties in the classroom, however, has been typically left to chance (e.g., receiving training as a teaching assistant), and/or the instructor's own initiative. Even with some amount of training or experience, most university faculty are not necessarily fluent with either a process for instructional design or the many education-related theories of learning that describe the impact of the instruction or teaching style on the students' learning experiences.

Furthermore, in this age of technology, there is a surprising paucity of effective tools available to the instructor to help bridge this gap in knowledge. Today's educational "productivity" tools in the academic environment center around web and slide authoring tools, generation of automated tests and communication-enabling technologies (e.g.,
email, electronic forums, video-conferencing, etc.) (The equivalent of this ten years ago might have been to say that the typewriter or a word-processor and a thermal transparency machine were "productivity" tools.) If faculty are to keep abreast of the changing face of education, it is our contention that they should also then be provided with a suite of tools, preferably on their desktop, which will assist them in critical tasks such as: formulation and organization of course content, design of classroom activities, and delivery of course artifacts.

Our research group is therefore currently working on the design and development of a set of such tools called "Instructional Design Agents" (IDA), and this paper describes the work in progress on this project. It is an interdisciplinary effort that aims to produce intelligent interactive support agents for instructional design in an academic environment. Our approach is to apply practical and theoretical aspects of human-computer interaction, artificial intelligence, cognitive science, educational psychology and educational technology to the problem of helping faculty become more effective and efficient in their roles as course designers, developers and managers. We have adopted a user-centered approach to this project, and have identified four initial categories of activity: 1) the conduct of detailed interviews with course instructors, and observations of them in the processes of both designing and delivering courses, 2) in-depth cognitive, task and content analyses of a specific set of courses, 3) rapid prototype development of a number of small, dedicated stand-alone agents, each of which focuses on some aspect of instructional design theory (e.g., Bloom's Taxonomy, Learning Styles and Multiple Intelligences, to name a few), and 4) deployment of these agents in the academic community for feedback and iterative improvement.

Our next goal is then to combine these individual agents into an integrated intelligent desktop agent which will interact with an instructor to assist in development of a course from the initial outline, through the analysis and organization of the content, to the production of educational artifacts for each class session (i.e., lecture notes, interactive class activities, multimedia presentations, web-based documents and animations, etc.). With such an agent to provide basic support, particularly in the early time-consuming content development and structuring phases, the instructor would then be free to address the more creative aspects of course delivery, and to devote more time to individual student interaction. Our emphasis at this time is to provide collaborative assistance for the instructor, rather than the automatic generation of "ideal" course outlines.

A longer-term goal is to incorporate a learning component in which the agent obtains feedback on the outcomes of its recommendations, and then provides improved suggestions the next time. If multiple instructors are using them, the agents could even learn from each other, comparing notes, and sharing successes and failures with their human counterparts.

Related Work

If we turn to the field of Instructional Systems Design (ISD), we find a domain in which many of these activities have already been formalized into models. They typically consist of five basic processes: analysis, design, development, implementation and evaluation, which are then configured in a variety of ways. (see Gagne et al. 1992 or Seels & Glasgow 1998). In addition to the large sector of professionals who have made a career out of implementing instructional design, a number of high-powered computer-based products are also available in the marketplace. However, the current lack of such facilities (either human or computer-based) in the daily professional lives of most academic faculty suggests at least two major obstacles: 1) access to formal instructional design software packages and/or ISD professionals is very expensive -- certainly beyond the reach of most academic faculty; (ironically, this problem is exacerbated at institutions whose primary mission is teaching, where funds are usually limited and there is little opportunity to invest in such high cost "facilities" for faculty); 2) it appears that the most successful work in the ISD field has focused on development of industry-style training courses, rather than academic-style teaching/learning courses. Although many researchers in the field of ISD also mention academic content in their descriptions of ISD models, it is often as an aside, and it's not clear that these systems-oriented process models really fit the goals, objectives and desired outcomes of academic course delivery. Seels and Glasgow discuss this in relation to public school implementation:

"Although ISD has been adopted by many corporations, the military, and many government agencies, the impact of ISD in public schools has been low. Some of the reasons for this low impact are that (a) the responsibility and authority over instruction are vested in the teacher's direct contact with students, rather than in the development of systematically designed materials; (b) the rigidity of the daily schedules are defined in terms of hours spent in a classroom with a teacher, rather than the learning outcomes achieved,
and (c) the amount of discretionary funding available to support systematically designed technology-based instruction is low (Seels & Glasgow 1998).

Although the above quotation only mentions public schools, it seems that ISD impact is also poorly represented in the higher education environment, possibly for similar reasons. This suggests that perhaps these techniques and models do not fit the realities of the academic world, although there are some who would say that the academic world should be changed to be more in line with the ISD kinds of approaches.

In industrial training settings, where learning objectives frequently correspond to concrete, well-defined job-related skills, computerized systems, which implement the linear configurations of the majority of instructional design models, may be extremely effective. However, it is our hypothesis that in the more traditional academic setting of higher education, activities such as course design may be modeled more appropriately as opportunistic problem solving, similar to other complex domains such as architectural design or medical diagnosis. That is, the problem is too complex, uncertain and unspecified to be easily tackled in a procedural or algorithmic fashion. Furthermore, there is no one necessarily "right" answer (i.e., a perfect complete course specification) -- a partial or less than optimal solution may be the best we can do, given the various constraints which impact not only the design process, but the final delivery as well. Rather, the instructor thinks about different aspects of the problem almost in parallel, and "islands of partial solutions" develop and compete with each other for the person's cognitive attention until eventually there is a sufficient amount of structure from which to go forward. The instructional design model most closely related to this approach is that of (Kemp et al. 1998), which has nine design elements that can be approached by different paths, and which are surrounded by two outer ovals, which indicate revisions occurring throughout the process (similar to that of user-centered design in the human-computer interaction community).

Bloom's Taxonomy Agent

The first Instructional Design Agent under development in our project is based primarily on Bloom's Taxonomy, and we are using this as a basis to explore a number of design issues:

- how can theories related to instructional design be used proactively by instructors to articulate, structure, design and implement academic courses?
- what kind of knowledge is needed by the agent not only to capture the concepts of the theory but also to understand and respond to the problem-solving behaviors of the instructor in the process of design?
- what kinds of data/knowledge representations are needed to structure the relationships between course content, theoretical constructs and classroom artifacts?
- what kinds of information visualization techniques can be employed most effectively to allow instructors to: a) navigate their design problem space, b) to detect patterns in the relationships of concepts, and c) engage in "what if" scenarios, where the effects of changes in certain parameters (e.g., order of course material) on other course components are immediately visible?
- can we effect a noticeable shift of cognitive load so that the instructor can operate primarily as a content expert, and have the agent provide the infrastructure and expertise which a human instructional design assistant might otherwise afford?

The Taxonomy of Educational Objectives was developed in the 1950s by a team of educational psychologists, headed by Benjamin Bloom, as a tool for classifying educational goals and outcomes (Bloom et al. 1956). Of the three domains of behavior described in the original work, the cognitive domain is the one most associated with educational outcomes, and it is described as a hierarchy of six major components, each increasing in complexity: knowledge, comprehension, application, analysis, synthesis and evaluation. From the literature it appears that use of this particular taxonomy as a context for designing instruction has focused primarily on classifying goals, objectives and/or test items once they have been devised (see Jonassen et al. 1989). This suggests that the instructor has somehow been able to break down the components of the course into atomic pieces, which then can be labeled. However, it is our contention that such detailed a priori analysis of course content and delivery strategies is rarely accomplished, at least in the first few years of teaching a course. This suggests that devising the course outcomes, goals and objectives themselves (i.e., developing the mental model of the course) is a challenging task, and that perhaps the intelligent assistance agent should first aim to help the instructor articulate these preliminary building blocks. In order to accomplish this, our agent embodies Bloom's Taxonomy as an interactive design tool, which
Initial System Design

In order to further constrain the problem, we have selected the freshman computer science course, CSC 101, as the focus for our first prototype system. A preliminary set of interviews conducted with two groups of experts (educational theory experts and instructors of CSC 101), provided the foundation for our initial design decisions:

- course objectives, content and outcomes are the three main components to be addressed, and appropriate mappings among these three kinds of elements must be defined;
- Bloom’s taxonomy provides one kind of hierarchical approach to the expression of the course objectives and/or the outcomes – therefore the tool should provide assistance in articulating the objectives/outcomes as well as in authoring the content in the context of those objectives/outcomes;
- the course design process should not be overly constrained by the taxonomy itself – this suggests that the agent should be functional in at least two modes: 1) explicit taxonomy, where the instructor wishes to do the course development in the context of the formal objectives and outcomes, or 2) transparent design, where the focus is on the content development, and the agent keeps track of objectives and outcomes “behind the scenes”.

With these ideas in mind, a metaphor of a “course design space” has been developed, which we define as the environment that contains all the resources an instructor needs to design a course. This environment includes electronic resources such as our software agent, content authoring tools, and the World Wide Web, as well as physical artifacts such as textbooks, videos, demonstration equipment, etc. The user interface of our agent reflects this notion of course design space by supporting asynchronous problem solving. Unlike the physical artifacts of the course design space, the agent is dynamic, in that it demonstrates how a change in one aspect of the design is reflected in other relevant components.

The presentation of this work in progress will include an overview of the design of the Bloom's Taxonomy agent, a demonstration from our first prototype, and preliminary results from our first round of functionality and usability testing.

Abstract: This article examines Solver Learning Environment, methods and main results of the study dealing with mathematical abilities and development of mathematical word problem-solving skills in a technology-based learning environment. To collect data a teaching experiment was arranged at Kaukajarvi School in the city of Tampere, Finland. The participants of the study were fifteen years old. In the study empirical group comparison methods were used. During the teaching experiment the group A studied mathematical word problem-solving in the technology-based Solver Learning Environment. The group B studied the same material with conventional teaching methods, using paper and pencil only. A control group did not take part in the problem-solving lessons, they just participated in the tests. Several tests were arranged to measure pupils' mathematical word problem-solving skills and to evaluate their mathematical abilities. In this paper we present the study design and main results of the study, too.

1 Introduction

The aim of this study was to examine the connection between different learning environments with the development of problem-solving skills of pupils on different levels of mathematical abilities. In this study we compare the development of problem-solving skills achieved in a technology-based Solver Learning Environment with learning environment of conventional paper and pencil tasks. During the teaching experiment we collected data on Solver's suitability to develop pupils' problem-solving skills on different levels of mathematical abilities. (See Ruokamo-Saari 1996a, 1996b, 1997.)

This study was an independent part of the Schools to Information Superhighway (SISU) Project (see Koskelainen et al. 1996a, 1996b). A group of mathematics teachers at Kaukajarvi School prepared mathematical word problems and their model solutions for Solver Learning Environment in co-operation with the author. Solver was produced as a part of the Nääsnett Project of Multimedia Services of Alexpress Ltd. of Aamulehti Group Ltd. The Nääsnett Network Multimedia Project was part of The Finnish Multimedia Programme (FMP). Later on this study became a part of Distance Learning in Multimedia-Networks Project (<URL: http://matwww.ee.tut.fi/kamu/> ) of the Finnish Multimedia Programme (FMP) (see Pohjolainen & Ruokamo-Saari 1997; Pohjolainen & Ruokamo 1998, 1999; Ruokamo & Pohjolainen 1999).

This article describes the Solver Learning Environment, design and main results of the study, too. Participants of this study were ninth grade pupils (N=66). The contents of Solver Learning Environment were designed taking into account contextual approach and transfer: word problems were connected to real life situations and thus to the real world. Problem-solving was done collaboratively and the view of learning was "moderate" constructivist (Reusser 1991a). Solver was designed to support pupil's own activity and reflection. (cf. Ruokamo-Saari 1996a, 1996b, 1997.) In this paper we present the main results achieved via the teaching experiment using quantitative research methods.
2 Solver Learning Environment for Solving Mathematical Word-Problems

Solver is a technology-based learning environment that includes different presentation forms of hypermedia (e.g. hypertext, graphics, animation, sound, video) and network properties, social interaction, physical learning activities and mental thinking processes in learning situation. (See Ruokamo-Saari 1996a, b; Ruokamo & Pohjolainen 1998.)

Solver was used to study the connection between the level of pupils' mathematical abilities and development of their problem-solving skills when working in a technology-based learning environment (Ruokamo-Saari 1997). Solver was designed on the basis of an existing computer-based program developed for word problem-solving by Reusser et. al. HERON (see Reusser 1988, 1991a, 1991b; Staub et. al. 1994; Reusser 1993, 1995). In the Solver Learning Environment pupils solved word problems by constructing solution trees with cognitive tools. This process ends up with final result that solves the problem posed in the text. (See Ruokamo & Pohjolainen 1998.)

In Solver Learning Environment the properties of on- and off-line hypermedia were connected together. The on-line part was designed to be used via the WWW and the off-line, local part was programmed with Multimedia ToolBook 3.0. Figure 1 presents the user interface of Solver Learning Environment (in Finnish): the tools, solution tree, and equation in off-line ToolBook application are on the right and the tools and problem text of an on-line HTML document are on the left. (See Ruokamo & Pohjolainen 1998.)

![Figure 1: The user interface of Solver with on-line and off-line tools](image-url)

Problem tasks, hints, the model solutions, and a bulletin board were programmed using HTML, so that these can easily be distributed via network, and they can be updated later on. In creating the problem situations a contextual approach was adapted: the topics chosen for the word problems were based on pupil inquiry: the pupils were asked about real life problems they would like to solve. Video material was produced to introduce the problem situations for pupils. (See Ruokamo & Pohjolainen 1998.)

In the problem text there were links, by activating them pupils could get definitions, rules, formulas, and other information about the subject. If a problem was too complex to solve, the user may select the hint tool to obtain tips for constructing the solution. Pupils may ask hints from each other in problematic situations when constructing the solutions. Using the bulletin board, pupils were able discuss with other pupils or with their teacher methods for solving the problems. On the basis of these conversations they could further develop their own constructions. (See Ruokamo & Pohjolainen 1998.)

In the Solver Learning Environment the model solution for a given mathematical problem was presented step by step, and the pupils were assumed to discover the solution procedure. The pupils' solutions were saved to be analysed later on. (See Ruokamo & Pohjolainen 1998.)
Solver does not tutor pupils in the problem-solving process, unless asked for help or hints. This property was thought to be suitable for especially better problem-solvers who do not necessarily need any tutoring but are able to conduct autonomous and original problem-solving. Tutoring was designed with those pupils' needs in mind who had difficulties in problem-solving. It was also important that pupils had a chance to notice by themselves possible mistakes they made during problem solving. When a user asked for a hint during the solution-process, Solver tried to find a so called context sensitive hint related to the user's situation in his/her solution. If the user's way of constructing the solution was very original and Solver could not help him/her, it asked the pupil to try to find support from other pupils via bulletin board or to go on and check the final result at the end with the checking tool. (See Ruokamo & Pohjolainen 1998.)

The user could start modelling in any situation and move on to an open solution space. In principle, he/she was able to construct the whole solution without tutoring until the final stage, where Solver asked the pupil to evaluate the final equation. If the user made mistakes in constructing the solution, the checking tool informs him or her about wrong results. After checking the results, the user could see a representation of the model solution and could compare it with his/her own solution. Even if the solutions were not similar, they could be correct. All the pupils' solutions were saved to files, so that the problem-solving processes could be examined and compared later on. The new solutions proposed by the pupil can be used as examples of alternative ways to construct solutions. (See Ruokamo & Pohjolainen 1998.)

3 The Methodological Solutions

In addition to measuring mathematical abilities, the study examined pupils' word problem-solving skills and their development using the Solver Learning Environment as opposed to a traditional pencil-and-paper method. A second goal was to determine whether there is any connection between the development of word problem-solving skills and pupils' gender, attitudes and experiences and mathematical abilities.

In this study we compared differences in the problem-solving skills of pupils on different levels of mathematical abilities. Pupils studied in different learning environments: in the technology-based Solver Learning Environment and in a learning environment of conventional pencil-and-paper tasks. The study was an experimental comparative study. Experiment group A studied in the technology-based Solver Learning Environment and experiment group B studied in the conventional way. The control group did not study problem-solving, they only took part in tests. (Ruokamo-Saari 1997.)

3.1 Experimental Design and the Participants of the Study

The research was an empirical and experimental comparative study of randomly chosen pupil groups. The experimental groups were made by lottery. The experimental design of this study is presented in Figure 2. below:

<table>
<thead>
<tr>
<th>Experiment group A</th>
<th>MR ------ M1/A1 ------ TBLE/S1 ------ M2/A2 ------ MM ------ M3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Experiment group B</td>
<td>MR ------ M1/A1 ------ PP ------ M2/A2 ------ MM ------ M3</td>
</tr>
<tr>
<td>Control group</td>
<td>MR ------ M1/A1 ------ M2 ------ MM ------ M3</td>
</tr>
</tbody>
</table>

Figure 2: Experimental design of the study

In the experimental design MR (for all the groups) refers to the matrices test of Raven, M1 refers to the pre-test of problem-solving skills and M2 to the post-test. A1 and A2 are tests of attitude towards mathematics, word problem-solving, information technology (IT) (A1) and towards the environment used in the teaching experiment (A2). MM is a test that measures essential mathematical knowledge (Kupari 1983). TBLE and PP are environments - TBLE is technology-based Solver Learning Environment and PP is conventional environment of pencil-and-paper tasks. (cf. Cohen and Manion 1987.) S1 denotes an inquiry associated to Solver. M3 (for all the groups) refers to delayed test of lasting quality of problem-solving skills. The control group took part into the pre-, post- and delayed tests and measurements of mathematical abilities. The purpose
of these tests was to find out the differences between the pupils who have practised and who have not practised problem-solving. (Ruokamo-Saari 1997.)

It was decided to change the ordinary grouping. The groups were divided so that they were as homogenous as possible. Pupils were selected randomly. The division into groups was made randomly so that each group consisted of 11 girls and 11 boys. Pupils in the technology-based learning environment group were grouped into working pairs on the basis of gender and of success in the pre-test. (Ruokamo-Saari 1997.)

3.2 Measurements and Data Collection

Data was collected on mathematical abilities with two different kinds of tests: The Standard Progressive Matrices (SPM) of J.C. Raven (1958) to evaluate reasoning ability, and a test made of tasks of mastery of core mathematics by P. Kupari (1983). With this test we tried to evaluate the pupils' mathematical knowledge. We also evaluated the pupils' mathematical abilities on the basis of their average grades in mathematics. We made pre-, post- and delayed tests of mathematical word problem-solving to collect data of pupils problem-solving skills. We also made attitude tests in regard to mathematics, word problem-solving, information technology (IT) and learning environments.

3.3 Teaching Experiment

The teaching experiment and data collection lasted 11 hours. In the first lesson we measured the reasoning ability of the pupils (N=66) with the SPM by Raven. The Raven Test was the first part of the evaluation of pupils' mathematical abilities. In the second lesson we arranged a pre-test of pupils' problem-solving skills. After that we also arranged an attitude test. With that test we evaluated the pupils' motivation and their attitudes towards mathematics, towards mathematical word problems, and towards IT. We collected data during the six consecutive math lessons, simultaneously with different groups. The pupils were grouped randomly into an experiment group A (N=22) and an experiment group B (N=22) and a control group (N=22). Group A and group B (N=44) were studying mathematical word problem-solving. Experiment group A worked in pairs during lessons collaborating with other pupil pairs, and group B studied in a conventional way. The post-test of pupils' problem-solving skills was arranged after the teaching lessons, when we also measured pupils' attitudes towards learning environments and also to the experiment. After the post-test we arranged second test of mathematical abilities: a test of mastery of core mathematics. One and a half months after the lessons we arranged the last test of the experiment, the delayed test. (see Ruokamo-Saari 1997.)

3.4 Methods of Analysis

In this study we analysed data using various quantitative methods, and the research data was handled by SPSS 8.0 for Windows (SPSS Advanced Statistics 7.5. for Windows). The data comprises the scores of the tests of mathematical abilities and the scores of the pre-, post- and delayed test and the scores of the motivation and attitude tests. The usability of the statistical methods was affected by the number of pupils actually participating in the experiment (N=66). The quantitative analysis methods used include frequencies, correlation, variance analysis, regression analysis, factor analysis and covariance analysis.

4 Main results

The Solver group did best in the delayed test. Problem-solving skills also developed best in this group among those pupils who scored highest in mathematical abilities. Results are not statistically significant, possibly due to the smallness of the sample. No connection was found between gender and mathematical abilities, problem-solving skills or their development. A positive attitude to math correlated with success in math, likewise with problem-solving skills. Boys had a more positive attitude toward IT than girls and were more likely to view math as a hobby. Math enthusiasts had better problem-solving skills, and IT enthusiasts showed the greatest improvement. Gifted pupils opted for harder courses. Attitudes to word problem-solving correlated with mathematical abilities and problem-solving skills, except for success in the Raven Test. Girls reacted more positively towards the situation model as a tool and to the contextuality of the Solver Learning Environment.
Gender affected interest in all six series of tasks. It may be concluded that the Solver Learning Environment helped to improve problem-solving among mathematically gifted pupils. Further research should undertake a qualitative analysis of pupils' problem-solving processes.

5 Conclusions

This article described the Solver Learning Environment, the methodological solutions and main results of the study dealing with mathematical abilities and development of mathematical word problem-solving skills in a technology-based Solver Learning Environment. In this paper we described experimental design, measurements, and data collection of the study. We gathered data from the teaching experiment that was organised in spring 1996, in this paper we also presented quantitative analysis methods of the data and main results of the study.

Is Computer-Mediated Communication (CMC) Really Open and Flexible?

Malcolm Ryan, School of Post Compulsory Education and Training, University of Greenwich, UK.
m.ryan@greenwich.ac.uk

Abstract: This paper considers the concepts of openness and flexibility and the extent to which computer mediated communication supports these approaches to learning. Following an examination of aspects of open and flexible learning, the nature and role of Computer Mediated Communication (CMC) is considered within a context of continuing professional development. Models of curriculum delivery employing CMC and experiences of using these with adult learners are examined. Student feedback is used to illustrate positive and negative aspects of our approach. Barriers to learning flexibly when employing CMC are identified and conclusions drawn about the extent to which such strategies are open and flexible.

The concepts of open and flexible learning

Open and flexible learning (OFL) are characterised in the literature by the extent to which they enable students to access learning opportunities. The literature reveals such learning to be 'resource-based', exploiting a range of media from printed texts to intelligent tutoring systems using the latest information and communication technology (ICT). The use of a wide range of resources normally results in such learning being 'self directed' including a number of 'self assessment' activities.

A major advantage for students of this approach to learning has been its 'time-location independence', removing the need to travel to a particular physical location in order to study. This aspect of OFL has led to the development of global education opportunities, enabling students, irrespective of their geographical location, to undertake a programme anywhere in the world.

The availability of quality materials on a wide range of subjects has enabled 'learning on demand' to occur, independent of a tutor or educational institution. Being the recipient of a range of learning resources has required students to become 'self managed' and led to greater 'autonomy'. 'Guided discovery' and interaction with these materials replacing the large amounts of information that were often delivered in a didactic and sometimes authoritarian manner in large lecture theatres.

This move towards OFL methods of delivery has resulted in a changed role for the teacher. No longer is the tutor the fount of all knowledge, the 'sage on the stage', or a deliverer of content; instead s/he has become the 'guide on the side', a facilitator of learning. Another significant element of OFL, has been the extent to which peer networking and collaboration are being encouraged in both physical and virtual classrooms.

Rowntree (1992) maintains that open learning is both a philosophy and a method concerned with, "reducing the barriers to access and giving learners more control." He claims that open learning provides opportunities for:

- **Access** - enabling more people to learn
- **Time-Place Independent study** - when and where
- **Individual pace** - to suit own style/circumstance
- **Learner Autonomy** - greater individual responsibility and negotiation

Increased access to higher education has been a government target within the UK in recent years and student numbers have increased dramatically. This has led to a shortage of accommodation and a concomitant growth in open learning in an attempt to address overcrowding in classrooms. Many institutions have converted
classrooms into open learning centres or invested large sums of money in building new centres, often combining traditional libraries, computing facilities and individual and small group learning spaces.

Whilst being freed from the constraints of timetables and physical spaces can have a liberating effect on students, there is evidence to suggest that not all learners either appreciate nor benefit from this apparent freedom. Anecdotally, having to attend a physical class often provides students with the necessary discipline and focus to engage with learning. Evidence from our own post-graduate students suggests they appreciate the flexibility of open and especially, distance learning because they are better able to self-manage studying, work and personal (including family) commitments. However, when questioned, many say they would have preferred to attend a traditional class with a tutor and peer group on a regular weekly basis but their personal circumstances make this a non-viable option.

Linked to this self-managed learning are issues of learning style (or preference) and pace. Given the circumstances of many of our adult learners, studying for a professional qualification, working full-time and participating in family life, organising learning around these diverse demands is seen as advantageous. Having the freedom to engage with materials and undertake activities at a time of the day or week that suits individual circumstances is, for them, the most attractive aspect of flexible learning. However, unless a student is highly self-disciplined, this freedom can be abused and lead to irregular and unproductive periods of study, resulting in loss of motivation and high rates of dropout from courses.

Greater autonomy may enable an adult student to manage their time but there are assessment targets to meet and courses often start and end at times which are more convenient to the host institution than the individual student. This can generate stress, frustration with the system and result in loss of motivation, failure and dropout.

So, OFL provides students with the opportunity to, "take greater responsibility for their learning and to be engaged in activities that meet their own individual needs," (Wade, 1994). It is free of time and place constraints and allows access to a wide range of resources as and when required but does not suit all learners, especially adults.

The nature and role of CMC

These philosophies of openness and flexibility can be realised through a variety of approaches and those that employ Information and Communication Technology (ICT) are regarded as 'new forms of learning' (Laurillard, 1994). According to the UK's Further Education Funding Council (1996), "exploiting emerging (new) technologies will lead to more open systems allowing students to study away from institutions, at a time, place and pace to suit individual circumstances."

The University of Greenwich has been using CMC with adult students on a range of courses for several years. The main reason for using it is that it facilitates, "interaction between students and tutors irrespective of geographical location or time zone." (Ryan, 1997) Exploiting the unique features of technology enhances the student experience (Anderson, 1996) and leads to new forms of learning and teaching.

Our use of the groupware product, Lotus Notes with customised desktops being distributed to students, led to the creation of a Virtual Integrated Learning Environment (Ryan and Culwick, 1997) and the discovery of a number of unique features (Fig.1).

Figure 1: Features of CMC and traditional distance modes compared

Firstly, students have access to a learning community that helps address the feelings of isolation so often experienced by distance learners. Within a traditional distance learning context, students normally only have access to their peer group if they attend a study day or weekend. The second novel feature associated with the use of CMC is that all discussion is archived and becomes a much-valued resource by students and tutors. (Ryan, 1997)

Our experience of using CMC indicates that it has considerable potential for facilitating collaboration between students although they are studying at a distance. Within a conventional distance learning context, such collaboration is only possible if students come together for a study day in a physical location. Though regarded as invaluable by students themselves, if one is working with a global cohort then, it is unlikely that students will be able to attend such events. The quality of collaboration we have experienced, particularly with health professionals engaged in paper writing activities, has been excellent.

Team teaching, now considered too expensive in physical classrooms, is both possible and cost-effective within a CMC programme. There is a steep learning curve when tutoring in a virtual classroom for the first time (Ryan and Woodward, 1998). Once tutors are accustomed to operating differently, it is possible for several colleagues to provide multiple perspectives on a topic, at no additional cost. Within a traditional distance learning context, team-teaching is usually only apparent in the writing of materials or at study days. However, the costs of employing several tutors are considerable and something of a luxury in today's financially constrained environment. Print-based materials are commonplace in distance programmes but are expensive to produce, store and revise. They quickly lose their currency and as ICT systems provide us with up-to-the-minute data and become more widespread, they are likely to replace print-based materials in all learning and teaching contexts.

Traditional and CMC delivered distance modes share the facility for students to reflect on content and their responses to activities. Another shared feature is that both modes are independent of time and place, though traditional distance learning is more independent because one does not need access to ICT.

Models of Computer Mediated Curriculum Design

Mason (1998) suggests the emergence of distinct approaches or models to CMC delivered or supported OFL programmes.

Content and Support

The content and support model is often applied to existing programmes of study where students receive content through a variety of media and ICT is used as just one of several support mechanisms. This may take the form of; simple e-mail, a bulletin board, bespoke conferencing software or a web-based system such as WebCT. Because CMC is only one of many means of communicating between students and tutors, it is often under utilised and its unique features go unexploited. Many institutions begin to explore the use of ICT in an OFL
context by adopting this approach. It has the advantages of being relatively cheap to set up and does not necessarily require any major changes to either the content of a course or its delivery.

Wrap Around

The second approach is known as the 'wrap around' or 50/50 model. The content of the programme is provided through a single medium, such as a published book or multiple media, and some form of conferencing mediates all interactions and communications. This has become a very popular way of employing ICT in support of students operating at a distance because it often uses existing materials. However, as all of the interactions employ new technology, it is vital that students and tutors have regular and frequent access to appropriate ICT tools and support. For many participants, interacting via a computer is a new and strange phenomenon requiring a different set of skills to those normally employed when learning and teaching at a distance.

Integrated

The third emerging model is the integrated approach where both the content and the interactions are delivered and managed by an ICT system. This is perhaps the most difficult to establish because it often requires a revision of all materials and a complete review of learning and teaching strategies. Its major advantage is that one platform can be used for both delivery and support, but this can also be a major shortcoming. If access to the technology is restricted for any reason, for example, a technical breakdown, then the programme ceases to function until connectivity to the system is restored. As with the wrap around model, familiarisation with the system and an opportunity to explore this new way of learning and teaching is vital to the success of any programme using the integrated approach.

As a long-term strategy, the adoption of the integrated approach has the potential to provide global education opportunities using the most up-to-date materials and research. Before an institution can embark upon programmes using this model, a satisfactory system for the delivery of materials incorporating sophisticated conferencing tools and facilitating the full range of interactions between participants must be established. Once established, the benefits in terms of cost and learning effectiveness can far outweigh the associated risks.

These last two models exploit the unique features of a CMC delivered OFL curriculum. They allow students to have asynchronous access to the learning community, at any time, irrespective of their geographical location. Secondly, most conferencing systems keep an archive of interactions so any participant can review and reflect upon entries at their leisure. Many systems provide message threading and can graphically display such activities as brainstorming and complex discursive interactions. Opportunities for collaboration are present although participants are geographically dispersed. Tutoring in a virtual environment is very different to either face-to-face class teaching or supporting students on a traditional OFL programme (Ryan and Woodward, 1998). It is vital that appropriate staff development be undertaken to ensure that tutors have the necessary ICT skills and are aware of and can manage those factors which influence the quality of interactions in a computer mediated classroom. (Salmon, 1998)

Drawing upon experience

Schools at the University of Greenwich employing CMC have found that where it is integrated into the curriculum process it provides valuable, additional learning and teaching experiences (Lewis, et al, 1997; Jordan and Ryan, 1997; Hodges and Ryan, 1999). Over a five year period each of these emerging models has been applied to different programmes of continuing professional development (CPD).

As an illustration of the support model, Lotus Notes was used to support adult distance learners engaged in a teacher education programme. The students received materials in the form of printed texts that included a range of activities. Contact with the peer group was minimal except at induction and optional study days. Telephone, fax, and occasionally e-mail provided tutor support. The use of this groupware allowed students to interact with each other and their tutors more regularly. However, the materials had been designed for a traditional distance
programme, which resulted in some confusion over the purpose and status of activities delivered on-line, versus those in the printed materials. Because the use of CMC was optional, only those students who engaged regularly with the system and recognised its potential, actually benefited. The experience of using CMC was new to both students and tutors. A Notes desktop was provided for all participants but there was little evidence of improved learning and it would have been an expensive system to operate with large numbers. However, many students welcomed the opportunities for interaction and increased access to their tutors even if they didn't always fully exploit this additional support.

The wrap around model is currently being used by the Natural Resources Institute (NRI) who are delivering a grain storage management programme at masters level to a world-wide audience. The original programme involved students being resident in Britain for periods of time, combined with study in the host country and tutors from the NRI visited and assessed students abroad. Building upon their expertise in delivering face-to-face workshops and providing high quality materials, a team of subject specialists worked in conjunction with curriculum and ICT developers to produce a new distance version of this existing programme. Essential elements that needed to be retained included; diversity of subject specialist inputs, opportunities for students to apply new knowledge to their working environment in their own country and sharing of peer expertise and experiences. The rationale for developing such a programme focused on the need to reach new markets and to be more cost-effective. Employing the wrap around model allowed the essential features to be retained but the costs of international travel and accommodation and separation from families on the part of students were removed. As the programme is only in its first year of operation, it is not yet possible to say whether it has been successful. Anecdotal evidence suggests that the tutors, who undertook considerable staff development, are committed to this new programme and believe that it fulfils all of the outcomes of the earlier traditional model. Student feedback has been limited but the indications are that the experience of working within a virtual environment has been positive.

Two schools currently employ the integrated model; one to deliver an experiential course in computer mediated tutoring (CMT), the other is a Masters in CPD for health professionals. These programmes fully exploit those innovative features of CMC outlined earlier in the paper and include electronic submission of assignments and on-line anonymous evaluation. In both cases, a face-to-face event precedes the virtual delivery, which is provided by customised Lotus Notes desktops. These desktops include the virtual classrooms, electronic resource and information centres and a student common room. Apart from a programme handbook, course outlines and instructional materials to aid students with the installation and operation of Lotus Notes, all other materials, activities and interactions are delivered within this Virtual Integrated Learning Environment (VILE). An in-depth evaluation of the Masters programme, which has just had its first graduates, has revealed many benefits to learners and overall satisfaction. Within the University of Greenwich, this programme is considered highly innovative and many other schools are seeking to adopt the model.

Issues Raised by Evaluation

Whilst there have been some negative criticisms of the use of CMC in support of OFL programmes the majority have been positive. “With CMC there are a lot more advantages than with other distance learning because you have the support of your peers and their instant availability.” Another student said, “the asynchronous medium has been wonderful for me because I don’t think easily on my feet. I do like to ... be able to sit back and reflect before I put my thoughts forward.”

These comments serve to illustrate a number of important issues. Firstly, those students who are prepared to make a commitment to the learning community, which includes connecting to the system regularly and frequently, are more likely to have a positive experience which can result in learning gains. The claims made about the use of CMC and its ability to address issues of isolation, facilitate collaboration and reflection are supported by student evaluation. However, critical comments suggest that there are potential barriers to employing CMC.
A questionnaire given to adult students said, "I have no access to e-mail & the Internet and if I did I would be reluctant to use it. A second student indicated that they, "personally prefer 'old-fashioned' methods of communication." A third said, "If I had the time, I would have used the On-Line Campus." Finally, another said it is a, "very good idea if it is not going to be a substitute for (face-to-face) tutorial support."

Whilst this feedback was in connection with the use of CMC as a support tool, some of the comments echo remarks made by students both on-line and in end of course evaluations with regard to the integrated model. I stated earlier that access to reliable equipment and systems is a prerequisite for using CMC within an OFL context. Students and tutors who have access to a computer both at home and work are in a better position to exploit the advantages of virtual learning systems. Despite the media hype that implies every home in the UK has a computer connected to the Internet, this is far from the truth. Where there is a computer, often the children within a household have the skills and spend the most time interacting with the technology. For some adult students, even if they have access to a computer, they claim to lack the necessary range and level of skills required to make the most effective use of the software.

It is not just the apparent lack of time or ICT skills that prevents some adults from engaging with a CMC programme. We need to undertake more research into the relationship between learning styles and ICT, but experience suggests that adult students often encounter significant difficulties in adapting to new ways of learning and teaching. Both the wrap around and integrated models require students to engage with the materials and then interact with their peers, even if their preferred style of learning is to work as an individual at their own pace. Many of our adult learners find it difficult to commit regular amounts of time to studying each week. Their comments suggest that on occasions, several weeks may elapse before they undertake activities contained in a printed text. Within a virtual environment where tutors are extolling the virtues of interaction with the peer group and expecting students to participate in collaborative activities, it is essential that everyone attend regularly. This concept of 'virtual attendance' can be a real barrier for many students.

Another feature of this new way of learning is the facility to read the entries of other students before composing their own. Many consider this to be cheating; though, several have commented favourably, suggesting that they sometimes learn a lot from the inputs of other students and have little of significance to add. Furthermore, traditional distance material can be didactic in its approach partly because it assumes little or no opportunity for interaction between the learner and tutor. Many adult learners, even when pursuing an open or flexible programme, have an expectation that they will be 'taught' by an expert. The approach to learning embodied within most of our CMC supported programmes is much more-student centred, partly because we seek to exploit the novel features afforded by the technology. This clash of cultures, students wanting to be taught, whilst tutors see themselves as facilitators of learning, is an additional barrier.

Some conclusions

When employing CMC models within an OFL context, there is a general shift towards activities that require collaboration and peer exchange. In a CMC environment students are encouraged to become more dependent on the learning community and there may be peer and tutor pressure for virtual attendance on a regular and frequent basis. Traditional OFL programmes do not require students to be so dependent upon the peer group or tutor and there is usually no requirement to study within such prescribed time frames. This allows students to be more autonomous, independent, self-managed and some might say, more flexible and open. Additionally, where access to and use of a computer is not a pre-requisite, one might claim students have access that is more open. Certainly some barriers to access are reduced, if not entirely removed, if students do not need to be ICT literate or need to acquire the skills and attitudes needed to learn in this new way.

Within our CMC programmes, we have witnessed some tensions between the autonomy of the individual and the needs of the learning community. Whilst we continue to advocate the benefits and novel features of using CMC our experience suggests the approach may be less open and flexible than more traditional systems of delivery and support.

Abstract: Internet has brought language learners great benefits such as instant access to global information and many chances to come in contact with their target language. In order to improve language ability effectively, making good use of these benefits, some system of encouraging learners' pre-knowledge to develop and expand is required. This paper introduces a distributed notebook system for vocabulary learning, which integrates electronic dictionaries and database and is implemented by Java RMI technology. Since this system can work on different operating system, it can be used for not only self-learning but also as group ware. Possible use of this system will be listed.

1. Introduction and background of this study

The wide spread of internet has brought great benefits to language learners, in particular, who study a target language in a non-native environment (foreign) such as EFL (English as a foreign language) learners. For example, since the internet enabled language learners to easily access and to get information written in target language, they became to have many chances to encounter new words and to expose to the target language in daily life. Since the use of the internet is also not influenced by the restriction of time and place, learners are able to study target language with internet at any time and any where they want. Recent trend of language learning and teaching makes use of information got from internet as "authentic materials" instead of ordinary materials such as textbook. The internet has really influenced the way of language learning and teaching which we have been doing.

However, though internet has provided the benefits and useful chances for language learners, these factors neither directly encourage learners to deep understanding of words nor improve their language ability. In other words, only increase of the browsing and exposing time can not lead learners to improvement of language skills. Thus, we think that some system or tool of encouraging learners' pre-knowledge to develop and expand should be introduced in the now environment in order to improve language ability effectively.

In this paper, we introduce a distributed notebook system for vocabulary learning. This system focuses the purpose of use on vocabulary learning. There are several reasons for this. First, the vocabulary learning is an important key to improve language skill such as reading and speaking. To deep understanding of words means to know the concepts behind words, the types of collocation and language use as well as their meanings. To acquire these knowledge facilitates communication, and moreover, leads improvement of language skill. Second, vocabulary learning is suited to an environment like internet, which has good chances of encountering frequently "un-
known words" and repeatedly "previous words" which learners have already learned. Hatch and Brown 1995 stated that the important point to deep understanding of words is to encounters with the same word in multiple sources rather than in just one source. Internet meets this requirement. Third, vocabulary learning need constant practice. Thus, learners should keep on learning wherever they are. Since the use of internet is not influenced by the restriction of time and place, it will be helpful to learners for constant practice. Fourth, vocabulary learning involves activities of repetition and confirmation when learners memorize new words and review the previous learning. If database is used for these purposes, learners are able to access the previous learning easily and to confirm the specific words repeatedly. That encourages learners to give any further attention the previous learning. Thus all the effort given to the previous learning will not be wasted.

Based on these reasons, we implemented a distributed notebook system for vocabulary learning. This system consists of two parts functionally: the electronic dictionary part working on network; the notebook part connected with remote and local database, which can exchange data with each other. When to encounter new words, language learners are able to look it up easily with the electronic dictionary of this system, and to write information, the result of learning such as word meaning and its use in the notebook. Since the information written in the notebook by learners are stored in either remote or local database (elective), learners need not to worry about loss of the data, different from the data written in paper. It is also possible for learners to see the stored information again and to add new information to it. Thus, the past effort given to the learning of new words are not wasted. This system is also implemented in Java and learners are able to use this system at any time and anywhere without restriction of operating system, if they use different types of operating system between home and school.

2. Distributed notebook system for vocabulary learning

2.1 Concept of this system

It is said that vocabulary learning is a difficult part of teaching in language learning. Because there are a lot of words that learners need to know and it takes much time to teach them in classroom activities. In most cases, vocabulary learning is left entirely to learners' effort and their self-study.

We develop a distributed notebook system for vocabulary learning, which is designed for every learner to learn vocabulary effectively and is based on Nation's methodology (1990) and McCarthy's (1997). According to their methodologies, vocabulary learning is involved in two kind of learning : receptive learning and productive learning. "Receptive learning involves being able to recognize a word and recall its meaning when it is
met". (Nation 1990) On the other hand, "Productive learning involves what is needed for receptive learning plus the ability to speak or write needed vocabulary at the appropriate time." (Nation 1990) They stated that in order to make their receptive vocabulary (acquired by receptive learning) productive, learners should learn not only the meaning of word, but also how it is used, its grammatical characteristics and which words it is usually associate with etc.. They also stated the importance of dictionary use, of vocabulary note book for writing down new words and expression, and moreover, of reviewing vocabulary repeatedly and increasing in the frequency of encounter.

Taking account of what has been said above, we designed a distributed notebook system for vocabulary learning. This system consists of three components:

1) WWW as information resources and learning-materials
2) Electronic dictionaries on network
3) Vocabulary notebook connected with database on network.

This vocabulary notebook (See Fig. 1) includes some checkbox of choice (noun, verb, adj, adv,...) for concentrating learner's awareness at grammatical characteristics of the word. It also includes some textfields for writing the word, its meaning, the sentence containing the word the sentence found in the dictionary, new sentence containing the word.

2.2 Learning process of when using this system

![Fig. 2: Learner's learning process of when to use the notebook system](image)

Learner's learning process of when using this system (See Fig.2) can be performed the following three steps. Repeated these steps, you can be getting acquired from receptive vocabulary to productive vocabulary.

Step1: When you find a new word in WWW and other resources that you are reading.
(System) open the dictionary, if necessary. Look carefully new word in the sentence and judge whether it is noun, or verb, adj, adv... Mark the grammatical characteristic of the word on the check box of vocabulary note. Next, write in vocabulary note the word, its meaning, the sentence containing the word in WWW and resources, the sentence found in the dictionary, new sentence containing the word. Then, push the save button and these information are stored in remote database. As URL of WWW and frame number of the dictionary are also stored with time.
When you find the word again you have seen before.

Though you know the word as receptive vocabulary, as you need to learn other expressions of the word and appropriateness, open the vocabulary note. Vocabulary note automatically counts the frequency of encounter of the word. The frequency can motivate you to fix the word in your memory. (System) open the dictionary, if necessary. It is also possible for you to open some dictionaries at the same time. Look carefully the word in the sentence, concentrating on which words it is usually associate with. You find that the word is another kind of part of speech. Mark the grammatical characteristic on the check box of vocabulary note, and add another meaning, another sentence containing the word in resources, another sentence found in the dictionary and make new sentence containing the word yourself. Save them and these information are added to database.

Step 3: When you need to know the expressions of the word

When writing essay, you suddenly become want to know the meaning of a word and expressions. Look at the list presented from your database and look for an appropriate word and expressions. If necessary, search dictionaries and compare with them. You will find the appropriate expression in the context. If you find a new expression in another resources, add them to database again.

This system provides learner with many chances to remember the word: for example, letting learner judge grammatical characteristic of word, and write a new expression, reconfirming other expressions that have seen before, and moreover, showing frequency of encounter, showing window(vocabulary note and dictionary) as the need arises.

3 System architecture

This distributed notebook system (See, Fig 3) consists of two parts functionally: (1) the Notebook system part, which is connected with remote and local database; (2) the Dictionary system part. The notebook part is further divide into three components: the database for storing vocabulary and data, the server, and the client for inputting new words and showing data. As Fig. 3 shows, there are two kind of database: SQL database and simple Hashtable database. These databases/servers can be selected with easy operation, according to the user's purpose.
and environment. On the other hand, the client consists of two parts: the notebook client and the dictionary client, which are integrated with each other (See Fig. 4). The interface of notebook client is designed as card type of GUI (See Fig. 2) in order to input and see new words and data easily. Since it also provides user with flexible operation that user are able to open any client windows at the same time, user can work efficiently, comparing one window with another. Dictionary client is connected to the dictionary server by Java socket interface. The dictionary server system (Dserver) is available for CD-ROMs in EPWING. Dictionary client can switch any dictionaries from one to another and also use them at the same time. The shown data on the dictionary client can be handled with simple operation: Copy and Paste. Thus user can paste a sentence from dictionary into vocabulary notebook. In addition to these two functions mentioned above, this system provides a function of accessing information stored the database via WWW browser (See Fig. 4 below).

Fig. 4: Data exchange between client cards

Fig. 5: Example: a use of notebook system

Since this notebook system is implemented in Java, all system components (database, server and client) can work on different operating system (Mac, Windows, and Unix). Since whole system is also made by Java RMI technologies, it is possible to arrange or rearrange the working position of system components on the network,
according to user's the purpose/environment of use. For example, database and server component can be put on Unix system. Notebook client can be put on Macintosh system, dictionary client on Windows (See Fig 5). That is, it is possible to put each system component on different operating systems. (Actually, we always use this system like this)

This distributed notebook system provides learners with the new studying environment, which frees learners from the restriction of studying location and using systems. Because of the system being unrestricted from the working platforms, learners can use the system not only computer in the school, but also their own computer in the home. This means that after the classroom learners can continue to use the same system and continue to study in their own house.

This system can be applied not only for learner to study vocabulary as self-learning, but also for teachers to use as group ware in classroom. If user change the interface of vocabulary learning into that of another purpose, this system can be applied to different fields. For example, a notebook for collecting information, glossary of technical terms, and collaborative tool.

4. Future work

We now develop a new system which connects the distributed notebook system for vocabulary learning with small PDA terminal. This future system will make it possible for learners to study the vocabulary from the mobile environment. In Japan, it generally takes a lot of time, approximately one hour or more, to commute from home to school/company. Many students always spend such long time learning something (ex. learning language) in bus and train. Thus the learning system with PDA will be very useful for them.

On the other hand, voice memo system with small IC recorder is available on the market. We think such equipment with audio tones will be also useful for vocabulary learning. We also now try to integrate this voice memo with our notebook system. Moreover, in the near future, the integrated system will be combined the sound tool for editing speech signal called “Sound Cutter” (Sagisaka and Munakata 1999) which we developed last year. As the Sound Cutter is also written in Java. Our goal is to realize the distributed environment for language learning, which includes not only text but also sound.

5. Conclusion

In this paper, a distributed notebook system for vocabulary learning was introduced. This system was developed for vocabulary learning, making good use of network and Java technologies. It also provided learners with new learning environment, which freed learners from restriction of place and time, and moreover different platforms. This system can be applied to different fields, if user-interface is changed for different purpose of use. Further development of this system will bring language learners more useful environment.

Abstract: In this paper, we describe the development of an Organizational Learning and Information Support System (OLISS) that serves a diverse group of users for a wide variety of purposes. Designed for a government agency, the system is developed to support the application of "standard" business policies and practices across the organization. The system provides "just in time" capabilities for users of the system to apply these standard business policies and practices within the ongoing context of their everyday work. Users come to the system from different jobs, experience levels in their jobs, and knowledge of the standard business policies and practices. All the capabilities, in one form or another, provide not only a mechanism for individual learning but also a means for capturing and disseminating newly created knowledge in the organization.

Introduction

The growth and sharing of knowledge is recognized as an important element in becoming a "learning organization" (Easterby-Smith, 1997; Marsick and Watkins, 1994; Senge, 1990). However, what is missing, according to many researchers and practitioners in the field, is the development of theoretical frameworks for thinking about how people learn and perform in an organization (Raybould, 1995). Furthermore, the few theoretical frameworks that have been developed and presented for consideration are highly abstract and lack a description of a practical mechanism for the capture and dissemination of organizational learning. To address this situation, this paper uses a case study to describe a theoretical framework with a practical mechanism for capturing and disseminating learning at the organizational level. The theoretical framework includes a knowledge creation process that can be used to grow and share knowledge -- an essential part of becoming a learning organization. The framework relies on technology -- a Web-based Organizational Learning and Information Support System (OLISS) -- to assist in the capture of expertise from individuals and make it available to other members of the organization.

In the following paragraphs, we describe how the capabilities of a Web-based OLISS serve a diverse group of users for a wide variety of purposes. Designed for a government agency, the system is developed to support the application of "standard" business policies and practices across an organization. It is performer centered (Laffey, 1995) and its use applies the principles of situated cognition (Brown, Collins, & Duguid, 1989; Laffey, 1995). That is, it supports "just in time" capabilities for end-users to apply standard business policies and practices within the ongoing context of their everyday work. All the capabilities, in one form or another, provide not only a mechanism for individual learning but also a means for capturing and disseminating newly created knowledge in the organization. This continuing knowledge creation and capture process becomes an organizational performance/learning cycle (Raybould, 1995) as members access expertise in the system, modify that expertise, apply it to the problem at hand, and add their learning to the system. In this cycle, the Web-based OLISS is an enabling technology that provides the link between individual learning and organizational learning (Kim, 1993).

The OLISS Capabilities

In Figure 1, we list the major capabilities of the Web-based OLISS and the categories of end-users for the system. End-users are "members," "managers," and "customers." Members are members of the organization and are directly responsible for correctly applying the business policies and practices on an everyday basis. Managers are
supervisors of the members that apply the policies and practices but managers do not use them as part of their own daily work. Managers are, however, responsible for the correct application of the policies and practices by the members of the organization that they supervise. Customers take possession of the products that result from the application of the policies and practices by the members of the organization. Customers have a vested interest in the correct application of these policies and practices since it affects the quality of the product that they receive.

A checkmark in the intersection between the row of a capability and the column of an end-user category indicates that it is a capability designed for that type of end-user. For example, in the second row of the reference materials capability, related materials, there is a checkmark for the members category and no checkmarks for the categories of managers or customers. This means that members of the organization will use the related materials but managers and customers will probably not use them. Managers and customers will probably get all the reference documentation that they will require by accessing the procedure & policy documentation on the OLISS Web site.

We believe that having online reference materials is an important capability for a Web-based OLISS site. As Figure 1 shows, all end-users will benefit from easy access to online documentation describing the policies and practices. Organizational members, however, will also benefit from the easy access and cross-reference of related online materials. It will help them to ensure that the application of the policies and practices are consistent with the other regulations that they must follow. Managers and customers do not benefit as much from access to these related materials.

Figure 1 also shows that the search capability provides an important service to all end-users of the OLISS Web site. It allows a free-form text search where end-users can input keywords or phrases to the search engine and receive references to all the pages on the site that match the search criteria. It provides quick access to materials that relate to specific topics.
The communication capability of the OLISS Web site has three features. The first one is a "points of contact" e-mail feature -- allowing users to contact experts within a subject area. The second feature is a threaded discussion list that allows users to follow ongoing discussions of those issues that concern them. The third feature provides a means to collect frequently asked questions into a "FAQ" list.

As shown in Figure 1, these communication features extend the methods available for end-users of the OLISS Web site to grow and share knowledge. Members, however, will benefit the most from using the features. Previously, members communicated only through face-to-face meetings, telephone, or mail. Now, members increase their productivity by sharing with one another about lessons-learned in conversations that are easily assessed, organized, and not bound to specific time frames.

Instruction is an important capability in the design of our OLISS Web site. In Figure 1, we see that members of the organization will benefit from all the instruction that is available -- instructor led and stand-alone. One advantage of instructor led instruction for members is that it provides an opportunity to ask questions concerning specific details about applying the policies and practices. Managers and customers, in general, can meet their needs with stand-alone instruction.

The decision support capability for the OLISS Web site has two types of features that benefit organizational members the most. The first one provides a guided search option for policies and practices. The second feature provides guidance in the completion of the steps for a policy or practice. These features facilitate knowledge transfer in the organization. Experienced members provide the expertise for the decision support capability. Members with less experience use the embedded expertise to find and complete the policies and practices. Managers, with less detailed knowledge of the policies and practices may also benefit from use of the expertise in their supervisory role.

The knowledge acquisition capability of the OLISS Web site also has two types of features that mostly benefit the members of the organization. One feature is a means to organize and store case studies. Case studies are general examples that illustrate the correct application of a policy or practice. Most of the time they are created for use as examples during instruction. The other feature enables the organization to store "real life" examples that illustrate the correct application of policies and practices in the field. With these two features, the knowledge acquisition capability facilitates the capture and sharing of new knowledge as it is created in the organization. Managers, who are not creating new knowledge from direct application of the policies and practices, may improve their decision-making through access to this expertise.

Example Scenario with the System

In the following paragraphs, we describe how organizational members may use the capabilities of an OLISS Web site to capture and disseminate knowledge across the organization. In this case study, other categories of end-users (e.g., managers, customers, etc) typically do not create new knowledge but access the knowledge created by the members of organization that directly apply the business policies and practices in their daily work.

In the following scenario, shown in Figure 2, the organizational member is not sure exactly what policy or practice they are looking for, but the member has a vague idea what it is and where in the larger work process it is used. For example, a member knows that he or she will need to complete a change document that describes the changes that have been done to a design document but the end-user is not sure what kind of change document should be completed. The organizational member begins looking for change documents by clicking on a menu selection that brings up the entire process of producing a product. The end-user then selects the sub-process that contains the design document. The member clicks the design document option and is given a list of two selections for design change documents (change document A and change document B). Here, the OLISS Web site prompts the member with the following guidance to assist in determining which change document to complete: "If you have not released the design document, then complete change document A, else (you have released the design document) complete change document B."

After selecting change document A, the member now sees a description of change document A on the screen. Along the sides of the screen are menu selections for the other capabilities: reference, instruction, knowledge acquisition,
and communication. The member selects the reference materials option and views all the references in the related design documents that refer to change document A. Afterwards, the member clicks on the instruction menu and decides to take a five-minute tutorial on change documents.

Next, the member clicks on the knowledge acquisition menu, selects examples, and the OLISS Web site provides a list of example groupings. The member clicks on one of the groupings and sees a list of examples (additional levels of groupings can be used to differentiate examples). The metaknowledge, used to group the examples into meaningful categories, provides guidance for members to find examples that closely relate to the task at hand. The member examines these examples and finds an example of change document A that is very similar to the one that the member will have to create. Finally, with one question left unanswered, the member clicks on the communication menu, selects "points of contact," and posts the question to another member of the organization. When the answer is returned, the member has all the knowledge that he or she requires for developing a solution to the current problem, i.e., create a change document A. Lastly, the member updates the system by uploading the new solution; thereby, creating a new unique example that will be available during the next time the system is accessed.

Discussion

Does the case study presented in this paper provide any insight into how organizations can use technology to support the process of creating new knowledge? Or how organizations can make knowledge explicit once it has been created? And finally, how they can convert knowledge into different forms for effective dissemination across the organization?

What has been retrieved from the OLISS Web site in the scenario is what Nonaka and Takeuchi (1995) describe as "explicit knowledge" -- a meaningful set of information articulated in clear language including numbers or diagrams. Note that the member did not find a complete solution from the OLISS Web site -- requiring no modification -- to his or her current problem in the example scenario. The member found an example with guidance
from knowledge supplied by the system, gained knowledge through reference materials and instruction, then modified the example to create a unique and new solution for his or her current problem.

This new solution is the creation of knowledge; however, this new knowledge is tacit and cannot be used by anyone since it resides in the head of an individual. It is knowledge that needs to be made explicit. Furthermore, it needs to be converted to several types of knowledge before it can be effectively disseminated across the organization. The first step is that the solution itself needs to become an example for the next time the member, or another member, is confronted with a similar problem. To accomplish this technically, an online form is filled out and the new solution is attached, which is then uploaded to the OLISS Web site. The solution becomes a form of explicit knowledge; what was implicitly known by only one individual is now available in an explicit form for the other members of the organization. The process of placing the new example in the correct category of examples, or creating a new category for the example, is the creation of new metaknowledge -- knowledge about how to find the new example. This is the knowledge that is traditionally thrown away. Organizations may keep the new example but later don't know under what conditions it should be used.

The second step is to ask if the other members of the organization will use the new knowledge often. If the answer is yes, then it may be analyzed and converted to other types of knowledge that are represented in the OLISS Web site. For example, the new solution may be analyzed to determine what steps are necessary to arrive at the new solution. These steps are documented as procedural knowledge and placed in the online reference materials. Furthermore, if the new solution will be frequently used, then this procedural knowledge may also be placed in the decision support capability to guide members to the new solution. Finally, if the new solution represents a new approach to conceptualize problems, then it would be analyzed for the general truths and associations that describe this new approach. The resulting declarative knowledge would form the basis for creating new online instructional materials for inclusion in the OLISS Web site. In this way, the OLISS Web site supports the process of creating new knowledge, making it explicit, and converting the knowledge into different forms for effective dissemination across the organization. It becomes the mechanism that provides the rapid capture and dissemination of organizational learning that Raybould (1995) describes in the fifth phase of his Organizational Performance/Learning Model.

Abstract: The development of online courses is becoming increasingly popular. In addition to the multimedia benefits that the WWW offers, institutions can enhance existing courses using WWW technologies such as chat and discussion tools. These tools can allow students from different institutions to participate in group work which is pedagogically sound as well as a valuable cultural experience. On-line collaborative courses are an ideal way to expose students to different cultural perspectives.

This paper discusses the development and implementation of an online collaborative course used to teach advanced international business at undergraduate level at Auckland University of Technology. The paper discusses the nature of the collaborative exercises undertaken by the students and concludes with a reflective evaluation of the course.

Introduction

The Bachelor of Business (BBus) is a four year undergraduate degree in business which has seven majors, including International Business. It is offered by the Auckland University of Technology, Auckland, New Zealand.

The aim of the BBus is to develop confident capable learners who have a broad understanding of business and of the relationships between business disciplines, specialist knowledge in one or more fields of business, and personal and professional capabilities in communication, team work, interpersonal skills, critical thinking, research and use of technology.

The approach to learning in the BBus is student-centred and reflects a philosophy that knowledge and understanding are constructed by the learner, not supplied by the teacher. Students learn through action, interaction and reflection (Ramsden 1992). The teacher is a facilitator of learning as students interact with each other, develop ideas from their reading and discussion and work with peers.

Computer Mediated Communication

Studies show that classroom learning improves significantly when students participate in structured learning activities within small groups (Brown & Palincsar 1989). The educational value of the collaborative process has led to the development of computer-supported collaborative learning (CSCL) tools (Lund, Baker & Baron 1996; McManus & Aiken 1993). These tools enrich learning in a setting that encourages students to communicate with each other (Goodman et al. 1998).

Studies of computer mediated communication and computer conferencing (Harasim 1995), identify benefits to students such as convenience and flexibility. Higher levels of student-student interaction and of teacher-student interaction have been reported and linked to the electronic environment. It is perceived as less intimidating and allowing more equal participation. Other benefits include improved learning through the opportunity to reflect, especially critically, on material and discussions and to develop understanding through sharing diverse views, collaborating in writing and re-thinking and re-writing one’s ideas. Disadvantages include technical difficulties in gaining access, the extra time it may
take compared to face to face classes, the lack of the social, visual and aural cues which assist
discussion, lack of immediate feedback in asynchronous communication, dealing with information
overloads and tracking the flow of discussions.

The way in which computer mediated communication is included in the structure of learning and
teaching in the course is important. (Savard 1995) and (Ruberg et al. 1996), report that using computer
mediated communication does not necessarily lead to increased student participation or interaction
between students. They argue for the importance of integrating computer mediated communication
activities with the rest of the course, especially in the assessment programme ensuring that students
perceive its benefits. (Tagg 1994) reports on a postgraduate course where a change to having students,
rather than the teacher, facilitate discussions and summarise results encouraged students to be more
active in discussions and eliminated some of their reluctance to subject their ideas to critique and
questioning by other students.

International Business Major

The international business major of the BBus aims to provide the BBus graduate with a broad set of
cross-cultural capabilities developed through international experiences. Working with students from
other countries challenges students’ ideas, values and judgements and enables them to understand and
develop sensitivity to different cultures, respect for difference and flexibility in working with people
from different cultures.

Increasingly international business requires effective use of communications technologies. These
include email, for discussion, establishing, negotiating and monitoring contacts, contracts and other
business interactions. The use of computer mediated communication for collaborative team projects
can involve people from the same or different organisations working in different countries and time
zones. The ability to use these technologies to achieve organisational goals in the complex cross-
cultural e-business environment is a key to successful international business in the future.

Advanced International Business (AIB) is the capstone course in the BBus major in International
Business. The course aims to examine theoretical and practical problems in international business
through multi-disciplinary perspectives. Planning of the online development was carried out in
Semester 1 (February–June), 1999. The first stage was then implemented in July 1999.

During the semester three forms of computer mediated communication were used. They were:
- Online participation in synchronous (real time) class chat discussions.
- Leading a threaded discussion using an asynchronous discussion tool (BSCW) with a group of
  five other students.
- AUT students working asynchronously in pairs with students from International Business
  Academy, Kolding, Denmark to jointly analyse an International Business case and write a
  report.

In addition to the online work, AUT students had one scheduled class of two hours per week for
classroom activities. These included case analyses, class and group discussions and individual and
group presentations. Students are accustomed to and expect that their learning in the BBus will be
interactive and involve group work. What we were adding was experience in carrying on such activities
online using asynchronous and synchronous communication tools.

Synchronous chat

During the course there were two online chat sessions to enable the class to participate in discussions
on international business issues. These were not assessed as part of the students’ grades but intended to
assist their learning, develop skills in online synchronous communication and identify students who
had difficulty with the electronic environment so that they could be given help before they undertook
assessment in online work.

Electronic Discussion Leadership
During the first week of the semester, each student identified an international business issue relevant to the course. The teacher clustered these into groups of three to five ensuring that each group had a range of different issues. Over five weeks students took turns as online discussion leader, introducing a topic, managing the different discussion threads, motivating group members to participate, commenting on group members' contributions, developing depth of analysis in the discussion, summarising and drawing conclusions.

Leadership of the electronic discussion comprised 30% of the course grade. The students submitted a report of the discussion, included a transcript of the discussion and a statement in which each student reflected critically on the content and process of the discussion which they led.

Case Analysis Report

The case report was prepared in pairs – one student from IBA in Denmark and one from AUT. The students undertook this collaborative assignment in the context of their different courses, using agreed case materials and guidelines for writing a case analysis report. It required students to manage a cross-cultural group task, deal with communication and technology issues and negotiate with another student a report on a complex international business case.

The case analysis report comprised 35% of the final course grade and, like the e-discussion, included a reflective statement evaluating the content and process of the collaborative work.

Evaluation

Student evaluation of the course and the online components was conducted through surveys at the beginning and end of the semester, an in-class discussion on the chat sessions and the reflective statements submitted with the e-discussion and case analysis. The results are set out below.

Beginning of the semester

The AIB class in semester 2 1999 comprised 21 students in their third or, more typically, fourth year of undergraduate study in the BBus. Nineteen students were aged 20-24 with two students aged 18-19. There were fourteen women and seven men. At the beginning of the semester students were asked about their level of comfort with electronic communication and expectations of the course. All but two of the class reported that they were either comfortable or very comfortable with the use of email and approximately one quarter had experience with chat groups. All students but one had used the WWW for study or leisure.

All students were excited by the online collaboration and saw in it the opportunity to develop effective communication and cross-cultural skills relevant to e-business and the changes in the international business environment. Women were more likely to identify the development of communication skills and cross-cultural capabilities. Three particularly expressed interest in learning to communicate and achieve group goals without the usual visible cues such as facial expression, body language.

Online chat

The students were positive about the online chat sessions. Students felt that more of them were able to participate in the discussions and as a result the discussions included a wider range of ideas than a face to face classroom discussion. They felt freer to put their ideas, there was more input from students, and it there was less guidance from the teacher.

Concerns were expressed that the sessions went too fast, students could not always keep up, there was no time to reflect and at times there were private conversations going on as well as the class discussion.
In discussion about how to improve the chat sessions, students agreed that each entry into the chat should contribute to both the content and the process of the discussion. They felt that this would slow down the discussion, reduce casual chatter and lead to more thoughtful replies.

**E-Discussions**

Students' comments on the e-discussions were similarly positive. These comments were made in the reflective statements submitted by each student and in the end of semester evaluation. All students said e-discussions were better than face to face discussions. They found facilitating the discussions was fun, interesting and motivating.

Students reported higher levels of motivation and enjoyment than with traditional group assignments. They felt that they learned more. Some students felt that the electronic format gave them more control over their learning as they set the direction of discussion and managed others. One student however, felt uncomfortable with this and wanted some supervision by the teacher of the discussions.

There was more time to read, think and reflect on the comments of others before responding. Students felt they were more careful in writing their submissions and responses to ensure that they clearly communicated their ideas. They had a record of the discussion. One student commented that he learned better this way because he was writing down his ideas more clearly so that others could understand, then he received comments back from other students which assisted his understanding.

Students said that the lack of body language and social cues meant it was harder to check understanding and move the discussion along. Students reported that they could not always get access to the discussion site, email messages were lost and they sometimes resorted to the telephone to keep the discussion going. The most commonly reported technical concern related to frequency of logging-in and slowness of the process. Students had to wait for a response and did not know when that would come so they had to log in frequently. If they checked in too late other students might have responded and they lost their opportunity to contribute. Information overload was an issue as responses got longer and managing the multiple discussion threads became difficult.

**Case Analysis**

The case analysis exercise provided the online cross-cultural collaboration we considered important to international business graduates. It had an uncertain start as the first business school partner we had arranged, withdrew at the last minute. We were very lucky that IBA Kolding, Denmark agreed to participate at short notice. However, there were difficulties with this arrangement as the IBA students were not as advanced in their international business studies as the AUT students and consequently their understanding of international business issues was less sophisticated.

AUT students commented that the main benefits of collaboration with the Danish students were receiving ideas and critique from a different cultural perspective and learning to deal with differences in English language and the misunderstandings which occurred. One student said that he and his partner avoided this problem by always providing examples to illustrate their ideas. Another observed that because he had to ensure the Danish student understood his messages, he felt that he put more time into thinking them through and keeping them as concise as possible. He felt that this had enhanced his learning from the case and illustrated the benefits of peer tutoring. Other students talked of the increased understanding they achieved through having to carefully explain and justify their ideas and arguments. Students commented that they had to learn to be more patient with each other and aware of each other’s needs.

AUT students found the exercise more difficult and frustrating than they had expected yet still rated the exercise highly in its contribution to their learning. Time management and differing levels of participation by students were obstacles to easy completion of the task. One student observed that this was an issue with face to face group work so she was not surprised to encounter it in the electronic working environment. Another student said she did not want to appear too pushy and risk losing the contribution of her partner but felt that she had a greater sense of urgency and commitment to the task because of its significance in the AUT assessment programme. Most AUT students reported difficulty in contacting their Danish partners and in receiving responses which advanced the discussion. They felt
that the Danish students were not as committed to the exercise. On the other side the Danish teacher reported to AUT that their students thought the AUT students did not seem to be as hardworking or conscientious in applying themselves to the task.

AUT students said that responses which were timely, not too long, provided critique and new ideas rather than constant agreement were best for advancing the discussion. They recommended that the teams agree, at the beginning, the roles of each student and expectations for the communication and work. Also attention should be paid to creating rapport and attending to the social side i.e. getting to know the other student not just attending to the work. Showing your partner that you valued their opinion assisted their motivation and prevented major misunderstandings according to one student.

Students experienced lack of control of the group process in the electronic environment. They observed the importance of developing trust that your partner would contribute. This was more difficult because all communication was remote and the students could not meet.

End of Semester evaluation

At the end of the semester students were asked to complete a detailed evaluation questionnaire. Responses were received from 8 students out of 21. This low rate of return occurred because the survey had to be posted out after the end of the semester rather than being handed out and completed in class time. However, the results of the survey mirror comments in the reflective comments that were received from all students.

Students approved of the electronic environment, the way in which it was introduced and the innovative and challenging nature of assessments. Students indicated that they were satisfied or very satisfied with the module. In evaluating the contribution made to their learning by the online strategies, students were most positive about the e-discussion and case analysis. They were less positive about the chat sessions.

All the students said they would like more courses to use electronic discussion tools and to be made available online. Some commented on the need for training of students so that they can be successful. Internet access at home was another issue. Students commented that online communication means less time in class and gives students more flexibility. All commented that familiarity with use of synchronous and asynchronous discussion tools was important for their futures, in both social contact and work. One student was concerned not to lose face to face contact with lecturers and other students.

Discussion software was useful because it made it easier to organise discussions, you could see all contributions at once and students could contribute whenever they were ready rather than having to wait to receive an email. Many students preferred email because of its familiarity and ease of use. Email did not require them to go to a different site and log-in and it did not crash as often as did the discussion software.

Changes to the course

As result of our experience in 1999 and student evaluations we have made changes to the online course for 2000.

These include:-

- an improved look to the online site and navigation
- synchronous chat and asynchronous discussion tools are integrated with the site so that students only log-in once and have all the communication tools available
- when students first log-in they get a list of new messages and the week’s programme for their course. This includes reading, online and other activities
- a messaging system has been incorporated into the site
- each student has a personal journal for their notes and work
- teachers and students may upload and download files of course materials or other work on to the site for others to access
- online help and tutorials
students may choose a different look or skin for the site
- dedicated technical support on site
- teachers are able to monitor the progress of the students and obtain reports on how long students spend on-line, how they use the course, information on the use of the chat and discussion groups.
- Incorporation of a dynamic roster (study guide) containing class preparation, in class activities, assessment and weekly reviews.

The online collaboration in the case analysis is being continued. We have arranged a different partner in France where the students will be of a similar level to those at AUT in international business. The 1999 pilot demonstrated the importance of students having a similar commitment to participating and seeing the analysis completed to a good standard, so we have ensured that it forms part of the assessment requirements for all students. (Collis & Remmers 1997) suggest that, in courses which require this type of cross-cultural collaboration, care should be taken to ensure that students understand the expectations of the communication, formality, who initiates, length, style and level of debate. They point out that we should not assume that more interaction is better than less and to be aware of the difficulty of communicating across language and cultural barriers. While we did provide guidelines on the case analysis for both groups of students and the teachers spent time with the students to assist their understanding, this is an area we will aim to improve in 2000. Having teachers monitor the discussions will be easier because of the integrated site in 2000. This will also enable us to address a concern of the teacher that the depth of analysis and critical thinking displayed in the online work was not consistently of the level to be expected of senior students.

Next Steps

Our evaluation of the 1999 course consist mainly of survey data together with examination of the students' reflective statements submitted with the e-discussions. The next phase of evaluation will aim to investigate the effects on student learning of the use of the collaborative tools. This will use online evaluation tools which examine registration data, session log data and analyse patterns of use and types of student interaction. (Sallis & Masi 2000) have used text processing algorithms from computational linguistics research and the application of connectionist methods, especially fuzzy labelling and neural network simulation to analyse the students' reflective statements and provide feedback for further refinements to the course. This approach will be developed further. Structured interviews will be used to examine student perceptions in more depth. The curriculum development team is also aiming to develop evaluation tools to assist in assessing the extent to which learning has been promoted and particularly the effects on higher order thinking. (Burge 1994), (Ruberg et al. 1996) and (Webb et al. 1995) provide examples of studies attempting to evaluate these more complex aspects of computer mediated communication in learning.

The curriculum team encountered difficulties in developing and delivering the course. It took a great deal of work to set up and maintain the online course compared to the classroom-based course. The development team was, in 1999, based in different countries and this placed a huge strain on communication and teamwork. This has changed in 2000 and the team is now all based in Auckland.

Our experience in 1999 with Advanced International Business demonstrated the value of using online forms of collaboration to enhance learning in international business. More importantly students enjoyed it and appreciated its benefits.

Abstract: Learning is frequently assumed as a natural result of projects performed by groups, and cooperative work tools availability within a computational environment is enough to motivate or to induce cooperation among participants. However, many times cooperation simply does not happen within the environments, or it has to be externally articulated by a tutor. We claim that CSCL environments should be built under an explicit cooperation model to be efficient. The goal of this work is to present a Cooperation Model for Learning which is described through a system of patterns.

1. Introduction

Learning is frequently assumed as a natural product of projects performed by groups, and the availability of cooperative work tools within a computational environment is enough to motivate or to induce cooperation among participants. However, as literature tells (Roussos, 1997), in many situations the cooperation either is non-existent or needs to be promoted out of the environment by a tutor. Even in these cases, the role that the teacher should carry out to guarantee cooperation is not explicit. Besides, many proposals neither have been proved yet, nor present an explicit cooperative process model to clarify how they would operate.

We identify the following reasons to the problem of low cooperation level within CSCL environments: Culture - one of the difficulties that determine negative results in the use of CSCL environments is that people are not used to working in groups; Stimulus - most CSCL environments exclusively offer tools to support group tasks execution, instead of mechanisms that favor group functions such as cognitive activity, support to individuals and well being of the group; Context - CSCL environments usually have a specific educational objective or an organizational practice training goal, but besides it, they must be integrated within other activities on which students participate; Technology - there is no tool integration within environments, and in general, people have difficulties to deal with it.

We claim that CSCL environments must address issues related to these problems in order to promote learning in a real cooperative way. So, we understand the necessity to provide a Cooperation Model specific for Learning, where solutions for identified problems should be contemplated. The goal of this paper is to describe a Cooperation Model for Learning composed by a set of elements, which characterizes most CSCL study areas. For each of these areas, the model includes descriptions of problems and their corresponding solutions in a pattern format.

The model will work as a repository of problems and solutions patterns found in the literature or specifically developed for the area. The resulting patterns are interrelated, forming a system of patterns, which aims at addressing several CSCL issues. The system of patterns can be used as basis for CSCL environment development process. The rest of this paper is divided in 4 sections. In section 2, the Cooperation Model for Learning is described. In Section 3, some related works are presented. Section 4 concludes the paper.

2. Cooperation Model for Learning

Kumar (1996) emphasizes that one of the most important fields for research in CSCL is the cooperative activity modeling. According to him, modeling should involve among other things, the representation of cooperative actions, such as conflicts, resolutions and cooperative pair roles, that could be modeled according to characteristics and deepen of the cooperation process.

This work is concerned to a representation of most CSCL issues in such a way to make it easier for those who want to develop an environment not to skip important aspects, such as cultural ones. Regarding this goal - to facilitate development - the model is described through data elements. Each of these elements represents one CSCL study area, which are expanded in deeper levels of details and can be described by a system of patterns.
The core of this model is the objective and the cooperative process proposed within an environment. These two elements will determine all the characteristics that the CSCL environment should have. So, the first level of granularity of the model is presented in Figure 1, where issues Context, Culture and Stimulus are addressed:

![Figure 1 - Generic Cooperation Model for Learning](image)

The Cooperation Model is based on the Objective that one wants to reach, for example, learning a certain concept; and on the Process, that is related to the cooperative actions, for example, cooperative edition of a text. The Objective of the proposal brings all the issues related to group Context and Culture, which will determine how the process should be implemented in order to stimulate cooperation. It is related to 4 aspects: Previous Knowledge - background knowledge representation of the group; Learning Theories - a learning theory should give basis to the learning environment; Cooperation Forms - the cooperative way chosen by the group to work; Cultural Aspects - the cultural factors, which determine the context on which the group is inserted.

The Cooperative Process is the element that describes “what people is going to do” within the environment. So, its components must define everything related to the flow of work, such as tasks to be performed, how to know if they are being rightly done, and mechanisms to support the work. A good flow of work definition, in which interdependencies are established, allied with mechanisms to support work in-group, guarantee that cooperation process will be stimulated. The Process element is related to 6 issues and is linked to the problem of Stimulus: Activity - activities to be developed by the group; Roles - functions that group members can assume, which can be different according to process diverse stages; Memory - storage of everything related to the way activities happen; Coordination - related to process controls and help to the learner; Evaluation - mechanisms to support evaluation of learning; Awareness - elements responsible to guarantee that people understand, and are conscious of the process.

Now deeper level elements of the model, which correspond to expansions of the first level, are described.

### 2.1. Activity

Activity refers to the learning tasks proposed within an environment, which will be developed by participants during cooperative learning process. Actually, there are moments to work individually (Individual) and other ones to work in group (Cooperative). Besides, activities can generate Products. Cooperative activities own a special Dynamics, because of the interaction among people, which involves Protocols and Shared Objects.

![Figure 2: Expansion of the element Process](image)

### 2.2. Roles

According to the activity proposal, it can be necessary that group members play different Roles. Defining roles within an environment makes it possible to designate specific tasks and to best coordinate the execution of them. It is also important that people can assume different roles during the process in order to try different
responsibilities. The model should make a description of the different possible roles (Definition), provide ways to nominate roles (Nominating), and define how these roles will stand along the process (Formation Rule).

In addition, it is necessary to implement Interfaces appropriated to each role, and to supply necessary awareness mechanisms to the various tasks performed by the group.

2.3. Memory

The cooperative activity development should be traced and stored. It is very important to preserve not only the products generated during an interaction, but the way it took place. Saving the memory of an activity might be very useful as it makes the produced material available, and shows how the process of cooperation happened to other groups. The Memory of the activity involves the following aspects: Elements related to the Activity that one wants to keep persistent; Capture of these elements; Storage and Retrieval, that are related to how to store and to retrieve elements.

2.4. Coordination

Coordination is related to process controls and help to the learner. This is done using Guides or agents that should monitor accomplished tasks and supply help or procedure indications.

2.5. Evaluation

Evaluation is composed of important mechanisms, that measure whether objectives are being reached or not, and because of this it should be done during the whole process. It is expected that each individual reach a certain knowledge level about concepts presented, so Individual Results should be measured. Besides, the group as a whole must produce some results, which must also be observed (Group Results). The evaluation is made by mechanisms that analyze the Process and the Products generated by the group.

2.6. Awareness

Awareness is the element responsible to guarantee that people understand, and are conscious of the process, and of the participant's interaction within the environment (Figure 5). Four types of awareness must be provided: Social- social connections within the group; Tasks- the way tasks should be taken; Concepts- how knowledge is distributed within group members; and Workspace- interactions within the shared environment.
2.7. Previous Knowledge

A learning environment will propitiate a specific content knowledge gain. Even so, this content appropriation will only be possible depending on previous knowledge that people have. This way, it is very important to provide support to identification of group members’ background. This background can be appraised under appropriated methods - Previous Knowledge Evaluation. The group as an entity also owns characteristics that evidence its knowledge background. Group Formation, which refers to scholarship level, group interest areas, and homogeneity, can configure three kinds of knowledge: Acquired Concepts; Acquired Abilities and Meta-abilities (Figure 6).

![Figure 5: Expansion of the element Awareness](image)

![Figure 6: Expansion of Previous Knowledge](image)

2.8. Learning Theory

A cooperative learning proposal should be based on a learning theory that supports social interaction elements. Learning Theory should supply subsidies for composition and structures of learning activities, indicating how interaction can be accomplished, what should be avoided, and what is or not important in this process. There are many leaning theories that mention interaction and cooperation as means to promote. To represent them in this model, we choose Dillenbourg’s work that indicates three basic approaches. Dillenbourg et al. (1994) state that there are three different theoretical approaches able to understand the nature of cooperative learning: either focusing on the individual’s vision (independent cognitive systems that interact), or on the group (cognitive system with own characteristics): Socio-Constructivist Approach; Socio-Cultural Approach; and Shared Cognition Approach.

2.9. Cooperation Forms

A Cooperative learning proposal can be centered in different forms or models. This is related to level and engagement in the cooperation process. Depending on how the group has been working or how a new proposal is made, a work configuration can be defined. Brna (1998) describes some of these models and affirms that being conscious of which one is used can improve computational support.

In the context of this work, six Cooperation Forms will be considered: Work Division - in this case a division of tasks is made, and each member of the group is responsible for a task; Cooperation State – there are individual and in-group work moments, but the group is sharing a cooperative state; Cooperation as Final Purpose - the work objective is to learn how to cooperate; Cooperation as Means - the objective is to learn something, using cooperative techniques; Formal Cooperation – group members make an agreement to accomplish a work cooperatively; Informal Cooperation - group members work cooperatively, but there is not a formal agreement, the cooperation happens spontaneously.

2.10. Cultural Factors

A proposal that involves interaction among people cannot avoid considering cultural factors related to context where the group is inserted. Some problems that may arise within the group could be predicted if the culture was previously identified. Besides this issue, the group can be motivated according to its necessities and expectations. The environment can develop ways to integrate people using common communication patterns. According to social sciences researchers (McGrath, 1993) and works on organizational culture, a set of Cultural Aspects (Figure 7) specifically for cooperative learning environments was specified. These factors are divided in Individual Properties (each person owns individual components that will influence group behavior), and Group Structure (demonstrate how the group is organized, and how people fit within it).
2.11. Description of the Model through Patterns

For each element of the model described, the most important problems are identified and described as patterns, like the example presented below Pattern Workspace Awareness in CSCL (Figure 8), related to the element Process-Awareness-Workspace (in Figure 5).

According to Johnson (1997) patterns are attempts to describe a problem to be solved, a solution, and the context in which it is applied. A pattern captures, structures and presents key information about a domain familiar to specialists. There are some kinds of patterns (conceptual, design and programming). The patterns of the Cooperation Model for Learning are in conceptual level. Conceptual Patterns are standards whose forms are described through terms and concepts of an application domain; they are set in metaphors and restricted to an application domain.

The patterns are interrelated, forming a system of patterns developed from an analysis of several environments described in literature, accomplished under the optics of the Conceptual Frame for Analysis of Computer Supported Cooperative Learning Environments proposed by Santoro et al. (1999). Some patterns of the system are being directly transformed into design patterns, while others will be used just as a guideline to the implementation. As an example for the first case, the conceptual pattern of Figure 8 will have an associated design pattern representing the software design of the solution. As an example of the second case, a pattern related to a learning theory approach will only guide how to deal with evaluation techniques.

**Pattern Name:** Workspace Awareness in CSCL

**Problem:** What elements should be disposed in a CSCL environment in order to guarantee workspace awareness among the members of the group?

**Context:** In a CSCL environment, awareness of participants is one of the key elements to promote an effective interaction. Knowing what someone is doing in a certain moment can make people interact easily. The access to information on contributions and tasks already completed is also an important factor, because it can approach people with common interests.

**Forces:** Workspace awareness reduces the overhead of the work in-group, allowing a more natural and effective interaction.

**Solution:** The environment should provide a representation of each member of the group within the workspace, so that the whole group can visualize "where he is", "what he is doing", and "what he had already done". This representation can be graphic, iconic, through windows, or virtual reality.

**Related patterns:** Social Awareness in CSCL, Task Awareness in CSCL

**Known uses:** CSILE implements workspace awareness through structured message notion, where an author is represented by its initials, and therefore other members get to know what he is doing or have already done. Following the same line, CSILE, Collaboratory Notebook, and CaMILE also implement structured messages where the authors are identified by their names.

In NICE (Roussos, 1997), the participants of a work section are represented by avatars and everybody can visualize their movements and actions inside of the workspace. CLARE supplies a vision of all the works accomplished by group members in a specific window.

**Figure 8: A Pattern Example**

3. Related Works

In the literature we can find some works on development of groupware for learning. Becker and Zanella (1998) introduce a structured cooperation model to aid the teaching/learning process of modeling disciplines.
The process is defined through development of exercises, criticism and discussion of them. A general framework defining a process, roles, and shared objects are provided. This work is restricted to a domain of applications (modeling) and to a specific kind of process.

SECAI Model is defined within CLARE Environment, which is a distributed learning environment which goal is to facilitate learning through collaborative knowledge construction (Wan and Johnson, 1994). The SECAI Model (Summarization, Evaluation, Comparison, Argumentation, and Integration) defines an explicit model of process for collaborative learning of scientific texts, that metaphorically "pulls" the apprentices of an external, isolated and individual position to an internal, integrated and collaborative perspective. This model is limited to represent some issues of the cooperation process. Our proposal goes further than these works defining a complete conceptual model, addressing issues, such as cultural ones, learning theories, roles and evaluation of learning.

4. Conclusions

Research in the area of CSCL found that many of the developed environments do not reach the intended success, that is, to promote cooperation among members of a group to improve learning. Most of the problems are related to stimulus, context, culture and technological problems. We present a Cooperation Model for Learning as part of a proposal to solve some problems in the area of CSCL. The goal is to facilitate the development of cooperative learning environments, supporting the aspects mentioned previously.

We claim that building CSCL environments based on a safe model should produce effective learning by cooperation as a result. One major contribution of our proposal is to analyze non technical problems- cultural influence, educational approach, environmental context - and conjugate them to cooperative activities and the issues associated to them- objects sharing, coordination, evaluation, awareness - providing guidelines for implementation of the activities with a good theoretical basis.

Comparing related works with our proposal, we conclude that few of them are based on an explicit model, and also none of them address all the issues that we intend to support, even for a specific domain. Despite the number of computer supported cooperative learning environment proposals, the use of patterns was not yet explored in CSCL, and specific frameworks practically does not exist for CSCL processes.

Our model includes a series of learning theory approaches, cooperation forms, cooperative activities, and context issues. The system of conceptual patterns obtained from the model will be translated into design patterns and then a software framework can be developed. The framework should be restricted by a set of choices made from those available in the model and should be defined to a particular domain of tasks in order to implement an environment. The resulting environment will be used in a real situation in order to demonstrate the advantages of our approach.

Initiating Constructivist Learning Strategies through Computer Generated Concept Mapping

F. Thomas Scappaticci
King’s College Education Department
U.S.A.
ftscappa@kings.edu

Abstract: We have all felt movement of the tide in education toward resurrecting the concept of constructivism in the hope of increasing meaningful learning for our students. The question of why it has met with so little success in the past has to be pondered, and we have to ask what it is that has to be done if such a worthwhile concept is to prevail in the future. One speculation as to why constructed learning has not met with success in the past is that it may have been over sold as unstructured discovery learning. Discovery learning may be an ideal, but too often the approach is just too impractical. Perhaps we need to bring educators into discovery-learning constructivist practices more gradually. This paper deals with one attempt to do so by introducing constructivist learning strategies more gradually through a guided discovery approach that employs computer-generated concept mapping.

The constructivist view of learning holds that meaningful learning occurs when people use existing knowledge schemes and the viewpoints of others to interpret the world around them with the result being the active creation of knowledge structures from personal experiences. This is at the very core of constructed learning. A “constructivist approach” is a general term used to label all those approaches that hold to the assumption that students should build, that is construct knowledge for themselves. While constructivist explanations of learning are not new, since noted scholars such as John Dewey, Jean Piaget, Lev Vygotsky, and Jerome Bruner to mention a few, have given support to the approach; there has been a resurgence of constructivist thinking in recent years.

More and more contemporary theorists and practitioners have been holding to the idea that children do construct their own knowledge rather than simply learning what someone tells them to learn (Ormond 1995). The personal construction of knowledge concept is based upon the belief that the essence of one’s knowledge can never be totally transferred to another person, because knowledge is the result of a personal interpretation of experience that is influenced by a myriad of factors such as age, gender, ethnic background, and knowledge base (Snowman 2000).

Since constructivist approaches are basically discovery oriented (Lefrancois 1997), the question that we as professors and teachers have to ponder is, “How will this affect our own personal teaching styles and approaches to student learning?” Most of us who teach, whether we care to admit to it or not, tend to fashion our pedagogical approaches to reflect the way in which we were taught, namely via the transmission model. However, even if we were to adopt a more discovery oriented constructivist leaning approach, we still would have to deal with the fact that discovery learning is not without a problem. A faithful application of Piaget’s and Bruner’s ideas suggests an unstructured discovery approach, but research does not support its efficacy (Resnick & Klopfer 1989)(Brown and Campione1994). Students engaging in unstructured discovery activities tend to become lost and even frustrated which can lead to misconceptions. Therein lies the dilemma. The basic underlying assumption of discovery learning, which is at the core of constructivist learning philosophy conflicts with strong evidence that suggests when discovery is presented in the unstructured manner as suggested by Piaget and Bruner, is less than compelling. This paper suggests a more balanced structured discovery-based approach; one that mitigates the problems of an unstructured discovery approach and yet still encourages discovery learning. It is called guided discovery. While it is not an unstructured discovery approach it still embodies the essence of student centered discovery learning (Branford 1993). Studies have shown that when utilizing guided discovery approach students have achieved more transfer of knowledge and more long-term retention than those taught with a more traditional transmission of knowledge model. (Hillocks 1984) (Alexander&Murphy, 1994).

One specific method that seems to have promise in promoting the basic tenets of guided discovery learning is concept mapping. Basically, concept mapping is a technique that allows one to understand the relationships of ideas by creating a visual map of the connections among these ideas. Concept mapping allows students to see the relationship between the knowledge they already posses and the knowledge to which they are
trying to connect, what ever that source might be. Concept mapping can also organize a myriad of ideas in a logical kind of structure employing a type of visual language that also encourages students to operate at all six levels of Bloom’s Taxonomy of the Cognitive Domain (Bloom 1956) (Gaines, Shaw, 1999)(Novak and Gowin 1984). Concept mapping focuses on a topic or an area of interest, and involves input from one or more participants. It can be utilized by an individual student or any number of people in a cooperative learning strategy. The result is an interpretable pictorial view of the ideas and concepts constructed; it graphically shows how the ideas that have been generated from one’s own knowledge schemes are related to the environment attempting to be explained. (Trochim 1999). A well-conceived concept map graphically reveals the shape of the structure, the relative importance of the information and ideas, and the way that the information relates to other ideas. They can be used to think through complex problems by viewing the overall structure of the subject and to associate ideas and make connections that would otherwise appear to be too unrelated to be linked. Another strong advantage of using concept maps is that once a student either individually or cooperatively has developed a concept map, the organization and details of the map tend to be remembered for a much longer period of time than is usually the case when trying to remember the material in text form. (Mind Tools, 1995). The concept maps when utilizing a guided discovery format promote constructivist thinking because it is still the students themselves that build or construct the map with all of its relationships, but the students are not far afield because they are still receiving guidance from the instructor.

In the field of education, the use of concept maps probably began with Ausubel’s learning theory treatment of advanced organizers and meaningful learning which holds that in order for meaningful learning to take place, students must relate new knowledge to relevant topics that they already know, and that teaching strategy in and of itself does not necessarily result in meaningful learning. (Ausubel1963) Ausubel’s work in turn prompted Novak (1977) to develop a system of concept maps which have been applied in a variety of ways within the school setting. (Lambiotte, Dansereau, Cross and Reynolds, 1989) However concept mapping did not have the success that it deserved, namely because they were cumbersome and difficult to draw by hand. This was the case in the past, but fortunately, today we have software that is capable of generating concept maps easily and efficiently. One such program is Inspiration. Inspiration (1999) is a software package that is specifically designed to facilitate the construction and use of concept maps. It is a powerful visual-thinking tool that helps clarify and organize ideas and information. It helps facilitate brainstorming, planning and the explanation of relationships between processes, variables and events by providing some basic tools in the application that make the process of graphing the concept map a relatively easy one. It can easily be adapted by teachers to promote student-centered, discovery based, constructivist, type learning.

Some of the Basic Tools of Inspiration That Can be Used to Facilitate the Construction of Concepts Maps

A. Diagramming: Helps you to quickly record, link and map out concepts within a symbol, and the rapid fire element allows you to put the ideas down as fast as you can think of them while constructing the proper linkage among the ideas.

B. Moving a symbol: A symbol can be moved at any time and when it is moved, Inspiration automatically adjusts the link to clearly show the new relationship.

C. Adding Unconnected Ideas: Sometimes you may have an idea, but are not certain about where it belongs in the whole scheme. The program allows you to add an idea anywhere within the diagram and adjust it at a later time.

D. Changing Symbol Shapes: Inspiration provides a large menu of symbol shapes to represent any number of concepts. These shapes can be easily changed at any time in order to further clarify or emphasize the relationship of ideas or concepts.

E. Drawing A Link: Symbols are connected automatically, but unconnected links can be connected manually at any time, and the program will make the link precise.

F. Adding Text to A Link: When additional information needs to be added to a link in order to further clarify or emphasize the relationship, as is the case in many concept maps, the program easily allows for it.

G. Scrolling and Magnification: The application allows you to move the diagram around within the window or zoom in or out of the diagram.

H. Formatting Symbol Text: Text font, and font styles can be set for the entire diagram or selectively.
I. **Printing to fit:** The print to fit option allows you reduce the diagram to fit to one page or to any number of pages specified before printing.

J. **Switching Between Diagram and Outline Views:** You have the option of working in either outline view or diagram view for your text, and you can alternate at any given time.

K. **Importing and Installing Graphics:** Color or black and white graphics created in other applications can be imported into the *Inspiration* diagram or installed in the *Inspiration* User Symbol Menu.

A thorough grounding in the techniques of concept mapping and the *Inspiration* program will provide all the foundation necessary for utilizing concept mapping successfully in the classroom.

With proper preparation, concept maps that are computer generated can be effectively used as a teaching tool in classes from elementary through college to promote more efficient learning through a constructivist guided discovery approach.

Certifying Technological Proficiencies of K-12 Teachers

Carol Scheftic
University Center for Teacher Education
California Polytechnic State University
San Luis Obispo, CA 93407-0389 U.S.A.
scheftic@calpoly.edu

Abstract: New technologies are regularly introduced in the home, community, workplace, and educational settings. How do teachers, in particular, learn to appropriately integrate new technologies into their personal, instructional, and professional activities? How does a current or potential employer determine the level of proficiency that a given teacher has achieved in a range of technology-based areas? This paper describes how one local educational agency, the San Luis Obispo County Office of Education, has approached those questions, and how their answers fit into guidelines currently under development by the state of California.

The Context

Excerpts from two reports will be used to describe the context in which the work reported in this paper was undertaken.

"Any nine year old who has ever commandeered her parents' computer to surf the Internet, asked a NASA scientist about acid rain, or designed a multi-media language arts project knows what dozens of blue-ribbon panels have concluded in vastly more syllables: 'Computers are cool!' Technology has the power to teach, to motivate, to captivate and to transform an ordinary classroom into a training ground for the next generation of artists, entrepreneurs, and government leaders. The ability of teachers to use technology to promote students' acquisition of basic skills and subject-matter content is critical to education's success. Accomplishing this objective requires front-end preparation, as well as ongoing training opportunities and incentives... to integrate technology into the content and performance standards that will be used as the basis for setting policies for preparing, hiring, evaluating, and promoting teachers." (California Education Technology Task Force, 1996, p.1).

"The California Commission on Teacher Credentialing was mandated ... to establish 'standards of program quality and effectiveness relative to the use of computers in the classroom for preliminary credential candidates, and to establish standards of program quality and effectiveness relative to advanced computer-based technology for professional credential candidates'. As provided by law ... and practice, the Commission elected to select a 'Computer Education Advisory Panel' which was charged to make a comprehensive review and make specific recommendations with regard to computer competency standards." (Computer Education Advisory Panel, 1998, in the Foreword). This report was adopted by the California Commission on Teacher Credentialing [CTC] in December, 1998, and on July 12, 1999, the CTC issued official guidelines describing the new technology standards and the process and timeline for implementing them (Swofford, 1999).
The Issue

Knowing that performance standards for educational uses of technology were coming, in the Fall of 1997 the San Luis Obispo County Office of Education [SLOCOE] put together a group to look at the potential impact this would have locally, on both pre-service and in-service teachers. This group included classroom teachers and technology mentors from the public schools, building principals and district supervisors, technology specialists from the county office and faculty from local teacher training institutions. This Advisory Board proposed a “Technology Certification Program” for teachers, site administrators, and other instructional staff (San Luis Obispo County Office of Education Technology Certification Advisory Committee, 1999).

In developing its recommendations, the Advisory Board first agreed on a number of parameters for a certification program. It was seen as important to provide for multiple levels of certification: basic-level personal computing skills, intermediate-level skills specific to the teaching and learning process, and advanced-level skills relevant to various types of leadership roles. Training would be provided to help educators reach the various levels, but the times, locations, and designs for such training had to be highly flexible. Entry to and exit from training programs had to be as open as possible, and it was important to provide opportunities for people with experience in an area to demonstrate their proficiencies in meaningful ways outside of a formal training program. Finally, evaluation of whether or not people had acquired various skills, either on their own or as part of a formal training program, had to be based on actual performance.

The Process

Based on the recommendations of the Education Council for Technology in Learning [ECTL], a three-tier structure was developed for evaluating the level of proficiency with technology of both educators (California Technology Assistance Project, 1997a) and students (California Technology Assistance Project, 1997b). The educator levels are:

- Level One: Personal Proficiency
- Level Two: Instructional Proficiency
- Level Three: Leadership Proficiency

Educators at Level One are able to use a range of tools for their own purposes. They are able to send and reply to electronic communications in a number of contexts (e.g., personal mail, threaded discussion groups, online chat rooms), and to use basic Internet tools (e.g., web browsers, file transfer protocols). They can use common productivity and display tools. They need not, for example, be expert users at desktop publishing, but they are able to put together a simple newsletter to send home with their students or to help promote a school club’s activities. They need not be able to use all the advanced features of spreadsheet and database packages, but they can use a gradebook program that incorporates those kinds of features. They do need to be aware of legal and ethical issues in computer use, and they must know how to use various tools in a responsible and professional way. They also need to know how to use a range of resources such as manuals, help files, tech support lines, and how to provide a meaningful bug report when seeking assistance. They should feel comfortable with technology: they don’t need to know and remember every trick for every program at their disposal, but they should have both the skills and the confidence to learn new features or programs as the need for them arises.

Educators at Level Two are able to take their Level One skills and extend them to a range of specific instructional settings. They can design and implement activities where students use desktop publishing or display tools to present reports, where they use the Internet to gather and share information or data in various ways, or where the students use a database to organize information and/or a spreadsheet to help analyze it. They know how to appropriately integrate into their instruction and manage a carefully selected set of tutorial and practice software available at their site. At this level, the educators’ own basic technology skills are also improving: they can install, configure, and run more products, and they can do more basic hardware and software trouble-shooting on their own instead of typically reporting problems to a support person.

The expectations, both in the original ECTL report and in the local committee’s recommendations, were that all teachers should be able to reach both Levels One and Two. The SLOCOE panel said nothing about how long it
should take everyone to achieve this, nor about whether schools could or should require their employees to do so. It
did, however, offer mechanisms for both helping schools to provide opportunities for their instructional staff to
improve their skills and for certifying achievement of the proficiencies.

Educators at Level Three were the keys to this plan. This was perceived as a special category, one that only some
educators would be expected to reach. The people at this level are those who act in a mentorship or leadership role
with respect to the uses of technology at their individual schools or across their district. Indeed, it was even
proposed that there would be at least two such types of high-end proficiencies. To present the differences via an
example: a mentor might develop and offer a workshop on personal or instructional uses of databases, while a
leader might review a series of gradebook packages and recommend one for district-wide use. Mentors would
model and serve as advocates for effective and efficient uses of technology, and serve as a coach to their peers.
Leaders would have a major role in development of technology plans, policies, budgets, etc., and would
systematically manage a range of technology resources. A given person who achieved Level Three might function
as a mentor or as a leader, or as both, and there would be distinct certificates to represent each role. But one key to
achieving Level Three status involved being someone who helped to support those striving for Levels One or Two,
or even three, and who understood the certification process well enough to be able to determine if individuals were
meeting the various criteria. Level Three status, furthermore, would need to be re-evaluated on a regular basis. In
order to have their certification at that level renewed, every two years Level Three educators must submit evidence
of the things they are continuing to do to provide such support and of their growth in knowledge of appropriate
emerging technologies. On an ongoing basis, then, individual schools and districts could use their Level Three
people to help identify and meet the professional development needs of those teachers wanting to learn the material
for the various proficiency levels, and the regional certification team could use the Level Three people to do initial
screening of those seeking certification.

Portfolios were chosen as the mechanism for documenting achievement of the various proficiencies. For each level,
there exists a list of competencies, and a number of suggestions for artifacts that can be used to demonstrate each
one. The artifacts are to be assembled into a binder that can be viewed by a Level Three person doing the
preliminary verification, by the regional certification team that reviews portfolios before issuing a certificate, and by
other appropriate people involved in the hiring, evaluating, and promoting of the person. Considerable effort went
into developing the competencies so that they were both specific about the type of skill to be demonstrated, yet
open-ended about how achievement could be demonstrated so as to accommodate site-specific variations in both
expectations and resources. Considerable time also went into determining the possible formats for a portfolio:
although they are being used to demonstrate proficiency with electronic media, it was decided that there needed to
be print-based evidence of the various skills. A few of the criteria can be documented via letters of
recommendation; several others, by having a Level Three educator sign a form stating that the skills have been
demonstrated in person. The majority of the proficiencies, however, are to be demonstrated by hardcopy
documentation. Additional artifacts in electronic form may be included (e.g., on diskette or CD, via URL), but the
panel felt it was important for the portfolios to be able to stand on their own to avoid the restriction that a person
reviewing a portfolio might need a particular computer system or software tool or net connection to view the
material being used to document a given competency.

Once the proficiency levels were defined, the criteria for each level determined, and the process for evaluating
portfolios developed, the next step was to start soliciting portfolios and evaluating them. Since the program was still
in the beginning stages, a small group of Level Three candidates was identified first: people already clearly
recognized as technology leaders in several local districts. The panel worked with this group as they developed their
portfolios, documenting issues that arose and revising the guidelines as needed. These people were required to
submit portfolios that addressed all of the Levels: One, Two, and Three. As the advisory board evaluated the
portfolios, they continued to look both at how well the person met the requirements and at issues in how the process
itself seemed to be working. Once the panel refined the evaluation guidelines, these educators were issued
certificates at all three levels. They were also given guidance on how they were to evaluate the future applicants.
People assembling a portfolio do not have to complete a level before getting a preliminary review. Instead, they
can have a Level Three educator “sign off” on individual competencies to get ongoing feedback on their progress
towards the requirements at a given level. An applicant can, in fact, have different Level Three people sign off on
the various individual competencies: as part of the classroom observation process, during in-service workshops,
after independent study, and so on. All complete portfolios at each level are then reviewed by the program
certification team. This is done to maintain quality control on the process: if a certain Level Three person seems to
be signing off on competencies without documentation that is consistent with the overall guidelines, then action can be taken to make sure that everyone understands the expectations and the need to uphold standards in a consistent manner. When a portfolio passes the certification team’s review, the educator is issued an appropriate certificate from the SLO County Office of Education.

The Next Phase

The SLOCOE process was begun barely two years ago. The Advisory Panel hoped that it would eventually grow into a widespread program, but they did not anticipate the speed at which it has already spread both locally and regionally. In the meantime, as stated in the background section above, the state of California has recently come out with its official standards. The certification panel is currently reviewing the state standards to determine how, if at all, the local proficiency criteria must be adjusted to be in alignment with those. Once that is sorted out, the group will return to the development of a set of recommendations for artifacts that would be appropriate for administrators to assemble into a portfolio demonstrating the technology proficiencies appropriate to their responsibilities.

Some Already-Known Consequences

Some Local Consequences

Individual districts have adopted the certification process in their own individual ways. For example, a few have said that Level One and Two certification will be required within a given timeframe, regardless of any exceptions to such requirements that the state might eventually permit. Others say that a person need not go through the program, but only those who have a certain level of certification are eligible to get new hardware or software. Some offer actual salary increases to those achieving certification, while others provide time or money incentives to attend workshops for developing proficiencies. Some have tried to implement their own version of the program in a certain way, but have had to change their process due to conflicts with things like state formulas for how funds can be allocated or specifics of union contracts. Nonetheless, every district in the region is participating in the process in some way.

The San Luis Obispo County Office of Education has developed a Tech Mentor Program that is designed to give additional help in using technology for the improvement of student learning to schools and districts in its local service area. Each district (according to its size) is allocated a certain number of Tech Mentor service days during which support or training can be provided at no cost to the district using money from several local funds; districts can also buy additional days from their own funds if desired. Tech Mentors are chosen from a pool of Level Three Educators who have registered a list of specific workshops they can offer under various general categories. A school or district person contacts a potential Tech Mentor to discuss the local needs (e.g., dates and times, how much customization is needed, etc.) and to complete a SLOCOE service contract. Since all the Tech Mentors are certified as Level Three Technology Educators, they offer not only the specific training requested but also any needed guidance on how participants can demonstrate relevant proficiencies in their technology certification portfolios.

Some Regional and State-Wide Consequences

In part because of their work in developing this local process, one member of the SLOCOE Advisory Panel was invited to be a member of the California Computer Education Advisory Panel [CEAP] that developed the recent state-wide technology standards, and several others served as reviewers of CEAP’s preliminary recommendations. While the new state-wide technology standards do not mandate a process of portfolio evaluation such as SLOCOE developed, those standards are consistent with such a method.

Word of SLOCOE’s work has spread, and the education offices in several other counties have either adopted a similar program or are looking into the possibility of doing so. The new regional group will typically set up their own certification team that will meet with the San Luis Obispo group to go over the process and consider the impact of variations the new group would like to propose. (Some of those ideas have been good enough that the SLOCOE board has revised its process to match. Others have been ones the SLOCOE group already tried and discarded, and
they are discouraged. And a few have been accommodated as minor variations in the programs across different counties.) The new group and the SLOCOE panel also typically meet to review the first round of a region’s Level Three portfolios together, discussing how to handle any issues that arise.

So far, such certification of in-service teachers is still being handled regionally. The state, through the California Technology Assistance Program (CTAP), has begun to look at ways to handle it state-wide. The initial developers of this process are hoping that CTAP will do something along the lines of SLOCOE’s design: CTAP could review and approve a series of regional programs (as regional groups do for Level Three personnel), CTAP could let the regional panels handle local reviews (as Level Three educators can initially sign off on Level One and Two competencies), and CTAP could still review select procedures and artifacts to make sure the regional programs are maintaining the common standards (as the regional groups do across their local districts).

The work reported in this paper was supported by the San Luis Obispo County Office of Education [SLOCOE] and the California Technology Assistance Project [CTAP]. SLOCOE has an Instructional Technology Specialist position that is staffed on a rotating basis by local educators, and reports to Gary Schonfeldt, Director of Educational Services. The Technology Certification process was conceived, and the original advisory panel was organized and led, by Sheldon Smith (ssmith@mail.sloco.k12.ca.us), Director of Technology and Information Services, Paso Robles Public School District, during his term as IT Specialist (1997-1999). The program is continuing under the direction of the current IT Specialist (1999-2001), Cheryl Hockett (chockett@mail.sloco.k12.ca.us), while she is on leave from the Atascadero Unified School District. The local advisory panel that developed and maintains the program typically has about eight members at any given time, and thanks are due to about two dozen local educators who have participated on the panel at various points along the way. Sheldon Smith, Jim Martin (of Atascadero), and the author of this paper are the members of the current panel who have served with the group continuously since its inception.
Abstract: This paper looks at the connection between organisation, collaboration and learning in virtual learning environments (VLEs). Our main points of focus is investigating the extent to which course developers and course instructors need to consider organisational measures and design to trigger (self-guided) learning and collaboration of participants within online learning environments and how deeply individual learning processes are stimulated by intercultural collaboration in multinational groups. The design of these virtual learning environments or learning networks involves an intricate balance between the organisation of the content; how the instructional activities are sequenced; how the interactions between students, tasks, and materials are structured; and how the learning process is evaluated. Mentorship must be present throughout this process. Aspects of mentorship can manifest themselves in a variety of ways including: asking an expert, true mentoring, tutoring, and peer to peer support.

Introduction

Our starting point and subject of this study is the "Online Seminar" of the University of Innsbruck and the Saarland University, which has run six times over the past few years, and has dealt with various topics (http://seminar.jura.uni-sb.de). Special concerns for this course include:

- It is directed towards an international audience
- It accommodates a large number of participants (100-250 people)
- It has diverse student profiles, i.e. a mixture of students and people already working in their profession (mixture of university and continuing education)
- It actively integrates all participants
- It utilises collaboration as a vital part of the course concept
- It is transparent in all activities
- It provides constant evaluation
- Keeping the course concept as flexible and open as possible

One advantage of online courses is the potential for communication, collaboration, and the constant exchange of knowledge between students and educators, which brings them closer to (and perhaps supersedes) "real life" teaching. The Online Seminars has opened up new possibilities for students and teachers, and permit interdisciplinary and international collaboration but have also proven to be far more time and personnel intensive than regular courses. Computer-Mediated Communication (CMC) therefore becomes an important research area for education. In this paper some basic thoughts about the development of communication-centred online web-based courses will be discussed and related to some of our experiences concerning the development and administration of such courses. For this purpose the structure and content of the recent online course will be
described identifying problematic aspects specific to online courses and how those issues might be resolved in future courses. Our investigation explores the role of organisation of communication and moderation, the analysis of interactivity and working styles, and the results of the learning process. The questionnaire filled out by the participants points out student opinions and finally adds another perspective concerning the effectiveness of such kind of courses.

Designing collaboration and learning

These issues are complex and varied. Some of the requirements for designing and developing effective online courses are, attention to motivation and that it must afford interactivity. A vast investment of time and energy during the design, development and the realisation of such online courses are mandated to ensure organisational and support activities to ward off potential problems. Online VLEs present technical, transitional and pedagogical concerns. As (Harasim et al. 1995) notes, "an online mentor is a professional in a particular subject area who provides on-going feedback until the apprentice (student) masters the learning task. At that point the mentor fades away, and the apprentice engages in the exploration of expert practice." Mentorship then takes on several added dimensions within a virtual learning space. The VLE presents a new atmosphere that the student and teacher must learn how to navigate. Online support must, on one hand, mentor technical work and on the other hand provide online course support to mentor content and guide the learning process. This melding of mentorship and purpose begins to reshape the face of learning and education. Without the active help of professors and lecturers (occupied with content support, management and didactics) as well as a number of students who volunteered to assist as moderators during the online course the high goals set for the course could not have been reached.

In an online environment you can expect mentoring to take on a new dimension. Here we are challenged to mentor in ways that (Feuerstein et al. 1980) and others define as mediation. By facilitating, modelling, and coaching we begin to have new insights into mediation, instructional strategies, response to learner queries, and facilitating online discussion and fostering critical thinking. We anticipate, through an analysis of the discussion threads and collaboration threads, that we will be able to identify types of dialogue as well as a framework for guidance to support and facilitate a collaborative online environment.

Dialogue and inquiry become a powerful medium for collaborative learning. Discussion begins to carry a flow a meaning. Threads of conversation can be woven together. Opinions and points of view become circulated as observations, assumptions and interpretations become visible. Effective guidance and mentoring can be achieved through selective intervention. A skilled moderator is a mentor who can keep the fragile balance between advocacy and inquiry. The moderator must facilitate rather than dominate the discussion. When we focus on (Vygotskys 1978, 1986) idea of the learner's zone of proximal development, scaffolding, and dialogue, we have to turn our attention to fostering learning via virtual discussions, using strategies that include "voice", address learning and writing styles, and utilise Socratic dialogue. These ideas require us to tend to both the individual and group learning process. If we want to further online discourse, it is important not to forget that this learning process is complex, social and interactive. Research in social collaboration and negotiation in the vein of (Slavin 1987) and others, calls attention to the design and support of what these learning environments require. Responsibilities for discussion become shared, feedback becomes integral, and all participants, including the moderator, are equal. Both instructor and learner are challenged to grow and develop in this environment. Instructors grow to become moderators and guides and students grow as learners.

Our goals as moderators and discussion facilitators is to keep the "conversation" flowing, focus and refine ideas, challenge/ask learners to explore deeper into critical issues, and support and scaffold an online community. Facilitating this critical thinking begins with the questioning process. Questions need to stimulate creative thinking and exploration of a topic. Marrying strategies related to electronic communication and critical thinking will help foster a community of learners in a virtual environment. If the moderator demonstrates skilful and thoughtful questioning to engage discussion participants, learners begin to learn how to ask questions of each other. Engaging questions will stimulate discussion and participation, if discussion lags; the attentive moderator will step in to perturb the process. Although there are no right or wrong answers, there are right and wrong questions. The "right" questions provide the seeds for conversation that empowers the learner to actively participate and contribute. Student ownership of information, their ability to present and defend a position, and the exchange of ideas all enhance the learning process.

1030
Online collaboration as well as effective moderating *must* be designed if it is to have comparable impact to face-to-face instruction. Through conscious effort and application "virtual" moderators can bring voice and tone into an otherwise sterile and distant environment, accompanying the learner as a reflective guide or maybe even much like a personal muse. Moderators are mediators and facilitators; generative guides and conceptual facilitators. The same issues that can be a weakness in a virtual learning environment can be exploited creatively to make learning come alive.

Active learning is at the heart of the design of the Online Seminar. Designing activities that ensure active participation is part of the moderation and discussion process. Facilitating the discussion is one aspect. Another aspect is making the discussants responsible for their own learning by sharing the responsibility and leading group discussion and work. Roles that are scaffolded and modelled by the facilitators become shared then taken over by the participants. All participants in the course are provided the opportunity to experience being facilitators in discussion, team leaders, presenters of information, observers, and all are responsible to provide feedback and input into the learning process. However, for any of this to occur, a certain amount of control needs to be relinquished and turned over to the group. Moderators must stay in the shadows allowing the learner to shine.

But perhaps at the heart of design is the feedback, feedback that the moderator needs to provide in order to support the learning process. Feedback that promotes and encourages continued growth as a learner and encourages collaboration. Substantive feedback not only needs to be built into the course design, but also needs to be modelled by the facilitators if we are to expect quality feedback from students. Feedback needs to be constructive. Connections need to form between participants; commonalities as well as differences need to be discussed. A shared interdependence creates a collaborative environment.

Our goal was that course design and development would reflect a commitment to high quality related to state of the art research for teaching and learning. Hence, "active learning" and a focus on the "communicative process" between and among students and teachers were considered to be essential as we investigated designing "rich online learning communities". Since it is a virtual environment to be implemented based on the Internet, it was clear that quality could be enhanced if the potentials of the Internet could be exploited. Those potentials include information and communication potential; the flexibility of time and space of learning; and access for everyone without the need of additional financial investments in equipment or tele-communication. Therefore the design of a flexible learning environment needs to consider:

- **Openness in design towards;** user-groups to address needs (cultures, disciplines, professions, number) for teaching and learning, media being integrated, implementation of pedagogical features and feedback from learners and other participants
- **Flexibility towards;** applied educational concepts and their evolving updates, contents to be delivered, applied pedagogical modes and methods for teaching and learning, duration of courses, application of (and changing) technologies and evolving design
- **Realising an active participation of all persons by;** supplying and integrating the communication tools needed and integrating motivational features for improving/enhancing interaction
- **Easy-to-use for learners and instructors, in form of low technical barriers, motivational atmosphere and providing administrative tools**
- **Taking into account existing resources concerning, technology, personal and finances with a clear perspective for future continuation (no project status!)**
- **Integrating a platform for following research interests and improving education (e.g. via evaluation).**

There is a tension between pedagogical needs and resources and efforts in regard to finances, organisation and technology. Therefore a compromise must be found for defining the requirements taking into account economical and technical issues as well as specific legal regulations in formal education that define obligations related to privacy, fees, etc. when running an online course.

As (McGreal 1998) notes that commercially available integrated distributed learning environments such as CourseInfo (http://www.blackboard.com/) are popular given: the lack of sustained yields for individual course development within curriculum, the high time investment for instructors, and the lack of a supportive technology infrastructure. Despite the administrative and implementation advantages these course management systems offer, these packages lessen the authoring power of the instructor, assume specific pedagogical approaches, confine in some ways the delivery of instruction, and limit the control of the instructor over the learning environment. Given our requirements and needs, we wanted control over the tools and delivery method to be able to be responsive and adaptive to learner and instructor needs relative to the content being
presented. We wanted the learning environment to be able to evolve and grow. We also wanted the environment to be learner centered and learner driven – hence our focus on creating community and a collaborative learning environment. Subsequently design looked to the aforementioned needs for input rather than limiting the design and development to adhere to a singular learning theory. Rather, we focused on developing a set of tools for the learners and designed how we asked that learner to engage the information to create the kind of interactivity and the level of ownership needed within the learning process. We intended to create a "rich" learning environment, which Wilson describes as a setting in which the student is "engaged in multiple activities in pursuit of multiple learning goals, with a teacher serving the role of coach or facilitator" (Wilson 1996).

Since the idea is the building of "learning communities" to achieve better and more active learning processes by the students a definition of constructivist learning environments given by (Wilson 1996) would fit best to the Online Seminar environment: “a place where learners may work together and support each other as they use a variety of tools and information resources in their guided pursuit of learning goals and problem-solving activities”. However, not all tasks performed within the courses are constructivist. It is Apparent within the design the influences of other learning theories and pedagogical assumptions e.g. such as cognitionism and social constructivism. Cunningham et al. (1993) listed several principles for the design of a learning environment:

- Provide experience with the knowledge construction process,
- Provide experience in and appreciation for multiple perspectives,
- Embed learning in realistic and relevant contexts,
- Encourage ownership and voice in the learning process,
- Embed learning in social experience,
- Encourage the use of multiple modes of representation
- Encourage self-awareness of the knowledge construction process.

These principles becomes instructionally designed focused and more concrete when taking a look at (Xiadongs 1995) presentation of a typical instruction design process:

- Identify objectives (e.g., what do you want students to be able to do when they have completed the instruction?)
- Assess students' prior knowledge and skills (e.g., determine whether the target students have the prerequisites to benefit from the instruction)
- Specify the content to be taught (e.g., what content skills should be taught to students?)
- Identify instructional strategies (e.g., what instructional methods should be used?)
- Develop instruction (e.g., a learner's manual, instruction materials, tests, and an instructor's guide)
- Test, evaluate, and revise (e.g. how should students be evaluated to determine the degree to which students have meet the performance objectives?)."

It must nevertheless be stated that providing education in virtual learning environments requires a multitude of facets to be considered as can be seen from this preceding list.

Organising collaboration

The online seminar is a co-operative international venture. The roles of each of the co-operating institutions dependent on the focus, resources, personnel, and disciplines of these institutions. Currently (Summer 2000) this collaborative venture involves participation of Higher Education institutions in Germany, Austria, Sweden and Kazakhstan. Each of these institutions may in turn collaborate with other local institutions. Co-operative decisions are based on common educational and research interests, competence, persons in charge, technical resources and the cultural background. Educational interests can therefore be implemented in ways not known before ICT (Information and Communication Technology) and the Internet was available.

On a broad scale, collaboration takes place among students, between students and teams, and among team-members. Student collaboration needs to be organised and co-ordinated too. No learning environments are known in formal education, where students meet voluntarily in order to collaborate for performing certain certified tasks. Taking a closer look at the role of collaboration will show considerations to be globally viewed on four levels; On the students level within the course, on the team level within the course, on a local level and finally on an institutional level: i.e. collaboration between international universities.

The Online Seminar-environment different teams consist of some 30 individuals from many different countries. These team members are lecturers, agents, volunteers, former seminar participants and students...
doing research work. Most of today’s volunteers in the moderation of group discussions are former students of the seminar. Several tightly bonded groups have been formed as a result of the seminar on varying levels. For example "Cyber Grannies" was formed by some of the student cohort during the 1999 seminar. Consider too, this paper is a result of collaboration between the principal project investigator, and two former students of the seminar who are now members of the team. Learning processes are also encouraged for the team – currently we are developing training for moderators. As you can see, design is complex and multi-faceted.

Learning within the environment is structured to be multi-levelled and complex. Learners are learning from the team, but also from other learners. The team is learning from learners and other team members and participating institutions are learning from learners, teams and other institutions. These complex webs of different learning levels are intimately related to the collaboration taking place across all these levels. Meta-learning is built into the design. Feedback has shown that learners rate this collaboration structure highly.

Learner Profile of participants in the 1999 summer term Online Seminar in short are; 224 students from 46 different universities, 19 academic specialties were represented from humanities to technology, 88 participants held some form of employment, 37 countries were represented an the ages ranged from 20 to 64

A questionnaire was administered to determine attitudes towards the Seminar and the model of online collaboration and learning. Seminar students where asked to grade the seminar on a scale from 1 (very bad) to 10 (excellent). Of those grading the seminar (80 respondents), 70,1 percent gave a grade of 8 or above, and only 5 percent gave a grade below 5. Apparently the participants have high regard for the Seminar. Still the really interesting question is whether the participants perceive any improvements in their skills. The theme for 1999 Online Seminar was "Using the Internet in Professional Life", and the participants where asked a few questions on whether their abilities in using the Internet had changed. Most of the participants were active students, and their professional use of the Internet is primarily for studies. This activity may or may not include using Internet in their chosen field of future professional careers. Two question on this subject where given to the participants, who using a 5 point scale where, 1 = no improvement and 5 = very much improved. On the question if the Seminar helped improve the participant’s ability to use Internet in studies, 77,6 percent gave a grade of 4 or 5:

This seems to indicate that a goal of these participants was to learn new ways to use the Internet to facilitate studying. The 1999 Seminar topic was in Legal work, participants were also asked if their knowledge in this area improved during the Seminar. Although the answers on this question were a bit more evenly distributed, the overwhelming majority responded that their skills had improved.

Group work is central to the Online Seminar. Given that the requirements are to collaborate with "strangers", this requirement becomes embedded in the strategy of the course design to promote active learning. Given this social dimension, it is critical that design supports this framework for building learning communities. As already stated by (Hermes 2000) students learn "to take responsibility in their hands and work in groups as autonomous learners". They build "virtual teams" (Berg 1999) and follow strategies in completing their tasks by developing and transforming their ideas.

A lot of planning and creativity has gone into the design of the tasks for participants. Special care has been given to developing questions that require the active use of Internet, and facilitate extensive co-operation of group members. This deliberate design opens up the possibility of meta-learning, i.e. changed knowledge regarding online group work. And it is interesting to find out that the students, in general terms, are grading their improvements higher in these areas. Almost half of the respondents (44,7 percent) graded their improvement as high as 5 (on the 5-point scale) and another 34,2 percent graded the improvement as high as 4. Additionally, when participants are asked if the seminar should be offered in the future, 68% of respondents have rated this response with a 5.

Conclusions

We have investigated several aspects related to creating a socially constructed course design model. We have also reflected on, and asked if teachers and learners are flexible enough to adapt to these innovative forms of education. Active learning needs to be encouraged and facilitated through supportive design. This design needs to have structure and clearly demarcated support, the learner, especially within the current education system, cannot solely construct it. But there need to be guidance for teachers as well in order to get acquainted with and used to new methods and attitudes of learning.
The future of learning is still to be found by exploring the connection between organisation and collaboration. Organisation will be facilitated through carefully constructed collaboration. There are still questions to be answered. How are media selections for communications viewed and preferred by participants— and why? The research related to administrative functions is sparse. Collaboration needs to be organised on three levels: institutional, conceptual, and on an individual level. Investments of time, money, and effort need to be considered.

As we consider the Online Seminar several things have become apparent to the team in the design, development and delivery of this course. Current work and research has been based on face-to-face instruction, we are only just beginning to compile information and experience for virtual learning environments. Adapting pedagogy from face to face instruction to virtual environments is first step in the emergence of a pedagogy that is rooted in VLE’s. For example, research in computer-mediated discussion in quasi-synchronous environments has found that the learner assumptions and interpretations are very different in a VLE because their assumptions and interpretations are based on face-to-face interactions. Continued efforts and investigations will help refine the research process.

The courses within this collaborative learning environment demonstrate that there is no need to discuss whether there will be a future for teacher’s profession competing with online courses. The concept of this environment foresees a very active role of the teacher as an organiser, mentor and/or moderator. But there are still strides to be made in the research on applying effective methods for teaching in collaborative learning environments.

What has the Online Seminar accomplished so far? It is believed that progress to date has produced a very good test bed for investigation of the following aspects: the organisational methods for this kind of activity, methods of training teachers in online teaching, and how to use available resources more effectively.

Flaming, Banter, And Bonding: Understanding The Rhetoric Of Electronic Groups

Rae C. Schipke
Department of English
Central Connecticut State University
Schipker@ccsu.edu

Abstract: This paper discusses group process and development from the perspective of language use in the networked interactive writing context over time. It asserts that cohesion is a significant factor in group development and that the degree of peer pressure in the form of "writing behaviors" is very strong at the beginning of a group but lessens over time to bring about a cohesive functioning of that group. It begins with a definition of what a small group is, continues with an overview of the research on classrooms, socio-psychological environments, and computer-mediated versus face-to-face groups. It provides an overview of several applicable models in the group development literature as a conceptual framework for studying how students communicate in electronic groups, and concludes with suggestions for needed research on electronic groups.

Introduction

The advantages of working together for common benefits are often unmistakable. Collaboration allows students to combine intellectual expertise and material resources to accomplish a project or task of mutual interest (Kraut, Egido, and Galegher 1990). It also allows them to undertake problems that they are incapable of working on alone because of limitations, resources, and time. When students work together on electronic networks, teachers need to view communication and development as part of a larger phenomena--small group process. To successfully manage electronic groups, teachers need to understand both the nature of the electronic classroom context and the behavior of the students in it. It is through the language-based dynamics and variables that are at work in these contexts that teachers can become aware (1) that language use in the form of "writing behavior" reflects the process of group development in electronic group situations and (2) that time and peer pressure are two key factors which seem to directly affect the development of the electronic group. This understanding will require considerable study.

The Small Group

The term small group applies to both face-to-face and electronic groups. A small group is usually considered small if it has 2-30 members. However, even larger groups can have small group characteristics. What differentiates a collection of individuals from a group is that "group members (1) have shared values that maintain an overall pattern of activity, (2) acquire or develop resources or skills to be used in their activity, (3) conform to norms that define roles to be played and have a sufficient level of morale to provide 'cohesiveness,' and (4) have a specific goal with the coordination, usually through leadership, to combine the resources and the roles to accomplish the goal" (Hare, Blumberg, Davies, Kent, 1996). Most group members also need time to develop intimacy.

The Nature of Classrooms

Like networked environments, regular classrooms are very unique environments for learning in their own right. Doyle (1986) in his work on classroom management and organization, notes that there are six features that make any classroom a unique environment of its own. These features are:

1. Multi-dimensionality -- many different events and tasks occurring
2. Simultaneity -- many things are happening at the same time
3. Immediacy -- events are taking place at a rapid pace
4. Unpredictability -- events are taking unexpected turns
5. Publicness -- events are witnessed by many
6. History -- classes develop their own past--early events shape subsequent actions

In a sense, then, any classroom is a highly complex and potentially unstable environment. This is even more true of the computer classroom, for when we add network technology, we create even more complex types of social forums. On electronic networks students can enter a group, experience group process dynamics, and engage in social discourse without ever having encountered another human being in face-to-face interaction. Given the complexity and unpredictability of such classroom environments, the teacher understandably is going to be concerned primarily with classroom (or network) management--taking the necessary steps to ensure that the students are both attentive and not disruptive. Leadership and management skills, then, take on a whole new dimension in these classrooms, as do the underlying social philosophies and pedagogies.

Classroom Environments: The Research on Socio-Psychological Environments

If most classrooms provide highly complex and potentially unstable environments, requiring such management skills, there would be benefit in knowing what factors suggested in the literature contribute to a more simple and stable environment for students. The research on socio-psychological environments suggests that the socio-psychological environment, for example, correlates highly with both student attitudinal and achievement outcomes. Hattie, et al. (1987), who looked into perceptions of students' preferred learning environments, concluded that students preferred environments that provide more teacher friendliness, less competition, and greater cohesiveness. A research synthesis by Haertel et al. (1981) found that improved achievement was present in classes where there was greater satisfaction, more goal direction, less disorganization and friction, and greater cohesiveness. Moos (1980), who evaluated 200 classrooms using the Classroom Environment Scale (CES)(Moos and Tricket, 1974) concluded among other findings that classrooms that combined warm supportive relationships with a focus on academic tasks and accomplishments in well structured surroundings tended to lead to a gain in achievement and led to personal and creative growth as well (see Figure 1). What is suggested by the findings of this research is the general importance of the socio-psychological environment in student learning and a general consensus that an effective environment addresses both student perceptions and results in better achievement.

Supportive relationships
+ Well Structured Surroundings
= Achievement, Personal Growth & Creative Growth

Figure 1: Components of an effective learning environment.

Networked Environments: The Research on Computer-Mediated and Face-To-Face Groups

While classroom environments solely involve face-to-face interactions between and among students and the teacher in the classroom, computer-mediated groups in networked environments (with the exception of classroom-based LAN's), have primarily electronic interactions. In addition to the research on socio-psychological environments, there are findings in the research on computer-mediated and face-to-face groups which suggest the highly complex potentially unstable nature of the electronic environment (see Figure 2). For example, studies using small experimental groups of variable duration found that computer-mediated groups had a more equal participation rate (Easton et al.; Hiltz, Johnson and Turoff 1986; Siegel et al. 1986) and took longer to reach consensus (Gallupe et al. 1991, Siegel et al. 1986) than face-to-face groups. They also found that computer-mediated groups engaged in more inflammatory communication (Siegel et al. 1986), task-oriented behavior (Hiltz et al. 1986), and socio-emotional communication (Hollinshead, McGrath and O'Connor 1993). The lack of consistency in these findings in terms of task and communication variances can be explained in Walther and Burgoon's (1992) research which found an interaction effect of social behaviors and task orientation. They found that in extended time
asynchronous computer interactions, computer-mediated groups became less inflammatory, less task oriented, and more social.

Figure 2: Research findings on face-to-face and computer-mediated groups.

---

**The Common Ground**

What is apparent from these findings on both classroom environments and computer-mediated versus face-to-face groups is that communication is at the heart of any group situation, whether it is a traditional classroom or an electronic group, particularly as it relates to the human intimacy in the interaction. What is also apparent is that all types of social interaction are an attempt by participants to 'fit in', much in the same way that teenagers attempt to fit into the peer group. According to communication theorists, all behavior is communication and all effective communication requires a shared culture. If cohesion is a consistent outcome in student perception of what constitutes an effective environment as well as in achievement ("a shared culture"), then time will play a significant role in achieving cohesion. If behavior is communication, then the students' writing will reflect that behavior. Lastly, if peer pressure influences behavior, it also makes sense that students' "writing" behavior will change over time in the electronic group context.

---

**Working Within Established Models and Formulations on Group Development**

Face-to-face group development research suggests that groups do, indeed, move through stages associated with specific turning points in group activity. Many researchers, for example follow the formulation of Tuckman (1965). Farrell, Heinemann, and Schmitt (1986) following the formulation of Tuckman, distinguish four phases which identify the change in salience of roles. In phase one, referred to as testing and dependency, group members are uncertain by what is entailed in group membership and what is to be gained by it, while at the same time trying to gain some sort of orientation and guidance. In phase two, or conflict, there is a great deal of polarization and conflict, which is followed in phase three, known as cohesion and consensus, by members beginning to trust one another and to master work demands. In phase four, referred to as functional role relatedness, group members have achieved a structure and culture for the group and fully cooperate on tasks.

Robbins (1993), also proposed a model using the terminology of Tuckman (1965) and also the theoretical underpinnings of Gersick, whose work addressed the factor of time. Tuckman's stages of development include (1) forming, (2) norming, (3) storming, (4) performing, (5) and adjourning, and according to Gersick (1988, 1989), group development is underscored by periods of inertia and highlighted by periods of change. The model proposed by Robbins, therefore, addressed both the sequential and cyclical aspects of Tuckman and Gersick and had five stages which included (1) forming and norming, (2) low performing, (3) storming, (4) high performing, (5) and adjourning. (see Figure 3)

Srivastva, Obert, and Nielsen (1977) offer another valuable perspective on group development by presenting their five stages both in terms of the structural issues and in terms of the basic issues that are being dealt with by the group (see Figure 4). They suggest that group members move from wanting inclusion, to dealing with influence, finally arriving at intimacy.

**Needed Research**

Each of the previously discussed models, focuses on various factors in group development. They suggest as did the literature on socio-psychological environments and computer-mediated groups the central importance of communication and time in the group development process and the important role communication and time play in lessening peer pressure and thus creating cohesion in groups. However, social understanding of student behavior will only come with the study of the interactions of students within smaller communities such as the classroom (face-to-face) or within the shared culture of a small electronic "peer" group. One study which began to address this need, Schipke (1992), summarized the characteristics of student writing behavior and language use over time on a computer network. Based on a review of electronic transcripts and data it was found that when the group lacked cohesion and peer pressure was strong students engaged in unproductive writing behavior and language use. When group cohesion was attained after a period of time, peer pressure lessened and students began exhibiting more positive and productive writing behavior and language use. These findings applied to the revelation of thoughts and ideas; to response time, length, correctness, direction and focus; and to language choice and use (see Figures 5 and 6 for a presentation of the specific characteristics in the context of the Farrell et al. and the Robbins models respectively).

**Conclusion**

Understanding what transpires in electronic groups will take considerable investigation. The literature suggests that such investigation will need to be conducted over time to understand the growing pains of the electronic group through the kinds of communication taking place in that context. It also indicates the importance of such factors as cohesion, peer pressure, and writing behavior in furthering our understanding. These aspects will be important, but will only be a small piece of the research understanding necessary to teach effectively using electronic groups. Understanding will also require the study of assorted types and sizes of groups, different technological platforms, diverse communication processes, various roles and behavior, group tasks, group functions, socio-emotional variables, and comparisons to face-to-face and/or classroom contexts, just to name a few. However, these kinds of longitudinal observations can reveal valuable insights into effective pedagogy and management for the electronic instructional context.
PHASE ONE: Testing and Dependency

Self-conscious about revealing their thoughts and ideas
Lag time in response to posted comments
Express themselves using brief comments or short sentences
Overly concerned with grammatical or spelling errors
Discussions seem chaotic and undirected
   Lack focus and commitment
Tend to play using language

PHASE TWO: Conflict

Engage in grandstanding behaviors through
   Disruptive comments
   Obscenities
   Iconoclastic use of language

PHASE THREE: Cohesion and Consensus

Enthusiastic and willing to share thoughts and ideas
Quick response time to posted comments
   A more fluid dialogue tempo is maintained
Write longer, more reflective comments
Less concerned with surface errors/more concerned with expressing their
   ideas correctly
Discussions and interactions appear to have direction and purpose
Tend toward playful use of language/compete for originality of content and form

PHASE FOUR: Functional Role Relatedness

Engage in group and task maintenance procedures through
   Supportive and focused comments, Constructive criticisms, Suggestions
Engage in Closure through
   Ending comments including reflections, congratulations, goodbyes.

* Identifies the four phases in group development (Farrell et. al) following the formulation of Tuckman (1965), and notes the
language behaviors (Schipke 1982) that are prominent during each phase.

Figure 5: Group development from the perspective of student writing behavior over time In the context of
Farrell et al.’s four categories.

FORMING AND NORMING:

Self-conscious about revealing their thoughts and ideas
Lag time in response to posted comments

LOW PERFORMING:

Express themselves using brief comments or short sentences
Overly concerned with grammatical or spelling errors
Discussions seem chaotic and undirected
   Lack focus and commitment
Tend to play using language

STORMING:

Engage in grandstanding behaviors through
   Disruptive comments
   Obscenities
   Iconoclastic use of language
HIGH PERFORMING:

Enthusiastic and willing to share thoughts and ideas
Quick response time to posted comments
A more fluid dialogue tempo is maintained
Write longer, more reflective comments
Less concerned with surface errors/more concerned with expressing their ideas correctly
Discussions and interactions appear to have direction and purpose
Tend toward playful use of language/compete for originality of content and form
Engage in group and task maintenance procedures through
Supportive and focused comments, Constructive criticisms, Suggestions

ADJOURNING:

Engage in Closure through
Ending comments including reflections, congratulations, and goodbyes.

* Identifies the Five Stages in group development (Robbins 1993) who used the terminology Tuckman (1965) and the theoretical underpinnings of Gersick (1988, 1989), and notes the language behaviors (Schipke 1982) that are prominent during each phase.

Abstract: As faculty and institutions continue to adopt the World Wide Web for delivering course materials, they are encountering a host of related problems. Institutions must from everyone from novice users to faculty who want to go beyond the normal capabilities of HTML. Sites must often brand themselves with a uniform "look and feel" and also support easy updates to that look and feel. Sites must also support some form-based page generation.

In this paper, we discuss SATIRIC (Site Authoring Tool Incorporating Regular Expression In Context), a pattern-based translation language developed to support these and other activities. We argue that a pattern language is an appropriate solution for many tasks. Novices can write text files and use preferred shorthands; the transformation language can turn those shorthands into HTML, XHTML, or XML. Experts can write new tags and define transformations from those tags. Institutions can define standard page templates and transformations that convert inputs to those templates. For a new look and feel, they can just change the templates.

1. Introduction

Web authoring once was fairly simple: those who wanted to use the Web created a few pages a favorite authoring tool (or "raw HTML") and put it on the Web. The enormous growth of the Web has changed everything, particularly in academia. Institutions must now worry about supporting a wide range of page authors, from faculty reluctant to going online to faculty eager to adopt every new technologies. Similarly, the movement toward sites containing thousands of pages has led many to brand sites through uniform designs. Unfortunately, support for these different issues is often handled in a somewhat ad-hoc method, often leading to contradictions. For example, novice faculty are often trained in simple packages (often PageMill or "save as HTML" in newer versions of Microsoft Word). But neither PageMill nor Word's save as feature make it easy for novice authors to adhere to a site style. (Thimbleby 1997) has suggested that we can support uniform site styles through templates plus variables. That is, we can extract information about a page (author, body, title, etc.) and then reflow that information into a template that provides the site style.

But this is not the only way to transform pages to meet stylistic needs. Pattern-based page transformation languages (e.g., (Rebelsky and de Beer 1998) can permit site designers to specify standard changes to pages, such as "change all body tags so that documents use the following colors and fonts" or "change all list items to use filled circles". By careful design of rules, it is possible to automate most important aspects of site design.

In this paper, we describe a particular pattern-based page transformation language, SATIRIC, the Site Authoring Tool Incorporating Regular Expressions in Context. Unlike general-purpose pattern-based languages, such as Perl and Awk, SATIRIC is designed specifically for developing and transforming formatted text. SATIRIC supports rich patterns through the use of regular expressions. It adds power to these patterns through the use of variables and by permitting regular expressions to be applied in only certain contexts.

SATIRIC is designed so that a wide variety of users can easily write rules. Typically, authors will describe their general intent and programmers will develop the rules to meet that intent. However, we are developing a user interface that permits authors to write English-like text to describe their rules. For example, someone might write that "A blank line signals the end of a paragraph" or "At the start of a section, increment the heading level and generate an appropriate heading tag; at the end of a section, decrement the heading level".
In Section 2, we introduce the contextual patterns of SATIRIC through a number of related examples. In Section 3, we delve more deeply into regular expressions, which serve as the patterns for SATIRIC. In Section 4, we describe the architecture of SATIRIC and the SATIRIC assembly language. In Section 5, we suggest applications of SATIRIC for advanced HTML authors. In Section 6, we discuss future directions for SATIRIC.

2. Supporting Novice Authors and Plain Text Authors

As institutions are moving toward online course delivery and support, they are finding it necessary to support faculty who are less comfortable with computers than early Web adopters. Some of these faculty don't see a purpose to Web-based delivery, and those faculty are a special problem. Others are interested in going online, but don't have the time or energy to devote to learning a new computer program, even one as simple as PageMill or FrontPage. While it is possible for such faculty to use a favorite word processor and export as HTML, the resultant HTML is often unsatisfactory to both faculty member and site designer.

However, experience shows that most faculty (and most writers), use “shorthands” to indicate common typographical issues. Consider the sample text in (Fig. 1), which one might type in plain text to describe the formatted text in (Fig. 2). In (Fig. 1), a blank line indicates the end of a paragraph, an asterisk at the start of the line indicates a list item, text surrounded by underscores is emphasized, text in brackets is a link (to a bibliography entry), indented text is a quotation, the underscore indicates a subscript, the caret indicates a superscript, and so on. The first goal of SATIRIC and its predecessor, SiteWeaver/SH (Rebelsky and de Beer 1998) is to support the transformation of such shorthands to HTML or other markup language.

In our analysis of [Jones 1998], we found that it is trivial to improve his algorithm from \(O(n^2)\) to \(O(n \log_2 n)\), using a simple *divide and conquer* strategy. Jones writes,

The algorithm must visit each element of the collection, one-by-one. Although a few elements need not be visited, because they are irrelevant, the number of visitations in one round is clearly \(O(n)\).

However, we have found that it is possible to preprocess the data with the following strategy:

- Select a _separator_
- Divide the collection into two equal halves using that separator
- Recurse on the two halves

**Figure 1:** Shorthands in plain text.

In our analysis of [Jones 1998], we found that it is trivial to improve his algorithm from \(O(n^2)\) to \(O(n \log_2 n)\), using a simple divide and conquer strategy. Jones writes,

The algorithm must visit each element of the collection, one-by-one. Although a few elements need not be visited, because they are irrelevant, the number of visitations in one round is clearly \(O(n)\).

However, we have found that it is possible to preprocess the data with the following strategy:

- Select a separator
- Divide the collection into two equal halves using that separator
- Recurse on the two halves

**Figure 2:** The same text, reformatted.

How do we translate these shorthands into HTML? We need patterns to describe the various shorthands. For example, in the standard regular expression notation, `\^\*\` represents “an asterisk at the start of the line” and `\n\n` represents “a blank line”. Yet these patterns are not enough. Observe that the context of a pattern has some effect on the application. For example, any blank line you encounter signifies the end of a paragraph, as long as you are in a paragraph. Similarly, an underscore has two possible meanings: emphasis or subscript. How can we tell which the author means? Typically, through the context. For example, if the underscore is used as part of a mathematical formula, it is likely to be a subscript. (Fig. 3) shows the translation of the original text to HTML.
In our analysis of [Jones 1998], we found that it is trivial to improve his algorithm from $O(n^2)$ to $O(n \log_2 n)$, using a simple divide and conquer strategy. Jones writes,

> The algorithm must visit each element of the collection, one-by-one. Although a few elements need not be visited, because they are irrelevant, the number of visitations in one round is clearly $O(n)$.

However, we have found that it is possible to preprocess the data with the following strategy:

1. Select a separator
2. Divide the collection into two equal halves using that separator
3. Recurse on the two halves

Figure 3. The HTML for (Fig. 2), created by SATIRIC from (Fig. 1).

The use of shorthands is common enough that major applications, such as Microsoft Word, now include a small set of specified rules (such as the rule that an asterisk at the start of the line indicates a list item). However, authors cannot design their own shorthands; while they can use any shorthands they wish, they cannot make Word acknowledge them. By allowing authors (or their support staff) to write patterns, we allow each writer to design his or her own shorthands, or a group of authors to agree on a common set of shorthands.

Recent events on the Web suggest another important use for shorthands. There is a growing tendency to build new pages from input given on forms. For example, a student might submit short notes on a form, or add annotations to a page using a form. Unfortunately, malicious users have now targeted form-based authoring; such users add inappropriate scripts and links to pages (CERT 2000). This is because most form-based authoring systems take the form text “as is”, allowing it to include HTML markup for more advanced authors. (CERT 2000) recommends checking for particular tags (e.g., script, applet, and form) and eliminating those tags. However, this strategy requires that site authors update their “disallowed tags” regularly as malicious users find new techniques. A better strategy is to disallow any HTML in forms. Instead, authors can use a shorthand like that given above.

The EdMedia 2000 submission process suggests a similar reason that shorthands are useful. Authors were required to submit only plain text files. Given that most authors are now accustomed to using formatting to highlight semantic intent (e.g., italicizing emphasized words) it is difficult and inappropriate to return to plain text. A set of common SATIRIC rules would allow authors to mark their plain text in such a way that referees can easily read formatted text.

We have used similar techniques to mark up text for a composition course. One of the lessons that students need to learn is to associate nouns with the actors in a sentence and verbs with the actions of those actors. SATIRIC permits us to mark the sentence once, using convenient shorthand (e.g., asterisks around verbs, brackets around actors) and then format it in different ways for presentation to students.

3. The Power of Regular Expressions

As (Sect. 2) suggests, we have chosen to use regular expressions for our patterns and then add a context to those expressions. Why regular expressions? Because regular expressions are a powerful but fast way to describe many different kinds of patterns. In particular, regular expressions support

- **Alternation**: Match “this pattern or that pattern”. Takes the form \( (t h i s) | (t h a t) \).
- **Sets**: Match “any one of these characters” or “any character between this character and that character”. Takes forms like \( [a e i o u] \) (any vowel) or \( [a-z] \) (any lowercase letter).
- **Elimination**: Match “anything but this character”. Takes the form \( [^c] \).
Regular expressions have been used for a variety of different applications, from improved search and replace in BBEdit (Bare Bones 1999) to the sophisticated analysis of student hypertext use logs (Jones and Jones 1997).

But regular expressions cannot match all of the common patterns. Hence, we increase the power of regular expression by adding contexts to the patterns. This addition makes it easier and more natural to express many common patterns. For example, while a blank line typically indicates an end of paragraph, a blank line in a preformatted section should be left as is. Context also extends the computational power of the language.

In some cases, rules will need to keep track of what has been seen before (e.g., the title of the document) and use that value. We include rules that incorporate variables similar to those used in most programming languages. Rules can get and set variables, append to variables, and increment and decrement variables.

At first glance, typical regular expressions are difficult for human beings to read, although they are easy for computers to parse. Some describe complex regular expressions as "write only" in that you never modify a regular expression because it is too hard to figure out what is going on inside. However, it is also fairly easy to turn common English pattern descriptions into regular expressions. A current project is to identify common pattern utterances and write patterns to transform those utterances into regular expressions.

Let us consider a few examples of the relationship between English text and the corresponding regular expression. The pattern utterance "a body tag" can be represented as the regular expression `<\[Bb\] [0o] [Dd] [Yy] ([^>]*>)`. This pattern matches text that begins with a less-than sign, then either B or b, then O or o, then D or d, then Y or y. Finally, there are an arbitrary number of non-greater-than signs (representing optional parameters), followed by a greater than sign. Other tags can be handled similarly. The utterance "text surrounded by asterisks" can be represented as the regular expression `\*([^\*]*\*)`. The asterisks prefaced by slashes represent "just an asterisk". The asterisk without a prior backslash represents "as many copies of the prior thing as you can". Hence, this pattern is "an asterisk, followed by as many non-asterisks as you want, followed by an asterisk".

4. Architecture

Given a source file and a set of patterns, SATIRIC builds an HTML file using the steps (Fig. 4) illustrates. First, the English-language rules (typically entered in a Web page) are converted to high-level rules. The high-level patterns are then translated into simpler rules. Finally, the rules are applied to the file.

What is a SATIRIC assembly program? It is a collection of simplified rules. These simplified rules provide all the power of the higher-level design rules, but are easier to implement quickly. There are a small number of assembly rules. Each rule has a pattern, an optional context, and a corresponding action. The basic SATIRIC assembly rules appear in (Fig. 5). Note that these differ slightly from the currently implemented version, which handles context in a different manner.

**Figure 4: The Components of SATIRIC**

What is a SATIRIC assembly program? It is a collection of simplified rules. These simplified rules provide all the power of the higher-level design rules, but are easier to implement quickly. There are a small number of assembly rules. Each rule has a pattern, an optional context, and a corresponding action. The basic SATIRIC assembly rules appear in (Fig. 5). Note that these differ slightly from the currently implemented version, which handles context in a different manner.

**Replace:** Generate replacement text
**Enhanced Replace:** Generate replacement text that may include part of the text as well as variables
The rules fall into a number of different groups. The first three types of rules (Replace, Enhanced Replace, and Load text) all generate replacement text for the matched text. The next two (Set, Update) modify the values of variables. There is no corresponding Get operation because variables can be used in replace and enhanced replace. The next four instructions provide control over the operation of SATIRIC, limiting the operation of rules with contexts and adding rules to the current rule set. The final operation is HTML-specific and was added to help support better HTML authoring; when authors close a tag, they can use this operation to ensure that all intervening tags are closed.

As this description suggests, the language includes rules to start and end contexts. In a related language (Rebelsky and de Beer 1998), HTML tags determine context. In that language each start tag begins a context and each end tag ends it. The new design possible to use a variety of different mechanisms for denoting contexts. However, we still typically use HTML tags to indicate contexts.

These rules are not applied to the whole file at once. Rather, the file is separated into smaller chunks and each chunk is processed in turn, as (Fig. 6) shows. The technique used to “chunkify” the file depends on the type of the input file. HTML files are typically split at each tag. In a future implementation, we anticipate providing rules that affect the technique used, so that different parts can be chunkified differently.

5. Supporting Advanced Authoring

A key part of this design is that the source file need not be a plain text file. The transformations can be equally well applied to existing HTML files, and we have successfully used SATIRIC to reformat such files to add functionality. Typically, new tags provide this functionality. For example, we have used a version of SATIRIC to support footnote, tables of contents, and section tags. It is easiest to understand their implementation in the higher-level design language, which is less repetitive than the corresponding assembly language.

A rule for the footnote tag (or, more precisely, the end-footnote tag) does three basic steps. It increments the footnum variable. It appends an anchor and the footnote text to the footnote variable. Finally, it replaces that text in the main body with a link to the footnote, using footnum. How do we get footnotes? A rule for the end-body tag says to insert the footnote variable. Other special tags are implemented similarly.

While the current implementation of SATIRIC is targeted toward HTML, we have also used SATIRIC in selected experimental situations for other purposes. For example, we have used an early version of SATIRIC to turn text files into Microsoft Word RTF files. In this case, we can use the same patterns as we would with HTML, but write different result texts. For example, instead of “given text surrounded by underscores, generate the same text surrounded by \textit{ and }”, we might write “given text surrounded by underscores, generate the same text surrounded by \textit{ and }”. Writing such rules requires some understanding of the output markup language, but the rules only need to be written once and then applied to as many files as are available.
SATIRIC is also being used within Web Raveler (Kensler and Rebelsky 2000) to provide a simple mechanism for transforming pages. Web Raveler permits readers to specify modifications to Web pages that should be applied before the pages are sent to the browser. The modifications include filtering of images and adding of interactive facilities. One such facility, Blazer (Glynn et al. 2000), allows faculty to create annotated trails on the Web. SATIRIC is being used for the annotations.

SATIRIC is also appropriate for transforming existing pages to meet new stylistic guidelines. Such transformations will typically be used with individual tags, although more complex changes are possible.

6. Summary

A number of common Web applications require Web authors and Web designers to convert existing files, from plain text files to existing Web pages. SATIRIC, our pattern-based page transformation language, supports a wide variety of transformations. SATIRIC has already been used for a number of simple but useful applications, from providing a shorthand for authors to supporting special features, including footnotes, on Web pages.

Abstract: The Maryland Electronic Learning Community (www.learn.umd.edu) is building a multimedia digital library of educational resources. Now in the fourth year of the project, we evaluate early decisions we made about segmenting and indexing videos. We also discuss an experiment in encouraging collaborative community indexing with a Quick Indexing Tool. We conclude that a broader base of users would better support the infrastructure requirements and we propose ways that such a broad base can be developed while also providing a framework for local learning communities. We propose a federated system of collaborative indexing communities.

Introduction

The Maryland Electronic Community (MELC) was designed to investigate how the professional development of teachers could be supported with information technology (Rose et al. 1999). One focus of this project has been the creation, maintenance, and cultivation of a digital library for the teachers to use as they develop interactive lesson plans (ILPs). While the original emphasis was on the needs of social studies and science teachers, in recent months the community has grown to include mathematics and language arts teachers.

The digital library contains over 3,200 multimedia resources, and by August 2000 this number is expected to exceed 6,300. The collection is comprised of text documents, audio files, video segments, still images, and Web sites. There are public domain items from the National Archives and NASA; proprietary items that have been contributed by project partners Discovery Communications and Maryland Public Television; and personal contributions from MELC members themselves. Each resource is identified by a set of standard metadata elements and then indexed according to Topic, Subtopic, and Standard (corresponding to national standards). Efforts at collecting and cataloging these resources was initially the responsibility of the team at the University of Maryland, but this work is gradually being handed off to the teachers as the external project funding ends.

By analyzing the Web logs, we can determined that the following resources as shown in Table 1. We are particularly interested in how the video clips are being used. Currently there are 50 videos in the library: 24 science, 25 social studies, and 1 language arts. Seven of these are in the public domain (from the National Archives and accessible by anyone) and 45 are private (from Discovery Communications, Inc. or Maryland Public Television and accessible only by MELC members). Of the video clips downloaded, only 10 were public domain. The average video clip is about two to three minutes in length and approximately 15 MB. The Web logs show evidence of teachers downloading new videos from the server even before CD-ROMs are available. Putting the clips on the server reduces the time it takes to make the videos available to the teachers since creating and distributing the CD-ROMs is time consuming.
In this paper, we examine issues related to the use and development of the resource collection including:

- the flexibility of digitized video segments (as opposed to full-length film on the VCR),
- appropriate indexing and metadata elements, and
- collaborative indexing and the Quick Indexing Tool (QIT).

Segmenting the Videos

While the library contains images, audio, and video, we focus here particularly on the video because it is attractive to students, adds a unique dimension to lesson plans, and is invaluable to visual learners. The full-length educational videos are divided in one- or two-minute segments for a number of reasons. First, we consider the video segments to be building blocks for the teachers as they construct their lessons. Second, our technology was inadequate for the task of managing digitized full-length videos, especially at the beginning of the project. A third reason for using segments is that they encourage cross-curriculum tie-ins. For example, "The Real Ben Franklin" is a film about the life of a great American and as a whole is clearly within the purview of the social studies department. However, it includes several fine illustrations of scientific principles and inventions that would be useful in a science class. As a result of the segmenting, science teachers can now use resources that they otherwise might not have been aware of or able to access.

While there has been a great deal of research in computer science on segmenting videos based on scene changes, we felt that truly meaningful units could be obtained only by manual segmentation. Unfortunately, while this kind of segmenting yields useful material, it is very labor intensive, requiring approximately seven minutes of processing for every one minute of video. In order to standardize the process, we have developed a set of guidelines.

As we have teased out the threads of these educational videos (interviews with experts in the field, historical footage, animations, demonstrations, re-enactments, first-person narratives, etc.), we have come to realize many ways that these segments might be re-constructed or regrouped by the teachers. Perhaps they will string together the re-enactments of Singbe Pieh and his fellow Africans aboard the Amistad, or pull out the animated graphics that show how black holes warp time and space. Thus, we try to segment along the different interviews or footage or speakers.

There were times when we chose not to segment the most discrete pieces of information, as when the sum of the whole was greater than the sum of the parts. This was most often when the medium itself, video, was providing something that could not have been captured and conveyed by other media. For example, near the end of the video "The Real Thomas Jefferson," the narrator stands on a balcony in Jefferson's American Room in Monticello. The camera pans around the room and as it passes over the artifacts the narrator briefly identifies them. Important though the images and the identification of these ancient Indian artifacts are, of greater importance is the panoramic view of the room itself. Similarly, we tended to give priority to the video's visual presentation of information over the text or narration that accompanied whatever was happening on the screen. Words can be gleaned from books or audiotapes, moving images come only from video.

We have developed several search tools that allow teachers to view these relatively small and discrete pieces. The most ambitious tool, the Explorer (Rose et al. 1995), gives teachers a visual representation of the
entire collection, allowing them to select the data elements that will be displayed on the axes. With this tool, they can isolate all of the photographs from the African Americans in World War II photograph collection from the National Archives, or the resources that deal with aquatic habitats and that also satisfy the Personal and Social Perspectives objective of the National Science Education Standards (1995).

**Metadata and Indexing by Content**

Effective indexing is essential for any digital library and, in general, metadata and indexing should reflect the likely information needs of the library's users. Because this project was started several years ago and was focused upon the needs of a single school system, we had to develop much of our own metadata. The original indexing system was created by library-science students who tailored it to the needs of a specific group of middle school teachers. They reviewed science and social studies curriculum objects and textbook headings to determine what the list of topics and subtopics would be and compiled a lengthy set of instructions for future indexers. The result was a 60-page manual that outlined a system for assigning metadata elements (see [http://www.learn.umd.edu/blcmanual.html](http://www.learn.umd.edu/blcmanual.html)) and specific details for assigning the descriptive elements: Description, Topic, Subtopic, and Standard.

Although a 60-minute video in its entirety may clearly belong in the social studies category, many of the segments from it could be cross-indexed to other topics. Unfortunately, many times these topics are far beyond the scope of our index. While it is probably a hallmark of high-quality educational resources that they use the familiar to introduce students to the unfamiliar, for the MELC community this is at once a blessing and a curse. As indexers, it leaves us with lots of segments for which we have no appropriate Topic or Subtopic, or which we can only index partially. The Discovery video entitled "Unearthing South America" is full of curriculum-related segments about early Indian civilizations, but many of these segments also deal with the culture's traditions of mummification and the archeological digs that are revealing much about these ancient people. Archeology is not a unit of study in the middle school curriculum, and so we have no way of capturing this essential data. It most cases we have adopted a "best fit" mentality and tried to shoehorn these segments into related categories.

A second stress upon the indexing system has been our growth as a community. As our ranks have swelled in recent years, we have embraced teachers from other areas, most notably mathematics and language arts. We have a handful of alternatives to accommodate this expansion. One would be to slow down the processing of videos and take the time to construct an index that is similar in scope and detail to the indexes for science and social studies. However, not only is this a very labor-intensive task, but it would suggest that we have learned none of the lessons of our own recent history (what if the foreign language teachers join us next month?). Our discussions centered on two other viable options: (1) distill the descriptive indexing down to the most basic and community-specific of categories and simply assign segments to the curriculum unit(s) where they are most likely to be used; or (2) broaden the descriptive indexing structure to encompass all possible subject areas by using a scheme such as Dewey, which in theory covers the entire body of knowledge.

In retrospect, we might have limited our index to the broadest of categories for the subject areas, including many beyond the curriculum, and emphasized techniques for keyword searching in the Description field. Concurrently, we would have enriched the descriptions. Rather than simply giving a brief one- or two-sentence summary, we would have made a greater effort to get the transcripts for the videos and simply copied the relevant passages directly into the Description fields, thus providing the teachers with richer text to mine. Regardless, we have come to discover that having the transcripts for any sort of video indexing is highly desirable. Short of taking the time to implement a controlled vocabulary or develop an authority file, it is important to refer to the same entity in a consistent fashion. For example, a recent addition to the library has been a video on HIV and AIDS. In a system based on simple character string recognition, it is imperative that the teachers know if the film presents information on "CD4 T cells," "cd4 t cells," "C D 4 T-Cells." or "see, de four tea sells"?

Our custom-built indexing effort may not be sustainable. We feel our efforts would be better spent to some national metadata standard such as the Dublin Core or GEM (Sutton 1999). While we do index to the National Science Education Standards and the Curriculum Standards for Social Studies, we do not have sufficient data to suggest that this field is being used by the community. Similarly, we have considered
Collaborative Indexing

Our goal has been for MELC to become a self-sustaining community when the project funding ends. At the heart of this community of educators would be the digital library that supports their work in the classroom. In order for this project to be self-sustaining within the current framework of the Baltimore City Public School System, we believe that the indexing of new resources would have to be done collaboratively by members of the community.

While our effort is on a much smaller scale than the CORC project (OCLC 1999), we certainly share their vision. Perhaps there are even some parallels between the indexing of the multimedia content and the manner in which Varian (1999) has suggested that quality control in scholarly publishing can become self-regulating.

Quick Indexing Tool (QIT) and Collaboration

Our first effort at fostering a system of collaborative indexing, the Quick Indexing Tool (QIT) (http://209.48.188.166/bclib/quickindex/), is designed to let the teachers capture descriptive and bibliographic information (metadata) about resources as they add them to the digital library. Having come to know both the capabilities and needs of our users, we have designed a simple interface that lets them capture the greatest amount of information with the least amount of effort.

Along with several simple fields for each QIT submission, we have included a description field that encourages teachers to jot down a brief statement or vocabulary from the page itself (keywords) as a way of representing the content. In the second half of the form, we ask the grade, subject area (social studies, math), and unit of study (Baltimore uses the Berri Curriculum) for which they envision this resource will be useful.

We anticipate that these particular required fields will not dampen enthusiasm for the tool by implying that all teachers should be expected to know about the specifics of all units of study across all grade levels and all subjects. We anticipate that sixth-grade math teachers will be entering Web sites applicable to the sixth-grade math curriculum and seventh-grade science teachers will be entering Web sites applicable to the seventh-grade science curriculum units, and so forth. Having the resources selected by these subject experts should greatly increase the usefulness and quality of the library.

The QIT was introduced to the MELC teachers in August 1999. As of March 2000, 94 resources have been added using this tool including 25 of the 27 math resources. It has helped us expand the library to include the new content areas of math and language arts by having the new teachers themselves make contributions. Each of the 27 math resources in the library have been added by math teachers who used the QIT.

Pros and Cons of Collaborative Indexing

In a system of collaborative indexing, all community members would be responsible for resource acquisition and cataloguing. Resources can be found items, such as Web sites; proprietary items, such as the Discovery video segments; or self-generated items, such as the photographs of Baltimore and Europe taken by various teachers who scanned them and then entered them as digital images. The benefits of such a system are obvious and important:

1) In theory, it guarantees that each item will be have high relevance to some subset of users. Only resources that other members of the group have identified as being specifically related to the curriculum will be part of the collection.

2) Not only will the items all have high levels of relevance, but they will also be of high quality. Each item will have been judged useful by a subject expert.

3) Moreover, the activity of creating a QIT entry may lead to reflection by the teacher about the value of the item. The time involved in entering the bibliographic data, which includes their name and e-mail, will serve as further impetus for maintaining quality control.

However, there are a few difficulties in expecting teachers to use the QIT on a regular basis:
1) Becoming a contributing member of a digital library community means more work for a group that is habitually overworked. Society, school administrations, and parents already expect them to perform a myriad of functions within their classrooms. We are asking them to perform yet one more.

2) The community of users probably will not find as many resources as a library media specialist would. Although the community users will be able to index the resources they do find, they may be overlooking many others. For example, the media specialist knows that many valuable sites are only available to users who know to execute a search on the main page or by searching the site index, and that these pages cannot be found through the major search engines. Unlike today's librarians, teachers have not necessarily been trained to manipulate the search engine algorithms as a way to refine the search process.

3) The community users probably will not find resources of the same quality as a media specialist. The reason for this is similar to the argument made in the previous point.

4) The community of users and the QIT will not exist in an equilibrium. As we have discovered, changes in the environment can have messy implications for the system as it was originally conceived. If they are not provided with the technical skills or training to respond to these changes, then the slightest shift in the equilibrium may well overwhelm them.

**Conclusion**

Based on our experience, we envision an extended collaborative indexing system that is overseen by a professional librarian with whom they have ready access and easy communication. This professional librarian would serve as a resource to be used by the community members on an "as needed" basis, although this professional will also be an equal contributor to the endeavor and a person who will no doubt have many useful things to share when it comes to the selection, acquisition, organization, and use of resources. We envision an iterative process:

- an individual or subset of members approaches the media specialist with a request for information,
- the media specialist will interview them to further understand the nature of their information need,
- the media specialist will provide the user with a list of resources,
- the teacher will examine the resources,
- the teacher will select and index (with QIT) the ones that meet his/her need, including those that he/she may have found on their own.

This scenario strikes a balance between two extremes. It leaves ultimate responsibility for resource selection to the community members, thus ensuring high relevance and importance to the curriculum, but it lets them have the option of having input from a professional whose intervention represents a great deal of "value added" to the final product.

Finally, it also suggests a way that we can provide a useful framework for the local learning community, yet provide an infrastructure for a broader community. Once a media specialist has compiled a listing of resources that would be useful for an eighth-grade lesson plan on meteorology, it is a relatively simple task to share that list with other teachers in other local learning communities.

Perhaps the solution lies in a federated system of collaborative indexing communities. In this arrangement, many small groups of collaborative indexing communities join forces to benefit from the sharing of resources, expertise, and support that are inherent in a larger federation. Suppose an individual member of Community A has annotated and cataloged a resource in a way that has made it useful to the specific needs, parochial though they be, of the members of her immediate community. An individual in Community B, upon perusing the digital library holdings of Community A, accesses this same resource but represents the descriptive data differently in his catalog. For his users, he includes information about how the resource correlates to statewide standards outlined by the governor's task force. On a macro level, the members of Community B benefit from having access to the resources in the digital library of Community A; on a micro
level, they benefit from the refining process that defines collaborative indexing systems.

We have plans for adding tools similar to QIT that will allow teachers to index video segments, materials from online archives, and other multimedia items. This will be accomplished by redefining the metadata fields in the top half of the form so as to prompt users to give more resource-specific information (e.g., audio tapes often have narrators, computer images come in varying file formats).

We continue to believe that educational video can be highly absorbing and can be an important resource for middle school teachers. However, many of the costs for the digital library (indexing, segmenting) would be better borne by a very large constituency. The issue becomes maintaining a sense of involvement from the local learning communities. The QIT is one example of a community-oriented tool. Other such tools might include social collaboration tools (see Allen 1997).

MELC is part of the larger Baltimore Learning Community (BLC), a group funded by U.S. Department of Education Technology Innovation Challenge Grant (#R303A50051) to the Baltimore City Schools. The MELC partners are the University of Maryland at College Park (UMCP); Baltimore City School System; Apple Computers, Inc.; Discovery Communications, Inc.; National Archives and Records Administration; and Maryland Public Television.
Computers in Education should go beyond task simplification in teaching-learning processes in order to become a strong and effective resource for the construction of knowledge. For computers to fit into a constructivist approach, it is necessary to find a way to develop computer tools in which dialog and comparison with the student's mental and formal models is possible, focusing on the achievement of meaningful learning.

Hypermedia Concept Maps (HCMs), as a way of representing ideas, have a great deal to offer to the development of models for diverse study phenomena and to the adoption of the appropriate pedagogical approach to include computer technology and adapt it to such approach. Here, we propose the use of HCMs to create, together with a specific platform for working with them, an open computing learning environment. New learning development implies, in some cases, a review of the previously acquired knowledge and, in all cases, an integration of newly and previously acquired knowledge. In order to work in this direction, we suggest an environment that supports HCM interconnection and we define the options required to enhance the existing platform.

Introduction

Few activities of man and society have escaped from the impact of computer technology. In education, the attraction of technical features presented by new tools has diminished the attention on how they should be incorporated to learning processes. Technology in itself does not give satisfactory results in education if it is not integrated to an approach in which we wonder about its real power in this field. Computers in Education should go beyond task simplification in teaching-learning processes in order to become a strong and effective tool for the construction of knowledge.

Computer technology should be understood as a means and not as the exclusive purpose of education. For teaching and learning this technology constitutes an additional tool, often appearing to reinforce behavioral and verbalist learning frameworks. To be in agreement with a constructivist approach, it is necessary to find a way to develop computer tools in which dialog and comparison with the student's mental and formal models is possible, not forcing the student to obtain a result but, instead, stimulating his or her knowledge building process and reflection on it. In order to achieve this, it is necessary to focus attention on how these tools are going to be added to the educational process and not only to the contents they are going to introduce.

It is worth remembering what Fenstermacher said about the relationship of ontological dependence existing between the concepts of teaching and learning, and how the central activity of teaching is to facilitate the student to develop learning tasks. That is to say, "to teach is to make learning possible, to provoke dynamics and situations in which the learning process can take place in the students". In this sense, the skill of the teacher in selecting the best tools for the achievement of meaningful learning is very important, [Fen86].

Hypermedia Concept Maps (HCMs), as a way of representing ideas, have a great deal to offer to the development of models for diverse study phenomena and to the adoption of the appropriate pedagogical approach to include computer technology and adapt it to such approach.

Neither computer technology in general nor hypermedia in particular can solve completely nor directly the problems posed by knowledge acquisition within the teaching-learning process; success depends exclusively on the way in which it is applied.
Learning Environments

The purpose of incorporating the computer to learning processes is identified with the development of thinking activities, and with the idea that a computer is a support for the student to build his or her knowledge in his or her mental model structuring process.

A learning environment can be defined as an environment formed by a non-homogenous set of elements that are able to create or recreate situations from which students can build knowledge. Although it is an expression that appears linked to Computers in Education, it is used in a wider sense and it can be used even without the use of computer technology. These environments are presented as sites with a great pedagogical value, extremely favorable for learning and metalearning experiences. Regarding computer learning environments, we can distinguish two large groups:

Closed Environments: those that consist of an integrated software and hardware system that does not require any other system outside it except for the students that interact with it.

Open Environments: the computer system forms part of the environment together with other elements and persons, and the role of the teacher clearly stands out.

Within the second group we can include HCM work. In this case, the environment will consist of a computer with the specific platform to develop and read these maps, different kinds of bibliographical material, map authors or readers, and the proper participation of the teacher to assess the map semantically.

HCMs, as a way of representing knowledge, can cover the expectations of the meaningful learning model, and they constitute an important basis for computer technology introduction in new educational processes.

It has been proved that work with HCMs is very valuable for meaningful learning building. Concept selection and its correct hierarchical organization are directly related to the previous knowledge of the map's author and to the structural organization of this with the newly acquired knowledge.

On Hypermedia Concept Maps

HCMs preserve all the educational richness of Novak's CMs enhanced with the benefits of hypermedia technology: easier operational handling, greater richness and versatility for information patterns, and motivationally more attractive, especially for young learners, [Sen96a].

Definition

An HCM is a hypermedia document in which each of its nodes has a collection of no more than seven concepts interrelated by linking words. Each one of these nodes is called a view.

There are two types of concepts: those owned by the view and those imported to the view. The former constitute the initial concepts of the view and the latter are the image of concepts that belong to another view that are created in order to establish relationships among concepts of different views.

Relationships among concepts of the same view are called internal and relationships among concepts of different views are called external.

In each view, the owned concepts are represented by means of labeled ellipses, imported concepts by labeled rectangles, both with the name of the concept that they represent, and relationships (internal or external) by arcs labeled with linking words.

In order to represent external relationships, a labeled arc is established between the owned and the imported concept. Such relationship appears in both views.

A name and a color identify each of the views. The name corresponds to the most comprehensive owned concept and the color is used in all the ellipses representing owned concepts. Imported concepts keep the color of the view where they were originally defined.
Given a view V1 and a concept C belonging to V1 we can say that C explodes in another view V2 when such concept C develops in V2, i.e. C constitutes the root node of the map developed in V2. In this case we can say that the map represented in view V2 is a submap of the one corresponding to view V1.

The ellipse representing an owned concept exploding in another view is an elliptical button that allows direct access to that view. The rectangle representing an imported concept C is a rectangular button that allows direct access to the view where C is defined as owned.

We can associate to a terminal concept (that is not a button) different features such as graphics, sound, animation, etc. Any concept can be associated to a feature since there will always be a CM view in which said concept is defined as terminal.

Each HCM presents two strata: the strictly speaking HCM and the underlying hypermedia database created from the resources that originated the HCM. Access to it can be achieved during map navigation. Thus, those concepts in an HCM that, due to their richness, can provide new information, can be more deeply explored by means of hypermedia. Both strata can be queried alternatively. HCMs go beyond the educational possibilities of Novak's traditional CMs. This hypermedia bibliography is extremely useful for those interested in reading further about the topic, as well as those assessing it, [Sel96b].

**Elements in an HCM Learning Environment**

In order to focus the HCM author's attention in the most important and richest aspects from the educational point of view -such as concept selection, hierarchical classification and relationship establishment- and, in order to avoid distractions in building aspects and implementation options that lack any pedagogical value, the platform for HCM work and a methodology for HCM development is introduced into the environment, in addition to bibliographical material on the subject and the corresponding simulation systems for HCM study.

**Platform for HCM Development**

The design of a specific platform for dealing with HCMs aims at having exclusively those resources necessary for HCM development. Those characteristics can be found in the specific platform for HCM development and reading presented in [Mor96a]. This platform has two work modes, one of them corresponds to the author -map development and modification- and the other corresponds to the reader -map perusal and inspection. Immediate interaction between the two modes is allowed. The author mode presents specific characteristics for HCM development that makes the user completely free from dealing with any aspect that goes beyond the understanding of the topic. It has a graphic interface that offers a tools bar with the different options available for map development and modification and pull-down menus for editing.

**HCM Learning Environment Enhancement**

New learning development implies, in some cases, a review of previously acquired knowledge, and, in all cases, an integration of newly and previously acquired knowledge. Thus, we propose an environment to develop HCM interconnections. The main reason for this task is given by the need to integrate new knowledge with previously acquired knowledge and the wish to relate different points of view of the same topic.

**HCM Interconnection**

The interconnection of two HCMs can be carried out from different situations. Let's consider A and B the topics -between these there is some semantic relationship- and HCMA and HCMB the corresponding maps already developed. The idea is to obtain only one HCM from the two existing ones, without having to do all the map again and leaving the corresponding relationships established. This can be done as follows:

i) Establishing a relationship R between a concept C1 of HCMA and a concept C2 of HCMB. From the point of view of learning psychology it is an integrating action that implies a semantic review of the newly learned knowledge in relation to the including knowledge. From the point of view of operation, it is equivalent to the establishment of an external relationship between two concepts of the same HCM, since C1 and C2 are in different views.

ii) Concept C is detected in HCMA and in HCMB. At first, we suppose it is the same concept and that it is represented by the same name; later we shall deal with concepts with synonym and homonym names. Then, there is
a view V1 in HCMA and a view V2 in HCMB where C is represented by a labeled ellipse. We can also see that it is possible for another view with an elliptical button labeled C to exist; but in such case, C explodes in a view that contains it as an ellipse. That is to say, in all cases it is possible to find a view in the map where concept C is represented by an ellipse.

What are the possible solutions to keep the following properties P1 and P2 of the HCM in the map resulting from the interconnection?

P1: Each concept appears represented as an ellipse only once in the map.

P2: The maximum number of concepts of a view does not exceed from seven.

A first approach could be the following: Both views V1 and V2 are reorganized in one or two views according to the number of concepts that both views have.

For example, if V1 and V2 are the views in Figure 1, both could be replaced by the view in Figure 2.

If, instead, V1 and V2 were like in Figure 3, where the number of concepts gathered between both views largely exceeds the upper limit proposed, they could be replaced by the views in Figure 4, where the original hierarchy among concepts has been taken into account for its organization. We can see that in the first view C is represented by a button.
Problems arise with this approach when in HCMA or in HCMB there are views different from V1 and V2 that have an elliptical or rectangular button labeled C. In that case, two views with the same elliptical button exploding in another view will remain in the new map. Interconnection would imply redoing an important part of the map, losing the pedagogical objective that we have in mind. This situation gets worse when the interconnected maps are in turn the result of previous interconnections, since a cascade effect takes place.

The following is a second approach in which the problem is solved: C is identified in both views by means of an external relation called "equal". In this way, in both views the rectangular button that will allow scrolling from one view to the other will appear, being possible to see C in both contexts, as we can see in Figure 5. The overlapping of the rectangle and the ellipse graphically reinforces the idea of referring to the same concept.

The establishment of an "equal" relationship between concept C of both maps determines a circular behavior in the access to the views from the use of rectangular buttons labeled C. If HCMA and HCMB are connected and one of them is already the result of an interconnection (for example, HCMB) the following situation may arise: concept C appears in one HCMA view and in two HCMB Views.

We can see that access circularity through rectangular buttons involves the three views after the interconnection, as shown in Figure 6.

![Figure 5: Second approach - general case](image1)

![Figure 6: particular case](image2)

Now that we have discussed the advantages of this last approach over the previous one, we consider this is the solution for item ii).

The following special case may come up. In HCMA view V1 has a concept C represented by a labeled ellipse that is a leaf. The same concept C appears as root of view V2 in the HCMB and there it is represented by a labeled ellipse. In this case, the interconnection transforms the C labeled leaf of view V1 in an elliptical button exploding in view V2.

Synonyms: when two maps are interconnected, the same concept may appear represented by different names that are synonyms. In this case, the author may choose between:
- unifying the names and proceed according to ii).
- establishing an external relationship between both, such as "it is a synonym of".

Homonyms: if two different concepts appear represented by the same name, this does not require any special deal for the interconnection, the meaning of each concept will be shown through the concepts and relationships that form part of their respective contexts.
Adding the interconnection option to the existing platform. The current platform allows for HCM construction and reading. It is possible to open two already created maps, for example HCMA and HCMB, leaving all their views available.

**Platform Enhancement**

Interconnection: the choice of this option works on open HCMs. From there, the platform considers all the views of said maps as views of the recently created HCM. Then, the following interactive process begins: the platform asks the author a name for the new map. Once it is entered, if there is some pair of views with the same color associated, the list with the names of said views and a dialog box to allow for the color change in one of them automatically appear, so that different views do not have the same color. Next, the list of concepts represented by labeled ellipses that are present in two or more views of the new map appears on the screen. When selecting each of them, the corresponding views appear and the author, after analyzing them semantically, will decide the effective action to take.

Equal Relationship: the choice of this option will allow for automatic creation of the "equal" external relationship in each of the views, pointing out the equal concepts of the different views indicated and leaving the rectangular buttons with the proper references for a circular visit of the views.

If, instead, V1 and V2 were as in Figure 3, where the number of concepts gathered between both views largely exceeds the upper limit proposed, they could be replaced by the views in Figure 4, where concept hierarchy has been taken into account for organization.

**Conclusions**

The learning environment proposed for HCM work that includes the possibility of interconnecting maps and enhancing the platform with that objective, enlarges the richness of the work with these maps as a valuable and proven resource for the representation of ideas. It expands its potential since it allows to work expressly on the correct relationship between recently learned and previously acquired knowledge or between different approaches of the same topic. It is a proposal for Computers in Education that goes beyond task simplification in teaching-learning processes, and it appears as an effective tool for the construction of knowledge according to a constructivist approach.

EDUCATIONAL TECHNOLOGY AND ITS TERMINOLOGY: NEW DEVELOPMENTS IN THE END OF THE 20TH CENTURY

Peter Serdiukov
School of Education
University of Utah
U.S.A.
serdiu_p@gse.utah.edu

Abstract: This paper is a report on the findings of a quantitative study of the Educational Technology terminology conducted on the materials of several AACE Conferences. These findings allowed us to single out different technologies used in education, to define the structure of the ET, observe the changes that have been taking place in this field over the years and describe the most important events. The list of the most frequent terms and their analysis are also presented.

Introduction

A language is like a living organism - incessantly developing and modifying, losing some elements and creating the new ones while adapting to the constantly changing environment. Terminology of a special subject field is a part of this organism that reacts most tangibly to the impact of the outside changes.

Educational Technology (ET) is a field that has been rapidly developing toward the end of the 20th century due to the outstanding innovations in Information Technologies (IT) and their growing application in general and professional education and training. These developments could not have failed to affect the ET terminology that reflects everything that is happening in this field. Yet, however important is the terminology itself for the functioning of this field, by studying terminology we can also judge of the latter's current state. Moreover, observing the development of terminology over the years, we take the prints of various periods of time and compare them, thus discovering similarities and picking out the differences, which report of the occurring changes. This paper is a further development of our research in ET terminology (2, 3).

Materials and Methods of Study

Our analysis of ET terminology is based on the Proceedings of the AACE EdMedia World Conferences that took place from 1996 through 1999 (1). Four years is certainly too short a period of time to make far-reaching conclusions - the last 15 years would have been much more demonstrative, still it was sufficient to discover remarkable changes in ET. The papers contained in these Proceedings were processed by a concordance program to obtain alphabetic and frequency lists of all the words that occur in these texts. The lists were then investigated by a number of parameters using expert and statistical methods. Some of the findings are presented in this paper.

The first observation was a sharp growth of the volume of these Proceedings: in 1996 the volume of the papers included in these Proceedings was 579,256 words, whereas in 1999 it reached 887,630 words (an increase of 53 percent). This increase reflects a rapidly growing activity in ET. The total volume of each of the Proceedings is statistically representative to make grounded conclusions regarding the issues of interest.
The Most Frequent Terms

We focused our attention on the terms specific for ET and attempted to observe how this field has changed in this short period of time. The terms of this field include both the terms characteristic of IT only and the terms pertaining to General Education, Psychology, Theory of Instruction and other relevant areas. One of the stages of the investigation was devoted to the analysis of the most frequent terms (frequencies ≥ 1000) from the 1999 file and comparing them to the most frequent terms from the 1996 file. This analysis yielded 39 words that are arranged below in the order of the decreasing frequencies. These words are very important for ET terminology as they reflect the most significant objects, phenomena and processes that are developing in it, thus allowing us to judge of the contents of this special subject field, its current state and changes that have taken place between the years.

Table. The most frequent words of ET field and comparison of their ranks in 1999 and 1996.
The position of each word in this list is taken as its rank that reflects the value of the term in a given list. The ranks of the words in the two lists were then contrasted against each other (1999:1996) to demonstrate the shift in their relative values over the three years.

Analysis of the most frequent terms and comparison of the two groups of the most frequent terms taken over a 3-year period, as we can see from the Table, allowed us to make the following conclusions:

1. The inventory of the group changed over this period by 12.8 percent (5 words of the 1996 list — application, hypermedia, video, interface and interactive were replaced with the words activity, online, virtual, Internet and distance in 1999). This change reflects the general shift of the ET focus in the direction of the Telecommunications Technology and Distance Education. It is interesting to note that all these changes concerned only the words in the bottom part of each list.

2. The most remarkable changes affected the value of the terms Web, project, group and research that moved up in the list during these three years, whereas computer, multimedia, material, communication, software and model moved down. This observation supports the abovementioned conclusion and also shows an increased interest in research and group activities in the area of ET.

3. No changes occurred in the value of the terms design, mode and study, and very small shift in the rank of the terms student and learning that replaced each other at the top of each list, and content. This is the evidence of the ET overall stability based on the student-oriented approach with attention to research in this field and to the content of education.

The terms from the 1999 list were later distributed into five topical subgroups (some words fall into different subgroups and are counted in each of them, e.g. information, system, user, etc.):

1. Education: learning, course, education, educational, teaching, knowledge, process, content, activity, material, information, system, design, environment, support, instructional, communication, program, development, study, problem;
2. Technology: Web, technology, computer, multimedia, virtual, Internet, software, tool, distance, online, information, system, design, environment, support, instructional, user, multimedia, communication, program;
3. Research: research, project, model, development, study, problem;
4. School: university, school;
5. People: student, group, teacher, learner, and user.

These groups define the basic contents of the ET field: there are general education terms (21 words), IT terms (20), research (6), schools (2) and categories of people involved in this field (5 words). The changes that had taken place in these subgroups since 1996 concerned only the first (one word), and the second (5 words) subgroups. The ratio in the number of terms in each list remained the same thus demonstrating stability of the ET structure. The most dramatic changes occurred in the inventory of the technological terms' subgroup.

**Technologies in Education**

This investigation also allowed us to define different technologies used in education (based on EdMedia 99 papers): Academic, adaptive, agent, architecture, ASP, automation, cable broadband, CD-ROM, classroom, CMC, collaborative, communication(s), computer, computer-based learning, computing, conferencing, course, database, digital, domestic, education, educational, educational communications, engineering, graphical, high, hyperlearning, hypermedia, imaging, human interface, information, instructional, instructional performance, instructional systems, integrated, interactive, interactive digital, Internet, Internet audio, Internet voice, learning, media, METNET, multidimensional analysis, multimedia, multimedia communications, network, new media, NCATE, optical fiber, participatory, projection, push, satellite, social, student-centered, subjacent, SUMMIT, teacher-centered, teaching, telecommunication(s), training, UTP, video, videoconferencing, Virtual Reality, voice, VR, Web, Web-based, Web-related, WMI, WWW - altogether 73.
We can hardly apply the words "academic", "classroom", "course", "social", etc. to a technology - these attributes refer to the area of application, whereas "multidimensional analysis", "collaborative" and "participatory" technologies are, actually, concrete uses of certain technologies. "Learner" or "teacher-centered" technology points out to the approach used in a technologically-based education. The terms "adaptive" and "subjacent" reflect inherent characteristics of the technologies, and "high" demonstrates the level of technology. But we certainly can differentiate between technologies on the basis of certain characteristics that can be utilized for their classification, namely:

Field: communication, information
Area: CMC, telecommunications
Application sphere: education, instructional, learning, engineering
 Principle of action: digital (vs. analogue)
Major tool or instrument: computer, satellite
System (organization): network, Internet, Web, WWW
Means of connection: cable broadband, optical fiber
Technique or device: database, projection, CD-ROM
Activity: computing, interactive, videoconferencing
Media: media, multimedia, video, voice, Internet, audio/voice
Structuring: integrated (vs. shared)
Combined: educational communications, instructional systems.

There can certainly be other approaches to classifying technologies.

All ET terms can be subdivided into four major groups: General Education, Computer Technology, Telecommunications Technology terms and terms belonging to other technologies (audio, video and projection). The ratio between the number of terms in each group is 40:24:29:7. This means that besides general terms related to education, the largest group of terms represents Telecommunications Technology.

It was curious to find quite a few neologisms the majority of which is based on the most popular roots net, tech, tele and web: Inet, technofatigue, teleinstructor, telepresence, webagogy, webber, webbook, etc. We noticed also a growing tendency to spell the composite terms without a dash, e.g. telelearning vs. tele-learning, website vs. web-site, etc.

Conclusions

Technology of a specialty field can be regarded as a system of units and laws that, on the one hand, describes the field reflecting its structure and processes occurring there over time, and regulates the correct use of the terms belonging to this field in the text, on the other. Investigation of the ET terminology using various methods gives us better understanding of the field organization and its functioning. The next stage of this study will be focused on identifying the changes that have taken place in ET in the last 10 years of the 20th century - this will help us discover and describe the trends in the historical development of ET and thus prepare for the future.

MULTIFUNCTIONALITY OF EDUCATIONAL TECHNOLOGY APPLICATIONS

Peter Serdiukov
School of Education
University of Utah
U.S.A.
serdiu_p@gse.utah.edu

Abstract: In order to make a technology-based education cost-effective, we need to find ways to intensify the use of Educational Technology tools in various teaching/learning applications. One of the ways to do so is to utilize the multifunctional potential of the technological tools that allows to use one and the same tool for various educational goals. A new approach to classifying Educational Technology is also proposed that allows to find different applications for the existing tools.

Introduction

A remarkable growth of Educational Technology’s (ET) applications in all forms of education and training is often undermined by the limited utilization of its potential: few educators fully exploit versatile capabilities of ET. This leads to its inefficient use in teaching and learning, lesser effect on the students, inadequate distribution of educational resources and extra expenses. However, practically each tool can be used to attain more than one goal in teaching and learning that can make ET-based education more cost-effective. Thus, we come to the idea of multifunctionality of ET according to which one and the same tool can effectively serve a variety of purposes. This idea is the opposite of the idea of integrated use of technologies that advocates building up a mix of various technological tools in one educational environment - integration is certainly very important but we suggest as well to find ways of intensive utilization of each ET tool for different applications in teaching and learning to maximize its effectiveness.

Theoretical Considerations

It is interesting to follow the development of this idea over the last 20-25 years. At first, teachers tried to find all possible uses for each new tool that appeared in schools and universities. For example, a slide projector was first used in foreign language teaching for the semantization of new words - by showing on the screen the objects these words denoted to the students (in this way, teachers avoided the need for translating these words into the students' native language). Then it began to be employed to develop verbal skills: the pictures served as objects for oral or written narration. Later, the pictures on the slides were found to stimulate communication in the target language by creating a communicative situation. Similarly, a tape recorder was used firstly to train the students to pronounce foreign sounds, then - to understand words and phrases, after - to develop listening skills; finally - to develop communicative competence.

Later, there was an attempt to integrate several different tools in one classroom and in one lecture or laboratory work, when the teachers as well as the learners began to realize that they needed a number of ET capabilities to assist them in the teaching/learning process. Thus, integral use of ET began to spread in 1980-ies that invited sequential or simultaneous use of several ET tools in one lesson. The idea of integral use of ET was grounded both on the necessity to use various media in information (text, sound and picture).
presentation - simultaneous use of a slide projector that produced static images with or without a written text and a tape recorder with an audio text and/or music is an example, and also on the desire to intensify the impact of the teacher's pedagogical actions and in this way to increase students' perception, cognition and learning outcomes on the whole. This approach was based on peculiarities of a person’s perception supported by the data given by E. Dale: we learn 11% of information through hearing and 83 through sight. People remember 10% of what they read, 20% of what they hear, 30% of what they see, 50% of what they see and hear, 70% of what they say during communication, and 90% of what they say in the process of some activity (cit. by K. Spencer 1991, 116). It has been proved that education and training based on the integral approach to information presentation and its use in learning activities could improve students' cognition and provide efficient knowledge construction (Dovgiallo 1990, Spencer 1991, et al.).

Due to the versatility of contemporary ET tools, primarily a computer, the idea of multifunctionality revived again and replaced with the time the idea of integral ET application, at least partially, though later it underwent modification and now can be viewed from a different angle: PC capabilities today are extended with a number of peripheral devices - printer, scanner, LCD plate, modem, video camera, loudspeakers etc. that serve as its extenders and provide the multifunctionality of its application.

The use of technological tools for different educational goals is based on the tools’ technical capabilities, on the one hand, and on the principle of multifunctionality, on the other. This principle first formulated in 1984 (Serdiukov 1984) and further developed in our later works (1990, 1997) states that one and the same tool can and should be used for various educational purposes. Implementation of this principle results in greater effectiveness of teaching, training and learning, and in savings on technology expenses.

Still, it is quite obvious that each tool is intended for one major purpose (selective application), so in a systemic approach to the ET application (see Serdiukov 1997, 410-419) one tool may not be sufficient to solve a particular educational problem. Then we have to look for other tools that can supplement the primary one. This approach is used in integrated systems. Supplementing one tool with other tools allows designers of educational software and practicing teachers to find the best solution to instructional problems.

**Principles of ET Application**

Multifunctionality of ET tools application is a complicated domain, and it should be appropriately structured. We suggest that the use of ET tools in education and training be based on the following three principles: selectivity, multifunctionality and suppletivity.

*Selectivity:* Application of each ET tool for specific educational goals is regulated by its technical and pedagogical capabilities.

*Multifunctionality:* Practically any ET tool can be used for a variety of educational goals; these applications are allowed by the tool’s technical and pedagogical capabilities.

*Suppletivity:* If a given ET tool utilized for a particular application cannot offer the best performance, another tool with a better capability for this application can be used together with the first one, supplement or even replace it so as to increase its efficiency and achieve the desired goals.

**Multifunctional Use of ET Tools**

There are many instances of the multifunctionality of ET tools. Let’s consider a few examples.

*Word processor*’s main use is, clearly, text generation and processing; however, it also finds use as an educational tool for writing instruction, composition skills formation, and project development (Scrimshaw 1993). Along with developing writing skills, it indirectly helps to develop reading skills as well (Serdiukov 1997). Work with the text in a word processor also stimulates thinking (Marcus 1993).
Textual Activities

- Text Generation
- Text Processing

Composition

- Drill & Practice
- Project Development
  (Writing and reading)

Learning Activities

E-mail is used predominantly as a communication tool, but, at the same time, it is a great instrument for writing instruction, individual and group tutoring and consultations, question and answer exercises, problem solving and role play (Warschauer 1995):

Communication Activities

- Dialogue
- Group Discussion

E-mail

Writing
- Question & Answer
- Problem Solving and Role Play
- Tutoring

Learning Activities

Video can be used not only for the teaching material presentation (both visual and audio-visual), but also for training (problem solving, role-play, and simulations), for group discussions, and for information database creation and research. The Group Discussion application is particularly important for professional training when a videotaped real-life situation is used for group analysis and discussion (Payr 1999). It can also be used as an assessment instrument when the student's real activity in a predesigned situation is filmed and later used in the class collaborative work and group communication (both face-to-face and virtual/electronic) for analysis, discussion and evaluation (Serdiukov et al. 2000):

Material Presentation Activities

- Visual
- Audio-visual

Video

Training
- Group Discussion
- Database Creation
- Research

Learning Activities

ET applications cannot be limited only to the delivery or presentation of information, or to the development of certain skills, they also affect emotional state and cognitive processes of the learner. Thus, pictures, colored and moving, are able to grasp our attention far better than a plain text - hence a dramatic spread of videos and video games and the ensuing tragic decline in reading among school age children and many adults. Music is not just an acoustic accompaniment of still images or video: it can influence the learners' mood and stimulate cognition - we found these effects in our research and practice of intensive foreign language training (Serdiukov 1984).
Multimedia with its unlimited capabilities is certainly the best example of multifunctionality of a computer: student's interaction with multimedia programs takes place at various levels of perception and cognition. Hypertext is another example of multifunctionality at a different scale - the scale of information depth: it offers a hierarchical network of information tools and databases that can serve multiple applications in teaching and learning. Hypermedia is a combination of both.

Versatility of the WWW adds up to the ET multifunctionality: videoconferencing, streaming video, multimedia and various communication capabilities (synchronous and asynchronous communication, on-line and off-line dialogues, and group forms of interaction - bulletin/message board, chat, on-line conferences, etc.) that support electronic communication between students and their teachers, among students and with anybody in the world on any topic are another manifestation of multifunctionality of ET tools.

Suppletivity can be illustrated by using information activities as an example. Students have traditionally obtained information for learning primarily from the textbooks. Today they also use computer-based and web-based courses that provide all the necessary information and also support knowledge construction. Besides, now they have access to web-based databases and distributed Internet resources, such as electronic university and web-based libraries, information sites, databanks, journals, etc. Finally, they utilize e-mail for collecting information from other people (fellow students, instructors, experts, etc.). All these sources supplement each other.

Multifunctionality of ET brings us before the problem of choice: what tool and what application is best for any particular teaching/learning case? The right answer depends mainly on educational goals, potential characteristics of the available ET tools, ingenuity of the courseware designer and teacher's pedagogical and technological expertise and skills.

Table of Multifunctional Applications of ET Tools

Before we deal with these concerns, we should rather analyze various applications of ET tools in students' activities (See the Table).

We arranged students' learning activities into six groups and matched them to the existing tools so that we could have an opportunity to see which activity could be performed with which tools. There are the following activities: information activities: information search, processing and presentation; textual activities: text processing, editing and generation; learning activities proper: question-answer, drill and practice, problem solving, role-play and simulation; research activities; communication activities: dialogue, group discussion and conference, and assessment activities (quizzes and tests).

Technologies are divided into two major groups: computer technology that offers computer-based courses, automated/computerized tests, word processors, spreadsheets, databases, graphics and presentation software, and telecommunications technology that offers distance courses, distributed educational resources, email, videoconferencing, bulletin boards, whiteboards and chat. (We did not include other technologies into our analysis: audio, video, audio-visual, projection and TV, though they play an important part in education.)

As we can see from the Table, practically each tool can be used for multiple purposes. The widest multifunctionality can be attributed to the Computer-Based and Web-Based (Distance) Interactive Multimedia Courses - they must perform various functions in students' learning: from information search and processing to different learning activities and assessment. Telecommunications tools, such as Videoconferencing, Bulletin/Message Board and Whiteboard, are also multifunctional: they can be used for information presentation, several learning activities involving collaboration between students and communication with the instructor as well as within the student group. E-mail can be effective for communication and in supporting group activities, such as question/answer, problem solving, role-play and simulations, and exchange of information. There are two selective, monofunctional tools - presentation software and automated tests, though we are aware that the lesson presentation phase can be easily
converted into a learning activity phase by asking questions, posing problems, etc; in the same way many tests can be used for learning purposes and not only for the assessment.

Conclusions

Multifunctionality is a property inherent in almost any ET tool. The use of ET based on the principle of multifunctionality allows to expand the application sphere of ET tools and brings about greater effectiveness of teaching, training and learning, as well as significant savings on technology expenses that can make technology-based education more practical and cost-effective.

Table. Multifunctional Applications of ET Tools in Students' Learning Activities.

This Table is actually an attempt at classifying contemporary ET. It can be used by teachers and designers of educational software as a guide in the development and application of teaching/learning materials.

Our approach to classifying ET tools has semblance to the chemical elements' valences count: each tool has certain technical and educational capabilities that allow to utilize this tool for particular classroom applications. This approach is different from, for instance, B. Bruce and J. Levin's approach that suggests a four-part taxonomy based on J. Dewey's division: inquiry, communication, construction and expression (Bruce and Levin 1997, 79). We can find similarities between our classification and this taxonomy: information and research activities refer to the inquiry, communication is, clearly, the same, learning and textual activities relate to construction, and information presentation is expression. However, our classification embraces all major up-to-date technologies and more of the current applications of ET than other approaches, including the abovementioned taxonomy.

Student Satisfaction and Perceived Learning in Internet-Based Higher Education

Peter Shea, Educational Theory and Practice, University at Albany, USA, pshea@sln.suny.edu
Eric Fredericksen, The SUNY Learning Network, State University of New York, efrederi@sln.suny.edu
Alexandra Pickett, The SUNY Learning Network, State University of New York, apickett@sln.suny.edu

Abstract: In the fall of 1999 students in the SUNY Learning Network completed surveys regarding their level of satisfaction and perceived learning in an entirely on-line learning environment. The goals of the research were to begin to build a profile of satisfied, successful students studying in this environment and to tie the research to theory. To generate hypotheses social learning theory was used as a conceptual framework. Data were collected from 1584 students, representing the largest study of on-line student attitudes to date. The data was analyzed using univariate analysis. Results indicated that a number of variables were significantly correlated with high levels of satisfaction and perceived learning. These included level of interaction with the instructor and classmates, satisfaction with the Help Desk, and satisfaction with the administration of the SUNY learning network. The report includes an explanation of the results relative to social learning theory.

Introduction
The SUNY Learning Network (SLN) is an Asynchronous Learning Network (ALN) for the 64 colleges and universities and 400,000 students of the State University of New York. All of the activities that occur in a traditional college classroom occur on-line. These include, but are not limited to, lectures, discussions, written assignments, tests, labs, simulations, and opportunities to socialize with classmates. This study presents some of the results of a survey of students including relationships between student demographics and levels of satisfaction and perceived learning in the online environment.

Method
In the fall of 1999 students enrolled in courses in the SUNY Learning Network completed a survey, which asked them to comment about their satisfaction with and learning in this on-line learning environment. The survey consisted of twenty-five multiple-choice questions that utilized a Likert-type scale to assess degrees of satisfaction and learning. Demographic data were collected on variables such as student age, gender, academic level, distance from campus, and previous computer skills. These demographics were analyzed against items that assessed student attitudes about topics such as level of interaction with the instructor and classmates, level of learning compared to the traditional classroom, overall satisfaction with their specific course and with on-line learning in general. The data was analyzed for significant differences using univariate analysis of variance.

Review of Literature
Frequent reports in the popular media decry the lack of hard data on questions surrounding student attitudes about Internet based distance learning. This study was designed to provide such data, to determine how students who studied online felt about their courses and to discover whether the most satisfied students shared any characteristics. These are not new questions and a large body of literature points to similar answers. Most of these studies conclude that, regardless of the technology used, distance-learning courses compare favorably with classroom-based instruction and enjoy high student satisfaction. (Phipps, Merisotis, and O'Brien, 1999): It has been reported however that research in the area of distance learning suffers from several weaknesses. Phipps, Merisotis, and O'Brien (1999) summarize these:
"...the methodology of many of the research designs is weak, with regard to such factors as the populations being compared or otherwise studied; the treatments being given, the statistical techniques being applied, and the validity, reliability, and generalizability of the data on which the conclusions are based." (Phipps, Merisotis, and O'Brien, 1999; p. 28)

Other areas of weakness identified by the authors are

"A. The research has tended to emphasize student outcomes for individual courses rather than for a total academic program. B. The research does not take into account differences among students. C. The research does not adequately explain why the dropout rates of distance learners are higher. D. The research does not take into consideration how the different learning styles of students relate to the use of particular technologies. E. The research focuses mostly on the impact of individual technologies rather than on the interaction of multiple technologies. F. The research does not include a theoretical or conceptual framework." (Phipps, Merisotis, and O'Brien, 1999; p. 11)

The authors conclude that although a great deal of research supports the notion that distance learning compares favorably to classroom based learning, the research is so weak that no clear conclusions can be made. While these criticisms cannot all be addressed by a single work, this study will attempt to account for as many of these weaknesses as possible. To address Phipps' et.al. first concern (A) this study will emphasize student attitudes not for individual courses but for the entire program represented by the SUNY Learning Network. In all the data used in this study represents more than 250 instructors and courses and over 1500 students. As such the data in this study represents a very large sample without the weaknesses identified by analyses of individual courses. With a sample of this size it can reasonably be expected that a wide variety of students and learning styles will be represented thus accounting for student differences in (B) and (D). Further, this study will look specifically at student differences such as age, gender, academic level etc. in an attempt to sort out how such differences affect student satisfaction and learning. Inasmuch as these courses utilized a wide variety of technologies (computers, audio, video, the Internet) it does not focus on a single technology as in (E). This study will also present a conceptual framework for understanding student satisfaction with online learning, accounting for (F). Unfortunately dropout rates (C) are not addressed by this study.

Conceptual Framework

"Learning, both outside and inside school, advances through collaborative social interaction and the social construction of knowledge" (Brown, Collins & Duguid, 1989).

Learning has been defined very cogently as a social process (Vygotsky, 1962, 1978; Bruner, 1990; Brown, Collins & Duguid, 1989; Lave, 1988, 1990) and any learning environment that is meant to foster understanding must account for the social nature of the endeavor. If an overarching framework for understanding student's feelings about working in the relative isolation of a virtual classroom is to make sense, this framework must account for mechanisms that overcome such isolation. Students learning in a virtual environment can be expected to require several support mechanisms in order to feel satisfied and to learn. These include the support of the faculty, classmates, the administration of the environment, as well as the technology, and content. If faculty are trained to recognize the affordances and constraints of virtual learning environments, if students and instructors are offered a variety of support mechanisms for overcoming social isolation, if courses and course content are designed with an understanding of the requirements of learning at a distance, then it can be predicted that student satisfaction and learning will be relatively high. In the absence of these prerequisites students can be expected to experience confusion, frustration and isolation. For a detailed description of the planning and execution of the overall program of the SUNY Learning Network, which describes the strategies employed to ensure that these prerequisites were met, see Pickett, 1999.
When learning is viewed primarily as a social process a number of predictions can be made about student affect in virtual learning domains. An obvious hypothesis is that interaction between student and teacher and student and student will be of great importance. From this conceptual perspective one would hypothesize significant relationships between students satisfaction with levels of interaction with the instructor and fellow students and their overall satisfaction with the learning experience. A second prediction - in as much as resources such as Helpdesk, technological tools and system administration break down barriers to collaborative social interaction, student satisfaction with these supports will be significantly related to overall satisfaction and learning. These predictions, stemming from a conceptual framework in which online learning is viewed primarily as a social process, are tested in this study.

Results

The results of the survey were quite positive overall. When asked, "How satisfied are you with your course?" the most common response was the highest rating available (very satisfied). Forty nine point seven percent (49.7%) of students gave this response. Another thirty eight point five percent (38.5%) gave the second highest rating (satisfied). Thus, overall, eighty eight point two percent (88.2%) of students were at least satisfied with their online course regardless of their background. Eight point five percent (8.5%) were "not very satisfied" and three point three percent (3.3%) were "not satisfied at all". When asked, "How much did you learn in your online course?" the most common response, once again, was the highest rating (A great deal). Fifty three point nine percent (53.9%) of students gave this response. Another thirty eight point six percent (38.6%) gave the second highest rating (sufficient). Thus, overall ninety-two point four percent (92.4%) of respondents felt that their level of learning was at least sufficient in the online environment, regardless of student background. Six point nine percent (6.9%) felt that their level of learning was "insufficient" and point six percent (.6%) felt that their level of learning was "none".

Among these students certain characteristics are significantly related to satisfaction and reported learning. When asked to rate their level of interaction with the instructor the following results were found. Thirty three percent (33%) of the students rated their level of interaction as "a great deal", the highest rating available. Fifty one percent (51%) felt that their level of interaction was "sufficient". Thus a total of 84% of the respondents felt that their level of interaction was at least sufficient in the online environment. Fourteen point six percent (14.6%) felt that the level of interaction was "insufficient" and one point four percent (1.4%) rated their level of interaction as "none". When the students level of satisfaction and learning are compared to their level of interaction with the instructor we find, as predicted, a significant relationship between these variables. Students who reported the highest levels of interaction with the instructor also reported the highest levels of satisfaction and learning.
As demonstrated in Table 1, each increase in students' level of interaction with the instructor is related to an increase in both satisfaction with the course and the student's reported level of learning. These increases are significant at the .000 level as demonstrated in Table 2 below:

Table 2: Analysis of Variance for Course Satisfaction and Level of Learning by Level of Interaction with the Instructor

Additionally, these differences account a relatively large proportion in the variance between students' ratings of their levels of satisfaction for all the variables examined as seen in the strength of association test in Table 3 below:
Measures of Association

<table>
<thead>
<tr>
<th>Course Satisfaction * Interaction with Instructor</th>
<th>Eta</th>
<th>Eta Squared</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.609</td>
<td>.370</td>
</tr>
<tr>
<td>Level of Learning * Interaction with Instructor</td>
<td>.529</td>
<td>.280</td>
</tr>
</tbody>
</table>

Table 3: ETA Squared Measure of Association for Course Satisfaction and Level of Learning by Level of Interaction with the Instructor

Ratings for interaction with the instructor account for the largest proportion of the variance for students' reports of satisfaction and learning. Additionally, high levels of interaction with classmates and high reports of learning and satisfaction were also significantly related. Students with the highest levels of interaction with classmates were also the most likely to report high levels of learning and to be the most satisfied. Due to space constraints, tabular information for these and other variables cannot be provided here. To see this information go to http://cms.suny.edu/research.htm#Results

Relationship of satisfaction and learning with other variables

As mentioned above, a focus on the social nature of learning leads to several predictions regarding online learning. In addition to the necessity of frequent interaction with the instructor and other students, online learners can also be expected to require other kinds of support in the potential isolation of the virtual learning environment. For example, the technical requirement of participating in such an environment pose a possible barrier to interaction, collaboration and hence the achievement of learning goals and attendant satisfaction. It can, therefore, be predicted that satisfaction with the administration of the environment will be significantly related to satisfaction and learning online inasmuch as the effective administration assists students to overcome these technological barriers to success.

An analysis of these variables does, in fact, show that they are significantly related. Other significant relationships that support the view that design and administration of online instruction should focus on the social aspects of learning include significant relationships between satisfaction with assistance provided by the Help Desk and high reports of student learning and satisfaction. Students who reported the highest levels of satisfaction with the Help Desk also reported the highest levels of learning and satisfaction. Similar relationships were found for students' feelings about technical difficulties. Those that felt that technical difficulties caused problems in the environment were also the most likely to report the lowest levels of learning and satisfaction.

One of the variables that do not appear to inhibit online learning is students' computers skill prior to taking the course. Students who reported low levels of computer skills before taking the course were no less likely to report high levels of learning and satisfaction in the course. As long as students were able to get assistance for overcoming technical difficulties reports of learning and satisfaction did not differ by prior computer skill level. The same can be said of online course experience. Students who had taken multiple courses through SLN were no less likely to report high levels of learning and satisfaction than students who had never taken an online course before. There is no evidence to suggest a "novelty effect" for satisfaction or perceived learning among these online students.

Another variable of interest was gender. Small but reliable differences exist suggesting that, women feel that they participate at higher levels than in the classroom, that they learn more, that technical difficulties are less likely to impede their learning, that they are more likely want to continue taking on-line courses, and finally, that they are more satisfied both with their specific courses at SUNY Learning Network and more satisfied with on-line learning in general than their male classmates. In summary, the on-line classroom appears to be a very female friendly place.
Discussion

The results reported here support the notion that online learning is best viewed through a focus on its social nature. Students who reported the highest levels of learning and satisfaction also reported the highest levels of interaction with the instructor and with other students, i.e. they had the greatest opportunity to collaborate. Students who reported the lowest levels of interaction with the instructor and other students reported the lowest levels of satisfaction and learning, i.e. they had the least opportunity for collaboration. Barriers to participation evidenced by dissatisfaction with the help desk and high levels of technical difficulties are also significantly related to satisfaction and reported learning. Students who reported the lowest levels of satisfaction with the help desk and high levels of technical difficulties also reported the lowest levels of learning and satisfaction. Inasmuch as interaction with the instructor and other students accounts for the most variation between students' ratings of their satisfaction and learning, it can be hypothesized that barriers to this interaction caused by technical difficulties and inability to get help with their resolution can be viewed primarily as barriers to student collaboration with instructors, peers and course content. Administrative process and instructional design in online learning should emphasize lowering barriers to and increasing opportunities for social collaboration and the social construction of knowledge.

Abstract: There are huge numbers of Web pages in the Internet. However, many learners tend to miss useful pages, miss valuable information in a page, or misunderstand the contents because there are huge amount of irrelevant information exist mingled with the useful information. To deal with this problem, we propose a "Web Recorder" system that provides functions for recording and replaying Web browsing operations and annotating pages. Instructors can create a Web browsing "scenario" to show learners Web information that is relevant to the learning objectives. We conducted experiments in real learning and teaching activities. The results indicate that the system made it easier for learners to become aware of and to understand important information dispersed in the pages. Improvements in teaching and learning effectiveness were observed in the course of these experiments.

1. Introduction

The Internet has become a common medium for the provision of information and services. Numerous studies have been done on how to create materials to be delivered via the Internet (e.g. Brooks 1997, McCormack, 1997) and there are projects where the creation of materials is used as a means for education (e.g. Thinkquest 2000). In these kinds of activities, the Internet is considered as a communication channel to deliver materials and to interact without regards to time and distance. On the other hand, the Internet, especially the Web system, can also serve as a huge database system consisting of sites around the world. We believe that the Web can be an ideal learning and teaching resource if the information meets the needs of the learners.

From the viewpoint of learners and instructors, there are several issues in using Web for learning. First, the Web contains a lot of information but not all of it was created for learning or teaching purposes. Even if a topic on a Web page is suitable for a learning activity, the page likely contains some useless information or insufficient information for the whole activity. Second, learners themselves have to decide which pages to browse, even though they may be unsure where to go. Third, it is hard for an instructor to control a learner's browsing operations. A learner in front of a Web browser is likely to click hyperlinks regardless of the instructor's intentions.

All these issues create difficulties during Web-based learning and teaching activities. We the essential problems are that (1) it is hard for learners to extract valuable information from large numbers of Web pages without any help and (2) it is hard for instructors to lead their learners to valuable information on Web pages.
To address these problems, we propose a method for showing Web pages by using the "Web Recorder" system. The Web Recorder enables an instructor to record and play back operations on a Web browser. An instructor can create a series of operations (which we call a "scenario") corresponding to the teaching intention. This paper describes experiments to investigate how the Web Recorder can improve learning and teaching effectiveness. In the next section, we give an overview of the Web Recorder system, mainly from the functional point of view. In the third section we describe our objectives, plans, and the results of three experiments. After that, we discuss the implications of the results, mainly as regards how the system changes a learner's behavior. Finally, we present our conclusions and outline future work.

2. System Overview

In this section we explain the functions of the Web Recorder. The Web Recorder is a software system that has functions for both recording and playing back a user's operations on a Web browser. To record operations, the Web Recorder gathers operation events on a Web browser. Each operation is recorded with a time stamp and parameters, and stored in a file as a "scenario." To play back operations, the Web Recorder throws events to a Web browser according to the scenario. The Web browser processes the events in the same way as an actual user's operations. In this way, the Web browser plays back the recorded behavior. Web browser operations that can be recorded by the system are as follows;

(1) Page loading
(2) Page scrolling
(3) Mouse movement
(4) Text, images, hyperlink, and voice annotation

Page loadings are recorded with related URLs to show the same pages during a playback. Page scrollings are recorded to show the same part of the page. Mouse movements are recorded to show the same mouse pointer movement. The recorded mouse pointer movements can mark the focus on a page. These three operations are available on the usual Web browser and the Web Recorder also enables users to make annotation operations (Figure 1). While recording on a Web browser, an operator (usually an instructor) can add text, images (e.g., illustrations or underlines), hyperlinks, and voice to Web pages without modifying the HTML files of the pages. These annotations are recorded as operations and stored in the scenario file. A graphical user-interface for annotation is included in the Web Recorder system. Thus an operator can add annotations without any special knowledge, such as how to use a page description language.

The Web Recorder was implemented with common Internet programming languages such as Java and JavaScript and runs in a standard Internet environment such as a Web browser. Thus the program and operation scenarios, which are plain text files, can be distributed via the Internet.

The details of the system are described in (Aoki et. al., 1999, and Aoki et. al., 2000).

3. Experiments in Class Activities

Two classes at Tamagawa Gakuen secondary school attended experimental lessons, which we organized in cooperation with the school's teaching staff.
3.1 Objectives of Experiments
Our main objective was to examine how the Web Recorder reduced the difficulties of using the Web, and improved learning and teaching effectiveness. We planned and conducted three experiments to examine the following points:
(1) The Web Recorder system as means of showing information.
Showing information is an essential function of scenario playback. It was compared with giving information on a sheet of paper.
(2) A method for improving teaching effectiveness with the Web Recorder.
The system enables teachers to indicate a focus and to show interpretations on parts of page. The effects of these techniques were examined.
(3) A method for organizing learners' net surfing.
The Web Recorder can guide learners around Web pages. We examined how it works in a class activity.

3.2 Experiment 1: Feasibility Study
First, we examined the properties of the system's functions for showing interpretations. The Web Recorder system has a function to show interpretations on the Web pages. The interpretations are presented as textual and/or graphic annotations. It can facilitate learning and teaching activities because the system shows the interpretations near the original information.

3.2.1 Experimental Method
We selected a unit in the English curriculum on understanding different cultures, and gathered various Web pages that were appropriate for the unit except for the difficulty of the English and the number of topics on the pages. We then added abstracts for the pages and notes (The pages were used after receiving the author's permission).
We divided the class into two groups (of 13 and 12 students) and conducted experiments in two sessions. In the first session we gave one group a Web page with annotations made with the Web Recorder. For the purpose of comparison, the other group saw the same Web page with annotations printed on a sheet of paper. In the second session, we prepared another topic. The group, that used the Web Recorder in the previous session, saw the new topic on a Web page with a sheet of paper, while the other group used the Web Recorder.

3.2.2 Results of the Feasibility Study
After each session, we asked the students to answer six questions:
(1) Was the session fun?
(2) Was the topic interesting?
(3) Was there enough time for you?
(4) Is it useful to use Web pages as we did today, in comparison with looking at Web pages by yourself?
(5) Did you understand the topic in the textbook better than usual?
(6) Would you feel more interested in English if we often have sessions like today?
Each question had five possible responses to indicate opinion ranging from the most favorable (e.g., It was really fun, really interesting, and so on) to the most unfavorable answers (e.g., It was not fun at all, etc.).

![Figure 2: Average Results from Feasibility Study Questionnaire.](image-url)
We converted the answers into scores ranging from 1 (most unfavorable) to 5 (most favorable) and averaged the results separately according to whether the Web Recorder was used or not. The scores were averaged to cancel the effects of topics and the competence of group members. Figure 2 shows the averaged scores for each of the questions. These results indicate that; the scores for recorder users exceeded those for browser and paper users in the results of five questions out of six. For Question 3, the score of the Web Recorder group did not exceed those of the other group. The question was about if the given time had been enough or not (a higher score indicates that they felt enough time was given). There was a system trouble with the Web Recorder that forced students to wait for a long time (it was solved before the second session). It is likely that the trouble caused a negative influence on the Web Recorder users' score for the question.

In evaluating the result, we have to take account of the presentation problems. Thus we believe we can conclude that the Web Recorder had equally good or better characteristics than paper as a medium for showing information.

3.3 Experiment 2: Focusing and Interpretation

In the second experiment, we examined the effect of focusing and interpreting on teaching activity in a classroom. We believe that teacher-led sessions are a common and valuable way of presenting ideas. It is meaningful to try to improve teacher-led sessions not only through the various merits of the Web such as volume, freshness of information and bi-directional communication, but also through the method of the Web Recorder.

3.3.1 Experimental Method

To observe how the system facilitated teaching sessions, we planned a review session after a presentation session in English to a class, which consists of students who have returned to Japan after living abroad. The educational objective was to give the students some ideas on presentation skills and to make them to think about how to improve their presentations. First, we recorded all of their speeches and created Web pages that reproduced their presentations, using conventional Web authoring tools. The pages consisted of their voices and scripts of their presentations. We selected the best two presentations and created the teaching scenario by using the Web Recorder to present these pages with annotations of major points. We also recorded the teaching presentation as an operation sequence.

The experimental session consisted of self-reviewing the pages created for each student, then a lecture on a sample presentation, using the Web Recorder, and a discussion of how they felt about improving their presentations. We gathered their opinions on their presentations and suggestions to improve them. We asked them to categorize their opinions and suggestions into those concerning presentation technique and those concerning contents. These opinions were compared with the opinions submitted at the end of the presentation session (i.e., before the experimental session). We observed the class session and evaluated how the recorder facilitated it.

3.3.2 Results of the Review Session

Differences were observed between the opinions received before and after the experimental session, in both number and quality. Before the review session, there were only 26 opinions from 15 students. After the review session, the number increased significantly to 63 opinions. The system contributed to the success of the class by focusing on many ideas, although this was not entirely due to the Web Recorder.

As regards the quality of the opinions, these after the review session concerned concrete methods for achieving concrete improvement. On the assumption that the opinions progress from vague impressions to concrete methods, they were categorized into three groups:

(Category 1) Abstract points for improvement
(Category 2) Concrete points for improvement
(Category 3) Concrete methods for achieving improvement

Table 1 shows the results of categorization:

<table>
<thead>
<tr>
<th>Counts of Opinion</th>
<th>Before the Review</th>
<th>After the Review</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category 1 (Abstract Points)</td>
<td>5</td>
<td>4</td>
</tr>
<tr>
<td>Category 2 (Concrete Points)</td>
<td>21</td>
<td>55</td>
</tr>
<tr>
<td>Category 3 (Concrete Methods)</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>Total</td>
<td>26</td>
<td>63</td>
</tr>
</tbody>
</table>

Table 1: Numbers of opinion in each category before and after the review session.
It is obvious that more opinions appeared in Categories 2 and 3 after the session. The system had succeeded in focusing and strengthening the presentation of the teaching materials, and had contributed to the success of the teaching session.

3.4 Experiment 3: Organizing Web Browsing

Third, we tried to organize class activities in net surfing with the aim of achieving a learning objective set by a teacher. It is hard for students to find and understand descriptions of a topic scattered over several pages. This experiment examined the effects of the Web Recorder system for guiding students to several paragraphs scattered over several Web pages and interpreting understanding them.

3.4.1 Experimental Method

We selected the topic "weddings and marriage" from a learning unit titled "Understanding different cultures." We decided that the educational objective of the teaching was to motivate English study by giving the students the experience of finding an interesting world of different cultures through English and the Internet. First, we searched around the Internet, then chose 13 pages containing descriptions related to the topic. We felt that 13 pages would be enough to simulate Internet surfing because this amount is enough for a one-hour class. We received the authors' permission to use their pages, and created link lists for these pages. We prepared translations for each page, because the English of the pages is too difficult for the students to understand without spending considerable time.

We then chose 8 pages containing descriptions of customs significantly different from those in Japan. From many interesting points in those pages, we selected 10 points for the class, and a teacher created a surfing scenario to see these points scattered among the pages.

In the experimental class hours, each student had a computer and was able to freely browse Web pages from the link list page that we had created. We divided one class of students into three groups, and divided a class hour into three periods. We showed the scenario to each group in a different period; for instance, we showed the scenario to group 1 in period 1, to group 2 in period 2 and to group 3 in period 3. One period was ten minutes, which was not enough to see the whole scenario, and the students could control the Web Recorder to progress to the next point. Each student had a sheet of paper to write down comments about what they found.

3.4.2 Results of Organizing the Web Browsing

Table 2 shows the averaged numbers of comments per person for each group and period.

<table>
<thead>
<tr>
<th></th>
<th>Group 1</th>
<th>Group 2</th>
<th>Group 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Period 1</td>
<td>1.8 (*)</td>
<td>1.5</td>
<td>1.5</td>
</tr>
<tr>
<td>Period 2</td>
<td>1.6</td>
<td>2.2 (*)</td>
<td>1.9</td>
</tr>
<tr>
<td>Period 3</td>
<td>1.3</td>
<td>2.0</td>
<td>3.0 (*)</td>
</tr>
</tbody>
</table>

(*) Groups saw the scenario by Web Recorder in this period.

Table 2: The averaged numbers of comments from the organized Web browsing.

Each group saw the scenario recorded by the Web Recorder in the period marked "(*)." Obviously, the members of each group expressed more comments in the period when they saw the scenario than the other groups in the same period, and than during their other two periods. We believe that this result indicates that the Web Recorder organizes the Web surfing to focus on points of the teacher's intention among large amounts of information.

We also noticed a decrease in the number of comments during the period after they saw the scenario even though the average increased. Figure 3 shows the average number of comments from all groups for each period:

Figure 3: Average number of comments from all groups for each period in the organized Web browsing
We believe this tendency resulted from the students getting the hang of the work. This is why we can see that the overall average increased, despite the previously mentioned decrease after seeing the scenario. We observed the following attitude among some students: "I have seen the contents of the scenario. What should I do now?" even though there were many points they had not focused on. This kind of attitude and the decrease in the number of comments after seeing the scenario shows that the students felt satisfaction and had an illusion that they had seen all the topics.

Figure 4 shows the average number of comments for each group in whole period.

Figure 4: Average number of comments for each group in the organized Web browsing.

The average numbers may have been affected by the period when they saw the scenario. We believe that they were not significantly affected by the ability of each individual group, because we took care to create groups of equal ability. To put it simply, we feel these averages indicate that the scenario should be shown at the end of the class hour. We can conclude that the Web Recorder helps learners to focus on the exact point selected by the educator, but we have to be aware of the feeling of complacency.

4. Discussion
Besides presenting the results, we have to consider some limitations of our research. First, we conducted only one experiment of each type because we had limited time for these experiments in the regular teaching schedule. Second, the numbers of students are too small to prove the effects statistically. Also there should be a measurement method for education results beside the use of questionnaires. In spite of these limitations, we believe that the results indicate the software has some excellent features for education and suggest directions for the next experiments, which will investigate the system while addressing these limitations.

5. Conclusion
The Web Recorder has functions for showing important parts of Web pages without distraction from a huge number of pages or from a large number of topics in a single page. It also has functions for adding annotations to parts of pages to interpret them or provide the contextual knowledge required understanding them. We conducted three types of experiment involving real class activities to examine how these functions affected learning and teaching. The results indicate that the Web Recorder can eliminate some of the difficulties faced by learners because of specific properties of the Internet, such as excessive numbers of pages, excessive number of topics on a page, and lack of necessary background information. The Web Recorder improves learning and teaching effectiveness with Web browsing by improving the method of showing pages.

Abstract: A promising approach to support learning in and about complex domains involves the use of system dynamics as a methodology since it supports both the modeling of complex systems and interaction with those models (Sterman, 1994). Two central disputes among advocates of system dynamics based learning are: (1) the extent to which collaboration among learners facilitates learning; and, (2) the utility of making underlying models accessible to and modifiable by learners (Davidsen, 1996). Both of these issues concern the degree of learner engagement and appear crucial to overall learning effectiveness. Little empirical evidence has been gathered to explore learning effects of different approaches. This paper describes a methodology for evaluation of learning effectiveness in complex and dynamic domains and reports on its use in settings that include/exclude opportunities for collaboration, which show/hide the underlying system dynamics model, and which allow/disallow modification of the underlying model.

Introduction

Many excellent uses of system dynamics to support learning in complex domains exist and are available commercially. Learning environments to support learning about complex, dynamic systems include SimCity™ for helping children learn about factors influencing the growth of urban area and Beefeater™ for helping adults learn about factors influencing the growth of a particular business, and a host of other such environments which are now frequently used to support various types of learning activities. Such environments are consistent with a great deal of learning research concerning active learning (Bruner, 1985), cognitive apprenticeship (Collins, 1991), cognitive flexibility (Spiro et al., 1987), and situated learning (Lave, 1988).

However, there is very little evidence to demonstrate the impact of these environments and their overall learning effectiveness. Moreover, there is no established methodology to determine which design approach might be most likely to lead to desired learning outcomes in various situations. Our long term goal is to develop a methodology which can be used to insure consistent success in the effectiveness of system dynamics based learning environments, and to establish reliable measures of effectiveness for such environments. We shall describe an evaluation methodology that is particularly well suited to complex and dynamic domains. We shall then describe how that methodology can be used to evaluate the impact of different key design decisions in constructing such environments, including whether and how to support collaborative learning, whether and when to make the underlying model visible to learners, and whether and how to provide learners with control of the underlying model.
There exists a well-elaborated methodology for analyzing a complex, dynamic domain in terms of system dynamics (Davidsen, 1996; Spector & Davidsen, 1997). That model proceeds on several assumptions. First, the type of complexity involved is characterized by systems which involve nonlinear relationships, delays and internal feedback among several variables, systemic behavior which may change dramatically over time, and systems in which human perceptions and actions based on perception play an active role in determining performance and outcomes. That such systems can be effectively modeled using system dynamics is now quite well established (Forrester, 1961, 1985, 1992; Sterman, 1994). What is not well established is how such models can be optimally used to facilitate learning.

It has been argued that collaboration facilitates learning about new and complex topics (Salomon, 1993; Vygotsky, 1978). This belief in the utility of collaboration in learning, however, has not been demonstrated to be effective in the context of system dynamics based learning environments, although nearly all such environments in some way attempt to integrate collaboration with other learners into various learning activities.

Moreover, there is a clear distinction between a model of reality and the process of modeling reality. Many of those who support the use of system dynamics in learning about complex domains generally support the notion of constructivists that learners construct their own models of reality. Likewise, many who construct system dynamics based learning environments believe that active learner engagement with the underlying models is crucial. This implies that learners should be eventually be provided with access to underlying models and encouraged to modify and reconstruct those models.

Rouwette and colleagues (in press) further argue that group model building actively contributes to learning outcomes. They have produce some preliminary evidence that both the collaborative and the constructivist aspects of such system dynamics based learning environments contribute to improved learning. However, their research is largely based on data gathered from self-reports of participants and is difficult to independently confirm and validate.

From this brief review of design trends and beliefs with regard to system dynamics based learning environments, it should be obvious that learner engagement is generally viewed as critical to the efficacy of a learning improvement, consistent with the general instructional design and learning effectiveness literature. Moreover, the general belief in the system dynamics learning community is that collaboration with other learners enhances learner engagement as does the ability to manipulate existing and create alternative models. While we share these widely held beliefs, it is our intention to establish a methodology which can be used to determine to what extent these beliefs are true.

The Evaluation Methodology

It is possible to view learning from a number of alternative perspectives. The preferred learning perspective largely determines the appropriate learning effectiveness methodology. Sfard (1998) identifies a participation metaphor and contrasts it with an acquisition metaphor. She argues that both metaphors should be taken into account when considering learning from a larger and longer-term perspective. We agree with this argument. The implications for evaluation are twofold. When learning is viewed as acquisition of expertise, it makes sense to evaluate learning in terms of how learners are performing and thinking in comparison with experts. When learning is viewed as participation in a community of practitioners, it makes sense to evaluate how activities of learners are changing in various learning and working situations. When the domains are dynamic and complex, evaluation is more challenging since experts are likely to exhibit a wider ranges of performances and since activities are much more open-ended than is the case with simpler domains. Nevertheless, a scientific attitude with regard to the design of environments to support learning about complex domains implies the need to collect measures of outcomes in a variety of settings in order to determine what works best, when, and why.

We begin with the learning-as-acquisition-of-expertise perspective (Ericsson & Smith, 1991). With simpler domains, it has been demonstrated that experts do in fact exhibit similarities in their thinking, and, consequently, it is possible to capture initial learner thinking patterns in the form of concept maps, to see how those maps differ from concept maps of experts, and then track changes over time and after instruction and experience performing a variety of tasks (Schvaneveldt et al., 1985). The type of concept maps which have been used to capture learner and expert thinking range from association nets to semantic networks. Surprisingly, simple association nets have proven to be excellent predictors of performance in a variety of domains, including aircraft maintenance as well as formation flying (Schvaneveldt et al., 1985). These domains, however, are not complex and dynamic in the sense described earlier, so we still regard these domains as simple when compared with the domains modeled and supported with system dynamics (e.g., predicting the spread of an epidemic, macro-economic planning, environmental policy formation, etc.).
The type of concept mapping methodology which appears to be the most appropriate for the kinds of complex, dynamic domains which are well supported by system dynamics modeling and simulation techniques is causal loop diagramming. Causal loops are visual representations of the dynamic influences and interrelationships that exist among a collection of variables. Figure 1 depicts a causal loop diagram for typical workforce problems which project managers confront. This diagram consists of a number of key factors which are linked. The arrows and letters 'S' (same) or 'O' (opposite) indicate the direction and nature of causal influence. For example, hiring leads to an increase in the total workforce. An increase in the total workforce leads to a decrease in the workforce gap (those needed to fulfill task requirements). The double slash across a link indicates a delay. Identifying and understanding the nature of delays is especially problematic in complex systems. In this example, there is a delay indicated between the time an advertisement for a job is published and when a person is hired. A second delay is depicted between when an increase in necessary team size is identified and persons hired and placed onto the team.

It should be noted that this causal loop diagram is intended only to represent the general nature of causal loop diagrams. It does not necessarily represent how experts view a particular workforce problem. Much that is relevant to such problems has been omitted to make the problem and diagram easily accessible. For example, there is a significant delay between the time when persons are placed on a project and an improvement in overall project productivity. Often productivity even declines initially when additional persons are added because they are typically less experienced workers, require training and project orientation, and increase the communication overhead associated with an effort. The point here, however, is that it is just such subtle relationships and delays that expert project managers are able to anticipate and integrate into project planning. Moreover, it is precisely such delays and internal feedback that less sophisticated concept mapping tools fail to capture.

Our general hypothesis is that within the context of a problem area in a complex, dynamic system experts will construct similar causal loop diagrams. Furthermore, these diagrams will be noticeably different from those constructed by less experienced persons. As a consequence, the level of fit between a learner's causal loop diagram and that of an expert's will be a reasonable predictor of level of expertise in that problem domain. This particular
methodology is partly quantitative and partly qualitative in nature. A measure of fit between a learner's causal loop diagram and an expert's is derived based on similarities in the set of key concepts identified for a particular problem domain, and the types and directions of links. Additionally, subjects are asked to insert open-ended comments about links and key components. Protocol analysis is used to determine whether a subject's comments reflect an expert level of understanding of that problem domain.

When learning is considered as participating in a community of practitioners, a different evaluation methodology appears more appropriate. In this case, patterns of collaboration with peers, places where specific expertise is sought, how proposals are evaluated, interactions with and about various artifacts, and the like are more directly relevant. These data can be collected by interviews and observations and changes noted. The evaluation methodology in this case is primarily qualitative in nature, drawing on the notion of distributed cognition (Salomon, 1993) and the general approach found in activity theory (Nardi, 1996) from a learner-centered, phenomenographic perspective. Specifically, learners and teachers are interviewed prior to exposure to a learning experience with a participatory, system dynamics learning environment. That learning environment will constitute the primary mediating object. Questions are designed to establish current patterns of interactions with other learners and teachers, to determine attitudes about specific technology-based learning capabilities, and to record perceived learning value of those capabilities. During the learning experience and subsequent to the experience with the participatory learning environment, learners and teachers are interviewed and asked similar questions. Changes are analyzed so as to determine whether and how patterns of interaction and attitudes evolve as a result of participation in the continuing construction of a digital database or simulation on the web.

Discussion and Conclusions

The first step in developing the causal loop mapping tool was to determine if it was true that experts did produce similar causal loop diagrams for particular problem domains. Three quite different problems were selected for this purpose: (1) an inventory management problem; (2) an environmental policy formulation problem; and, (3) a problem involving interpersonal relationships. In each domain, five experts and five novices were asked to produce causal loop diagrams on paper representing the concepts, factors, and causal relationships thought to be associated with a short problem description (about two pages each).

Since there were obvious similarities in the set of expert causal loops diagrams, and because newcomers to a complex domain exhibited noticeably different causal loop diagrams, there is the possibility that the nearness of fit to an expert's causal loop diagram would be a predictor of expert understanding in a particular problem domain. Based on this initial confirmation, a tool was built to facilitate the creation of problem scenarios and associated causal loop diagrams. The tool is designed to proceed in two steps, first prompting subjects to create a list of annotated key concepts from the scenario, and then prompting users to create an annotated causal loop diagram based on those key concepts. Subjects are allowed to revise their ideas and all entries are recorded in a user log file.

Automating the process of performing the concept mapping is intended to make it possible to collect and analyze a great deal of relevant data to determine how effective particular learning environments are with regard to promoting understanding in and about complex domains. This approach is basically an extension of the pathfinder technology (Schvaneveldt, 1990) to include complex, dynamic domains and a concept mapping and analysis tool appropriate to such domains.

The qualitative methodology and interview techniques used for the analysis of participation in communities of practice has been used in other domains and independently demonstrated to be robust (see, for example, Nardi, 1996). Our findings from initial pilot tests indicate that both methods tend to produce consistent indications of learning effects. If this finding continues to hold as additional subjects are tested, and if there is independent confirmation that a correlation between these indicators and performance on complex tasks, then the advantage of the causal loop diagramming technique is that it can also support learning about complex domains and not merely evaluation of learning effects.

Abstract: This paper explores the validity of contentions made in the literature concerning the advantages of computer conferencing in facilitating learning. It asserts that much of the supporting research is lacking in conceptual clarity, methodological rigor and systematic analysis. The findings have frequently emerged from studies conducted under conditions removed from everyday instructional contexts. Consequently, these can only be generalised with difficulty to extra-research settings, if at all. The paper includes a report of case studies on the use of computer conferencing in settings that probably approximates more closely the typical instructional context in many institutions of higher education. Non-moderated computer conferencing was employed on a number of courses and the results compared to others that employed traditional, non-electronically mediated, pedagogic approaches. The results indicate that in the absence of any moderator input, students can achieve results comparable to those attained by more traditional methods.

Overview

The literature on computer conferencing is already very extensive and has periodically been subjected to extended reviews (e.g. Kaye 91; Mason 91; Paulsen 95; Berge) Although a significant volume of work has been undertaken to establish whether or not the deployment and use of electronic mediating technologies enhances learning outcomes, many findings have been called into question on conceptual, methodological and empirical grounds. (e.g. Schute; Russell; Neal; Cooper and Robinson; Springer, et al.) Moreover, the findings tend to be somewhat inconsistent, as Kaye (1991) has noted. Although there appears to be a broad consensus that computer conferencing can enhance the learning experiences of students, especially as far as distance learning is concerned, not much evidence has been adduced that the learning/pedagogic outcomes are in some sense superior to those attainable via more traditional face-to-face interactive forums.

Much of the literature is comprised of case studies of the ongoing experiences of educators. Generally, this has a tendency to be methodologically unstructured. It is often non-comparative in orientation, does not include adequate control groups, and is rarely enlightened by appropriate statistical analysis. Consequently, many of the findings are essentially anecdotal, being, for the most part, reports from the electronic frontier. Although it may very well turn out in the medium to long term that many of these “common-sense” assertions are borne out by subsequent research, at this juncture many of the claims that have been made appear to be unproven, not a few of which are, in Popperian terms, untestable.

To illustrate with one example, the literature abounds with claims concerning the benefits of computer mediated group work without specifying clearly what the dependent variables are, and what would constitute reasonably adequate confirmation. Thus, Henri (91; see also Kaye 91; Harasim 89) contends that group-work “consistently yields results of a higher calibre than those attained by the average group member. This is due to the greater amount of information available within the group, the greater diversity of interpretations of fact and the opportunity to test individual ideas. …the combination of social osmosis, the circulation of ideas, and the links established among the participants all contribute to the efficiency of CMC group exchanges.” Perhaps, but a very elaborate and problematic research design would be required to provide evidence attesting to this (see Berthold M.R. et al., 97, on mailing list interactivity). At present the most frequently employed objective evaluative criterion is grade performance, whilst the subjective counterpart is student satisfaction. Detailed qualitative analyses of exchanges are the only means of grappling with such wide reaching claims. The required research designs are intensively resource demanding, and the findings are unlikely to meet requirements of replication and objectivity, however loosely defined. (see Mason, 1991; Berthold et al.,97.; Henri 91; Graham, et al., 99, on the need for qualitative assessments of content)
In these reports there is all too often-insufficient consideration given to the large number of interacting variables plausibly associated with perceived outcomes, learning and other. Some of the most significant relate to characteristics associated with participants in conferencing exchanges. There is no question that until very recently most case studies were based on experiences with distance education students. (e.g., Kaye 91, Mason 91; McConnell 91) A disproportionate number involve students taking information technology related courses, students who can be expected to be more favourably disposed toward pedagogic programs employing electronic platforms (e.g. Hiltz 95). The student subjects in many studies tend to be older than the typical campus-based student, and differ from them in other important respects which probably have a direct bearing on learning related outcomes. Their motivation and commitments, their social relations, the nature of their social networks, their economic situation, and their pedagogic backgrounds and experiences, all potentially relevant to learning outcomes, are probably significantly different from those of the vast majority of students undertaking campus-based higher education courses.

The list of potentially relevant variables is too lengthy to include a detailed exposition on here. They include, but are by no means limited to: (1) the category of student [mature/school graduate; graduate/post-graduate; experienced electronic communication media users/inexperienced electronic communication media users; continuing education/life-long learning]. (2) The conferencing system employed and its organisation, [which relate to ease of use, difficulty of hierarchical inclusion and integration, feedback on activities engaged in by participants, availability of private and public fora, integration with other electronic applications and their transparency/ease of use]; (3) The extent to which the conferencing system is integrated with other electronic applications [e.g. use of the Web, electronic revision/testing applications]; (4) The role of the conferencing component in the overall structure of the delivery of pedagogic materials. (5) The overall pedagogic context and its structure.

Two other clusters of variables that I wish to draw attention to here are the instructional context and instructor moderation. In the research literature on computer conferencing there is often a failure to emphasise the somewhat ideal conditions under which a significant number of these projects have been undertaken. Many studies, as noted earlier, have been carried out on mature and highly motivated students, frequently undertaking courses at a distance. The sample sizes are frequently relatively small (e.g., McConnell 91; Soby 91; Warren and Rada 88; Mason, 91; Heath 98). Many studies have been funded with additional financial resources that have enabled instructors to carry out such projects unburdened by the teaching and administrative constraints that many instructors in higher education institutions have to contend with. The instructional context in which the case studies described below were carried out approximate more closely the conditions described by Hiltz as obtaining at NJIT, namely, “first generation college students”, who must work while attending school and who commute rather than live on campus, who are faced with overcrowded classes and lecture halls, and who are tutored by staff who are themselves under severe time constraints.

My use of the terminology instructional context subsumes the whole complex of pedagogical related experiences and programmes that the student encounters within the same time frame that includes the research project. The performance of students in a collaborative group environment, whether mediated by electronic platforms or not, is affected by the way in which that experience melds with the pedagogical approaches employed in other courses that they are pursuing. Many of the presumed benefits currently attributed to collaborative conferencing and other work might, in considerable measure, be a consequence of a high novelty factor, something that I would expect to be substantially dissipated if all courses were undertaken employing similar approaches.

As far as computer mediated communications based on conferencing applications are concerned, the role of the moderator has frequently been taken to be of critical importance. (Brochet 89, quoted in Paulsen 95; Paulsen 95; Feenberg 89; Mason 91; Collins and Berge 99; Berge; Kaye91; McConnell 91) Numerous roles are allocated to the moderator in the literature, most of which are deemed to be important to the success of conferencing outcomes. The more effectively implemented, the greater the benefits. Paulsen, who reviews the literature, lists 15. There is no reason to assume that if these roles are effectively adopted and implemented that students will not benefit. However, and related to the point that I made earlier concerning the relationship between the research and typical instructional context, this literature also stresses the amount of time that is required to carry out such roles effectively. Mason (91), in reviewing one such study, carried out under the auspices of the UK Open University, noted that the 300 students had the benefit of the attention of 16 tutors, in addition to a “super-tutor” who moderated and organized the conference, “under whom the other tutors made their own
contributions." This ratio of 1 to 18 is somewhat removed from that of 1 to 95-120 that applies with respect to the case studies that I discuss below.

Case Studies

Context:

The empirical study focuses on the analysis of computer conferencing by undergraduate students at the University of the West of England. The students were drawn from two programmes. Those enrolled in the Faculty of Economics and Social Science and undertaking one of the programmes of study in Social Science that it offers, and students who were taking an Inter-Faculty mix of programmes, one of the two strands being a programme offered by the Faculty of Economics and Social Science.

The University of the West of England is one of the newer UK universities. Located in Bristol, in south west England, it currently has an enrolment of some 28,000 students undertaking a wide variety of degrees, diplomas and certificates, ranging form sub-degree vocational courses to PhD programmes. It has a mix of full and part-time students, weighted toward the former.

The students who are the subjects of this study were all undertaking undergraduate programmes, the overwhelming majority of whom were 18 to 19 year-olds who entered university directly after the completion of their secondary education. Hardly any of them had had any prior experience of using a conferencing system. All students undertaking programmes offered by the Faculty of Economics and Social Science are provided with the opportunity to attend IT induction sessions, which include familiarisation with the use of FirstClass conferencing, the majority of whom take this up.

FirstClass conferencing is widely used by staff in the Faculty of Economics and Social Science, principally as a broadcast medium, providing information to students on administrative matters relevant to courses, and as a repository of articles and lecture notes relating to specific modules. Other than in the modules discussed below, FirstClass conferencing in the Faculty of Economics and Social Science is not employed in interactive mode, nor are conferencing contributions used as part of course assessments.

In the Faculty of Economics and Social Science the academic year is divided into three trimesters. In practice only the first two are teaching terms, the summer term being used principally for examinations.

Case Studies Course Modules:

The students whose conferencing work forms the basis of the discussion and analysis below were taking the following course modules. The term assigned work below refers to coursework other than tests or examinations.

(i) Methods of Analysis. A 1st year undergraduate module that all students studying Social Science programmes are required to take. Its aim is to provide students with critical appraisal of qualitative and quantitative research methods. The analysis and discussion below is based on work undertaken by students during the first trimester of the 1999/2000 academic year. There were 119 conferences. The total number of students taking this course in the first term of 1999/00 =420. Comparison was made with assigned written, non-conferencing, work carried out by students taking this course in 1998/99, the number of students =290

(ii) Introduction to Social Psychology. This is a compulsory module for those majoring in Sociology but optional for all those taking other Social Science programmes. It can be taken by 2nd and 3rd year students. Analysis is based on assigned work undertaken during the first trimester of 1998/1999 N=61, divided into 19 conferences, membership ranging from 3 to 6, 11 of which had 4 members, one with 6. Comparison was made with performance on assigned and examination work on other modules taken by the students, excluding (iii) below.

(iii) The Holocaust and Other Massacres. This is a compulsory module for those majoring in Sociology but optional for all those taking other Social Science programmes. It can be taken by 2nd and
3rd year students. Analysis based on those taking this course in 1998/99 divided into 22 conferences of between 2 and 6 members in the first trimester with 66 students, and 22 of between 1 and 5 in the second, also with 66 students. There was only one conference with 1 member. Most conferences had a membership of between 3 and 5, relatively evenly distributed in both trimesters. Comparison was made with performance on assigned work and overall results on other modules taken by students, excluding (ii) above.

Students were posed essay type questions relating to the subject matter of the courses that they were undertaking and were required to discuss this through the medium of the FirstClass conferencing system. Because of the large numbers of students involved, and student commitments and time constraints, very few of these students met face to face in connection with the fulfilment of conferencing course requirements. Students were allocated to conferences alphabetically, or on the basis of surname after they had chosen an assignment topic. They were assessed on the basis of the quality of the contributions that they made to the conferences, and written work that summarised their own conclusions concerning the essay questions. Students were given detailed information concerning what was expected from them as far as the volume of contributions they should make, when these should be made, the range of issues that should be covered (e.g., methodological issues, relevant theoretical frameworks, status of empirical data), and, in the case of course (i) above, requirements concerning alternating turn-taking in assuming a lead and reactive/interactive contributing role. All students were given the opportunity of having 30 minutes training using the conferencing system.

The overall course grades for (ii) and (iii) above are made on the basis of the assigned work and a final examination, each contributing 50 percent to the total. The assigned work was a mix of conferencing contributions and written work related to the question posed for conferencing contributions. All other modules are also assessed on a combination of written coursework and final examinations, each contributing, with few exceptions, fifty percent of the total. None of these other courses use conferencing for assessment purposes, although instructors on many courses employ the conferencing system as a broadcast medium. Students taking these courses take a total of six courses per year, with the exception of the very few part-time students. The performance of the students on the conferencing courses was compared with their performance on the other courses that they took in the same academic year. The comparison was with the average performance on coursework grades, examination grades, and the overall average of coursework and examination grades on these other courses. In most cases these were averages of performance on five courses. However, in some instances the comparison was confined to a comparison of performance on the conferencing related module with performance on four other courses, as some students opted to study both courses in the same academic year.

As far as the methods course was concerned, (i) above, comparison was made between the assessed work on the conferencing system of students in the first term of the 1999/00 academic year, with that of written coursework undertaken by students taking the same course in the first term of the academic year 1998/99. These latter students did not use the conferencing system for assessed work in any courses during that year.

Although I designed the essay questions, wrote the guidelines relating to conferencing work requirements, and administered the conferencing system, the assessment of conferencing contributions, written, and examination work, was undertaken entirely independently by the course seminar instructors. The methods course had 10 seminar instructors, whereas (ii) and (iii) had one each. None of the conferences were moderated. None of the instructors made any contributions to the conferencing discussions, with a few exceptions when it was necessary to intervene for administrative purposes, for instance, informing students that they were sending the message to the parent conference rather than to the project group conference. Consequently, students undertook all conferencing work independently.

Findings

With respect to modules, (ii) and (iii) student t-Tests, paired two samples for means, were carried out on a number of data series, the Null Hypothesis being that there was no difference between the means attained on conferencing work modules and the averaged performance of students on all other modules. For module (i) the t-Test two sample assuming unequal variance was employed. This was undertaken separately for the assigned coursework and examination grades. No significant difference was found at the .01 level in respect of (iii) for
the second term. There was, however, a significant difference for (iii) in the first term, the mean for coursework on the conferencing module being 3% higher than for the average for all other modules. There was a 6.7% difference between the final mark on the conferencing module and the overall final mark, for (iii) in the first term. Significant differences persisted when the tests were carried out separately for males and females. However, for (iii), term two, no significant differences were found respecting any of the data series, although the means for performance on all of the data series relating to the conferencing modules were higher than those with which they were compared. The differences between terms (i) and (ii) could conceivably be interpreted as being a product of the wearing off of the novelty effect, but many other explanations are equally plausible.

For module (ii), the only significant difference was between the means for the overall grade for the module and the average overall grade on other modules, the mean for the former being nearly 6% higher. The means in all other comparison were higher for the conferencing module.

For the methods course, (i) above, the t-Test between the written assignment work for the 1998/99 and the 1999/00 conferencing work was significantly different at the .01 level, the means differing by 4.2%, being higher for the conferencing work. The t-Test between the 1998/99 and the 1999/00 written work was not significantly different at the 0.05 level, the mean for the former being higher.

Case Studies Conclusions

The analysis, along with mixed effects regression and correlation analysis, not reported upon here, indicate that conferencing undertaken without the benefit of moderation is not reflected in poorer performance, as measured by grades in written and examination work, compared with courses using traditional higher education instructional modes. In fact, students performed better on average on two of the conferencing modules (ii, iii), than they did on other coursers. There are various reasons that can be advanced for this. As noted earlier, as the pedagogic context is one in which conferencing work is a novelty on the case study courses, this may impact on student interest, perseverance and motivation. Another possible explanation is the impact of what social psychologists refer to as social facilitation. It is also possible that the subject matter of the assigned conferencing work is perceived by students to be more interesting than that than which they are required to undertake on other courses. It is also plausible to argue that many of the benefits singled out by other researchers as being associated with collaborative work, are also active in the minimalist intervention computer conferencing contexts that applied in the present case studies.

Summary and Conclusion

Although there is now a substantial body of literature dealing with varied matters relating to the deployment of interactive communication technologies in educational settings, we are still a long way from knowing or understanding how to deploy them effectively in order to achieve pedagogic outcomes. This is hardly surprising given that disputes concerning the effectiveness of more traditional pedagogic mediums, such as lectures and seminars, are far from being settled. Some of the reasons are not difficult to track. Much research has been anecdotal, case study oriented, findings being applicable to very specific contexts, and therefore non-replicable. Much research has been carried out under conditions that do not approximate those of typical educational settings. Many of the assertions deployed with missionary zeal by educational technology enthusiasts have not been systematically tested. At the same time, it is possible to demonstrate that such technologies might be effectively deployed under less than ideal conditions to achieve modest improvements.

Tracking Human Expression Actions in Lectures

Tilmann Steinberg, Li Shen, Ling Cheng, Fillia Makedon
Department of Computer Science, Dartmouth College, Hanover, NH 03755
{tilmann, li, ling, makedon}@cs.dartmouth.edu

Abstract: Recorded multimedia presentations in the form of lectures, conference proceedings, commercial demonstrations or tutorials, are becoming increasingly available in multiple, diverse, and often heterogeneous formats. These materials are stored in databases or digital libraries where the user can search by a variety of mechanisms, ranging from keyword search to content-based queries. Tracking human expression actions is a valuable tool for mining information because it can add significance value to the materials being searched. In this paper, we focus on tracking the presenter’s pointing activity during a lecture, and show how this information can be used to provide the user with an improved overview of the lecture to quickly navigate to those points that the user might find the most interesting. The strength of this approach lies in the ability to correlate the pointing actions of the lecturer with other streams of data during the recorded lectures, such as audio amplitude, gesture motion, slide presentation, or text. In the absence of complete transcripts or manually added annotations, which are expensive to generate given the quantity of recorded lectures, the level and type of interaction of the presenter with the material can be analyzed to yield likely points of interest.

1. Introduction

As classrooms are increasingly equipped with presenting and recording technology, more and more recorded lecture material becomes digitally available for both local and remote students. Central repositories of such lectures are valuable assets for online education as students can re-create the environment of the lecture hall wherever, whenever, and however often they need to. Yet as such digital libraries grow in size, the problem of accessing or retrieving relevant information becomes increasingly pronounced. It is helpful to locate individual segments of lectures dealing with a particular aspect of a problem in order to view these segments side by side, rather than reviewing entire lectures sequentially. When reviewing a single lecture, instead of providing uniform access to any point, we focus on providing “relevance” by computing points of interest within a lecture. This is done by tracking lecturer pointing activity, a new data stream that can be combined with other captured streams, such as slides, audio, etc. Using lecturer pointing activity presents a new way for browsing/searching large digital libraries of lectures and for data mining higher level information, such as a lecture’s “hot spots”.

2. Related Work

In computerized classroom projects (e.g., Classroom 2000 project at the Georgia Institute for Technology (Abowd et al. 1998)), the idea is to capture and re-create the classroom experience. One pitfall is to store information graphically, not symbolically, which makes it very difficult to correlate diverse streams of data occurring during the lecture, and thus to do data mining, and increases the work necessary to analyze the content of lectures to add conceptual structure. Other systems are similarly based on the idea of providing sequential lecture material. Barry Arons from the MIT Media Lab developed SpeechSkimmer (Arons 1997), which tries to find the important parts of speech recordings in order to give quick overviews, saving reviewing time. Arons evaluated attributes in speech patterns that indicate where the speaker is placing emphasis. We translate this idea to the classroom recording: in our case, the protagonist places emphasis by interacting with the presented material, literally pointing out the important parts. At the Dartmouth Experimental Visualization Laboratory (DEVLAB), earlier projects focused on making electronic lectures and conference proceedings more interactive (Ford et al. 1998), and to correlate data streams of different modalities (Owen et al. 1999, Owen 1998). Currently, the DEVLAB is combining this previous work to extend the Authoring on the Fly (AOF) system (Mueller et al. to appear) developed at the University of Freiburg, Germany. Because of its capability to store lecture data streams symbolically, the AOF system is used by six major universities in Germany sharing lectures in real time via the Internet, and the University of Freiburg is creating an
online library of these lectures.

2.1 Processing parallel data streams during lectures

In order to extract higher level information about a lecture, it is necessary to correlate multiple data streams such as, speech, video, speaker's facial expression, speaker's head motion, and other data streams. Tracking the correlation between heterogeneous data streams allows us to perform data mining and determine, for example, where the highest pointing activity occurred during a slide presentation. Computing the synchronization between diverse data streams is the work described in the book by Owen and Makedon (Owen et al. 1999). We demonstrate this approach with the AOF (Authoring on the Fly) System (Mueller et al. to appear) which already captures diverse data streams in synchronized mode. The AOF system is used as an intermediate step on which to build the theory of multiple data stream tracking, and has been chosen for two major reasons: (a) it provides a symbolic representation of the data contained within a recorded presentation; and (b) it is easily extensible via helper applications.

The AOF system has a whiteboard (AOFwb) which is the electronic substitute of a blackboard. Lectures are created in two phases: (a) In the pre-processing phase, the instructor uses AOFwb to produce slides to present in class. The result of the editing process is a presentation file with a page structure based on SGML. (b) In the presentation and recording phase, the presentation file is loaded into AOFwb and used by the instructor to present, annotate, and orally explain the prepared material, i.e. the presentation file together with other material such as animations, simulations, audio or video files, etc. Annotations are made on a transparent overlay on top of the loaded page, using the same graphic and text manipulation tools available during authoring.

While the instructor is presenting the material, the recording facility in AOFwb captures the important data streams generated: the audio stream with the instructor's voice, the graphics stream of time-stamped graphics displayed during the presentation, the external applications stream, any video streams (of the instructor or audience), and any others depending on the presentation. At the end of the presentation, a post-processing step builds a self-contained lecture represented by an HTML overview with links between the presented slides and associated replay locations. The resulting AOF document can be replayed synchronously, i.e. the relation between the various captured data streams is maintained. (See (Mueller et al. to appear) for details.) The most attractive features of the AOF replay component are the random visible scrolling facility and the ease with which AOF documents can be integrated into web-based teaching and learning environments.

AOF's random visible scrolling facility permits fast browsing of a recorded lecture, similar to flipping through a book. Apart from this, however, the current AOF system does not have tools for retrieval of lecture content by importance of information or by lecturer activity. In other words, it is not possible for a user to query a database of AOF lectures for, say, all slides where certain phrases appear or where there are "important" parts for a given topic. In this paper we report on ongoing work that aims to enable queries of what is important in a lecture and what is not. We do this by observing that AOF records a great deal of information which is not utilized to its full extent. This information is valuable for supporting the retrieval of what is important content in a lecture and in segmenting the lecture (giving it conceptual structure) into parts of high, average, and low importance.

Using the AOF recording process, the respective data streams have already been aligned (e.g., slide-to-audio, application-to-audio, and video-to-audio alignments). This helps us use text queries to search for lecture parts because, as we showed in earlier work, we can do "cross modal information retrieval," i.e., search for information across modalities. For example, we can find the words spoken when high pointing activity takes place. Since the text and formatting information on all slides is available, and we know exactly when and where each annotation was made by the instructor during the presentation, we can use this information for retrieval either within one document or across many documents. Thus, a large repository of AOF documents becomes accessible via text queries. The HTML document automatically generated is not hierarchically structured but just a flat index. By slightly extending the AOF system in the pre- and the post-processing phase, a better clustering and structuring of information that enhances retrieval is possible. This leads to database and data mining facilities where lecture data streams are segmented and stored accordingly.

3. Tracking Lecture Activity: Why and How

Currently, it is very difficult to search for certain parts of recorded presentations (lectures, conference proceedings, commercial demonstrations or tutorials) that are stored in heterogeneous formats and in distributed databases. Users can apply a variety of tools, ranging from keyword search, to content based queries but this will not give them results to "what is important." We introduce a new "importance mining" framework, which works by tracking and correlating the different data streams generated by a lecturer during a lecture. We focus on a lecturer's pointing ac-
activity, such as pointing to items on a slide. Instead of searching by keywords, we introduce the idea of searching a digital library by a certain human activity. This has significant implications in the management of complex knowledge in future large-scale digital libraries of human presentations. For example, one can search for all places where the lecturer exhibited pointing activity over a certain threshold and a certain set of keywords appeared.

Assuming that locations of high interest have high pointing activity, then tracking pointing activity is an effective search “modality stream” in locating complex human information. If the pointing activity stream is the primary search stream, then we have a simple way to derive correlation between lecture structure and content based on the human tracking of the speaker. Here, we employ the built-in synchronization between the audio and the slide-based human actions provided by the AOF system. This is a common-sense mechanism of saving “hot spots” during a lecture. Our system generates an activity profile for a slide, a lecture, or a set of lectures. Visualization graphs are automatically derived, thus providing an intuitive and easy to use interface for the digital library user.

Capturing lectures by merely recording the video and audio streams is sufficient to deliver the information presented, but not for finding higher-level information about the importance of a lecture, especially if one wants an answer in a practical amount of time. Video processing is hindered by limitations in the image resolution and quality: discovering what a lecturer marked or what information was presented on a slide is very difficult and expensive to do by computer. On the other hand, using an authoring/presentation/recording tool such as AOF, one combines preparation of lecture material with the recording facility, thus incorporating “access markers” for finding lecture significance. AOF delivers not just the images of the captured lecture but also stores the lecturer’s actions during the presentation. With this information, it is relatively simple to deduce the interaction between lecturer and presented material, and thus to compute “pointing activity” for each segment of the lecture.

3.1 Determining lecture importance

The basic premise is that the level of interaction of the lecturer with the material being presented is an indication as to how relevant the current point in time is within the whole lecture. A lot of interaction means, in all likelihood, that the material is very relevant, as it augments the point that the lecturer is currently trying to convey to the audience. The more often or persistently a given element is, quite literally, pointed out to the audience, the more important this element is for understanding the information. On the other hand, no interaction is likely to indicate that the lecturer is giving secondary information, such as background or related material, that has no direct relation to the current slide, or that the lecturer is merely glossing over the material in order to move on to more important things.

Our approach allows a user to search for interesting points in a lecture or set of lectures because it can combine results from the following: (a) the value of lecturer pointing (pointing activity that a lecturer exerts on a slide or view graph); (b) the value from additional parallel lecturer-generated data streams: voice pitch, frequency, amplitude, head motion, eye direction, etc.; (c) the value derived from applying data mining algorithms. The results can be visualized and build what we call a lecture architecture, showing the peaks and valleys of lecturer pointing activity. Once a lecture has been processed, a digital library user may wish to search for all the sorting lecture slides that have high pointing activity and also exhibit audio amplitude within a certain range.

The fact that the system is slide-based is a conscious decision: the use of slides is a natural segmentation of a multimedia information stream (the lecture): it assumes that the material is presented via slides or similar media which contain enough information to automatically structure the lecture. In other words, the slides provide a form of segmented presentation, each being the visual encapsulation of a richer textual, audio or video content. At the lowest level, each new slide indicates a new segment; by adding section numbers to each slide, multiple slides can be grouped into sections or chapters. Using slides as “visual information holders” is not a new idea and is widely used on the web (thumbnails). However, what we propose here is an extension of this idea to include thumbnail hot spots.

The system we are developing does this automatically for AOF, which provides the infrastructure for correlating lecture structure. Most importantly, since the correlation information is stored symbolically, it can be shared over the web and thus the system has particular application to distance learning systems using digital library technologies.

Since the assumption is that intensive pointing indicates important information, we measure various parameters including: duration of pointing, locality (relative location of pointing activity to previous/following pointing activities), repetition, frequency, related text material, and attributes of the corresponding audio. These five parameters are assigned weights and the pointing activity is then ranked and visualized. Another facility may collect statistical data of these actions which are then mined for the benefit of the student.
4. Pointer Tracking

During a presentation involving slides, the lecturer can focus the attention of the audience to a slide element by placing emphasis on it. In AOF, this is usually done by using a telepointer or by drawing onto the slide, such as underlining a word, connecting items with a stroke, or similar marks. In either case, there is interaction between the lecturer and the presented material, and the more activity the lecturer devotes to a certain element, the more relevant that element becomes within the context of the lecture. To measure the relevance of a slide element, we therefore have to measure the interaction between the lecturer and a given element.

For example, we have done the telepointer tracking to a lecture on Binpacking by Prof. Ottmann. Its length is about 44 minutes. Table 1 shows the titles for the slides in this presentation. Figure 1 shows the comparison result among slides regarding their spending time and telepointer activity. From this result, we can see that slides 4 and 7 contain high levels of interaction. They turn out to be key slides in the presentation. Clearly, the telepointer tracking result can help retrieval system find interesting information.

Depending on the note-taking system, the lecturer can have a variety of tools that can be used to mark slide elements. In the following, we classify these tools by their impact on the presentation. We then describe classes of actions that pointer tools can perform. Next, we view these actions in context to one another, i.e. to distinguish different patterns of actions. Finally, we consider how the slide is structured; interacting with a slide that consists of text needs to be treated differently from interaction with slides consisting of graphics.

4.1 Pointer types

One can assign different weights of significance to different pointing actions during a lecture. We distinguish between the following types of pointers that a lecturer can use during a presentation to indicate areas of interest. These pointers are tools available in AOF but are general enough to apply to similar note-taking systems. The primary classification is by impact on the presentation: the arrow (or telepointer) is a non-intrusive tool, meaning that it leaves no trace on the slide, but also that its action has a time element; whereas the freehand tool leaves a quasi-permanent line on the slide, meaning that the only available time information is the appearing point of the line.

Arrow/Telepointer: a non-intrusive and easily visible pointer that can either indicate a single location or be used to trace along slide elements, e.g. to underline a word as it is spoken. Freehand (drawing) tool: similar to the arrow, but leaving a colored line on the slide for a more permanent effect. The freehand tool can also be used to add information. Line tool: usually used to underline or mark slide elements, or to show direct connections between slide elements. Rectangle tool: outlines a word or a block of text, such as a definition of a term, or a more general object. Move tool: this tool modifies the slide by moving existing slide elements around, either to rearrange the slide (e.g. to simulate animated effects), or to move an indicator, such as a rectangle.

What all these tools have in common is that they are used to direct the attention of the viewer to a particular section of slide in one way or another, which implies that the current point of interest is on the slide. Conversely, by locating a pointer action linked to a specific topic in a presentation, such as a query word, we have found a section of the presentation that is relevant to this topic. Analyzing the pointer action yields an estimate of the relevance of the section: the more the lecturer concentrates on a slide element, the more relevant it becomes. In this context, the type of the pointer bears significance: (a) Using the arrow may indicate a passing reference, as the highlighted element is no longer standing out once the lecturer moves on. Also, repeated highlighting increases relevance (see Pointer actions, below). (b) Drawing and moving tools have a more persisting effect, which translates into a higher relevance. Unlike the arrow, however, it is difficult to measure the amount of time devoted to the highlighted ele-
ment, meaning that taking successive actions becomes more important. The amount of drawing can also be considered a factor.

4.2 Pointer actions

As described above, segments of a lecture or presentation where the lecturer interacts with the material can be considered more relevant than the segments where there is no such interaction. Rather than simply assigning relevance for segments with interaction, however, we wish to refine the measurement of interaction. We thus classify pointing actions using the following attributes: (1) duration of interaction, (2) repetition of (same or similar) action, (3) location of action, (5) text in vicinity of action, and (5) speech audio levels and speech/facial motion attributes. Some of these attributes are explained in detail below.

Duration of interaction. The relevance of a slide element increases primarily with the time the lecturer spends on this element. The measurement of the time is straightforward in case of the telepointer, as the lecturer has to keep the telepointer activated (e.g. by keeping the mouse button depressed). Depending on whether and how much the pointer is moved during this time, the attribute can be either limited to a single object (on which the lecturer is focussing the whole time), or shared among the objects covered during the action.

The Move tool can be viewed as a hybrid case between the telepointer and a drawing tool: the action is limited by the time the lecturer activates the tool, but its effects are quasi-permanent, similar to the drawing tools. However, the basic usage of the Move tool more closely resembles a drawing tool in that the end result is the desired effect, so evaluation for the Move tool follows that of the drawing tools.

Repetition of actions. As mentioned in the previous section, repeated focus on a single element enlarges that element's significance for the current point in time. In particular, the number of actions associated with one element on a slide can indicate whether it is of central focus or "just" a member of a list of items being presented.

Location of actions. (Rus et al. 1995) uses the structure of a document to classify the type of each component. Thus, a word appearing in the title of a slide has more weight than a word appearing in an indented sentence at regular or reduced size. We invert this indication when it comes to activation, as a targeted element which was in an already elevated position, such as the slide title, is not made much more significant when highlighted.

Neighboring text. As a general rule, words that are pointed out gain more significance if they were equal to their neighbors before. For instance, highlighting a word buried in a paragraph increases its significance; whereas pointing at a single word on a slide does not change the fact that it is already the most significant word on this slide!

Audio. By correlating the pointing action to the audio stream, we can see whether emphasized speech coincides with pointing action, indicating a higher relevance than for regular speech.

4.3 Patterns of actions and data mining

There are two basic kinds of patterns: spatial and chronological. The former include basic movements of the pointing action on slides, e.g. top-to-bottom (indicating a list of items) or a star pattern (central item with secondary items around it). The timing between pointing actions can similarly indicate the relationship between the elements pointed at. One interesting question here is if there are "typical" patterns in presenting that can be used to build up a library of such patterns, either for generic or for lecturer-specific pattern recognition. We can use data mining techniques to find such kinds of patterns. Our objective is to build a model for a classifying attribute, using algorithms like SPRINT (Shafer et al. 1996), to classify interactions, e.g. into spatial or chronological patterns. Besides classification, there are other interesting mining issues (Fayyad et al. 1996) (e.g. associations, sequential patterns) for extracting knowledge for a large digital library of presentations that remain to be explored in depth.

4.4 Slide content: text vs. graphics

In the absence of a transcript or structural information on the lecture or presentation, the evaluation of the presenter’s interaction is limited to what elements are contained in each slide. As words can be viewed as forming individual objects, assigning a pointer action to a highlighted word is simpler and more concrete than connecting the action to an element of a graphic. Furthermore, in the case of automated retrieval of lecture material (cf. section 6 below), we need to be able to associate a slide containing only graphics with textual information in order to compare it to the query terms. We plan on developing methods by which we can use the surrounding slides with text to glean what connotation the graphics may have. Even in the absence of text, it is important to give slides with only graphics "credit" for interaction, as graphics are useful or used to illustrate points that the lecturer wants to convey.

5. Representation of Lecture Activity and Retrieval Applications

Traditional video presentation libraries represent a video clip with an icon and a caption for identification. The
icon is either a generic video symbol or a representative frame of the video clip, while the caption is usually the filename. When the user selects the video clip, it is played back from beginning to end. To control playback, the user is presented with a generic progress bar or similar timescale, and VCR-like controls. While this model is appropriate for short clips, it is lacking for videos of entire lectures or presentations of comparable length when the user is searching for specific information. A first, simplistic segmentation of a lecture would split it along slide changes: the user can now select a slide and find out whether the requested information is contained on this slide. If it is, the videoclip is started at the corresponding position and the user reviews the lecture from this point on.

An even finer segmentation of the lecture takes into account where the presenter interacted with the presented material, using this as an indication of when main points are discussed. Presenters tend to indicate an element on the slide as they begin talking about it, so by jumping to such a point in the lecture gives users a faster access to the main points. Once such a main point is found, the traditional controls can be used to rewind if necessary; depending on the style of the presenter, the actual beginning of a main point, in relation to the interaction with the slide, can vary significantly, and it is not clearly understood how to universally locate such beginnings. A corresponding user interface can feature either icons along a time scale to indicate overall or individual actions, or a graph-based track in which interaction is quantized, similar to the volume of the audio track.

6. Conclusion

We have presented a framework for improving browsing and querying digital libraries of recorded presentations which are not just audio and video data streams but also capture the interaction with the presented source material. By taking this additional information into account, lectures and presentations are enriched by an evaluation of their relevance at any given point, both in form of a contour spanning the entire document as well as a comparison to other documents within the context of a user query. Since lecturers and presenters have varying styles of presentation and form of interactivity with their material, our approach cannot universally provide good results: a lecturer who in his presentation does not discriminate between important and peripheral material, may even see skewed results as peripheral elements are given undue significance. However, a lecturer who takes care to place emphasis on important elements and, quite literally, points these out, will see more focus on the primary segments, which allows students to be more likely to get to the heart of the matter when reviewing the information.

We plan on using AOF in more realistic environments to learn from other lecturers’ styles and incorporate these findings in quantizing different kinds of interaction. One primary concern has to remain the system’s low profile during a lecture so that the presenter can concentrate on the material and the reaction of the audience.

oz-TeacherNet: Supporting teacher use of Information and Communications Technologies in the Elementary Curriculum

Jackie Stokes and Jennifer Masters
The Research into Information Technology Education Group
Queensland University of Technology
j.stokes@gut.edu.au  j.masters@gut.edu.au

Abstract: This paper looks at two action research projects supported by ozTeacherNet to extend the walls of three Queensland classrooms to the Yasuura education district in Japan. The first project extended a Book Rap to include a cultural comparison of the construct of age. It involved students in all four communicative modes of language and the development of webpages. The second project followed the visit of a Travel Buddy to Japan and back again.

Introduction

The oz-Teachernet is an on-line community facilitated by the Research into Information Technology in Education (RITE) Group at the Queensland University of Technology, Australia. The purpose of oz-Teachernet is to provide an infrastructure for using telecommunications to support teachers with professional development and curriculum activity. Williams (1997) highlights the need for teachers to be "connected" in a society that is increasingly dependent on the Internet for communication. Additionally, she stresses the importance of teacher support organisations in helping teachers learn about and excel in the new professional environments where teachers work. Consequently, the RITE Group offers teachers opportunities to both learn from and contribute to a dynamic virtual community. In doing so the RITE Group hopes to learn more about models of professional development and ways in which teachers can harness telecommunications for powerful learning experiences.

This paper will look at two action research projects which have extended oz-TeacherNet to Japan, meeting, and to a certain extent overcoming, the language (both written and oral) barriers. The first project looks at how the Book Rap project was adapted and extended to develop awareness of different cultural aspects of the regard for the elderly in the International Year of the Older Person. The second project focuses on the Travel Buddy Project and reports on the fostering of rapport between two school communities, one in Japan and the other in Australia through a Travel Buddy icon.

Project one: Investigating the use of Information and Communication Technologies in Languages Other Than English

Within the Queensland curriculum the study of a Language Other Than English (LOTE) is a requirement for upper elementary classes. Schools are able to choose which language they will study but seven languages are currently encouraged: Japanese, Indonesian, Korean, Mandarin, German, French and Italian. The Romance languages show the derivation of the English/Australian language, and the Asian languages, Australia's close proximity and economic interactions with Asia. Despite the concerns of some (Dabblestein, 1997) that a socio-cultural perspective marginalises the primacy of language acquisition as a discipline goal, at the level of elementary schooling this approach introduces students not only to basic language phrases but also to social and cultural aspects whereby Australian and other cultures can be compared.

Following research taken by the Australian Catholic University, Brisbane Catholic Education developed a position paper on Cultural Literacy and Languages (Brisbane Catholic Education, 1997) which identified five key concepts to develop through the teaching of this subject; culture, diversity, interdependence, identity and reconciliation. These five concepts formed the basis of research conducted with a primary school during 1999.
The action research project evolved from a request of a LOTE teacher of Japanese to incorporate Information and Communication Technologies into the upper elementary curriculum. The environmental aspects of the school play an important part in the conduct of the project and thus are elaborated upon at this stage.

The school

The school is situated in a garden suburb, eight kilometres from the centre of Brisbane, Queensland, Australia. It is a systemic Catholic school of 340 students. The predominant cultural derivation of the families is Italian. The school has a well-developed Japanese program, which unlike most schools, involves students from Years 1-7. The school is relatively well resourced with Japanese resources with a LOTE teacher who teaches at the school three days a week, in a specially allocated room. The school has yearly exchanges with a sister school at Yasuura, near Hiroshima, in Japan. These activities are being extended as the previous head-teacher from the Australian school has joined the Education Board in Yasuura.

The project

The action research project was planned in co-operation with the LOTE teacher, the Year 7 teachers, as well as the Library teacher, and the Book Rap co-ordinator from oz-TeacherNet, based at QUT. It extended a Social Justice unit that the Year 7 teachers conducted in first term, that had as one of its resources Wilfrid Gordon McDonald Partridge by Mem Fox (1987). This book is usually used in early childhood classrooms but a Book Rap was developed that allowed older students to reflect on their relationships with their grandparents and other older people that they came in contact with.

The book was seen as a vehicle to explore cultural differences on the way in which Australia and Japan viewed older people. The storyline of the book revolves around a little boy who lives next-door to an old peoples' home, and the friendships that develop between him and some of those who live there. Old peoples' homes (or nursing homes) are familiar in Australia but at present old people are usually looked after within the family home in Japan. Thus it was thought that the cultural differences would be easily noticed in a project that connected a school in Australia with a school in Japan.

Building on students' reflection on their own ideas about older people, students in Australia conducted an interview with an older person that they knew. Most students elected to interview one of their grandparents. They asked them about their hobbies and their favourite television program. They created an image of their 'Golden Oldie's' (GO) hobby and were asked to collect photos of them when they were young and a recent photo. These were to be displayed, with GO permission, on a webpage.

The LOTE teacher required that all four communicative modes were explored in the program. At first, the planned use of written script was a problem, as Japanese word processing applications used Romaji which the teacher did not want the students to use, preferring them to use Hiragana. However, it was decided that students should create a website that included a video clip of them talking about their Golden Oldie. They used Hiragana to write and learn their script. It was also anticipated that they would read Japanese script on the website of the participating Japanese school. In keeping with the philosophy of authentic use of language, the visiting Yasuura students were able to help the students rehearse their scripts before the recording during their visit to the school.

The use of Information and Communications Technology

The project was staged so that students could complete tasks either on the classroom computers or with the aid of the Teacher-Librarian (TL) in the library. The students used Paintbrush to complete the image for their GO's hobby. They scanned the photos with the aid of the TL. A template was set up on a laptop and students wrote in English about their GO on their webpage and were recorded on a video clip using a Sony digital camera speaking in Japanese. The mpg file was linked to their webpage. The site, once complete, was posted on the RITE server.

Five Dimensions of Cultural Literacy
The project to was able to facilitate learning across the five dimensions of the Cultural Literacy curriculum through the use of Information and Communications Technology.
1. **Culture** - use of authentic photos
   Students were able to discuss differences and similarities between both the young and old photos of both Japanese and Australian 'Golden Oldies'. The use of authentic photos enabled students to look at changes to other cultural aspects such as transport, clothing, hairstyles.

2. **Diversity** - comparison of graphs
   Students were able to see a diversity between people by looking at the hobbies and favourite television programs of the Golden Oldies and comparing them with their own favourites.

3. **Interdependence** - development of web sites
   A project such as this enables students to see how it is possible for different groups to co-operate across boundaries to take part in a project. Students were also able to explore the different relationships that they had with their Golden Oldies.

4. **Identity** - production of graphic for hobby
   Students were able to focus on older people as individuals by looking at their hobbies and television programs.

5. **Reconciliation**
   The teacher needed to be aware of the possibility that members of the age group of the Golden Oldies, both in Japan and Australia would have memories and may be personal experience of the hostilities between the countries during the Second World War. In only one case was reference made to this.

**Summary**

The culmination of the event was a Grandparents' day where participating Golden Oldies were invited to morning tea and the website was displayed. The classroom teachers commented on how involved the students became with the project. It strengthened family ties, especially for those grandparents who lived overseas and with whom the students had had minimal contact. It enabled them to see them as a young person and as a person with definite hobbies that the students had previously been unaware of.

The LOTE teacher noted how viewing the students' video clips had enabled her to be much more objective about their spoken language ability. She felt that it would give the host families an indication of the students' skills before they met the students in the student exchange program. All teachers commented that being in the project had increased their computing skills and had made them aware of how much they could do with their students by using computers with a curriculum focus.

**Project two: Establishing real audience and authentic experience**

Australia, merely by its physical location, is an isolated environment and population. As a result of this, Australians seem to have developed a strong sense of identity in which we can relate to our unique environment, flora and fauna and lifestyle as Australian cultural identity. Inversely though, because of this isolation, there is a danger that our people can become insulated from the rest of the world and don't develop a sense of a wider community from an international perspective.

As mentioned in the description of the first project in this paper, Languages Other Than English (LOTE) is a defined curriculum area in Australia and is one of eight Key Learning Areas (KLA's) prescribed by Education Queensland (Education Queensland, 1999), the government body for education in this state. While this curriculum area does involve a study of the chosen language, it also involves study of the cultural and physical perspectives of the country or countries in which the language is spoken. The rationale for this is that if children are going to learn a language effectively, there is a need to establish an awareness of the context in which the language is used.

Of course, the best way for a student to immerse in the context of a language is to actually visit the country. This option, ie. a school visit overseas, is becoming more common in Australian schools as the relative cost of airfares has reduced and the notion of travelling abroad is becoming a realistic concept for many. Never the less, the physical location of Australia and therefore the cost of travel is still a major impediment for schools. In cases where the chance to travel to a LOTE country is offered, it is usually every second year on a voluntary basis. It is likely that a student may contemplate an overseas visit once in their school years and then only if their parents can afford to finance the trip. It is obvious that another mechanism that will provide "real experience" is required to supplement this valuable but infrequent (and often inequitable) venture.

The Travel Buddy Project
The Travel Buddies concept is a valid way to meet this need. A Travel Buddy is a soft toy or puppet that travels the world as a representative of a school or class. The buddy may go on a cultural exchange with a single school or travel to many destinations on an itinerary planned by the travel buddy’s "family". The buddy becomes a member of the host class and participates in normal activities with the children, both in and out of school. Of course, they need to keep a record of their trip (eg. photos and a diary produced by the children looking after the buddy) and write emails home. At the end of the exchange, the buddy returns home with souvenirs and memories to share with the class.

The oz-Teacher net maintains the Travel Buddy Project through the Travel Buddy forum. The forum is a web/email-based community that provides teachers with an avenue to contact other teachers and establish exchange projects. While the projects that emerge from this program vary considerable as participants negotiate their own terms, the travel buddy character is the common theme of all projects. The role of the oz-Teachernet in this project is as a facilitator.

Keith Koala - A Travel Buddy

The Keith Koala project was designed as a simple action research that would be used to demonstrate the Travel Buddy project to educators around the world. In particular, it was displayed in a poster session at the International Conference for Computers in Education'99 that was held in Chiba, Japan. Additionally, this project was designed to inform future development of the Travel Buddy Project.

The "Keith Koala" puppet spent three weeks with a year six class (11 year olds) in suburban Brisbane, Australia. The brief that the children were given was that they needed to teach Keith about their lives in Australia. The evidence of Keith's experiences was presented in a diary, a collection of souvenirs that were placed in Keith's backpack and a web page about the project. The children also composed a class email to the school in Japan and recorded a digital video-greeting message in Japanese. At the end of the three weeks Keith was taken to Japan and the ICCE'99 conference. After the conference the puppet, along with the memorabilia of his travels was delivered to a parallel class in a Japanese school. The Japanese children in turn wrote in the Keith Diary, collect souvenirs, take photographs and draw pictures to portray their own lives for the Australian children. At the closure of the project, the buddy returned to the Australian class to share stories and presents, just as a real exchange student might.

The Keith Koala project provided some fascinating insights into the role that a travel buddy may take in a classroom community. The Keith travel diary is a rich source of memorable moments that captures the exchange perspective and the experiences that Keith had with the classes. Additionally the Keith Koala web site (http://www.fed.qut.edu.au/masters/koala/menu.htm) provides an engaging and informative record of a "real" adventure.

The Role of Information and Communications Technology

As many of the oz-Teachernet endeavours involve extensive and complex use of technologies, it was initially disappointing when it became apparent that computers and communication technology would play a very small role in this project. The Australian school had one computer in the classroom and an Internet connection in the school library, while the Japanese class had no computer access in their school, their only access being through a laptop and email account belonging to a parent and Internet access at the local community centre. However, as the conceptualisation of the project developed it became obvious that the technologies would actually play a key role in the venture.

The advantage of the travel buddy idea is that it can actually operate successfully with NO use of technology. As such, it provides an excellent mechanism to gradually introduce technology into school environments under real and meaningful context. In this instance, the project gave a great opportunity for the project officer to model and then support valid uses of technology for communication purposes. This included:

• the use of email to negotiate an exchange project
• the use of the classroom computer to prepare text files for later emailing
• using a digital camera to capture aspects of school community
• scanning drawings and photographs for electronic display
• creating a webpage to present the project to a wider audience
• using a digital movie camera to record a video message for a real audience
• using email as a fast communication device from remote locations in the world
Summary

Teachers who have used the Travel Buddy Project with their students often report on the way in which the buddy acts as a catalyst for all types of educational investigation. (Masters, 1999). It seems that the nature of this project is that it offers opportunity for any type of focus a teacher may wish to pursue. While the Keith Koala project was relatively modest in its aspirations, it certainly demonstrated the power of a travel buddy as a metaphor for real travel experiences.

Conclusion

The oz-Teachernet's axiom is "teachers helping teachers". It is through projects such as the two described here that the RITE Group can support teachers to become confident at using Information and Communication Technology for their own curriculum purposes.

A Teachware Management Framework for Multiple Teaching Strategies

Christian Süß, Fakultät für Mathematik u. Informatik (suess@fmi.uni-passau.de)

Rudolf Kammerl, Lehrstuhl für Allgemeine Pädagogik (kammer01@fsuni.rz.uni-passau.de)

Burkhard Freitag, Fakultät für Mathematik u. Informatik (freitag@fmi.uni-passau.de)

Universität Passau, 94030 Passau, Germany

Abstract: In this paper we argue that effective teaching is a multi-method process and propose a teachware management framework flexible enough to support multiple teaching strategies. We model e.g. behaviouristic or constructivist strategies based on a metamodeling approach to learning material. As the common implementation language we introduce the XML-based Learning Material Structure Markup Language which also facilitates the interchange and portability of learning material. Our teachware management framework has already proved its advantages from both, the author’s and the learner’s perspective.

1. Introduction

Learning processes depend on the individual properties of learners like age, level of experience, knowledge and interest which usually span a wide range. Thus, there is no best teaching strategy that applies to every learning situation. In fact, even for a single learner the best strategy may change over time. Students taking an introductory course on database theory, for instance, should be guided through the material whereas later on they may want to find out on their own about the SQL query language perhaps coached by a human tutor. As another example, students taking a course on the history of music may at one time wish to learn about operas by following a timeline-based tour through the musical epochs while at another time they may prefer to have more or less unstructured material on composers and their works available and to construct an individual map of the world of opera.

Apparently, teachware management systems or computer managed instruction (CMI) systems should support multiple teaching strategies. Moreover, as the examples above show, they should provide an appropriate data model, suitable abstraction mechanisms, and tools not only to authors but also to learners. It is obvious, that a flexible multi-strategy support and powerful application interface both require system properties that are beyond most traditional hypermedia systems and common techniques and tools for computer based teaching.

In this paper, we show how the required structural properties and multi-strategy support can be largely achieved in the PaKMaS teachware management framework (PaKMaS 2000) which is based on a meta-modeling approach (Süß et al. 1999) providing a flexible and adaptable data model and on the XML-based Learning Material Structure Markup Language (LMML). Some of the key features, of course, are a simple yet powerful component model, repository techniques that exploit the meta-data available, the strict separation of contents from structure as well as the capability of adaptive presentation and navigation.

The rest of the paper is organized as follows: In section 2, we have a look at the three most important learning theories and emphasize the need to apply multiple teaching strategies in teachware management systems. In section 3, we discuss our meta-modeling approach focusing on the concepts needed for the modeling of learning strategies. We also introduce a sublanguage of LMML, the Learning Material Structure Markup Language (LMSML). The benefits of the teachware management framework based on the meta-modeling approach and the LMML for authoring and application of different strategies are discussed in section 4. A comparison with related work can be found in section 5. The paper is concluded with a summary in section 6.

2. Learning theories and teaching strategies

Due to the heterogeneity of the goals aimed at, practical arrangements for teaching and learning are influenced by various didactical and learn-theoretical considerations. Consequently, teachware appreciating this variety of approaches and thus satisfying the requirements of practical teaching has to account for and give support to
different learn-theoretical foundations. The latter can be classified into behaviouristic, cognitivistic and constructivistic theories.

2.1. Behaviourism

The behaviouristic approach is based on the assumption that behaviours can be steered by external stimuli. Certain stimuli (S) cause related behavioural responses (R). Stimulus-response pairs (S-R pairs) can be chained and become habits. Teaching goals are to be achieved by presenting selected information and questions or exercises as stimuli, that are expected to cause a certain behaviour, to the learner. If the learner reacts in the expected way his or her behavioural response will be confirmed. The same principle applies to both simple and complex teaching goals. However, in the case of complex goals the entire process is broken into a collection of simpler steps which are normally ordered sequentially. The behaviouristic learning theory is chiefly materialized as a learning strategy by guided tours or linear presentations using multiple choice questionnaires or drill & practice modules. Teaching machines and the model of programmed instruction are early realizations of behaviourism (Skinner 1958). The basic principle of these approaches is the presentation of information followed by a collection of questions and according feed-back to the learner. Authoring systems (Chambers et al. 1980) support the development of behaviouristic teaching material. The overall teaching goal is the acquisition of factual knowledge.

2.2. Cognitivism

Cognitivism which relates to the theories of Piaget (Piaget 1977) and Bruner (Bruner 1966) considers the learner as an individual that processes external stimuli actively and independently and that can therefore not be steered by external impulses. As opposed to the behaviouristic view, the cognitivists believe that learning is based on cognitive structures. It is assumed that the learner perceives, interprets and processes impressions in a selective way according to his or her level of experience and personal evolution. The latter is characterized by the total of perception, comprehension and processing patterns and schemata that are at the command of the individual and constitute his or her cognitive structure.

Therefore the question what processes underly the interaction of learning material as the external condition of learning on the one hand and cognitive structure as the internal condition of learning on the other hand receives special attention. Within the cognition-theoretical framework there exist various different positions concerning (among others) the question whether the overall goal should be the construction of a knowledge structure or rather the development of a general problem solving ability or intellectual and moral capabilities, the practical means in both cases being hints and problems in simulations or case studies as appropriate to the individual cognitive structure. As another question it has been discussed how the learning material and related information is processed by the human brain and how content can be adapted accordingly, e.g. by relating notions to their conceptual environment or by mixing visual and textual presentations. The cognitivistic learning theory together with behaviouristic ideas has influenced the Instructional Design (Merrill 1991). However, essential aspects received attention only in connection with constructivistic approaches.

2.3. Constructivism

From the perspective of constructivism the potential of teaching media to steer learning processes is considered even lower than from the cognitivistic point of view. The active processing of external impulses is rated even higher. The learner is assumed to construct reality individually based on his or her subjective experience structures (Maturana et al. 1984). Although constructivism is an offspring of cognitivism it refuses the latter's objectivism (Jonasson 1991). Constructivism considers knowledge not as a reflection of an external reality but rather as a function of perceptual processes. From this point of view learning material is to consist just of collections of information units and tools that form the input of the learning processes built by the individual. It is assumed that learning material can neither control the learning processes nor provide any reflection of reality. Every act of perception creates a new world (Maturana et al. 1984).

As one possible realization of the constructivistic approach, learning environments can be provided that support the activity-based, explorative interaction with the environment. Three approaches to computerized learning environment are rooted in constructivism:

1. Cognitive tools are a collection of software programs that use the control capabilities of the computer to amplify, extend, or enhance human cognition (Kozma 1987). Cognitive tools support the learner in the formation of his or her own concepts. The learning environment is therefore formed and modeled by the learner.
2. Learning is understood as a communicative activity in knowledge communities. The construction of reality requires the interaction with the social environment, too. Communication, e.g. in networks, should therefore be supported (Brown 1985).

3. Learning is viewed as coaching based on a master-apprentice relationship (cognitive apprenticeship). The master offers advice but gives the apprentice more and more independence when he or she makes progress (Collins et al. 1989)

2.4. Multiple teaching strategies

Courses and seminars normally contain components belonging to different learn-theoretical positions. We are convinced that all three approaches sketched above should be taken into consideration. However, which learning theory is best suited to support learning processes depends on the teaching goals and the individual properties of the learner, i.e. level of experience and education, age, learning habits. To teach freshmen the foundations of database systems, for instance, could possibly be accomplished best by a guided tour, whereas more experienced students may be better served with an interface to a real database system together with hints, comments, documentation, and a facility to contact the responsible coach, e.g. by email. Consequently, a teachware management system should have the capability to support different teaching strategies. These can be materialized in the form of behaviouristic components like guided tours with multiple-choice questions. Likewise, a constructivistic strategy could be provided by a collection of informative components and tools that allow the learner to construct or change the learning environment, in a certain way being an author him- or herself. Besides, a coaching support and facilities for human communication should be provided. Most CMI systems implement only one single teaching strategy. To overcome this restriction a suitable modeling and implementation of multiple strategies are needed as well as an appropriate toolkit for authors and learners. Of course, a CMI system can provide means to develop and use teaching material. However, its success is largely determined by the knowledge and competence of the author.

3. A teachware management framework

3.1 A metamodeling approach to hypermedia teachware

We have developed a meta-modeling approach to hypermedia teachware (Süß et al. 1999), which is flexible enough to let the teachware management system PaKMaS support multiple teaching strategies (see section 2.4.). The bottom layer of our meta-modeling architecture consists of the subjects to be taught or learned. One layer up, hypermedia learning material are describing the given domain of application, e.g. database theory or the world of opera. They use domain-specific means, which are specified in domain-specific models and describe the conceptual content as well as the modular structure of learning material and different teaching strategies of a given domain of application. Finally, the common abstract meta-model specifies learning material in an abstract way. This includes aspects also of teaching strategy by specifying how both, authors and learners, can form learning material in general. Learning material consists of learning modules that are either basic modules or structure modules containing other modules. The former are the terminal nodes of a polyhierarchical hypermedia structure similar to directories or books, but allowing modules to belong to more than one super module. Indeed, each module has to be contained in at least one structure module. By composition, they dynamically adapt learning material to the needs of different groups of learners at the content level and realize the different teaching strategies of section 2 using appropriate meta-data. Basic modules, however, are the smallest self-contained units or building blocks of the modular structure of learning material. Representing conceptual units, they contain various content objects, which can be behaviouristic, e.g. drill & practice instructions and multiple choice questions, or constructivistic, e.g. coaching remarks, simulations or interfaces to real world systems.

3.2. Learning Material Markup Language

To represent learning material incorporating different teaching strategies, we need a data format, which is suitable for storing the content and structure of the material and which allows to access the stored modules or data, very much like objects in a database system. Moreover also the authors and learners should find it easy to read and use the information stored in the modules. As described in (Süß et al. 1999) we have developed a XML representation for course content and structure representation and interchange: the Learning Material Markup Language (LMML). It comprises two sublanguages, the Learning Material Content Markup Language, which is a syntactical representation of the conceptual content and the Learning Material Structure Markup Language, which represents the modular structure model. To implement multiple teaching strategies, it uses special
elements, e.g. *guidedTour* or *collection*, which are declared in the Document Type Definition (DTD) (PaKMaS 2000) and which have strategy attributes with possible constant values *beh* (behaviouristic) or *con* (constructivistic) respectively. On the one hand, the use of the XML-based LMML facilitates the interchange and portability of learning material (Süß et al. 1999). On the other hand, using metadata like those mentioned above, a teachware management system like PaKMaS supports authors wanting to create learning material using multiple teaching strategies as well as learners using the presented material.

4. Supporting multiple strategies

4.1. Behaviouristic strategies

Within our framework, teaching material can be presented hierarchically using a book metaphor with chapters and sections as *structure modules*. They can also be presented sequentially starting at a first *basic module* using a guided tour metaphor (Fig. 3). Both represent behaviouristic strategies where the author explicitly plots the route through the given learning material.

![Figure 3: Behaviouristic strategy using a guided tour](image)

If an author, for example, wants to create a section of a booklike course or a guided tour, she can create new behaviouristic *basic modules* using course units defined in LMCML which can be extended e.g. by question elements from the Tutorial Modelling Language (TML) (Brickley 1999). She also can query the systems repository for suitable basic modules, i.e. for modules with *strategy* attribute (see section 3.2.) set to *beh* (behaviouristic). PaKMaS uses these meta-data to answer questions like “Which basic units about the SELECT statement are appropriate to be used in a guided tour on SQL?”. For the *modules* found, the system can suggest a linear ordering or check the consistency of a sequence created by an author using the modules *prerequisit* and *objectives* attributes. As guided tours and sections or chapters are *structure modules* which impose a linear ordering to the children modules a teachware management system can offer navigation facilities with which the learner can sequentially walk step-by-step through the given *basic modules*.

4.2. Constructivistic strategies

Our framework is flexible enough to support constructivistic strategies, too. It provides *structure modules* like *indexes, glossaries, time lines* or even just unordered *collections* (see Fig. 4) of learning material.

![Figure 4: Constructivisc strategy using collections](image)
They all allow direct, non-hierarchical access. Special basic modules representing coaching units give some hints to the learner on the appropriate usage of the available material. PaKMaS supports cognitive apprenticeship (see section 2.3.3) using these modules and offering easy to use communication facilities with human coaches. Furthermore communication via email and chat with other users of PaKMaS as well as posting to appropriate newsgroups managed by PaKMaS support the creation of knowledge communities (see section 2.3.2.). A learner, for example, can freely browse through basic modules on composers or operas in any order, e.g. alphabetical or by date of birth. If provided by the author, she can use coaching remarks or hints in a coaching unit. Furthermore, she can communicate with coaches or with other learners in this domain of application.

Our framework allows the wrapping of simulations or real life systems into basic modules using LMCML. This way a learner, for example, in a database course can find out about SQL by herself using an interface to a real world database (Fig. 5). As another example, she can learn about harmony in a music course using a composing system thus acquiring complex knowledge by herself. It should be noted that we do not address the support for creation of constructivistic programs like simulations etc.

![Passau Knowledge Management System](image)

**Figure 5**: Collections with coaching unit, SQL interface and descriptions of SQL statements

In addition to the simple possibility to annotate learning material with individual notes, PaKMaS provides cognitive tools which are most important for the application of constructivistic strategies (see section 2.3.1). With these tools, learners can structure and form their learning environment with respect to the meta-model. For example, they can use existing structure modules to form own collections and to create own guided tours. Note that although the latter represents a behaviouristic strategy, creating a guided tour is a constructivistic learning step. To model their own learning material, learners can use existing content objects like definitions or examples. Beyond that learners can create new types of structure modules like slide show or new types of conceptual units like slides. Thereby learners can continuously form their learning environment with respect to the metamodel. Students in a music course, for example, can construct their own “map” of the world of opera using own concepts.

### 5. Related work

The Instructional Material Structure Description Language (IMSDL) allows to specify instructional models (Silberhorn et al. 1999). In contrast to IMSDL, we differentiate between different types of conceptual units or different types of content objects. Thus, we have the concepts and syntactical representations of coaching units or coaching remarks which are necessary in constructivistic strategies. We also differentiate between different types of structure modules to realize structures like books or collections. Finally, using a meta-modeling approach, we distinguish different domains of application and their specific needs with respect to teaching strategies. (IEEE P1484 1999) proposes a text-based programming language to describe courses which consist of blocks and assignable units. The former are the largest structural elements in a course and are comparable to structure modules, whereas the latter are programs or whole lessons launched by a CIM system. In contrast to our work, the order in which a student may go through a course is only implicitly given by the order of the blocks and assignable units or their prerequisites data. In the XML-based TeachML (Wehner et al. 1999), a course is the container of learn blocks, which contain any number of didactical paths. The latter contain at least one and at most four facts and one optional exercise. They seem implicitly to specify behaviouristic guided tours. In our
approach, teaching strategies are explicitly specified allowing the use of learning strategies different from behaviouristic guided tours, too. Finally, (Teege 1999) also proposes a XML-based TeachML. Here, the author recursively composes learning material from more or less large modules using XSLT. The resulting hierarchical structures implicitly realize behaviouristic strategies.

6. Conclusion

In this paper we argued that effective teaching requires the use of multiple teaching strategies. The metamodeling approach to hypermedia teachware which we have proposed allows the domain-specific modeling necessary for the authoring and application of different teaching strategies by providing appropriate structure modules, conceptual units, content objects and meta-data. We discussed how these concepts can be implemented using the XML-based LMML. On the one hand the Learning Material Content Markup sub-Language of LMML syntactically represents different conceptual units like coaching units or drill & practice units and different content objects like coaching remarks or instructions. The sublanguage Learning Material Structure Markup sub-Language on the other hand implements behaviouristic strategies using guided tours or books as well as cognitivistic or constructivistic strategies. Furthermore, appropriate meta-data are used by a teachware management system like PaKMaS to support authoring as well as usage. Finally, relying on the properties of XML, LMML can facilitate the portability and exchange of learning material.

Abstract: This paper describes the development and exploration of a model for professional development concerned with the integration of computing technologies into classroom teaching and learning. Grounded in situative theories of knowledge and learning, the model adopts a mentoring approach that places technology experts in schools to work with teachers to create technology supported lessons that meet the teachers' curricular needs.

Theoretical Perspectives

Recent large scale studies of computer usage in schools (Becker, 1994; Panel on Educational Technology, 1997; Educational Testing Service, 1998) have precipitated public debate concerning the efficacy of using computers to support instruction, and highlighted the need for professional development in this area. While highlighting such need and pointing to the relationship between professional development and more sophisticated uses of technology in schools, these and other studies have contributed little to our understanding of how professional development impacts technology integration, especially in terms of how it affects teaching, learning, and technology integration at the classroom level.

Indeed, teacher lore suggests that traditional inservice teacher education has little impact on teaching practices in general. Smylie (1989), for example, found that teachers ranked inservice training last out of fourteen possible opportunities for learning. What teachers ranked as most important was direct classroom experience. Other researchers report similar findings (Little, 1994), leading scholars in the field to develop lists of the features common to effective staff development activities (Little, 1988; Abdal-Haqq, 1995; Ball, 1996; Wilson & Berne, 1999). Putnam and Borko (1997), for example, reduce the essential features of effective teacher education to four:

- Teachers should be treated as active learners who construct their own understanding.
- Teachers should be empowered and treated as professionals.
- Teacher education should be situated in classroom practice.
- Teacher educators should treat teachers as they expect teachers to treat students.

In a more recent article, Putnam and Borko (2000) relate recent trends in research on professional development to new understandings of the nature of learning and knowing that have been collectively labeled "situative" (Greeno, 1997). They identify three conceptual themes central to situative perspectives – that cognition is situated in particular physical and social contexts, that it is social in nature, and that cognition is distributed across the individual, others, and tools (p. 4) – which they believe have important implications for professional development. Putnam and Borko argue that how teachers learn new methods of teaching is no different from any learning. If knowledge and learning are indeed situative, then the most effective inservice education will be situated in authentic
classroom practice and constructivist in focus. The situative perspective thus gives a theoretical rationale for previous findings concerning effective inservice activities.

To our knowledge, such perspective has not been used to frame either the development of, or research on, professional development programs aimed at technology integration, although a situative perspective is widespread in research and development of technology-based educational programs. Indeed, the Report to the President on the Use of Technology to Strengthen K-12 Education in the United States (Panel on Educational Technology, 1997) consciously grounds its recommendations concerning technology integration, professional development, and educational technology research within a constructivist and situative theoretical framework. The Panel's argument for these later approaches is analogous to Putnam and Borko's (1997) finding that teacher educators should treat teachers as they expect teachers to treat students; it only makes sense to model best technology integration practices when attempting to get teachers to use them.

It only makes sense, and yet most professional development programs aimed at technology integration are instructionist, application-driven, after-school workshops or summer "institutes" well removed from classroom practice. Some have argued (Wilson & Berne, 1999) that while not optimal, such approaches are often the only practical solutions to meeting large-scale professional development needs with limited resources. There has been very little investigation of the effects of these traditional professional development activities, however, on technology integration at the classroom level. In fact, what little research there is suggests such activities have little impact on the day-to-day integration of computing technologies into classroom teaching and learning (Becker, 1994; Panel on Educational Technology, 1997; Educational Testing Service, 1998).

It is hard to see how approaches that consistently have little or no effect on classroom-based technology integration can bee deemed "practical," thus we decided to try an "impractical" approach. In the remainder of this paper, we describe a professional development program which has adopted an approach to technology education that is situates professional development in day-to-day classroom practice.

The CATIE Program

The Capital Area Technology and Inquiry in Education (CATIE) program was established through the Institute for Pre-College Initiatives at Rensselaer Polytechnic Institute (RPI) as an innovative means for addressing technology-based, constructivist-oriented staff development in elementary schools in the greater Albany (NY) area. This unique program places technology experts in school buildings where they serve as mentors to teachers interested in integrating the use of technology into their day-to-day classroom activities. The school-based mentors provide training to teachers on technology utilization, but, more importantly, do so in the context of jointly designing computer-supported lessons that incorporate technology into existing classroom curricula. Teacher learning about technology integration is thus situated in authentic technology integration activities.

Typically, the mentors first meet with teachers, both individually and in groups, to discuss how technology might be used to enhance learning in planned units on particular topics. Mentors try to avoid planning that is either artificial or focused on specific software applications. They then work with teachers to design computer-supported lessons that are integral parts of larger, classroom-based learning units. They encourage inquiry-based, student-centered, constructivist uses of computing technologies, but do not insist on them. Often, mentors model best practices in computer-based teaching and learning by taking the lead in implementing jointly created lessons. They then guide teachers in designing and implementing their own computer-based lessons, finally fading their support as teachers become more confident in the use of computer technologies.

Mentor support, however, does not just disappear. Each mentor structures his or her schedule according to their school’s individual needs, but is generally available two or three days each week for a period of two years or more to work with teachers and their students on a continuing, as-needed basis. Many teachers, having mastered a particular technology tool, return to their mentor for help in utilizing other applications in their teaching. Some teachers just come to share with their mentors the ways in which they are using technology on their own, and some mentors meet regularly with groups of teachers to discuss technology integration. As mentors become a part of the culture of the school, formal and informal conversations of this sort become more common and ongoing, and a discourse community grows up around technology integration.
The major goals of the CATIE program are to foster individual teacher and student development of technological skills, to assist teachers with the infusion of technology into existing curricula, to broaden the use of computing technologies within the elementary school setting, and to foster constructivist teaching and learning around electronic technologies. It is an ongoing program and has grown from a single mentor in one school to more than ten mentors working in fourteen elementary schools in four school districts. Indeed, the model is currently being institutionalized in at least one of these districts as the preferred means of technology training.

Research Methodologies

In keeping with its constructivist goals, research on the CATIE program is being conducted using an action research approach. Mentors work with the researchers to set an evolving research agenda, collecting data and sharing it in weekly meetings with the researchers and each other. Of course, as with mentors work in the schools, constructivist approaches can be slow going, and this process has taken time. Data being collected to date centers on narratives structured to tell the stories of the mentors’ experiences and the themes that emerge from them. Other data being regularly collected include: time spent on particular mentoring activities, teachers worked with, lessons planned, subject areas and learning standards addressed, technologies used, and grading rubrics. The mentors have also been collecting student work, and project researchers are conducting observations in representative classrooms. In addition, outside evaluators have conducted interviews with each of the mentors and a sample of participating teachers.

Data analyses for the first year of CATIE’s operation concentrated on four objectives:

- documenting how mentor services were utilized
- identifying best practices in mentoring
- assessing stakeholder perceptions of the CATIE program
- identifying areas in need of change or additional resources.

Data analyses for this, the second year of CATIE’s operation will focus on:

- evidence of teacher change
- student learning
- mentoring themes
- categories of technology integration

Findings

Clearly, the CATIE program exhibits the features Putnam and Borko (1997) identify as essential to effective teacher education:

- Teachers involved in the CATIE program are treated as active learners who construct their own learning to meet their own specific professional needs. CATIE mentors serve as facilitators for that learning but follow and respect the directions it takes.
- Thus, teachers in the CATIE program are empowered to use technology in their teaching (through the on-site support of the mentors) and treated as the professionals they are.
- In the CATIE program, teacher learning about technology integration is situated in classroom practice.
- CATIE mentors model constructivist, student-centered teaching with technology in their work with both students and teachers. Mentors thus treat teachers the way they would have them treat students.

Most mentors spend the majority of their time working with teachers and students in the computer labs of their participating schools, although they also assisted some classes within their own classrooms. The latter is the goal of the program and something to work towards in the future. A related goal is to encourage teachers to look beyond their current uses of technology. This seems to be happening with the more technology-experienced participating
teachers, and with teachers involved in their second year with the program. The CATIE program has also made significant gains in helping teachers less familiar with educational technology become comfortable in its use.

Flexibility and adaptability were found to be central to best practices in mentoring. Mentors' ability to work with variations in teacher learning styles, pedagogical approaches, and prior experiences, as well as with existing school technology resources were found to significantly influence technology integration in schools and classrooms.

Teacher perceptions of the CATIE program were overwhelmingly positive. Teachers uniformly reported increased knowledge of computing technologies, greater confidence in using them, and more creative teaching with computers. Positive outcomes for students, including greater independence, heightened self-efficacy, and increased motivation, were also noted by participating teachers. In addition, the CATIE program has been a positive experience for mentors as well, giving them the opportunity to become part of school communities while learning more about technology infusion therein.

Finally, additional resources needed to improve the mentoring program included:

- **Time** -- More time is needed for teachers to work with the mentors and experiment with the technologies. Teachers would also like mentors to be available more times in the schools. Mentors would like more time to meet together to share strategies and projects.
- **Technology Resources** -- Many schools and/or classrooms had outdated hardware and software; access to better technology resources would make it easier to implement best practices.
- **Administrative Support** -- Administrative support can lead to changes in the culture of a school such that it supports technology integration. Administrative practices identified as most supportive of technology integration included: defining mentors' roles early in the school year, discussing technology integration with teachers, frequent visits to the computer labs, spotlighting teachers' technology-based projects and other systems of rewards for technology using teachers, and support for technology needs.
- **Additional Opportunities for Teacher Learning** -- Additional opportunities for teacher learning requested included: summer technology workshops, planning meetings with mentors before the beginning of school, and more one-on-one learning opportunities during the school year.

**Educational Significance**

Although early on in its development, the CATIE program seems to be positively affecting technology integration in the schools in which it is operating. Indeed, in its second year of operation, its effects are becoming clearer. Perhaps the best measure of its success is that one of the districts in which it has been implementing is adopting mentoring as the preferred means of technology training. Common sense indicates that the CATIE program is successful because it is reaching out to teachers in the physical and social context of their practice, because it provides ongoing, long-term support for technology integration, and because of the personal relationships mentors are forging with participating teachers and within the culture of the schools in which they work. Its success thus supports a situative perspective on teacher learning, especially teacher learning about technology and technology integration.

Electronic Literacy Standards for the 21st Century

Karen Swan
University at Albany
ED 114A
Albany, NY 12222
swan@cnsvax.albany.edu

Abstract: This paper explores the notion that the desired outcome of current technology initiatives is technology integration across the curriculum. It argues that technology integration across the curriculum can best be understood in terms of an expanded notion of literacy; that technology integration across subject areas and grade levels can best be guided and assessed in terms of the critical and creative uses made of nonprint media and computing and communications technologies. To such ends, it presents a possible set of performance-based, nonprint media and technology literacy standards for guiding and assessing technology integration across the K-12 curriculum.

Perspectives

For the past several centuries, the dominance of print over other forms of communication media has been overwhelming and largely unchallenged. Recent decades, however, have witnessed rapid changes in how we communicate with one another, entertain ourselves, conduct business, get information, create knowledge, and generally make sense of the larger world. Electronic texts are everywhere replacing printed ones as the media of choice in a wide range of human endeavors. Our notions of what it means to be literate are correspondingly expanding.

For example, the National Council of Teachers of English (NCTE) and the International Reading Association (IRA) state in their summary of the national Standards for the English Language Arts,

"... being literate in contemporary society means being active, critical, and creative users of print and spoken language, as well as the visual language of film and television, commercial and political advertising, and more. It also means being able to use an array of technologies to gather information and communicate with others." (NCTE/IRA, 1996a, p. 2).

Renee Hobbs (1988) similarly argues for a new definition of literacy. "Literacy," she writes (p. 7), "is the ability to access, analyze, evaluate, and communicate messages in a variety of forms."

Indeed, as we find ourselves on the eve of a new millennium, the question is no longer whether or not we should be using new media technologies in our nation's classrooms but how we can best integrate their use across the curriculum (Panel on Educational Technology, 1997, p. 90). The Panel on Technology (1997), for example, notes that the use of computers in American schools mostly focuses on either learning about technology or drill and practice in basic skills. Other national studies have reported similar findings (Becker, 1994; Educational Testing Service, 1998).

Researchers agree that the biggest reason for such under-utilization is lack of understanding. Our own research (Swan, et. al., 1997) suggests that teachers just don't know how to make nonprint media and/or computers and communication technologies an integral part of day to day learning in their classrooms. Teachers need to learn to treat computing technologies and other nonprint media in the same ways they treat technologies of print. In the rest of this paper, I describe a set of nonprint media and technology literacy standards for guiding and assessing technology integration across the K-12 curriculum which, I believe, at least begins a discussion that accepts the use of such media as literate behaviors.
Methodology

Diane Ravitch writes, “. . . those who develop standards should recognize their role is to discover and explain the very best existing standards, not to invent new and untried ones” (1995, xxvi). In the case of nonprint literacies, three more than adequate sets of national standards collectively identify the competencies in the use of nonprint media and communications technologies experts and practitioners believe students should have by the completion of elementary, middle, and high school. These are:

- National Educational Technology Standards for Students (International Society for Technology in Education, 1998),
- Information Literacy Standards for Student Learning (American Association of School Librarians, 1998)
- Standards for the English Language Arts (National Council of Teachers of English/International Reading Association, 1996b).

These three sets of standards were chosen because they are national in scope, because they are constructivist in approach (Panel on Educational Technology, 1997), and because they all address media and technological competencies as part of a larger notion of literacy. The three sets taken together address technological literacy, information literacy, and literacy in general. All three sets of standards were developed by the leading professional organizations in their specific areas of interest, and revised through extended, open processes of review and revision that included a variety of stakeholders as well as educational technology experts.

The nonprint media and technology competencies found in these three sets of standards were reworked to a list of simple performances identifying the competencies students should have at the completion of elementary, middle, and high school, and redundancies among them were eliminated. The resulting performance standards were then sorted into three categories — basic skills, critical literacies, and construction skills — to highlight the kinds of competencies many experts believe students should be developing around nonprint media and computing technologies (Panel on Educational Technology, 1997).

According to Tyner (1998), two kinds of literacy are taught in schools. Tool literacies focus more on simple meanings and basic functionality — what Hobbs (1998) calls “access”. In our list, these fall in the basic skills category. Literacies of representation, on the other hand, stress the need to analyze information and understand how meaning is created. Traditional (print-based) literacy addresses both. Too often nonprint media and technological competencies are only addressed at the tool level. We therefore have highlighted literacies of representation in the critical literacies and construction skills categories.

Results

Basic skills, critical literacies, and construction skills are described in the sections that follow, and specific competencies for each category are given at the elementary, middle, and high school levels. The lists of standards should be understood as tentative. It should also be kept in mind that the standards lists were derived from existing national standards, and were not constructed by us. Thus, while we agree with most of the individual competencies, we do not necessarily agree with all of them. We think there may be competencies missing that represent literate behaviors which are unique to electronic media. We feel confident in arguing, however, that these lists provide a good starting point for discussing nonprint literacy and for guiding and assessing technology integration in our schools. In particular, the sorting of the standards into basic, critical, and construction skills suggests more sophisticated and literate ways of understanding nonprint media and technology literacy and provides a way of assessing not just the extent but the quality of technology integration efforts.

Basic skills are competencies involving the use and simple manipulation of nonprint media and the recognition of common conventions used by them. They include competencies related to accessing, decoding, encoding, locating, etc. In the list which follows, the basic skills students should have by completion of elementary, middle, and high school are given, in that order. These skills should be understood as cumulative; that is, by the completion of high school, students should have acquired all of them.

**elementary**
- Use a mouse to successfully operate a computer
- Use a keyboard to successfully operate a computer
- Use a computer monitor
- Use a computer printer
- Use a scanner
- Use a digital camera
- Operate a VCR
- Operate an audio tape player
- Use interactive books
- Use developmentally appropriate multimedia encyclopedias
- Use content specific educational software to support learning
- Use a variety of nonprint media resources for directed & independent learning activities
- Use a word processor
- Use computers to compose texts
- Use computers to compose graphical representations
- Use multimedia authoring tools
- Use computers to search a variety of databases
- Use data collection probes
- Use calculators
- Use email
- Participate in online discussions
- Use a browser to navigate the WWW
- Use search engines to locate & access remote information
- Use productivity tools & peripherals to support personal productivity
- Communicate about technology using accurate terminology
- Demonstrate knowledge of video conventions
- Demonstrate knowledge of computing conventions
- Give examples of situations where more information is needed to solve a problem
- List ideas for identifying & finding needed information
- Describe several ways to organize information
- Name a variety of formats for presenting different kinds of information
- Practice responsible use of technology systems & software
- Work cooperatively using technology

middle school
- Use content specific computer simulations to support learning
- Use exploratory environments to support learning
- Use graphing calculators
- Use computers to search the Internet
- Use communications & computing technologies to locate information efficiently
- Brainstorm a range of information sources to meet a specific information need
- Use productivity tools & peripherals to support group collaboration

high school
- Take notes & gather data from nonprint sources
- Use online information resources for research
- Use technology tools & resources for managing personal/professional information
- Use technology tools & resources for communicating personal/professional information
- Use online resources to enhance personal/professional productivity
- Discuss real world applications of expert systems
- Discuss real world applications of intelligent agents
- Discuss real world applications of simulations
- Explore a range of sources to find information of personal/professional interest
- Use & cite others’ work appropriately & correctly

Critical literacies are competencies concerned with the ability to interpret, critique, and evaluate nonprint texts, to synthesize information found within them, and to apply them in solving problems and increasing personal understandings. They include such abilities as making sense, analyzing, evaluating, applying, etc. The cumulative critical literacies students should have by completion of elementary, middle, and high school are listed below.

elementary
- Make sense of a variety of graphical representations
• Demonstrate listening skills
• Make sense of films & videos
• Make sense of simple computer programs
• Make sense of WWW pages
• Use computer-based puzzles & logical thinking software to support problem solving activities
• Use a variety of graphical representation to acquire information
• Use audio presentations to acquire information
• Use films & videos to acquire information
• Use a variety of computer-based resources to acquire information
• Discuss & critique audio presentations
• Discuss & critique films & videos
• Discuss & critique computer programs
• Discuss & critique WWW sites
• Use a variety of nonprint media to build self-knowledge
• Use a variety of nonprint media to understand cultures
• Distinguish between accurate & inaccurate, complete & incomplete information
• Define &/or give examples of accuracy, relevance, comprehensiveness, appropriateness & bias in non-print media and/or electronic resources
• Distinguish between fact, opinion & point of view in a variety non-print media and/or electronic resources
• Evaluate the accuracy, relevance, appropriateness & bias of a variety of nonprint resources
• Define &/or give examples of equity in access to information resources & technologies
• Define &/or give examples of intellectual freedom
• Define &/or give examples of respecting intellectual property rights
• State the main points of school policy concerning computing & communications technologies
• Discuss basic issues related to the responsible use of technologies
• Demonstrate positive social & ethical behaviors when using technology
• Discuss the advantages & disadvantages of common uses of technologies
• Select and use appropriate technology tools to complete a variety of tasks

middle school
• Analyze & explain graphical representations
• Analyze & explain audio presentations
• Analyze & explain films & videos
• Distinguish the uses of graphical representations
• Distinguish the uses of audio presentations
• Distinguish the uses of films & videos
• Distinguish the uses of WWW sites
• Evaluate nonprint media
• Synthesize information from nonprint media
• Select & use appropriate technology tools & resources to complete a variety of tasks
• Explain how inaccurate or incomplete information can lead to faulty conclusions
• Compare & contrast nonprint information sources for accuracy, relevancy, comprehensiveness & bias
• Create a plan to access information that meets a particular need
• Analyze information from a variety of sources to determine its applicability to a specific problem
• Assess both the process & the product of a specific information search
• Use multiple & diverse information sources to answer questions or resolve problems
• Demonstrate positive ethical & legal behaviors when using information & technology resources
• Demonstrate knowledge of current information technologies
• Demonstrate an understanding of the effects technological changes have on society & the workplace
• Discuss the consequences of the misuse of information &/or technologies
• Demonstrate an understanding of the concepts underlying hardware, software & connectivity tools
• Apply strategies for identifying & solving routine hardware & software problems

high school
• Choose the most appropriate formats for presenting a range of information
• Critique & evaluate advertising campaigns for a variety of products
• Recognize & compare different media genres
• Evaluate the strengths & weaknesses of various creative presentations
• Judge the quality of one's own information products & solutions
• Judge the accuracy & completeness of information & support those conclusions
• Appropriately distinguish between fact, opinion & point of view in one's own nonprint work
• Evaluate the electronic information seeking process as it evolves & make appropriate adjustments
• Discuss & evaluate technology-based options for lifelong learning
• Identify capabilities & limitations of current & emerging technologies
• Assess the potential of current & emerging technologies to address personal & workplace needs
• Make informed choices among technology systems, resources & services
• Analyze the advantages & disadvantages of the widespread use of technology in society
• Advocate for ethical & legal behaviors when using information technology

Construction skills are competencies involving the creation and use of nonprint texts for developing ideas and opinions, for communicating and collaborating with others, and for enhancing problem solving and personal fulfillment. Construction skills focus on capabilities for composing, developing, integrating, presenting, etc. The construction skills students should have by completion of elementary, middle, and high school are presented in the list which follows. The skills should be understood as cumulative.

**elementary**
- Use computer-based writing tools to communicate thoughts, ideas & stories
- Use computer-based drawing tools to illustrate thoughts, ideas & stories
- Use digital cameras to illustrate thoughts, ideas & stories
- Use multimedia authoring tools in the creation of knowledge products
- Use presentation software in the creation of knowledge products
- Use WWW authoring tools in the creation of knowledge products
- Use audio tapes for self-directed &/or extended learning
- Use videos for self-directed &/or extended learning
- Use technology resources for self-directed &/or extended learning
- Use technology resources for problem solving
- Create nonprint media for personal fulfillment
- Explain basic strategies for revising, improving & updating nonprint media
- Use telecommunications technologies to participate in collaborative projects
- Work collaboratively to seek &/or communicate information in nonprint formats
- Work collaboratively to create simple nonprint information products

**middle school**
- Use nonprint media to create knowledge
- Use nonprint media to communicate
- Differentially organize information according to differing problems
- Choose appropriate media formats for presenting a variety of information
- Use nonprint media to create information products related to topics of personal interest
- Express information & ideas creatively in nonprint formats
- Design, develop & present videotapes that communicate curriculum concepts
- Use telecommunications & collaborative tools to collaborate with peers, experts & others on curriculum related problems
- Work collaboratively over distance to create & evaluate complex information
- Select & apply appropriate strategies for revising, improving & updating work

**high school**
- Use technology to collaborate with others to contribute to a content-related data base
- Select & apply technology tools to support research in content learning
- Select & apply technology tools for decision making in content learning
- Select & apply technology tools for problem solving
- Select & apply technology tools for information analysis
- Differentially organize information so that it is effectively presented in a single nonprint product
- Express ideas creatively &/or uniquely in integrative nonprint formats
- Collaboratively create complex information over distance
- Collaboratively evaluate complex information over distance
- Devise creative ways to use information to resolve problems &/or answer questions

**Educational Significance**

To reiterate, the above lists of nonprint media and technology literacy competencies are offered as a starting point. We hope they will begin a discussion of what one should know and what one should be able to do to be considered literate in the 21st
century. Thus, they are also intended to precipitate discussions of how we should be teaching and learning about literacy in our schools today.

Most importantly, we hope the lists will encourage educators to extend traditional notions of literacy to include critical and creative uses of images, video, and electronic texts of all sorts. We hope they will encourage educators to stop treating technology as a separate subject to be taught, often as a “pull-out,” and to start treating the use of electronic media as a form of literacy to be integrated across the curriculum. In particular, we hope that educators will take special note of the critical literacies and construction skills categories and make mindful efforts to include these whenever they incorporate technology usage in teaching and learning.

Changes in communications technologies over the past century have created a world culture that has extended and reshaped our symbolic environment. Today, most Americans receive the majority of their news, information, and entertainment through electronic sources. It only makes sense that we should teach our children to use those sources well, and that we make the use of electronic media an integral part of the daily activities in every classroom in this country. The nonprint media and technology literacy standards herein presented offer a starting point for discussion towards such ends.

Abstract: This paper presents the quantitative results of a study that examined the effects of the structure of learning activities and the learner characteristics of prior knowledge, ability and attitudes on students’ acceptance of control opportunities while using hypermedia software and consequent learning outcomes. Participants in the study were 101 year 8 students in two Australian schools. A confirmatory factor analysis of a model that theorized the relationships between the variables did not fit the data well, but careful substantively based amendment of the model saw the introduction of a new factor that resulted in an improved fit. The new factor was that of the school which students attended, a factor that proved to have greater influence than the hypothesized variables. This paper is supported by a related article which reports the results of qualitative data collected for the same study.

Introduction

Catering for the needs of individual students by offering some control over learning is a commendable ideal that has been seen by many as offering opportunities to help students reach their potential. Although research in the area of learner control has often been surrounded by a great deal of enthusiasm, the reality of the situation is that research findings in learner control are mixed and inconclusive. There are those who claim that there are no positive findings to support the enthusiasm (Nienmiec, Sikorski & Walberg, 1996; Reeves, 1993; Snow, 1980) and others who suggest the benefits are limited by contexts in which control is offered and by the characteristics of learners (Dillon and Gabbard, 1998).

One of the main problems in the area of learner control is the complexity of interactions that exist between individual learners’ characteristics and the environments in which learning takes place. The number of learner characteristics is substantial, as is the variety of learning environments created. Many studies have been undertaken, but they are difficult to compare because they use different combinations of variables. For this reason alone it is not surprising that results are mixed, inconclusive and contradictory.

There are individual characteristics that have been studied to a greater degree than others that do offer some more consistent, positive findings and which suggest promising trends or directions for classroom practitioners to cater for needs of individual learners. Some studies have found that learners with varied abilities (Gray, 1987; Hooper, Temiyakarn & Williams, 1993; Kinzie et al., 1988; Singhanayok & Hooper, 1998), learning styles (Ferguson, 1988; Klein & Keller, 1990; Santiago & Okey, 1992), preferences (Carrier & Williams, 1988; Hannafin & Sullivan, 1995; Hannafin & Sullivan, 1996; Hicken, Sullivan & Klein, 1992) and levels of prior knowledge((Gay, 1986; Gay, Trumbull & Mazur, 1991; Kinzie & Sullivan, 1989; Ross, Morrison & O’Dell, 1989; Shin, Schallert & Savenye, 1994; Stephenson, 1992) differently accept levels of control.
The importance of learner control research is amplified by technological developments allowing the creation of interactive learning environments that are being adopted rapidly and enthusiastically, with considerable investment of financial resources and practitioner time and effort. Hypertext, hypermedia and multimedia environments offer masses of information that can be navigated according to the interests and needs of users. Multiple links and reference points provide a network of possible paths for investigation. The problem associated with the use of these systems is that although learners are provided a high degree of control, they can become overwhelmed with the number and scope of choices available to them. Rather than accepting the myriad of opportunities offered by hypermedia learners may utilize only a small number of the choices available to them, failing to make effective use of the software. It is apparent that if we are to continue to adopt the use of hypertext, hypermedia and multimedia products in education then there is a need to identify how we might support students' use of the software and encourage them to make effective, productive and independent use of such systems.

One approach to supporting students is to attend to the design of the user-interface of software packages, finding ways to provide help for students within the software. This may be done by developing adaptive systems that respond to user input, limiting available options by providing a smaller number of options to novices and increasing available navigational choices as expertise and learning in a domain develop. Another approach to support student use of complex software packages effectively is to consider the learning environment in which the software is used and identify classroom practices and develop support materials that will encourage and support effective learning. Rather than developing software that attempts to cater for the needs of all students, it would be better to utilize the talents of teachers in catering for individual needs while making powerful resources available to them and their students. The main aim of the research presented in this article is to utilize existing hypermedia products available on the educational software market and find procedures and strategies that can be used in the classroom that will encourage students to make effective, productive and independent use of such systems.

Research Model and Study Description

There are a number of studies that have produced some arguably consistent findings regarding particular variables concerned with provision of learner control. These include the amount of control afforded to learners, the level of prior domain knowledge and prior system knowledge, ability, locus-of-control, and students' learning goals or task orientation. The findings for these variables have been reported in terms of achievement outcomes, motivational and attitudinal outcomes and learning efficiency. As it is not possible to effectively address all of the above mentioned variables in a single study, a subset of variables form the focus of this research. Those examined were selected because they have a history of research findings that provide a sound theoretical base.

A theoretical model based on the variables of interest and their hypothesized effects on each other can be expressed in the form of a covariance structure model. Such a model is presented in Figure 1. The model illustrates the theory that prior domain knowledge, learning activity structure, ability and attitude causally affect the acquisition of knowledge and students' post attitudes indirectly through a learner's acceptance of control opportunities. Also, prior domain knowledge directly affects acquisition of task-specific and non-task-specific domain knowledge and software structure knowledge; ability directly affects the acquisition of task-specific and non-task-specific domain knowledge and acquisition of knowledge of software structure; and, prior attitude directly affects post attitude. While it was expected that the weights of the direct effects would be fairly strong, for example prior attitude would have a strong effect on post attitude, it was also predicted that the weights of the indirect effects mediated by acceptance of control opportunity would not be insubstantial.
To investigate the variables of interest identified by the research questions and hypotheses, a 3x2 factorial design with three levels of structure (worksheets of high, medium and low structure) and two levels of prior knowledge (high and low) was utilized. So that an authentic educational situation could be the focus of research intact classes were used for grouping. In addition, as the research literature indicates that boys tend to dominate activity in coeducational computer-based activities (Culley, 1990; Fatouros, Downes & Blackwell, 1994; Hattie & Fitzgerald, 1987), single gender schools were used so as to remove the effects of gender interaction and increase the generalizability of the findings. Rather than fully replicating the study with six groups in both boys' and girls' schools, the strategy of fractional replication was employed in this design. This was done to remove the effects of gender interactions as an uncontrolled variable, while allowing the practicalities of conducting the study for each gender to be met. Participants in the study were 101 year 8 students in two Australian schools who examined software on the topic of the Australian federal parliament.

Measures for quantitative data are shown in the rectangles in (Fig.1). Data were collected by asking students to complete questionnaires for attitude measures and written tests of knowledge to help determine levels of domain specific, non-domain-specific and software-structure knowledge. In addition student interactions were recorded by the software in the form of audit-trails that stored information about every active choice made in the software during five 40 minute lessons. To supplement the quantitative data that aimed to identify 'what' students did, qualitative data in the forms of student interviews and analyses of navigational choices aimed to identify 'why' students made particular choices and adopted particular navigational strategies. Qualitative results are discussed in a related article.

**Results**

**Quantitative**

A confirmatory factor analysis of the covariance structure model shown in (Fig.1) produced goodness-of-fit indices that were very good for the left-hand side measurement model (Goodness of Fit (GFI)=.96, Comparative Fit Index (CFI)=1.0, Standardized Root Mean-square Residual (SRMR)=.051), but not acceptable for the right-hand side measurement model (GFI=.85, CFI=.91, SRMR=.099). With the poor fit of the right-hand side measurement model it was not surprising that the structural model, whose analysis is based on the two measurement models was less than ideal (GFI=.72, CFI=.74, SRMR=.12).

Careful, substantively based post-hoc analysis resulted in the identification of a modified model that produced a better fit than the originally proposed model (GFI=.87, CFI=.91, SRMR=.071), and which could be described as a marginally good fit. This alternative model is shown in (Fig. 2), including the standardized parameter estimates and error terms. The most important feature of the alternative model produced was that a new factor...
was introduced, and that this factor produced the highest parameter estimate between an exogenous variable and acceptance of control opportunity (.62, p<.001). This variable was introduced due to observed differences between the navigational approaches of students at the two schools when the study was being undertaken, supported by statistically significant differences on the measures of acceptance of control opportunity between the two school groups. The implications of this introduced factor are addressed in the later discussion.

**Figure 2:** Alternative model showing completely standardized parameter estimates and error terms.
Note: # indicates the y-value for each factor that was set to 1.0 to establish the scale of each factor resulting in no test of statistical significance calculated by LISREL. * p<.05, ** p<.01, *** p<.001

**Qualitative**

While the quantitative results identified that the school students attended was an important factor influencing choices made in the use of the software, this methodology can not identify why this may have been the case. An analysis of the qualitative data for this same study identified three possible factors that may have influenced the strength of the school factor: specifically these were, the gender differences of students at the two schools, the epistemological beliefs of students and the different cultures and learning environments that existed at the two schools. A more comprehensive report of the qualitative findings is presented and discussed in detail in the supportive short paper ‘The Emergence of ‘School’ as a Factor Influencing Patterns of Navigational Choices in Hypermedia’ in this ED-Media 2000 conference proceedings.

**Discussion**

The research reported in this article identifies an unexpected factor, that of the school which students attend, as having a greater influence on students’ software use than those identified in the literature as being potentially influential. Unfortunately the adoption of a fractional replication in the 3x2 factorial design, based on the gender of students, did not allow the identification of specific variables that may have caused the strength of the factor. Fractional replication was used in this study to remove the effects of gender domination in software-use, but in-fact caused complications in the light of the unexpected outcomes.

The unanticipated finding that the school which students attend can have an effect on navigational choices in software does have important implications however. The identification of this variable as being potentially influential on students' software choices is important in the design of any learning environment and to the policy decisions made about education and technology. The obvious question that arises is that of ‘... what are the important factors in the schools that influenced students use of software?’ The qualitative results from this study suggest three possible contributing factors, specifically those of the genders of the students, the
epistemological beliefs of the students and the learning environments created by the cultures of the schools. These potentially contributing factors are discussed in greater detail in the supportive article reporting the qualitative results of this study, and are also worthy of further attention in subsequent research studies.

Abstract: Using Web Pages for supplemental materials in the classroom is very popular. However, some Web Pages are not suitable for educational use as their stuffy description. Our research aims at translating these formal web pages into plainer Japanese sentences. We provide the system as a proxy program running on UNIX workstation. The main part of this system consists of three phases - morphological analysis, transformation, and mark-up. It is expected that students can read web pages easily by using our system. At the beginning of this paper, we describe the overview of our proxy program and implementation of it. Then we explain many functions of our proxy program. The functions are divided into two categories - “linguistic functions” and “multimedia and appearance functions.” At last, a brief experiment result is also mentioned.

Introduction

As the Internet has come into wide use, the WWW is rapidly becoming a great knowledge resource in the educational domain. Many teachers use a variety of web pages in their classroom. There are many culturally oriented web pages, for instance, those pages produced by museums, galleries, libraries, etc. They are suitable for supplemental materials in the classroom. However, the purpose of these pages is not always for educational use only. Often, an overly formal or “stuffy” language-style is used in conveying information. Students sometimes hesitate to read these formal language descriptions. Our research aims at translating these formal web pages into plainer language in order to better suit students' abilities and understanding.

We have implemented this translation program as a proxy program on our proxy server. The reason is that we do not have to distribute our program nor install it on students' PCs. Another merit of this implementation is that we can administer our proxy program.

The following sections in this article, we will discuss many Japanese-specific problems, as our target language is Japanese and we assume the input of our proxy program is the web pages created by Japanese cultural sites and the output web pages would be read by Japanese students. However, we also explain the language-independent functions of our proxy program, such as appearance functions.

In the following sections, we explain our proxy program overview, functions, a brief experiment and its result. Then we discuss the merits and the demerits of our proxy program in the considerations section. Finally, we describe our future plans in the conclusions section.
A Proxy Program Overview

Figure 1 shows the overall system of our proxy program. When students access any web pages that they have difficulty with, they can use our proxy server to translate the web pages into plainer language. Once they have set the proxy server to the URL of our site in their web browser setting, they don’t have to be conscious of our proxy program.

Figure 2 shows the flowchart of our proxy program. As shown, the program consists of following three phases.

1. Sentence resolution
   This phase resolves an input HTML document into sentences and HTML tags.

2. Translation
   This phase is composed of “linguistic translation” and “multimedia and appearance functions.” We will describe these functions in the following sections.

3. Document reconstruction
   In this phase, translated sentences and translated HTML tags are reconstructed as original documents.

Linguistic Translation

Linguistic translation process is composed of following three steps.

1. Morphological analysis:
   In Japanese sentences, we can determine the part-of-speech of each word by morphological analysis.

2. Transformation:
   This is the main step of the linguistic translation process. The syntax of the input sentence will be changed according to transformation rules (described in the next section).

3. Mark-up:
   There are many technical terms in web pages. Our approach is to mark-up difficult terms with HTML tags. The user can then open a link to yahoo.com, or an on-line dictionary, by clicking on these terms. Optionally, we can replace difficult terms with easier expressions. However, these expressions may contain the main theme of the web page. Also, too much added description may cause the reader to become frustrated. Utilizing our proxy system, users can specify the difficulty-level for the program to automatically mark up text, thus giving the user a number of options to selectively control the proxy program’s functioning. Currently, we have catalogued approximately 6,000 Kanji characters, divided into various levels of difficulty, in order to create optional levels of automatic selection and descriptive narration for the user.

Transformation rules

1. Compound noun phrase transformation
Similar to English, Japanese sometimes uses long compound noun phrases. Long noun phrases give readers serious and formal impression. This category of rules inserts "no" (similar to "of" in English) at appropriate positions in order to make a phrase easier to read. The search algorithm for the appropriate position is based on [Tsutsumi 89]. Figure 3(a) shows an example of compound noun phrase transformation.

(2) Formal expression replacement

There are several formal expressions in Japanese sentences. "Formal expression replacement" replaces those expressions which contain adverbs and auxiliary words, as they are function words. Function words create a "stuffer" sentence than content words do. This rule replaces the formal syntax, which is determined by adverbs and auxiliary words, with a plainer syntax.

(3) Sentence length adjustment

If a sentence has more than ten phrases, the sentence will be divided at a conjunctive auxiliary into two sentences. This rule will supply a conjunction between the sentences. Figure 3(b) shows an example of sentence length adjustment.

Multimedia and appearance functions

(1) Iconization of hidden image
Web pages have many links to image with “here” or “this.” For example, “You can see the castle by clicking HERE.” This type of web pages is often dull. Therefore, we replace “HERE” with “FIG. 1” and place the iconized

(a) Compound noun phrase transformation

(b) Sentence length adjustment

Fig. 3 Examples of linguistic functions

(a) Original web page(s)

(b) Result web page

Fig. 4 An example of appearance functions

image of linked one. Students will be interested in the graphical pages. Figure 4 illustrates an example of iconization of hidden image. If the classroom computers are connected to the Internet via low speed line, loading the graphical pages needs students’ patience. We provide an option for this problem. After students choose this option, hidden image iconization function will not be effective.

(2) Font size replacement
We often use small font in order to show much information in one page. However, too small fonts make readers be tired of.

(3) Reformation of list-items
Students must push a scroll button many times, if there are too many items in a web page. This function divides list-items into several pages, and students can get next items by clicking “forward button” created by this function.

Pedagogical Evaluation
We have tested our proxy program briefly. The examinees are five junior college students. We first showed them translated web pages and asked whether the web pages are easy to read or not. Then we showed them the original web pages and got their impressions.

Table 1
“The translated web pages are easier to read.”

<table>
<thead>
<tr>
<th></th>
<th>Agree</th>
<th>Disagree</th>
<th>Not answered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Page A</td>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Web Page B</td>
<td>4</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Web Page C</td>
<td>5</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Web Page D</td>
<td>3</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

Some of the impressions are:
“It is clear to read.”
“Iconized images are good. If a web page is full of characters, I would hesitate to read it.”
“Too much HIRAGANA characters are messy to read.”

Considerations
In this section, we discuss the advantages and aspects of our approach.
(1) Usage
Students can easily use our program because our program is developed as a proxy program. Once students have specified our server as a proxy server, they will get translated web pages without any operation. This is very important in elementary school students. Most of them do not have computer operation skill yet.
If the classroom PCs are protected by a firewall and they must use the proxy server inside the organization, a way to use our proxy program is the proxy chain from the proxy server inside the firewall to our proxy server. However, you have to ask your system administrator to fix it.

(2) Performance
Our proxy program’s process is light because we only use morphological analysis. Unlike semantic analysis or syntax analysis, the morphological analysis is very fast and reliable. As our program is running on our server, we do not need high-speed client PCs. On the other hand, when many students use our proxy program at the same time, the turn-around-time would be very long.

(3) Transformation Rules
We have defined several transformation rules. However, we have to add some rules in order to improve the readability of the translated web pages.

(4) Dictionaries
We provide three dictionaries, analysis dictionary, Chinese character dictionary and Japanese-language dictionary. The analysis dictionary cannot be viewed from students. It is used for morphological analysis. Other dictionaries can be accessed via WWW. Chinese character dictionary is also used for translation level setting.
Adaptability to the multimedia technology progress

The multimedia technology has been rapidly progressing these days. We have incorporated an adaptive mechanism for future changes in multimedia technologies into our proxy program. To be concrete, our proxy program has an action table in which each file type is registered as an index of table with a program name. When the proxy program detects any file type in the table, a corresponding program will be activated. When your web browser cannot handle Quicktime movies, you can see the movies in MPEG format, if you have a format conversion program.

Mark-up

To mark up difficult words is for searching for words in a dictionary or searching for related items in web pages. It is necessary to build a web-based dictionary for users of this system in order to use this easily.

Conclusions

In this paper, we have described our proxy program to translate web pages into plainer language. Our program is designed to help students utilize cyberspace as an educational tool for sourcing out information related to classroom presentations and learning. Using our proxy program, students will not have to hesitate at formal language, as words that are difficult to understand are each marked-up to search for in a dictionary, or selectively replaced with a plainer syntax. Also our program rebuilds messy web pages to tidy web pages. These translations allow young students to start to read the web pages. We believe that our proxy program can be an effective tool for learners of Japanese as well as for young Japanese students.

Since our target language is Japanese, we have discussed some Japanese specific problems. For example, difficult-to-read characters are rarely appeared in English sentences. However, some functions of our program are language independent, such as multimedia and appearance functions.

Our future plans include further experiment and evaluation of our program in the classroom. We also plan to apply our proxy program to other languages.

Abstract: This paper analyses traditional methods of teaching Electronics to non-electronic engineers and proposes an alternative educational system involving theoretical and practical learning. The proposed system is divided into hardware and software resources. Hardware resources comprise a PC and external circuits corresponding to representative electronic systems. Software resources provide students with a unique environment containing hypermedia theoretical lessons, simulation tools and virtual instrumentation. Through theoretical lessons students access to simulation and practical exercises where they verify the behaviour of a real circuit using virtual instrumentation.

Introduction
Continuous training of engineers and technicians is one of the most urgent tasks of modern industry. This is mainly due to the vertiginous evolution of technology imposing very demanding competitive levels. That is the reason why both companies and governmental institutions promote applied research projects developing new teaching methods, contents and resources.

At present our research group is working on a project whose objective is the development of a system for non-electronics engineers training about the fundamentals and applications of Electronics. Even though the project contents are focused on a specific technological area (Electronics) the methods we propose can be extended to other educational levels and technology fields.

This project is a joint venture between the Institute of Applied Electronics "Pedro Barrié de la Maza" of the University of Vigo and TEFASA S.L., and is co-financed by the European Regional Development Fund (ERDF).

Background
Traditionally Electronics education of non-electronics engineers has been carried out combining theoretical education with the assembly of circuits using specific measurement instruments like power supplies, voltmeters, oscilloscopes, and signal generators (LAGO 93)(MIRI 93). But this method is very costly and it is not really useful for non-electronics engineers.

An alternative method is the system analysis using kits (COEL 96)(MICR 97)(SALE 96). The kits advantages are the low cost and the possibility of implementing them when and where convenient favouring the independent learning. Nevertheless from an educational point of view the role of the kits is very limited because they are only designed to show specific systems running and not to carry out measurements nor explain the concepts of system functionality.

The previously mentioned disadvantages can be overcome using computer assisted learning (CAL) methods. The potentiality of computer hypermedia resources, and the low cost and widespread diffusion of computers, convert CAL into an essential teaching tool. In the case of Electronics the computer can be used as support both for theoretical and practical teaching. In this sense three kinds of applications can be pointed out:
- Tutorial systems: Mainly oriented toward the explanation of theoretical concepts and self-evaluation allowing individual and non-presential learning (CUET 94).

[1] Spanish company dedicated to the development and marketing of didactic systems.
- Simulation programs: Oriented toward the analysis of circuits operation modes and fundamentals avoiding their practical implementation. Using simulation programs system design and faults detection is carried out before its implementation (MICR 96)(RASH 90).

- Virtual Instrumentation systems (VIS): Made up of a data acquisition board connected to the computer and a program controlling the data acquisition and the information processing. The results are shown on the computer screen using a format that resembles traditional measurement instruments (oscilloscopes, voltimeters, signal generators, etc.). From an economic perspective VIS represent a very appealing alternative in the cases where bandwidth and precision are not very important constraints. From a teaching/learning point of view VIS are low cost laboratories affordable to small and medium sized enterprises or to engineers interested in a continuous training at home (KEIT 97)(LABW 94).

CAL tools can be used for courseware development. Courseware combines computers with real circuit modules where students are able to measure some parameters without modifying their design or structure. These systems are principally based on methods based on proposing questions and analysing several solutions. In most cases they consist of lessons guiding the analysis of a specific circuit. These lessons are tutorials linked to simulation programs or virtual instrumentation systems to carry out measures on pre-established test points of the analysed circuit to verify its behaviour when some variations or faults are introduced (ALEC 95)(EURO 94).

Nevertheless, many research works point out that the methods based on problems solution and practical experimentation are the most adequate approach for teaching technologies like Electronics (BARK 95)(KLEE 94)(VIAU 94). From this perspective we considered the development of a new product oriented not only to the analysis of basic circuits as an introduction to Electronics (What they are and how they work?), but also showing different electronic systems applications.

The proposed system

The features of a system oriented to the education of non-electronic engineers of small and medium sized enterprises must take the following aspects into account:
- Consistent theoretical contents allowing progressive and individual learning.
- Availability of resources for simulation and analysis of real circuits, including faults detection and changes.
- Possibility of individual (at home) or co-operative learning.
- Low cost.
- Portability.

To meet these requirements we developed a CAL system combining theoretical lessons with simulation and experiments using adequately chosen electronic modules. The objective of our system is to achieve a consistent base of basic knowledge making the comprehension of present and futures technologies easier as well
as the development of skills for the verification and maintenance of electronic equipment. From the point of view of the system structure, it can be divided into a hardware system and a software one.

Hardware system

The hardware system consists of three basic elements (see Figure 1):
- A set of real circuit modules related to each lesson.
- A base to support the modules.
- A personal computer.

The modules are circuits oriented to the introduction of simple electronic devices or systems that can be interconnected to obtain more complex ones. Our proposal envisages the possibility that some modules be closed systems oriented to the analysis of circuits where modifications cannot be carried out. Other modules are open systems oriented to the design of simple circuits that engineers themselves can connect and modify if applicable.

The base to support the modules is the equipment where the circuit modules related to each lesson are connected. They are made up of:
- a) A control system that establishes the communication protocol with the computer, acquires data when a test must be carried out, or induces faults in specific points of the analysed circuits.
- b) Power supplies and common circuits (signal conditioning circuits, protective circuits, etc.) are placed.

The personal computer sends information to the control system for generating test signals or inducing faults. It also receives information from selected test points.

Software system

The software system is made up of:
- a) A hypermedia application oriented toward the presentation and evaluation of contents.
- b) Simulation tools to facilitate the analysis of circuits.
- c) Virtual instrumentation (oscilloscope, logic analyser, voltmeter and functions generator) for data acquisition from different test points.

Access to these resources is carried out from a main program (user interface) that resembles a Windows browser. In this way the user is provided with a familiar environment avoiding additional learning. Besides, a multiplatform system (Java interface) is used to guaranty its diffusion and the implementation of new functions not foreseeable in the first phase of the project, such as the use of networks like Internet.

Hypermedia application is the core of the system. It is made up of theoretical lessons complemented with simulation exercises and experiments. Each lesson has hyperlinks permitting access to other lessons, to the simulator or to the virtual instrumentation system.

At present the contents of the system are oriented toward the following areas of Electronics:
- Basic electronic devices and circuits.
- Analog circuits and systems and their applications.
- Digital circuits and systems and their applications.
- Introduction to embedded electronic systems: Principles and applications of microcontrollers.

Future versions will extend the system to other Electronic fields.

To guarantee progressive learning information is structured from general to more specific concepts using an original method for complex technologies education (VALD 97)(VALD 99). Users can navigate through the application linking related information which broadens their previous knowledge. Figure 2 shows some screens of the application that illustrate this methodology.

The first screen defines Electronics using a pyramidal structure with four levels corresponding to the main topics of the application: solid state electric phenomena, electronic components, electronic circuits and electronic systems. Each part of the pyramid is an active zone permitting access to the corresponded topic. For example clicking on "Electronic components" the second screen appears.

[2] The information in a hypermedia application is structured in nodes containing different concepts. Links can be established between related nodes (related information) providing users with different paths to analyse and understand a concept. Each user looks up the application in an intuitive way, pathing through those nodes that allow him/her to extend the information or introduce himself/herself in a new concept (LESK 91)(RAMI 97)(SHNE 89)(TERR 94). Besides, hypermedia applications include audio-visual resources (texts, images, animations, videos, etc.) especially useful to present many concepts which are very difficult to explain by means of words.
The second screen is the first one of the topic "Electronic components" and classifies them into linear, non-linear, passive, active and integrated circuits. This screen links with others where concepts related with each classification are explained. Navigating through the link "passive" of this screen users can arrive to the third screen of Figure 2 where the electrical characteristics and a typical application of a photodiode are presented as an example of a passive device.

![Screen 1: Electronics Definition](image1)

![Screen 2: Electronic Components Classification](image2)

![Screen 3: Passive electronic devices: Photodiode](image3)

**Figure 2: The hypermedia application.**

**Conclusions**

The system being developed is based on the new information technologies to achieve non-electronic engineers education about the analysis of basic circuits as well as electronic systems. To carry out the educational training a computer is used as theoretical and practical instruction tool (using hypermedia techniques and virtual instrumentation systems). As a result we develop a training system including the following features:

- Guided instruction using hypermedia applications.
- Circuits analysis using simulation programs.
- Testing of real systems by means of virtual instrumentation.
- Individual or co-operative learning.
- Self-evaluation.
- Possibility of expansion (contents and functions).
- Competitive cost.

Abstract: Changes in the educational methods of nursing students created great possibilities for the use of computer technologies. With the help of computer-based multimedia technologies we can build libraries of simulated clinical problems (patients encounters) that can serve to fill some of the gaps in the current educational systems. This paper covers the structure of a patient simulation system in the early stages of development, called CompuPatient. Feedback from a questionnaire sent out to collaborators on the project is being used as a foundation for the design of a system customized to fit the requirements of the collaborators. The outcome of the questionnaire will be discussed. This will be followed by a discussion on the users involved in a patient simulation system. The final section and also the focus of the paper is the basic structure of CompuPatient covering the primary modules involved and communication between them.

Introduction

The traditional way of teaching nursing and medical students using lectures can be enhanced by a more active and enjoyable approach, namely Problem-based Learning (PBL). According to Albanese and Michell (1993) as quoted by Finucance et al. (1998) PBL is "an educational method characterized by the use of patient problems as a context for students to learn problem-solving skills and acquire knowledge about the basic and clinical sciences". It seems that more and more nursing and medical educational institutions are integrating this approach in their curriculums (Finucance et al. 1998).

One way of presenting PBL to the students is by using sessions. A session, usually two to three times a week, will start with a presentation of a clinical problem in a small group setting. The group discusses possible causes and develops hypotheses and strategies to test these hypotheses. They are then presented with further information. Some information is omitted for self-study between sessions. The information gathered from self-study as well as the information presented to them is used to refine their hypotheses, and to finally reach a conclusion. A facilitator guides the students in this group-learning process. The student and facilitator evaluate the session at the end (Finucance et al. 1998).

A further possibility when using PBL is the use of a standardized patient, which is an actor that plays the role of the patient in the clinical setting or an actual patient. The students can interact with this patient. The use of standardized patients can enhance the presentation of the clinical problem.

Although PBL is widely used by educational institutions, disadvantages do exist. These disadvantages include a greater demand for teacher time, stress experienced by students and teachers, less knowledge acquired of basic sciences, the difficulty in implementing PBL with large class sizes, and finally the costs involved (Finucance et al. 1998). Standardized patients augment this list of disadvantages with the lack of appropriate patients, difficulty in scheduling a standardized patient for a PBL session and the inconvenience of using the same patients over and over
again (Roberts et al. 1995). When using an actor as a standardized patient another problem becomes apparent: an actor cannot have all the attributes of an actual patient.

Personal computers with multimedia support is more accessible than in the past making it feasible to implement PBL on them. The computer can simulate the clinical problem or patient, allowing interaction between the users (e.g. students) and the simulated patient. The user can ask the patient questions, examine the patient, request laboratory tests, etc. These systems are called patient simulation systems.

Patient simulation systems used to enhance or replace PBL sessions have some advantages over paper-based presentations and standardized patients. In the next paragraph these advantages are listed.

The faculty should see a reduction in labor cost from both teachers and facilitators (Gleydura et al. 1995). Patient simulation systems let the students analyze a clinical problem at their own pace, in their own way. Because the computer is consistent there is no fear that some group of students might receive better help from their facilitators than others. This is a potential problem when using 'human' facilitators (Vincelette et al. 1997). It is also much easier for the teacher to monitor progress of an individual student and groups of students. Students can receive detailed self-evaluation feedback on their abilities and mistakes made by the student can be simulated on the patient.

This paper covers the structure of a patient simulation system, called CompuPatient, in the early stages of development. We are working in collaboration with six Nursing Departments at South African Universities. A questionnaire consisting of nine categories covering over 125 features of patient simulation systems was sent out to the collaborators. These categories are applicability and scope, computing environment, human-computer interaction, simulation enhancement, patient-nurse encounter, additional assistance available to student, student assessment, feedback and the facilities provided to the teacher. The feedback from this questionnaire is being used as a foundation for the design of a system customized to fit the requirements of the collaborators. The outcome of the questionnaire will be discussed in the next section. Not all but some of the more important features affecting the basic structure of the system will be covered. The users involved in a patient simulation system were identified using the feedback from the questionnaire and used to refine the design of the system. They will be discussed in section 3. The focus of the paper is the basic structure of CompuPatient covering the primary modules involved and communication between them. The structure is discussed in section 4. Although the structure was thoroughly thought through, it is possible that the first prototype might have an influence on the structure.

Outcome of Questionnaire

The collaborators rated more than 125 features, indicating how important the inclusion of these features are to them. Although the questionnaire is being used as a foundation for the structure, the system developer could decide not to include certain features because of their complexity and present non-viability. In the following paragraphs the outcome of the questionnaire is discussed and the influence it has on the structure of CompuPatient.

When looking at the scope of the system it should not only support the training of nurses but also the training of medical doctors. The focus of the system should not be on certain areas in the medical field but accommodate a wide area of disciplines. It is important that the system is customized for healthcare in South Africa. These features will not influence the basic structure of the system.

A student could use the system in a laboratory environment and should be able to access the system over a local area network and from home using the Internet. Both of these are addressed in the design by creating a module responsible for network communication. The other modules do not have to know how communication take place over the network but only know how to communicate with this module. The system should run on a personal computer using Microsoft's Windows operating system. A decision was made to support Windows 95 or later, with the possibility of supporting other platforms using Java.

When looking at the interaction by the student with the system it seems that the collaborators were in favor of direct manipulation for patient examination and interaction with instruments. Natural language was the preferred choice for the implementation of other interaction options, followed by predefined menu choices. Because of complexity
of natural language it was ruled out for CompuPatient, however the design of the structure gives the possibility of accommodating this in the future. Predefined menu choices can be accommodated by the structure of the system.

The simulation should and will support the use of text, graphics, animation, audio and video. Although audio and video were seen as essential by some collaborators support for it over an Internet connection might not be viable at the present time because of bandwidth constrains. Some collaborators prefer virtual reality to simulate a patient or environment. Virtual reality simulations can have a great influence on the structure of the patient simulation system because of the tight integration of the student interface and the simulator itself and will not be supported in CompuPatient.

The system should monitor and give intelligent hints to the student. Additional assistance should also be available that can be activated by the student that could give background information concerning the patient's symptoms, information concerning the physical examination, information concerning the interpretation of the physical examination and pointers to resources (e.g. Internet references, books, etc.). A module responsible for help and hints will do this. Although electronic communication with fellow students and the teacher was rated as unimportant by some, provision was made for this in the structure because of the additional benefits it could have. This feature can easily be integrated into the system and be disabled when not used.

Evaluation of the student during the simulation of a problem, also called the case, is important and a "goodness measure" should be assigned to the outcome of the session. The teacher should also be able to specify the particulars of the scheme used to determine the "goodness measure" of an outcome. He should also decide if the evaluation result should be available to the student (e.g. after the simulation). An assessment module is responsible for the evaluation in the structure.

When looking at the facilities provided to the teacher it is clear that the system should analyze the evaluation results discussed in the previous paragraph giving suggestions on improvement of the students. An essential feature is support for the teacher to develop new cases and share cases with other institutions. Some collaborators need access management facilities while others do not. This facility can easily be disabled when not used and therefore included in the structure of CompuPatient.

Users of a Patient Simulation System

In this section the users identified from the questionnaire and the facilities that should be available to them are discussed. There are two primary users of the system, the student and the teacher. Two secondary users were identified, the administrator and the case developer. The teacher can also function as the administrator and case developer depending on the set up at the education institution.

Student

The first and most important user of the patient simulation system will be the student. According to Thomas (1997) the objectives of PBL are to "motivate learning; developing effective clinical reasoning; structuring knowledge in clinical contexts; and developing self-learning skills". These objectives are all focused around the student. She will interact with the simulated patient that responds to the requests and reacts on changes in the simulated environment (e.g. time). Actions available to the student might include reviewing the patient history, interviewing the patient, doing a physical examination, requesting laboratory tests, making a diagnosis and when necessary referring the patient to a specialist or other professional. The system might give intelligent hints when she seems stuck. Help should be available to the student that provides a connection or reference to related material that she can consult when more information is needed. Assessment of the student should be done by the system using an assessment technique defined by the system developer that uses case specific detail supplied by the case developer. The result of the assessment or evaluation should be available to the student after the session depending on the preferences of the teacher. The student could communicate with fellow students using a discussion group or with the teacher using private messages.
Teacher

Another user of a patient simulation system will be the teacher. The teacher's task in the patient simulation system will be to monitor and oversee the learning progress of an individual student or group of students. One of the benefits of computers is the large amount of detailed information that can be collected by the computer on a given student or group. This information could be analyzed by the computer and reports could be generated that can help the teacher to concentrate on problem areas in the field of study.

Administrator

The administrator will be another user of a patient simulation system. He will be responsible for administrating access to students and other users for particular cases and information. A typical patient simulation system will consist of more than one case or clinical problem. Depending on the current progress of the student the student has access to certain cases. The access restrictions can be automated to a certain degree, for example when the student finished case A successfully, access is automatically granted for case B. Another administrator task will be the management of student groups. It could be easier to grant access to certain cases by selecting a student group (e.g. first year students) than to select each student individually. The necessity of groups also becomes apparent when working with discussion groups where students can only communicate with other students within their group.

Case Developer

The final user of a patient simulation system will be the case developer. The case developer's main purpose will be to develop new clinical problems or patients for the patient simulation system. It is important to remember that case developers should decide which variables should be included and which variables should be purposefully excluded, and how those included should be presented to the student. The case developer will also be responsible for specifying any help and hints as well as reference material available to the student for a particular case. He should also define case specific assessment variables used for evaluating the students' performance for a particular case.

A Patient Simulation System Structure

Using the users and feedback of the questionnaire as a foundation, a structure for CompuPatient was designed. In this section the primary and sub-modules of this structure and the communication between them are discussed.

Modules

Five primary modules were identified (Fig. 1). The first module is the student's environment module. The purpose of this module is to provide an environment for the student to interact with the simulated clinical problem and consists of six sub-modules. The first sub-module is the student interface that defines the information presentation and is customizable to suit the preferences of the student. The case simulator is the second sub-module and is responsible for the simulation of the clinical problem. The case simulator is an essential part of the patient simulation system. This module takes interaction commands from the student interface and reacts on them by changing the presentation of the simulated patient. When using natural language another sub-module can fit between the case simulator and the student interface. It translates the natural language into a format understandable by the case simulator. The monitor module keeps a log of data received from the case simulator relating to the state of the simulation as well as interaction commands received from the student. The results are stored for analysis by the teacher's environment. The assessment module uses the data of the monitor to evaluate the student's progress during the session using case specific assessment detail defined by the case developer. The evaluation is available to the student after the session if enabled by the case developer. The intelligent help and hints module gives help and hints to the student, customized to suit the current progress of the student by analyzing the log from the monitor. The help and hints can consist of additional material or references to additional material available to the student. The final sub-module of the student's environment module is the communication interface. The communication interface is
responsible for the communication between the student's environment and the other primary modules. Although the primary modules can be on the same machine it is possible that they can be distributed over several machines connected to a network.

![Diagram of Primary Modules of a Patient Simulation System]

Figure 1: Primary Modules of a Patient Simulation System

The second primary module is the storage area and stores all data used by the other primary modules lasting more than one session with a user. This module is split into five sub-modules. The first sub-module called the case library stores all data of the cases available to the system. This data includes multimedia used to simulate the case, reference material, help and hints, as well as case specific variables used by the case simulator and assessment module. Maintenance of the users involved in the system and the cases and information they have access to are done by the access rights module. The next sub-module called the student records module maintains information about the student's case log received from the monitor and evaluation results received from the assessment module and is available to the teacher's environment for analysis. The communication message centre deals with the storage and distribution of messages sent between the teacher and students or between the students in a group. The final sub-module is the communication interface and is responsible for the communication between the storage area and the other primary modules.

The next primary module is the administration environment module that provides an environment for the administrator to add and remove users, maintain student groups and also grant and restrict access to cases and other information (e.g. student records).

The teacher's environment module is the next primary module in the system. The purpose of this module is to provide an environment for the teacher to retrieve and analyze student records. The teacher can view an individual student or group of students' records, view information about their evaluation, as well as problem areas identified by the system. This makes it possible for the teacher to concentrate on these problem areas in class or when developing new patients for the system.

The final primary module of the system is the case development environment that presents the case developer with an environment to develop new cases, alter old cases and import and export cases from and to other similar systems.
Communication between Modules

Communication between all the primary modules go through the storage area using a client-server approach. The storage area operates as the server and the other primary modules as the clients. An advantage of this approach is that the system can be updated to work not only on the local machine but also over a local area network or even the Internet without changing the structure of the modules. Only the communication interface of all the primary modules will change to accommodate the new communication protocol.

When the student signs on for a session with the system, communication is established by the student's environment with the storage area. The rights of that particular student for the case are verified with the access rights module in the storage area. If access is granted to the student, the contents in the case library for the selected case are transferred to the case simulator, not necessary all at once but can also be transferred on demand. This data includes the case specific variables and multimedia. The reference material, help and hints are transferred from the case library to the intelligent help and hints module. The monitor loads case specific assessment detail into the assessment module from the case library. The monitor queries the student record to see if the student previously suspended the selected case. If she did, the simulation starts with the state of the simulation just before the suspension. Otherwise it starts at the beginning of the case. Interaction between the student and case simulator is sent to the monitor by the case simulator. The monitor keeps a log of all interactions. The assessment and intelligent help and hints modules can use the log of interaction to make an evaluation or giving hints to the student. If the session is suspended or terminated the data in the monitor is stored in the student record. Communication messages sent by the student to the teacher or other students are sent by the student's environment to the communication message centre. The storage area keeps record of all open sessions and if a message arrives for a student currently using the system, the system sends the message through to the student's environment of that particular student.

This paper will not include a discussion on the communication of the case development environment, administration environment and the teacher's environment because of the similarities in communication with the other modules already discussed.

Conclusion

At the time of writing, CompuPatient was still in the phase leading to the implementation of the first prototype. When looking at the transition of education towards distant learning the possibilities of patient simulations are endless. Patient simulation might in the future revolutionize the nursing and medical education process.

Abstract: Synchronized Multimedia Integration Language (SMIL) enables web developers to create multimedia content for efficient delivery over the Internet. The objective of the SMIL Presentation Generator that this paper discusses is to make the capabilities and advantages of SMIL available to non-technical users. The SMIL Presentation Generator provides templates for the generation of RealText, RealPix and SMIL files. This enables non-technical users to create RealText and streaming media files which they can then synchronize using the SMIL generator templates for the creation of a web-based multimedia applications.

Introduction

Synchronized Multimedia Integration Language (SMIL) is based on the eXtensible Markup Language (XML). SMIL was developed by the World Wide Web Consortium (W3C) and enables Web developers to create multimedia content for delivery over the Internet. SMIL components consist of files and streams of audio, video, text, or image content. These components are transmitted separately over the Internet thus providing more economical and efficient use of resources. However, the components are then displayed together as if they were a single multimedia stream. This gives a more reasonable download time as compared to that required by traditional monolithic multimedia files.

The SMIL specification consists of XML tags that allow the definition of windows, multimedia elements, and their synchronization in time when displayed in a SMIL capable browser. In order to use SMIL for creating presentations, the developer must devote the time to learn the language. In addition, the developer must understand and be able to encode specifications regarding specific details about size, placement and structure of the windows and the placement of the multimedia elements in time for proper synchronization. This detail work is very exacting and time-consuming for the developer. Thus it is difficult for the non-technical user to take advantage of the capabilities provided by SMIL.

In order to make the advantages of SMIL available to potential non-technical users such as educators, tools with enabling interfaces are needed. The objective of the SMIL Presentation Generator that this paper discusses is to make the capabilities and advantages gained by using SMIL available to non-technical users. SMIL files incorporate RealText, RealPix, real audio and real video files. The SMIL Presentation Generator consists of editors for RealText, RealPix and SMIL. Many faculty are attempting to improve the instruction content of course material through the use of multimedia and also improve the availability of the material by deploying it on the Internet. The intent in developing this tool was to provide a user friendly front-end with general templates that could be used for the generation of SMIL web-based multimedia instructional modules. Through the use of templates that guide the developer in creating the files necessary for a SMIL presentation, more faculty members would have the ability to create their own SMIL presentations.
Use of SMIL Presentation Generator

The SMIL Presentation Generator provides an interface that enables a non-technical user with an understanding of the terminology and limited knowledge of the technical aspects of SMIL to generate files in RealText, RealPix and SMIL.

The interface for the RealText Generator looks like a usual HTML editor. The interface is divided into 3 major sections (See Figure 1). One section allows the user to select the window type from a list of possible types that s/he wants to include in the presentation. Another section allows the user to set the specific window properties of the type of window that the user has selected. For example, for a Ticker Tape window type, the properties are duration, width and loop. The working section allows the user to type the contents that are to be included in the RealText file or preview either the RealText file generated or the code. Icon buttons open dialog boxes for the user to do other tasks such as set the time for the display of the text, link to a player or to a browser, select font style and size, and specify background color.

```
<window type = "tickertape" duration = 60 bgcolor = "Synchronized Multimedia Integration Language (SMIL)"

Synchronised Multimedia<br/>
Integration Language

```

Figure 1: Interface for the RealText Generator

The interface for the RealPix Generator has four sections (See Figure 2). The Image Window allows the user to view images and add them to the presentation. The Images Window lists all images that have been added to the presentation. The Transition Window previews the source image and lets the user select the type of transition (crossfade, fill, fadein, fadeout or wipe) to be used. The Time Window lets the user sequence and time the use of images and transitions.
The interface for the SMIL Generator has four windows: Object Toolbox, Properties, Layout and Sequence (See Figure 3). Real time files can be added to the presentation by clicking on the appropriate button in the Object Toolbox Window. A dialog box opens and lists available files of the type specified. The user can then select the file to be added to the presentation. The added files can be viewed in the sequence window. The Layout Window is used to define the size of the real player screen and to create regions.
Technical Description of the SMIL Presentation Generator

The SMIL Presentation Generator is an application which facilitates the production of SMIL presentations by providing templates for the developer to use in order to generate these web-based multimedia presentations. The tool is composed of three programs: the SMIL Generator, the RealText Generator and the RealPix Generator. The SMIL Presentation Generator was implemented using Visual Basic. In addition to generating SMIL, RealPix and RealText files, each of the generators is capable of loading and interpreting the native formats and reverse engineering the output file type into the generator format. Thus, a user can create, load and save SMILs for deploying, editing and updating.

The RealText Generator helps the users generate their own RealText files in a format that meets RealText specifications. Using the generator, the user can either create an original RealText file or convert an existing text document into a RealText file. The users can select the type of window style and the rate at which the text would flow. They can also add links to web sites and presentations. The RealText application presents text in synchronization with other media elements. All contents of a RealText document are contained within the <window> tag and are stored in files with the .rt extension. There are four window types: generic (the default mode), ScrollingNews, TickerTape and TelePrompter. The markup is basically the same for all window types.
The RealPix Generator helps the users generate their own stream images in the RealPix format which meets SMIL specifications. The user can select images, can specify the order of the selected images, the time for which each image stays on the screen and the transition effects. Graphics in this format can be streamed over the web as part of a SMIL application. The RealPix file is defined between two tags which define the beginning and end of the RealPix file. RealPix can stream images in the following formats: GIF87, GIF89 (*.gif), and JPEG (*.jpg). Both interlaced and noninterlaced GIFs will work, but RealPix does not take advantage of any features of interlaced GIFs. RealPix does not support animated GIFs. RealPix can use RGB baseline JPEGs; however, progressive and grayscale JPEGs are not supported.

The SMIL Generator is a SMIL authoring tool. It can use the files produced by the RealText and the RealPix Generators plus additional types of media. As an authoring tool, it lets the user partition the presentation screen into a number of regions. The user can then define the type of media (video, audio, RealText, RealPix) associated with these regions. The user can also specify the time for which each of these media items would play in the specified region. The output from the SMIL Generator is a SMIL file that can be played using a SMIL capable browser such as the RealPlayer.

Summary

The emerging SMIL specifications provide new avenues for delivering multimedia applications that can be used in academia for web-based instruction. However, the use of SMIL requires technical knowledge and understanding. The SMIL Presentation Generator can be used by instructors who do not have this expertise but do have an interest in developing web-based instructional modules with ease. The information captured by means of the Generator's templates will be translated into SMIL presentations that can be made available over the Internet to students.

Abstract

The paper first reviews the authors' recent comparative studies of existing online learning environments and makes the case that no current commercially available system effectively supports intensive collaborative and creative discussion in a way that may compete with facilitated small-group methodologies such as for example the Harvard case study method. Second, it reviews earlier work, spanning some thirty years, on a methodology named Structural Communication that achieved some success in automating and individualizing such methodologies. Then, the paper describes a methodology that combines some aspects of Structural Communication with interactive Web-based discussion to create an effective and efficient alternative to classroom-based case study discussions. Finally, some key research findings are summarized, suggesting that this hybrid methodology may be more effective than the facilitated small group for promoting creative ideas, as well as being more efficient and multipliable.

Introduction: Key Issues in Use of CMC in Higher Education

The variety of Internet-based synchronous and asynchronous communication systems keeps growing. In addition to the already well known forms of asynchronous Computer-Mediated-Communication (CMC) systems, such as email, listserv and threaded discussion lists, we now use a variety of new synchronous communication alternatives, such as electronic whiteboards, Internet Relay Chat, Web-based audio and video conferencing and a growing variety of "groupware" packages. As the power of the Internet grows, so does the complexity of the material posted. Ever more ambitious examples of interactive multimedia are launched on the Web every day. A number of novel research questions and issues arise in relation to the design and use of these new systems.

Much existing research is related to earlier forms of text-based CBT. Some of these results may be equally valid within the context of multimedia distance education/training systems. However, we may expect many new issues and questions to emerge as these broad band multimedia, multimodal communication systems link both people and remote databases into one seamless information and communication environment. One recurrent problem is that we hop from one recently-emerged technology to another currently-emerging technology that promises some new potential, without ever learning to fully exploit the potential of the old. It is a sobering thought that in all the centuries since the Gutemberg print technology facilitated the mass dissemination of text, we are still struggling with the issues of mediocre textbooks, instructional manuals that fail to instruct and communications (including on-line texts and hypertexts) that just do not communicate.

In addition to the communication-technology and instructional design variables, another aspect to consider for improvement of existing on-line learning environments is the promotion of effective "conversational" interaction between groups of students (and instructors) engaged on a joint project. There is a growing need for the
implementation of learning exercises that prepare students for the new profession of “Knowledge Work”. These exercises should allow students to work creatively, collaboratively and at a distance on complex, leading-edge problems that impact their life and work. Teaching methods such as seminars or case studies are traditionally employed for developing creative thinking skills through collaborative effort. They are typically implemented in small or medium sized groups, led by skilled and experienced “facilitators”. The success of these methods depends much on the facilitators and the skill with which they perform their roles: focus the discussion; guide the approaches adopted by the participants; use the natural group dynamics to stimulate interest; promote and support participation and deep involvement by all; and pull together what has been learned in the final debriefing discussion. Can such participatory discussion methods be effectively orchestrated at a distance? How might this be done? And, most importantly, how might we do it so as to create practical and sustainable WBT systems that will survive the test of time as the initial enthusiastic “early adopters” move on to other projects and their place is taken by the rank and file of the teaching/training profession?

There are also other pressures, both organizational and philosophical, that are increasing the amount of autonomy, self-direction and responsibility that learners have in respect of their own education and development. Given the increasingly competitive nature of business in the international marketplace and the critical importance that access to and use of up-to-date information and methods plays in a company’s competitiveness, it is not surprising that the concept of human resources development as “self-development” is taking root. This concept sees keeping up-to-date and employable as the responsibility of every employee. The employer’s responsibility is to make this possible, by helping to identify the needs of the individual and by facilitating access to the resources necessary to satisfy those needs. This will ever less frequently call for lengthy courses organized either within the company or by outside providers, but will instead make much more use of networking, access to external databases and electronic libraries, small specialist group tele-training and self-instruction in all its forms (Eurich, 1990).

An integrated research agenda

The research focus adopted by the authors is on the effective implementation of group discussion, or “conversational”, methodologies on electronic telecommunications networks. This focus is particularly important, as we know much less about how to converse effectively on electronic networks, than we do about electronic self-instruction. There is a long history and fairly developed technology of the design, development and delivery-at-a-distance of self-study materials. There is much less known about the running of effective group-discussion sessions at a distance (Chang, 1994).

In a recent study reported elsewhere (Villalba and Romiszowski, 1999) the authors performed a comparative analysis of typical on-line learning environments currently used in higher education and the typical ways in which these environments are used to implement collaborative group learning activities. The findings indicated that few currently implemented on-line courses actually include a strong emphasis on collaborative small-group learning and, when such activities are implemented, this is generally as a relatively unstructured on-line group discussion, using either synchronous “chat” sessions or, more frequently, asynchronous email driven discussion lists. There is little if any research, however, indicating that such environments are conducive to in-depth reflective discussions of the type required to develop critical and creative thinking skills. And there are some studies (e.g. Romiszowski and DeHaas, 1989, Romiszowski and Chang, 1994) that suggest they are singularly ineffective in this respect. As a means of verifying these suggestions, the authors selected one of the previously evaluated on-line learning environments, Aulanet, for further in-depth study.

Aulanet is a web based instruction environment, developed in Brazil at the Catholic University of Rio de Janeiro (Lucena et.al. 1998) which is also available in an English language version. It was selected as it offered a wider variety of on-line discussion environments than most other currently available systems. In addition to the regular e-mail, both threaded and unthreaded asynchronous discussion environments and text-based synchronous “chat” rooms, options are available for audio, audio-graphic and full video-conference sessions in small or large groups. In addition, the creators of Aulanet claim the system is based on or influenced by contemporary theories of cognition and constructivism. The present authors have observed and analyzed the use of Aulanet as a delivery system for four courses running through the spring and the fall semesters of 1999. These courses form part of a graduate (Masters and Doctorate) program in Educational Technology in a leading North American Research University. The study
involved both the observation of student use of different collaborative learning environments provided within Aulanet and the analysis of student questionnaire responses and user-evaluations administered during the course of the 1999 academic year.

In that study the students made some quite significant suggestions for enhancement of the learning environment. A major observation is concerned with the structure of facilities for constructive educational “conversations”. The many and various components of Aulanet that permit both synchronous and asynchronous student/teacher and student/student interaction are seen to be no different from the facilities that exist in many other online learning packages currently on the market. Both faculty and students have come across limitations in the available group communication facilities that limit what they can implement in the way of “creative group work at a distance”.

In the present study we are seeking ways around these limitations. In order to perform this research we have developed a web based automated case discussion system. To do this, we turned to a methodology called Structural Communication, originally developed in the United Kingdom in the late 60's and early 70's as a methodology for writing and presenting interactive print-based exercises. An adaptation of this methodology had shown itself to be effective for automating and individualizing small-group learning methods such as the Harvard Business Case methodology (Hodgson et. al. 1971). Later studies demonstrated the effectiveness of the methodology in reducing the amount of human facilitator or monitor interaction necessary in order to lead the exercise to a satisfactory conclusion (Romiszowski, 1990; Romiszowski & Chang, 1992; Chang, 1994).

Structural Communication is an instructional approach that provides a simulated dialogue between an author of instructional materials and the students. It has been called "an interactive technique for communicating understanding" (Egan, 1976). Understanding is "inferred if a student shows the ability to use knowledge appropriately in different contexts, and to organize knowledge elements in accordance with specified organizing principles" (Egan, 1972, p. 66). The technique was designed to encourage creative thinking in learners, allowing them to develop an understanding of a topic, not simply to memorize facts. Furthermore, Structural Communication was designed to promote learning for social action. Hodgson, in line with many current constructivists, viewed the social contexts of the learning activity to be critical for the transfer of learning to practical situations (Egan, 1976). The distinctions between the learning of knowledge and the learning for social action are evident in the actual components Hodgson designed into the Structural Communication technique. The typical components of a Structural Communication unit are described below.

**Intention**

The opening statement, which defines what is to be studied, provides an overview, possibly an "advance organizer", and sometimes a rationale. It is used to provide a context for the content of the study unit.

**Presentation**

The material, experience, exercise, case study, etc. which supplies the essential facts and concepts of the domain being studied. This may be an existing text, a video, a case study, a simulation, or real-life experience, depending on the overall strategy of the exercise. This could also be any sort of computer-based instruction, including simulations.

**Investigation**

A set of problems for solution, which are designed to present the "intellectual challenge" that is an essential part of the Structural Communication methodology. These problems are interrelated and are open-ended to allow multiple responses and viewpoints. The purpose of the investigation section is for the learner to interact with the subject matter.

**Response Matrix**

A randomized array of items which summarize key parts, concepts or principles from the knowledge base that is being used and studied in the exercise. Often it resembles a "key point summary" of the Presentation. The student composes a response (outlines an essay) by selecting any number of these items as a "best" response to a given problem.

**Discussion**

The Discussion has two parts: a Discussion Guide and a set of Discussion Comments. The Guide is a set of if-then rules, which test the student's response for omission or
inclusion of certain significant items, or combinations of items. The Comments are constructive statements that discuss in depth the rationale for including or excluding certain items.

Viewpoints

An outline of the author's, and other alternative viewpoints; this may review some aspects stated in the Intention, make explicit some biases or standpoints held dear by the author, draw attention to other views in the literature, etc. Ideally, the viewpoint section plays a final, interactive role between author and learner.

An additional aspect of the Structural Communication study unit is the assessment of the learner's responses to the questions posed by the study unit. Hodgson developed a numerical measure called the coherence index. According to Egan (1976), the coherence index is an objective measure of how well the student organizes knowledge about the specific topic in the study unit. However, the constructivist may reject this interpretation, since it implies a correct set of responses based upon the ideal organization and analysis of the presented data. Constructivists are more likely to view the coherence index as an objective measure of the degree of agreement of the student with the author of the Structural Communication unit. They may well be more interested in measures of divergence of viewpoints rather than convergence on a uniform, or coherent, viewpoint on the issues being discussed.

A Revised Structural Communication Methodology

The original SC methodology was redesigned in order to create a somewhat more “constructivist” and collaborative learning environment. Some of the most important features of the SC method, for example individualized learning of basic content and access to expert opinions, were maintained. However, the revised form provides open-ended discussion environments for students to share, argue, persuade, and negotiate their perspectives on the expert's feedback comments as well as on their own opinions. In the original method, the planned learning activity ends with reading the expert's comments. Since the revised method is designed for small group collaborative learning, from this point on, further learning activity occurs collaboratively with group members. After completing their work individually, students browse what each group member did. A summary table tells the group members who selected which items in the response matrix during individual study. With the summary table as a guide, group members can access any item and read the viewpoints and justifications of other group members. They are asked to react to each other's justifications stating whether they agree or disagree with each other.

As the process continues, the pool of the students' discussion log grows. The software is designed to save every justification and discussion statement that students make, and to enable students to browse those reactions and opinions in a cumulative mode as the process continues. While they are performing these activities, the nature of their interaction may vary along several dimensions, which are under the control of the software. For example, they may, or may not, access expert's feedback comments to inform them on “what the experts say”. Similarly, they may have to construct their opinions and justifications in their own words, or merely select them from a long list. Four different versions of the revised Structural Communication software were developed for experimental purposes. These vary along “simple-to-complex interaction structures” and “more or less constructivist philosophy” dimensions (Chang, 1994).

Practical Conclusions and their Implications for Conversational WBT

Several conclusions were drawn from this study. One practical conclusion was that the discussion environments based more closely on the original SC exercise model, offer an appropriate environment for intensive small group conversational interaction via CMC networks, even if these seem to be less in line with currently popular philosophical positions. However, the environments must support the discussion process in an effective and efficient manner. This implies, among other things, ensuring that the discussion process is motivating and not over-taxing in terms of workload. The researchers found no trace of the supposed “perils” of limiting the creative and critical thinking of the discussion participants by exposing them to “expert” viewpoints. The more tightly structured SC environments produced more frequent creative insights than the supposedly more “constructivist” environments.
As regards student motivation, there is little doubt that exercises organized in the form of Structural Communication are most effective. The several hundred students who participated in the above-mentioned 4-treatment study worked voluntarily and without recompense in the form of grade points throughout a whole semester with very low dropout rates. The students in earlier studies showed similar levels of motivation. This finding is important in the context of conversational CMC-type WBT in that the study materials placed in a publicly "open" WBT environment will survive and prosper, or alternatively wither and die, as a function of their ability to attract voluntary participation from a significant number of WWW navigators.

It may well be that the reasons for the high levels of motivation encountered in these studies are not entirely and uniquely a consequence of the SC format. As mentioned before, the quality of design of the exercises themselves is probably a most critical factor. In Khan's recent collection of essays on Web-Based Instruction (Khan, 1997), two chapters are devoted to issues of motivation in WBI (Cornell & Martin, 1997; Duchastel, 1997). Both chapters review several well-known approaches and models for the design of motivational learning materials, such as ARCS (Keller, 1983). However, Structural Communication's unique mechanism of the response matrix is an approach that has been largely overlooked. The response matrix allows for easy and rapid responding to complex multi-faceted problems, at the same time allowing one to explore one's own and each others' cognitive structures in some detail. This is the inherent attractiveness of the methodology to the interested and reflective student.

We should not leave the question of motivation without also considering the motivation of the instructor or discussion facilitator. Cornell & Martin (1997) address the question of instructor motivation in Web-based learning. The authors mention seven reasons for lack of instructor motivation (as compared to twelve for student motivation) and, interestingly, this list of seven reasons does not include the avoidance of extra workload. However, experience and research suggest that CMC-delivered courses almost always involve significantly more instructor time than conventional courses. We therefore feel that one should add this eighth reason to the list. Furthermore, we believe that Structural Communication offers, at least in part, a solution to this eighth reason.

In discussions organized within a SC-based CMC environment, the problem of instructor overload is much reduced. The automatic generation of extensive and constructive feedback to students on the basis of the pattern of responses they select from the response matrix acts like a first-round live reaction from the instructor to specific aspects of the students' overall response. In practice, these automatically generated feedback messages satisfy well over 70% of the students' needs for clarification or orientation. The remaining 20% to 30% of feedback interactions generate second-round student responses in the form of electronic messages that pose supplementary questions or comments, usually at a deeper and more reflective level of discourse. The effects of this on the motivation of the instructor are twofold. First, the overall workload of responding to students (measured in terms of the number of messages to compose) is reduced by some 70%. Second, the messages to be responded are on issues that are often more interesting and always relatively original and non-repetitive.

Having touched on the issue of workload as it relates to the instructor/facilitator, we may mention our experience with the SC response-matrix mechanism as a device for the reduction of student workload. In selecting a subset of response elements from the universe represented by the items in the response-matrix, the student is in effect composing a complex, structured response to the problem under analysis. This is analogous to the preparation of an outline for an essay or live seminar presentation. The intellectual effort necessary to evaluate the relevance of each item of the matrix to the problem being studied is equivalent to that expended in planning an essay or presentation. However, the time and effort involved in writing an essay or preparing and delivering a presentation are saved.

We have also observed that students spend more time, more productively, in the intellectual restructuring of ideas and the creation of their own knowledge structures than is often the case in conventional instruction. To be sure, students do restructure their ideas when they engage in free, unstructured, small-group discussion with their peers and teachers, but not with the frequency and depth of insight that seems to be generated in the SC environment. And, in our view, the relatively unstructured discussion lists that abound in current WBT environments, even the popular "threaded" discussions, are less effective in promoting creative idea-generation. Furthermore, they are more wasteful of student time than both the SC environment and the conventional small-group seminar presentation, in that every single contribution must be produced as an original typed message.
In conclusion, it is not our argument to eliminate written communication from the ideal WBT environment. There are strong learning benefits to “putting pen to paper” (or fingers to keyboard). As Albert Einstein replied when asked what he thought of a novel scientific issue: “I do not know what I think until I have written it down”. However, as in real life time is always limited, why not use it most efficiently? In the SC-based form of WBT environment, the student is saved the effort of writing out surface-level arguments that mainly serve to “get the ball rolling” by acting as stimuli for comments from instructor/facilitators or peers. The discussion is set in motion by means of the response matrix. The writing of “what I think” then does occur at the second and subsequent rounds of in-depth discussion. We close by stressing the importance of implementing effective, efficient and multipliable small group collaborative learning environments online. Otherwise, due to the difficulties and costs of arranging sufficient opportunities for facilitated small-group collaborative learning by conventional means, tomorrow’s educational systems will offer “less and less of what learners need more and more”.

An Empirical Study Concerning Graphical User Interfaces that Manipulate Files

Maria Virvou, Katerina Kabassi

University of Piraeus,
Karaoli & Dimitriou 80,
Piraeus 18534, Greece
mvirvou@unipi.gr, kkabassi@unipi.gr

Abstract: This paper describes an empirical study conducted within users of Graphical User Interfaces that deal with files and folders in a similar way as the Windows 98/NT Explorer. 10 human experts analysed user protocols, which were collected using computer logging, so that the most common user errors could be identified. The comments made by the human experts served as a basis for the requirements specification of a second executable release of a GUI called IFM that incorporates intelligence. IFM reasons about users' actions so that it can provide spontaneous help to users' errors. The user protocols collected during the empirical analysis were used in the formative evaluation of the second executable release of IFM. The reactions of IFM were compared to the comments of the human experts that had taken part in the empirical study.

Overview

Graphical user interfaces are user friendlier than others, such as command language interfaces. However, as McGraw (1994) points out, they may prove difficult to traverse and use if they are poorly designed; hence in addition to basic user interface guidelines, developers may also want to consider the feasibility and benefits of using AI to enhance the user interface.

Intelligent File Manipulator (IFM) is a graphical user interface that incorporates intelligence. It is used for a file manipulation program similar to the Windows 98/NT Explorer. However, it can also reason about users' actions. IFM's main aim is to provide spontaneous help and advice to users who have made an error with respect to the hypothesised intentions. IFM is meant to operate like a human expert who watches a user over the shoulder and provides spontaneous advice. This advice may, in time, enhance novice users' skills in operating file manipulation programs. Therefore, IFM may also be used as a learning environment for novice users of a GUI (Virvou & Kabassi 2000).

Indeed IFM may provide an environment where novice users would be more protected from their errors and would have more informative advice from the system. In this way they could become familiar with file manipulation programs and thus learn how to use them. IFM can be used for teaching purposes in student computer labs. Each student can give a password so that s/he may get individualised support.

IFM has been developed based on an object oriented life cycle model, the Rational Objectory Process (Quantrani 1998; Kruchten 1999), which supports many iterations of the development phases. A first prototype of IFM has been completed (Virvou & Stavrianou 1999). Its design originated from another system called RESCUER that was meant to provide assistance to users of command language interfaces, such as the interface of UNIX (Virvou 1998; Virvou & Du Boulay 1999).

In order to enhance the design, the first prototype of IFM was evaluated. As (Dix et al. 1993) point out, evaluation is an integral part of the design process and should take place throughout the design phase of the life cycle; most techniques for evaluation at this stage are analytic and involve using an expert to assess the design against cognitive and usability principles. Evaluation of the design of IFM, at this stage, was conducted through an empirical study. Ten human experts commented on the actions made by users of a standard manipulation program (Windows 98/NT Explorer). The human expert's reactions were then compared to IFM's recommendations. All of the human experts who commented on user actions had a first and/or higher degree in Computer Science and had used-extensively used programs like a standard file manipulation program. Many of them had also teaching experience related to the use of such programs in computer labs.
The users who participated in the empirical study were both expert and novice. The experts who were involved as users were different from the experts who were used to comment on users. All users were asked to work with a standard file manipulation program, as they would normally do. Computer logging was used to record all users’ actions during their interactions with the system. Computer logging has been used in evaluating user interface designs for a long time (Bradford et al. 1990). The major advantages of computer logging are that it automatically and continuously collect objective data for further analysis and interpretation and does not interfere with users during their interactions with a system (Chou 1999).

The collected user protocols were passed on to the 10 human experts so as to analyse them. All of the human experts gave their comments on every user’s action. One of the aims of this kind of analysis was to find usability problems of a standard Explorer, through heuristic evaluation (Nielsen 1994). In particular, human experts were asked to focus on two usability heuristics specified by Nielsen:

1. Error Prevention.
2. Help users recognise, diagnose and recover from errors.

Therefore, the human experts’ comments should include whether they thought that the user had made an error and what sort of advice they would give to these users to recover from their errors. Hence, the empirical study revealed a lot of usability problems of a standard file manipulation program in terms of user errors.

Half of the user protocols were also given as input to IFM at that stage. IFM’s reactions were compared to the human experts’ comments. The conclusions from this comparison were used for the construction of a second executable release of IFM. In the second release, IFM’s knowledge base was enriched with categories of error that IFM could not recognise in the previous release.

A formative evaluation of the second executable release of IFM involved the rest of the user protocols, which had been collected during the empirical study, were commented by the human experts but were not used for the requirements specification of the second executable release of IFM. In most cases, IFM’s reactions were found-similar to the comments made by the majority of human experts at this stage. However, some limitations were also identified. These limitations are meant to be addressed in the third executable release of IFM.

Life Cycle of IFM

In the development of IFM, the iteration of several phases of the development was considered crucial. Therefore the Rational Objectory Process formed the basis for the life cycle of the system. Using the Rational Objectory Process, an iterative development is advocated, in which the architecture is actually prototyped, tested, measured, and analysed, and then refined in subsequent iterations (Kruchten 1995). Rational Objectory Process divides the software life cycle into cycles, each cycle working on a new generation of the product. The process divides one development cycle in four consecutive phases: the inception, the elaboration, the construction and the transition phase (Quantrani 1998; Kruchten 1999).

In the inception phase, a primary executable release of IFM was developed (Virvou & Stavrianou 1999). In the phase of the elaboration an empirical study was conducted involving a number of expert and novice users. All users were asked to work with the regular Windows 98/NT Explorer for two hours. While working, the system was monitoring users’ actions without interrupting them. The user actions were recorded using the computer logging method and then were analysed in order to identify the errors that users make while completing certain tasks. Human evaluators, using the video recording method observed the commands that the users issued during their interaction with the regular explorer and wrote down their comments about each action. The empirical study showed the misconceptions users have while navigating through the Windows 98/NT Explorer and which were not identified by the previous version of IFM. Based on the results of the empirical study, the extension of the design of IFM was described.

In the construction phase, the primary executable release of IFM was expanded based on the limitations of IFM that were identified during the empirical analysis. In the phase of elaboration, a formative evaluation of the second executable release of IFM was conducted. The outcome of the construction phase is a product ready to be used by its end-users (Quatrani 1998; Kruchten 1999).

Design of IFM’s Primary Executable Release

IFM constantly reasons about users’ actions, so that it can diagnose problematic situations and give advice concerning users’ errors. As Cerri and Loia (1997) point out, if error diagnosis is to be performed, a user
modelling component should be incorporated into the system. Therefore, IFM has a user modelling component that generates hypotheses about users’ intentions and possible errors. However, there may be ambiguities about errors, since there may be different explanations of observed incorrect users’ actions (Mitrovic et al. 1996). Ambiguity resolution about errors is done in IFM by using two different reasoning mechanisms: a simulator of human error generations and a limited plan recognition mechanism.

The simulator of human error generations is based on a cognitive theory that attempts to formalise the reasoning that people use. This theory is called Human Plausible Reasoning (Collins & Michalski, 1989). Intelligent File Manipulator uses an adaptation of this theory to simulate possible errors of a user. For example, if a user has clicked on a certain file having a certain name s/he could be considered to have intended to click on a different, similarly named, file.

The limited plan recognition mechanism is used by the system to improve control and is based on what we call “instabilities”. Every user action is categorised in one of four categories, namely expected, neutral, suspect, erroneous, depending on its degree of compatibility of the users’ hypothesised intentions. For example, an action is considered “expected” if it deletes instabilities. Instabilities are added and/or deleted from a list as a result of user actions. Instabilities are deleted when an action results in a file store state that should not contain them. In this sense the deletion of an instability represents the continuation of a user plan that started earlier. In the current implementation, a file store is considered to be absolutely stable if it does not contain:

1. empty directories
2. directories with only one child
3. multiple copies of a certain file
4. folders with the name ‘New Folder’
5. files with the name ‘New File’
6. a file placed in clipboard by a cut or copy command and not have further use.

**Empirical Study**

The empirical study involved 15 users. Among them, 7 users were novice and 8 users were experts. These users were given a program that was very similar to a standard Explorer and were asked to use it, as they would normally do. Computer logging was used to capture their actions in video, so that the human experts would be able to watch and comment them. 10 human experts were involved in the empirical study, in order to comment on the 15 users. All 10 experts commented on all 15 users. In some cases all of the experts made the same comment and suggested the same replacement command. In these cases we have 100% agreement of experts. In other cases there was a diversity of opinions. (Tab. 1) illustrates an example of a user protocol, among the ones collected, together with the comments that the majority of experts provided. The experts had actually seen the exact user actions, e.g. clicking on a certain object, dragging a selected object, and so on. However, for the purposes of illustration of the example in limited space, we use the meaning of each action rather than showing the exact screenshots.

Table 1: A real Explorer-user interaction with the comments of human experts
One of the aims of the empirical study was to identify the most frequent errors that expert and novice users may make while interacting with a standard Explorer. Another aim of the empirical study was to compare the human expert comments to IFM’s reactions, in order to identify IFM’s limitations. These would lead to further requirements specifications for a second version of IFM. Therefore, half of the protocols were given as input to IFM, in order to evaluate IFM’s reactions, in comparison to the human expert comments.

Some conclusions drawn from the empirical study, were the following:

- Users, expert or novice, tend to reproduce the same mistakes over and over. Therefore, user profiles can be very useful for providing individualised help.
- Evaluation of user auditing’s results showed that expert users generally make different types of mistakes than novice users. Consequently, we propose a different user approach, taking in consideration a user’s level of experience. Empirical study has revealed that novice users are usually very careful but make mistakes due to lack of knowledge, whereas expert users tend to be very confident but careless. This results in different categories of errors. For example novice users are prone to command selection and/or execution mistakes and experts usually confuse neighbouring objects with similar names.
- Frequent error categories, among the ones identified, are the following:
  1. Users tend to forget to rename a new object (e.g., a folder or a text file) from the default Windows name (e.g. ‘New Folder’, ‘New Text Document’). This results in a mess of identically named objects in the file store.
  2. Another error is that users often copy or cut one or more files but they do not know how to complete the move or copy operation. Finally, users tend to paste the same group of files to more than one location.
  3. Some of the recognised errors are believed to result from the novice users’ lack of knowledge of the regular Explorer’s structure. For example, they tend to confuse the parent folder at the left part of the Explorer with the folder shown at the right part of the program.
  4. Another significant error category, committed by both novice and expert users, concerns the deletion of objects. This error category is considered dangerous because the results of such an error can be devastating. Users often delete a folder whose content they are not aware of. A subset of this category concerns users that delete an object after they have copied it, though have not pasted it.
  5. Another conclusion derived from user auditing concerns object similarities, namely, the case when a user confuses an object with another. Users may mistake an object for another if they are neighbouring objects, or in case of objects with similar names. In the latter case, similarities in terms of names may be categorised.

The comparison of the human expert comments to IFM’s reactions showed that in cases where IFM had diagnosed an error, it had also been successful at generating advice, which was similar to the majority of the experts’ advice. However, a lot of limitations of IFM were also identified. These resulted in the enhancement of IFM’s design, as explained in the following section.

Design Extension after the Empirical Study

The conclusions drawn from the empirical study were used for the extension of IFM’s design. The results are described below.

1. New Instabilities added
   A. Observation: Users often neglect to provide a name for a new object.
      Addition: An instability is added in case of the creation of a new object. This instability is removed when the user renames that object.
   B. Observation: Users often tend to leave a copy/cut - paste task incomplete.
      Addition: An instability is added when a user performs the copy or the cut part of the task that places something new in the clipboard. In order to delete such an instability, the user has to perform a paste command.
   C. Observation: The user performs the paste part of a copy/cut-paste action more than one time.
      Addition: A new instability is added every time a user performs a paste command for the same object. Such an instability is removed when one of the objects being pasted has been modified.
2. Potential Deletion Errors Detected
   A. Observation: Users often do not pay great attention to the contents of a folder that is placed deeply in a path and this results in deleting objects without realising.
   Addition: IFM is constantly monitoring the user throughout his/her navigation. If the user has not visited the folder containing an object to be deleted, then the system considers the action suspect and informs the user. Otherwise, the deletion action is being performed without further notice.

3. Users' misconceptions
   A. Observation: Users often make mistakes due to neighbouring location of objects
   Addition: A new category of error was introduced, to detect erroneous actions that are caused by users' misconceptions about either neighbouring objects or objects with similar names.

4. Users' behavior
   A. Observation: Users reproduce the same mistakes.
   Addition: In order to have more individualised user advice, IFM keeps a long term user model, which consists of long term information about a user (Rich 1979; Jones & Virvou 1991). The long term user model holds the individual features of the user, that have been recorded in previous interactions, so that IFM can diagnose and provide advice in a more precise way.
   B. Observation: Users issued more commands than those included in the domain representation of IFM's primary design.
   Addition: The domain representation was extended to include several new commands.

Evaluation of IFM

IFM's second executable release was evaluated using half of the protocols collected during the empirical study. Again the human experts' comments were compared to IFM's reactions. (Tab. 2) illustrates the protocol example that was presented in the previous section. However, this time in the second column we show how IFM categorised each command of the protocol. In case a command was characterised as suspect or erroneous, IFM generates alternative commands and suggests the user to replace the issued one with the new one. In the third column, we give the degree of compatibility of IFM's suggestions to the human experts' suggestions for a particular command.

<table>
<thead>
<tr>
<th>USER ACTIONS</th>
<th>IFM SUGGESTION</th>
<th>DEGREE OF COMPATIBILITY WITH THE COMMENT OF THE MAJORITY OF EXPERTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Copy(A:\House2\Room2)</td>

<td></td>
</tr>
<tr>
<td>2. Copy(A:\House1)</td>
<td>A suspect command, IFM suggested the alternative command Paste(A:\House1)</td>
<td>100%</td>
</tr>
<tr>
<td>3. Copy(A:\House2\Room2)</td>
<td>A neutral command</td>
<td></td>
</tr>
<tr>
<td>4. Paste(A:\House1)</td>
<td>An expected command</td>
<td></td>
</tr>
<tr>
<td>5. Delete(A:\House1\Room1)</td>
<td>A suspect command, IFM suggested the alternative command Delete(A:\House2\Room1)</td>
<td>100%</td>
</tr>
<tr>
<td>6. Delete(A:\House2\Room2)</td>
<td>An expected command</td>
<td></td>
</tr>
<tr>
<td>7. Delete(A:\House1\book.bmp)</td>
<td>A neutral command</td>
<td></td>
</tr>
<tr>
<td>8. Delete(A:\House2\Room1)</td>
<td>An expected command</td>
<td></td>
</tr>
<tr>
<td>9. Cut(A:\House1\Room1)</td>
<td>A neutral command</td>
<td></td>
</tr>
<tr>
<td>10. Paste(A:\House2)</td>
<td>An expected command</td>
<td></td>
</tr>
<tr>
<td>11. Mkdir(A:\House3)</td>
<td>A suspect command, IFM suggested the alternative command Mkdir(A:\House2)</td>
<td>100%</td>
</tr>
</tbody>
</table>

Table 2: IFM's reasoning on a sample of a real Explorers' user interaction
IFM was quite successful at achieving a high degree of compatibility with the experts’ advice. However, in many cases there were a lot of alternative commands that IFM generated. In most of these cases, one of the alternative commands was compatible with the suggestion of the majority of the experts. Still, the limitation of the generation of many alternatives needs to be addressed in a subsequent executable release of IFM.

Conclusions

The empirical study conducted within expert and novice users of a standard file manipulation program has revealed a lot of usability problems of such programs. The incorporation of intelligence can indeed enhance a GUI in terms of user error prevention and recovery. IFM incorporates intelligence and provides spontaneous assistance to users.

IFM’s reactions as compared to the human experts’ comments who took part in the empirical study showed that IFM can reproduce a great deal of the human expert advice. However, there are still some limitations that need to be addressed in a subsequent version of IFM. One important limitation is that IFM generates too many alternative commands to be shown to the user in case it diagnoses that there has been a problem. This problem can be addressed by extending IFM to include a subsystem that would calculate certainty degrees about alternatives so that these can be ranked before being presented to the user.

Abstract: TeamCMU is an electronic toolset developed to support team collaboration and learning in team oriented, project based university level courses. It was developed to meet the needs of student teams and instructors efficiently and at low cost. TeamCMU provides most of the electronic support that work groups expect and need, but is highly configurable, easy to use, flexible, low cost, low maintenance, and portable.

Introduction

TeamCMU was developed at Carnegie Mellon University to meet the need for an enabling, electronic environment that supports learning through both theoretical and experiential exposure to complex team assignments and team processes. TeamCMU is an electronic, web based, integrated, easy-to-learn and easy-to-use software environment that supports collaboration and communication within and among student project teams. It is intended to provide students with the electronic support they need to develop complex systems projects. It was developed to meet the needs of student teams and instructors efficiently and at low cost. TeamCMU provides most of the electronic support that work groups expect and need, but is highly configurable, easy to use, flexible, low cost, low maintenance, and very portable.

Today's workplace increasingly emphasizes teamwork, especially in technical fields such as information systems. Employers of new college graduates in information systems, software engineering, technical communications and related areas value students' experiences working as members of a team. Academic classroom settings, however, have traditionally been successful in providing students with the theory and practical skills needed for small individually completed development projects. Students often have not had appropriate learning opportunities and skill-building support for larger team-based projects and, as a result, do not usually bring practical collaboration skills into the workplace.

At Carnegie Mellon University, students majoring in Information and Decision Systems, Technical Writing, Public Administration and many other disciplines complete substantial, live-client team projects as part of their courses. Students in these project courses deal with all of the challenges common to student project teams - difficulty coordinating schedules, synchronizing and stabilizing their work products, and communicating effectively with each other (Phan & Weinberg 1995). To complete their work successfully, however, members of software development teams must learn to successfully manage their time, their work products, and their interactions with fellow team members and their sponsoring clients. Effective coordination, communication, and use of shared resources are crucial skills for team members to master. The use of high quality electronic tools to support development team efforts can play an important and useful role in facilitating successful team collaboration and project development as discussed in (Humphrey 1997). With few commercial toolsets readily available, however, most project teams have had to rely on standalone products and email for effective coordination and communication of their work activities and work products.
The TeamCMU Project

Using TeamCMU, students gain familiarity and experience with the types of electronic support tools they will use on the job. Because the tools included in the TeamCMU environment are easily mastered, students can be productive with a minimum of training or faculty support services. Students gain valuable exposure to the types of team support environments they will find in industrial and governmental software development practice.

Additionally, TeamCMU includes facilities to support faculty needs in teaching project based courses. Faculty who use TeamCMU in their courses also gain experience in managing electronic communications in an organized way, reducing the need for email and other forms of communications with class members. The emphasis in the first version of the toolset is on team organization, communications, and process for software development project teams. Later versions will provide support for project management and project tracking.

The toolset is rich in useful features, flexible and extensible and provides support for both student teams and faculty. For student team members, the initial version of TeamCMU includes
- personal calendars
- team calendars
- course calendars
- secure server space for team work products
- version and access control with check-out and check-in protection
- time sheets for recording work hours
- meeting agendas and minutes
- discussion boards for course, team and client communications.

All facilities of TeamCMU are accessible to students from a homepage configured by the faculty in charge of the course. Because all communications and artifacts relating to a project are maintained and organized in a logical, cohesive way, TeamCMU reduces the need for members to communicate and share documents and electronic artifacts via email and other means. The TeamCMU project URL is: http://www.cmu.edu/acs/telab/teamcmu/.

TeamCMU helps keep students in team-based project courses focused on accomplishing educational objectives. Students easily learn the tools and apply them to their group project assignments. We expect students to benefit from use of the toolset in several ways: reduced process time, better coordination of team resources, enhanced communication among themselves and with their instructors, and reduced rework. Further, in the case of the Information and Decision Systems curriculum, it is expected that the students will mature in their use of the toolset during their junior and senior years, showing increased team integration, effectiveness and competence.

For faculty, Team CMU includes configurable links to supporting course documents including syllabus, course description, and faculty information. It also includes an announcement board for posting important course related information and assignment boards which enable students to submit time-stamped assignments electronically and securely. Faculty are permitted to access each team's public workspaces and discussion boards to view project progress and assess toolset usage. Further, the toolset includes background, passive instrumentation for faculty assessment and evaluation of toolset usage and team effectiveness. With minimal modification, individual faculty can tailor the toolset by adding additional features as needed.

To promote communications among faculty, two special teams exist - a faculty team consisting of all faculty members established in the toolset's installation and course-faculty teams consisting of all faculty members jointly teaching an individual course. Faculty in these teams may share documents and communicate using the same facilities as the student team members.

An important design objective has been to make the toolset very convenient and easy to learn and use for both faculty and students. The interface to the toolset requires only a web browser and a single login to provide authenticated access. Consistent with our design objectives, we have selected customizable components that are affordable, portable, extensible, and easily maintained. We have selected these components with an eye toward easy substitution as future technologies evolve and become available. Thus, the toolset itself is based on established web based, nonproprietary technologies – HTML, cgi scripting via perl, and SQL databases. To keep the toolset development costs and complexity down, some of its internal components are low-cost licensed software components and custom created databases.
TeamCMU can be customized or extended to meet the needs of a wide variety of individual instructors and individual courses. The tools will support the needs of faculty in evaluating student learning of content and process and in providing appropriate feedback grounded in the student’s work. For faculty assessment and evaluation of student teamwork, special modules provide administrative capabilities as well as online support for administering and collecting assignments, work products, periodic surveys, weekly hours-worked time sheets, peer assessments, and other research instruments. Faculty will be able to track project status and progress and follow team communications, as the majority of the team communications will be posted electronically. As students learn to use the tools and follow established team management procedures such as structured meeting management principles, more information will be accessible to the faculty. Grading for team projects will be enhanced based on factual information gathered from and via the toolset. Instrumentation built into the toolset will allow researchers to learn more about patterns of usage.

Over time, TeamCMU will be incorporated into numerous courses that teach or require skills in process management, team management and team organizational skills. We hope to use TeamCMU as a vehicle for better understanding how electronic tool support can enhance the teaching and learning process. While our initial efforts have focussed on supporting the needs of software development teams, the toolset was developed with a view toward more general applications for project teams, curricula, and content of various disciplines. Additional development in the future will support differing team-based methods used in other project courses.

Two departments at Carnegie Mellon University introduced TeamCMU into their courses as a pilot test during the Fall Semester, 1999: Information and Decision Systems (IDS) with two courses and Master of Professional Writing Program (English) with one course. Target courses are Fundamentals of Systems Development (a junior-level IDS course with 90 students), Information System Applications (a senior-level IDS course with 70 students), and Writing for Multimedia (a masters-level English course with 25 students). Other departments will be using the toolset during Spring Semester, 2000. After successful completion of the pilot testing during AY 1999-2000, the toolset will be made freely available to the Carnegie Mellon academic community with an eye toward wider dissemination in the future.

This project was funded, in part, by a grant from the US Department of Education.

The development TeamCMU was a collaboration between Randy Weinberg - faculty in Social and Decision Sciences – and Diana Bajzek, Director of the Technology Enhanced Learning Lab (TELab) a faculty resource center in the central Computing Services Division of Carnegie Mellon University.
Abstract: In this paper we present the design of a course on multimedia-based learning and a case study carried out at the Darmstadt University of Technology. We describe the course, the interdisciplinary audience and the employment of computer-based communication and cooperation. In more detail we introduce VITAL, a computer-supported cooperative learning environment. We state the results of the evaluation of the course. Finally, we come to the conclusion that by using the computer as a communication and cooperation medium new forms of discussion arise which have more of a brainstorming character than a continuous coherent discussion.

1. Introduction
Currently, we are experiencing a boom in demand for the use of multimedia technology to support teaching and learning at various levels of education and training. Multimedia technology (we use this term in short to refer to multimedia, hypermedia and telemedia technologies) is a basis for enabling new forms of teaching and learning in domains such as virtual universities, distributed organisations and lifelong learning.

In order to qualify students for designing multimedia learning units and environments we developed a seminar on "Learning with Multimedia" which is based on the following principles:

- Learning about new technologies in education should take place not only by hearing and reading about these technologies but by using learning software based on these technologies.
- Knowledge about learning with multimedia should not be learned isolated but embedded in an authentic context.
- The task of designing and realizing multimedia learning units and environments is complex and usually done not by a single person but by a team.
- These teams should consist of experts of various disciplines, e.g. computer science, pedagogy, and media design.

The course on "Learning with Multimedia" addresses these principles:
- The course includes lectures about educational technology as well as hands-on learning experiences.
- The learning software is used to learn about the content of the course - "Learning with Multimedia".
- During a larger part of the course the students work in small groups (2-5 members) on the task of designing a lesson about a specific subtopic of "Learning with Multimedia".
- Students participating in the course should have a background in a related discipline, such as pedagogy, computer science, psychology, or media design.
- In addition, seminar tutors should (re)present multiple perspectives on the topic, in order to foster interdisciplinary work in the teams.

In sum, our goal was to create a harmony between the content of the course and the methods used to deliver it. The ideal course should provide hands-on learning experiences punctuated with short demonstration and discussion sessions. At the end of the course, participants should be able to judge and design multimedia-based instruction.

The remainder of this paper is structured as follows: In the next section we describe the course "Learning with Multimedia". Then we sketch the virtual learning environment VITAL and the ways we used VITAL during the course. In section four we present some results of our evaluation based on interviews and questionnaires.

2. Course Description

The seminar took place in the summer term of 1999 at the Darmstadt University of Technology, Germany, lasting three months and taking two hours per week. The aim of the course is to learn about and discuss the basics of multimedia-based learning. The students are supposed to actively contribute to the seminar. The curriculum comprises the topics of learning with multimedia, web-based learning systems, tele-teaching, computer-supported cooperative learning, learning processes supported by computers, and new forms of teaching and learning. For this specific course the audience consisted of 15 students, ten with a more technical background (computer science and electrical engineering) and five with a pedagogical background. The lecturers of this course were also interdisciplinary: one with both a computer science and a pedagogical degree and one with a degree in Mathematics and Linguistics. The intention of the lecturers of this course was to teach the topics not only in a theoretical way but to give the students real experiences with these programs etc. The seminar was supposed to integrate the content with the way in which it was taught.

The students were divided into five interdisciplinary teams of three students each. Three of the teams included pedagogic students. These teams had two tasks: They each had to develop a lesson about one of the following topics:
- Hypertext learning system
- Cooperative learning methods
- Characteristics of geographically distributed learning
- Communication in CSCW (computer-supported cooperative work) / CSCL (computer-supported cooperative learning) systems
- Comparison of commercially available CD-ROM learning systems for Mathematics in elementary school
- Visualization with interactive simulations

The second task was to generate these lessons with computers and to present them as a computer program. To support communication and cooperation both within the teams and within the whole group
the students were asked to use the virtual learning environment VITAL which is described below in detail.

(The lecturers were aware of the self referencing: A seminar about multimedia-based learning were the students are supposed to work in a multimedia-based way on producing lessons about multimedia-based learning.)

The course started with four group sessions. The students were given an overview about the technical and pedagogical problems concerning multimedia-based learning, and an introduction to the VITAL system. This period was followed by three weeks of team work. During this time, VITAL served as a blackboard for announcements and references to literature. The students were invited to come to the course room and, if needed, seek for advice from the lecturers, but had to find their own way of working within the groups. After this period, the intermediary results of each team were presented to the other groups. Here, problems concerning information retrieval, using VITAL, finding a common language between the disciplines, selecting the suitable sections to present in a lesson etc. were discussed. After another week of team-work the final presentations were made.

During the period of working in a team, the students had diverse possibilities to communicate. They could meet face-to-face either with or without a lecturer, they could telephone, email, use the chat tool of VITAL, or employ the learning repository provided also by VITAL. Some of the groups communicated nearly exclusively via the computer environment, and some groups used more the traditional means including email.

Also the final presentations were performed differently by the various groups. One team, having used exclusively VITAL all the time, used also VITAL as a presentation tool. Others did not use a computer for the presentation at all. The team preparing the lesson about learning with hypertext presented their results as hypertext. The discussion about this took place as an asynchronous session within VITAL. For ten days this hypertext system was part of the World Wide Web and each student had to read it and had to take part of the on-line discussion.

3. The Virtual Learning Environment VITAL

The course design included the provision of rich opportunities for the students and the lecturers to communicate and cooperate during the course. In addition to standard communication means such as phone, email and the world-wide web, we used the virtual cooperative learning environment VITAL (for Virtual Teaching And Learning) developed at GMD-IPSI (Pfister et al. 1998). VITAL aims to support small and medium sized teams of adult learners. Its main objective is to enable users to learn about a large range of topics (i.e., VITAL is domain-independent) by providing a virtual environment and a set of tools that are intuitive to use and conducive to the coordination, communication and cooperation processes that are typical for learning.

In VITAL, all users work with cooperative hypermedia documents. They can view documents and create new ones of arbitrary complexity by means of introducing new links. Users live in so-called virtual rooms, which make up the learning world. Virtual rooms provide a metaphor that serves the purpose of supporting orientation and group-awareness in the learning environment. Users who occupy the same room have the same view on the presented material, they are aware of each other, can communicate with each other, and they are able to cooperatively manipulate documents. Virtual rooms are especially useful for providing smooth transitions between synchronous and asynchronous modes of learning, since persons in the same room have full group-awareness for synchronous work, but objects
(texts, pictures, etc.) remain persistent in a room for later asynchronous work. Figure 1 shows some major components and functions of VITAL.

A Chat-Tool supports text based communication

Specific roles (trainer, learner) are distinguished

A Shared Whiteboard is the cooperative working space

Different types of rooms are distinguished by color

A Telepointer supports synchronous communication by focusing attention

By introducing links a Hypermedia Document of arbitrary complexity can be created

Various multimedia objects can be integrated

A world-browser informs about available rooms and current inhabitants of rooms

Group-Awareness is supported by images of the currently present learners in a room

As can be seen in Figure 1, most of a virtual room consists of a shared whiteboard, where users can cooperatively view and create hypermedia documents. Group-awareness is supported by showing images of all persons currently in a room, and by using personalized telepointers. Synchronous communication is performed via a chat-tool, or by an audio connection. (The latter was not used in the case study because of technological constraints). Asynchronous communication is performed either by sending emails or by leaving text-messages on the shared whiteboard.

VITAL provides three types of virtual rooms: (i) private homes for individual study, (ii) group rooms for discussion and self-organized cooperative learning, (iii) auditoriums for presentation and teacher-guided learning. In an auditorium, two roles are distinguished, that of a learner and that of a trainer. The trainer controls the learners’ access to the material presented as well as to the cooperation tools.

In the remainder we focus on the following three usage scenarios of VITAL in the course:

- Synchronous distributed group work:
  Students meet in virtual group rooms and communicate via the VITAL chat tool. The chat tool provides only text-based communication. In addition learners can refer to material on the shared
whiteboard in the virtual room. The room also provides awareness of the other inhabitants of the room by the way of small pictures for each learner (see Figure 1).

- Asynchronous presentational discussion:
The students use the learning environment for discussion by sticking their contribution at an arbitrary position on the whiteboard in the virtual group room used for the discussion. Technically students add a link to another hypermedia page. This link can be labeled to express the core idea of the contribution. The referred hypermedia page can contain information in various formats such as text, pictures, and tables.

- Learning repository:
In this scenario VITAL is used as a persistent storage of arbitrary information. Thus, teams can deposit (intermediary) results for their colleagues or the tutors in their group room, the tutors can announce up-to-date information, provide references to the literature, e.g., in an auditorium, and monitor the progress of the group.

4. Evaluation

The evaluation of the course consisted of student interviews at the beginning and at the end of the course, and questionnaires in the middle of and at the end of the course.

An initial interview about their motivation to select this course discovered two main reasons for course selection:
The reason which was given by most of the participants was the interdisciplinary character of the seminar. The participants were curious about learning and working with students from another academic background. The second-most common reason was their interest in learning more about the topic of computers and learning.

In the middle and at the end of the course questionnaires were used to gather data from the students. The questionnaire consisted of 14 questions concerning the individual work and the team-work, the usage and usefulness of the communication and cooperation tools as well as of the tools for the realization of the team projects. Another set of questions addressed the satisfaction of the students with their group, the course, and the results of the individual work and the team-work. Due to the small sample size, all quantitative results should be taken as purely descriptive information (no statistical test were performed). Selected results are presented in Figure 2.
I reached my goal:

- in the middle of the course
- at the end of the course

Satisfaction with the team-work:

- in the middle of the course
- at the end of the course

Team atmosphere:

- in the middle of the course
- at the end of the course

Figure 2: Selected questionnaire results

The general acceptance of the course, the groups and the results was rated as fairly high. With respect to the usage of the tools, results are more mixed. Though students generally had a positive attitude towards the tools a few students had serious technical problems.

In addition to the quantitative questionnaire interviews with the students were conducted. The issues can be grouped in the following way:

- The interdisciplinary constitution of both the complete group and the teams provided some difficulties but very positively effected the methods and the results of the team-work and the course as a whole.
- The sequence and the proportion of sessions with the whole group and periods of team-work was perceived differently by various students. A trade-off between the depth and quality of team-work and of the work in the course with the whole group was detected.
- The computer-supported communication and cooperation was different from earlier experiences of the students.

In the following, we concentrate on the last issue:

The students described their experiences with the computer-based communication and cooperation during the phases of team working. Three kinds of such a communication were used:

- Synchronous distributed group work: Two groups never used this possibility. One team used it quite a lot for social chat but not for issues concerning the course. Two groups communicated via the chat tool occasionally. Both complained that it is laborious not only to type everything instead of just speaking, but to have to make explicit that which in a face-to-face discussion is expressed by mime or gestures. There was also a problem of sequencing since there were three students in each team and it was not always clear who answered whom. Nevertheless, the students judged this kind of communication of high value, when used for organizational matters.

- Asynchronous presentational discussion: Many of the students were disappointed by the standard of the discussion. Whereas they liked the fact that each student and both of the two lecturers joined
the discussion, they remarked that the contributions are not intertwined, but rather disjointed statements.

- Learning repository: The usage of this component was not uniform. One team split their task into three subtasks. Each student solved one of the subtasks and placed her/his results into the repository. The others read and debated this contribution. They met only occasionally. Another group used it to exchange literature. However, the other three groups did not employ the learning repository. One reason for this was the limited word processing facilities as well as the limited number of import/export facilities provided by the system.

Based on the results of the quantitative and qualitative evaluation of the case study we come to the following conclusions:

- Traditional forms of discussion cannot be transferred easily into virtual learning environments.
- Synchronous creative, productive discussions are quite hard and should be avoided for groups of more than two or three members. However, arrangements are made much easier than by telephone as soon as more than two people are involved.
- Asynchronous discussion of a bigger group based on a thesis or a work known to everybody, has more of a brainstorming character and should only be used for this purpose.
- Repositories make sense when they are integrated in the existing tools. Then they are very helpful for exchanging documents and for giving external users an impression about the status of the ongoing work. They also serve very well as blackboards for announcements and background information.

The results match to evaluation results of other courses in which the learning environment VITAL was used in a different setting during a synchronous lecture (Pfister, 1999). For the next run of the course, we plan to replace VITAL by its successor, the CROCODILE system. The CROCODILE system provides so-called learning protocols (Wessner et al., 1999) which help the learners to structure their cooperative learning process.

We would like to thank all participants of the course, especially Maike Gilliot and Clara Möller, for their enthusiasm and high degree of patience (with us and with themselves). We would also like to thank our colleagues at GMD-IPSI, especially Christian Schuckmann and Jan Schümmer for technical support with VITAL, and Hans-Rüdiger Pfister for the help with the evaluation design.
Teachers, Students and the University Walking Together in One Direction: Analyzing the Potential for ICT in Higher Education from Different Perspectives

Joachim Wetterling
University of Twente
Center for Telematics and Information Technology
Enschede, The Netherlands
Wetterli@cs.utwente.nl

Abstract: As technology changes so many parts of life also education and the academic society cannot escape. Because of the many different perspectives of people involved in higher education predicting success of innovations such as the integration of ICT is considered a difficult problem. The paper intends to structure the perspectives of students, teachers and management in higher education related to change. Survey data illustrate the conclusion that there is potential for change but potential success is often characterized by uncertainty such as attitudes, individual key experiences and support infrastructures.

Introduction

The quality of higher education is both very difficult to assess and very important as one of the indicators for decision-makers to allocate substantial resources for universities and colleges to maintain their academic education infrastructure. But how to measure the quality of higher education? And how to relate quality to efforts needed to achieve and maintain quality?

A term related to the improvement of quality in higher education which is used in the Netherlands is 'studyability' (in Dutch: studeerbaarheid) (VSNU, 1998). This term means 'the characterization of the optimal context for supporting students in achieving learning goals'. Avoidable obstacles for students are to be taken away as much as possible. It is expected that, when the 'studyability' of a curriculum is improved, also the efficiency will improve. Improvement of studyability at first sight concentrates on student characteristics and perspectives. But the teacher and the university perspective are also important to consider in the context. A research project has been started to investigate ways to improve studyability at the University of Twente by integrating information and communication technology in the curriculum (Wetterling & Moonen, 1998). The project called IDYLLE (IDYLLE stands for 'Innovative Distributed Learning Environments') is situated in the Center for Telematics and Information Technology (CTIT), a research institute at the University of Twente. In the CTIT research is done on telematics and information technology systems, including the application of these systems in user environments. The IDYLLE project is a multidisciplinary project containing components from educational technology, computer science and ergonomics.

The paper concentrates on one of the parts of the IDYLLE project that investigates the implementation process for university teaching staff as Information and Communication Technology (further to be referred to as 'ICT') is concerned and how to deal with problems occurring in this process. Accents are on the different perspectives of analysis, the uncertainty of decision-making and attempts to structure support mechanisms to improve effectiveness and efficiency of using ICT in higher education.

Scenarios for ICT Integration in Higher Education: Different Perspectives

The success of implementing ICT in higher education is determined by a variety of parameters such as educational, technological and organizational (Harmon & Jones, 1999). These parameters are operational at a diversity of levels such as the student level, the instructor level and the faculty / university level. Additional factors that make the implementation of ICT in universities and the prediction of success a complex issue are the rapid developments in the ICT and education sector and the difficulties experienced in research on evaluating
the impact of ICT on educational effectiveness (Moonen, 1997). The implementation of ICT in university teaching can be analyzed from the perspective of the student, the university or the instructor. Even tough all of these are relevant to the success of integration of ICT this paper concentrates on the teacher perspective.

As the student perspective is concerned, three aspects are to be acknowledged in the context of ICT in universities. The first two are related to the input and output of the university. Input means implementation targets are on serving a greater flexibility in student enrolment such as more part time students, continuing education target groups and distance students. ICT is integrated to optimize quality for a greater variety in student characteristics. Output means ICT is integrated to deal with more specialized requirements for graduates in their future work environment. As the measurement of input (enrolment statistics) and output (graduation rates and salaries of graduates) indicators are relatively easy the quality of the education process and the influence of ICT integration in the curriculum is more difficult. One of the indicators in this context if the time students spend on study tasks. Concerning this problem a survey was carried out within the IDYLLE project resulting in a model for determining factors that influence study time and study habits of students in university (Kamp, 1997a, 1997b). The University perspective concentrates on the macro level of analysis, which means preparing a situation in which ICT can be implemented successfully in parts or all of the university. At the University of Twente successful developments are on their way in this direction (Collis, 1997, 1998).

The remainder of this section concentrates on the teacher perspective, as the survey results to be discussed in the paper are directly related to this perspective. If the teacher perspective is compared to the student perspective one of the main differences is that teaching staff in higher education often has not such a varied background as students. Even tough there are old and young teachers, teachers with more or less experience with ICT and teachers in technical, social or behavioral sciences, they all have a common task in design, delivery and maintenance of courses in a specific domain area where learning and research should be integrated. And by integration of ICT roles and tasks for teachers change and there are differences in how teachers deal with these changes (Shotsberger, 1998). The teacher perspective in this paper is differentiated in three characteristics: first the educational scenarios, in which teachers deliver their courses, second the personal factors of the teacher and third the infrastructures of the faculty in which they deliver their courses.

A series of educational scenarios can be identified in higher education settings. First the traditional scenario as higher education has persisted for decades almost during the whole century. In this scenario students attend lectures and read their study material, mostly books or readers at home and sometimes they go to workshops where they discuss assignments or have practical lab work assignments. Then there is the scenario of distance education. This scenario is characterized by students who do not live near or on the campus, the (almost) absence of instructional activities where students and teachers meet at the same location and the accentuation of high quality study material to structure learning and instruction for students. A third and final scenario is project-based learning. In this scenario students are usually located near the campus. Traditional lectures and workshops are replaced by group discussions with a teacher who performs roles of coach, tutor or guide. Students also do a lot of literature study, assignments and practical work either individually or within the project group.

The use of the World Wide Web and other forms of ICT can be integrated more or less in all three scenarios. In the traditional scenario students can retrieve lectures from the web for later review and assignments can be structured on the web thus saving time at workshops for discussion. In the distance scenario written material can be enriched by multimedia and communication facilities on the web and it would also be easier to communicate between teacher and students. The work of project groups can be structured on the web using workflow management environments and offering discussion platforms for efficient interaction among group members and active learning opportunities. A really useful categorization of educational scenarios related to integration of telelearning was presented by Kerres (Kerres, 1998).

The personal characteristics of the teacher are one the most important factors to determine the success of the integration of ICT in higher education. Let’s differentiate four indicators for the personal profile of the teacher. These indicators are (1) the workload of the teacher, (2) the expertise of the teacher related to ICT, (3) the resources available to the teacher and (4) the attitudes of the teacher towards integration of ICT. These four indicators can be used to predict the success for a specific teacher to integrate ICT in his or her courses. The problem (and also interesting challenge) is how to estimate the parameters for the four indicators. As addition to these characteristics incentives are important to teachers. Change means more often than not extra efforts to be invested and extra efforts need incentives. The teacher perspective on ICT is to a large extent depending on external influences such as incentives and disincentives (Williams & Peters, 1997).
The past, the present and the future

The university of today is seen as a component of society. Today's society is rapidly changing due to technological, political, sociological and organizational developments. One of the main problems to keep universities up to standard in the curricula is that these curricula prepare students for work after graduation and thus that these students usually learn to work with technologies that are outdated when they are ready to apply them in their work environments. This means that universities either should come closer to requirements of business and society as technology and their applications are concerned; or a basic curriculum in ICT is offered followed by an advanced program for those needing more specialized skills and knowledge in the context of their working area after graduation. Both of these approaches show a need for a more flexible and individual learning program. Integrating ICT should be considered as one of the solutions to improve higher education and meet the goals of flexibility and individualization. But it is also acknowledged that it could be better to build new ideas on existing proven foundations instead of building new concepts from scratch with all pre-programmed uncertainty to consider (Holtham e.a. 1998).

Survey

How is the integration of ICT in the university curriculum perceived by those who have to deal with the innovation in their everyday job? A survey has been conducted among teachers at the University of Twente to achieve data on the perspectives of teaching staff on integration of ICT and telelearning. For the survey a sample was drawn of 100 instructors in 10 faculties from those staff members involved in one or more student courses. Subjects were sent an e-mail message with information about the survey. The survey questionnaire was attached to the e-mail message. A response rate of 28 was achieved for the survey. The results unveil two major characteristics of the analysis of success of potential ICT in higher education: these characteristics are uncertainty and trends. Uncertainty because of the difficulty to predict effects of decisions made today on tomorrow's situations and trends because of the preference at teacher and institution level to some ICT application over others. Another problem with interpreting results of the survey is the background of the respondents. Subjects that already either have a stronger attitude to ICT or use ICT in their courses can be more motivated to return the survey which can bias results. The questionnaire contained 12 closed questions about the following topics: Opportunities for ICT in university courses, instructors experience with different ICT tools, the ICT-infrastructure in the university, teacher support and reasons for using ICT.

The survey started with two general statements. These were used as indicators for the expectations of instructors from ICT on student learning and quality of education. The first statement was “ICT has a positive impact on student learning”. On this statement 11 respondents either agreed or strongly agreed. Three respondents disagreed and only one strongly disagreed. The second statement was “ICT will improve higher education quality”. On this statement 18 respondents either agreed or strongly agreed. One respondent disagreed and there were no 'strongly disagree' responses. Another item asking for longer-term expectations of ICT in university teaching confirmed these data as 14 respondents rated this high against 6 low and 7 had no opinion.

One item asked for the ICT tools from which instructors expected the most for improvement of the communication between instructors and students and among students. In this item e-mail and the World Wide Web were rated highest whereas chat and videoconferencing were rated lowest. This has a high correlation with item 4, asking for instructor's experience with ICT tools. Here also e-mail and WWW were rated highest and chat lowest. Another item later in the questionnaire asked what tools respondents used most. Here also e-mail and the WWW scored highest. The correlation between these two items is not unexpected. It also indicates that future developments should consider carefully the prior knowledge and experience of the teachers in the target group to optimize the impact. On the other hand low instructor experience should not be considered too much a reason to avoid investigating the potential of these technologies in the university.

Another item asked for the support instructors receive from the faculty or university level. Response shows a high perception of motivational (15 out of 28 (strongly) agree) and financial (12 out of 28 (strongly) agree) support from the side of the management but instructors do not often perceive they have sufficient time to integrate ICT in their courses (8 out of 28 (strongly) agree). The University of Twente has three major support institutes for the faculties. These are the libraries, the computing center and the educational support center. Respondents were asked how important they find these three institutes on a 5-point scale. 16 out of 28
respondents rated the educational support center as important or very important. 10 out of 28 gave this rating to the computing center and 11 out of 28 for the library. There is a trend to combine these types of support institutes in one large organization in order to make service more efficient and more effective within the university.

What factors influence the quality of ICT in university courses? Respondents were given five factors, which they rated on a five-point scale. These factors were: 'instructor capacities', 'student motivation', 'quality of learning material', 'technology policy of the university' and 'reliability of the hardware and software'. Four out of five of these factors scored very high in the item (21 or more out of 28 respondents found the factor important or very important). Only 'technology policy of the university' was rated a little lower, even tough almost half of respondents rated this as (highly) important. ICT is expected to have more impact in individualized, personalized education activities rather than in group teaching. Respondents were asked to indicate for a series of educational activities whether they think ICT could have a positive impact on the quality of these types of activity in the future. Activities in which the most respondents expected a positive ICT impact were the presentation of learning material, the coaching of project groups and the individual coaching of students.

The last item asked respondents about the reason why they use ICT in their courses. Respondents were given eight 'reasons' on which they could answer 'yes', 'no' or 'don't know'. The two reasons that scored highest on this item (18 and 19 times 'yes') were 'the course content has opportunities for ICT use' and 'the innovation-mindedness of the instructor'. About eight or nine respondents circled 'yes' on the reasons 'too many students fail exams on my course', 'the university wants me to use ICT' and 'students complain about the course'. A very small majority indicates that they use ICT to decrease their workload or to increase student numbers. No respondent uses ICT to decrease student workload in the course.

Conclusion

Getting ICT into the university and especially realize that staff uses ICT in a way that improves quality and efficiency of the university product such as education and research is perceived as a long and enduring process. All phases in this process have their own characteristics influencing the success or failure of the integration process. This includes situational characteristics such as the availability of resources or infrastructure but also personal characteristics such as the attitude of teaching staff and students or expertise of instructors. A large majority of these factors are expected to have impact on the probability of successful integration of technology. So what can be said about the way ICT is integrated in the university and the way instructors deal with this process on the basis of the data collected and analyzed in the survey in this study? First there seem to be high expectations and positive perspectives on the side of the instructors in higher education. But on the other hand many instructors have some resistance to ICT because of the initial efforts needed to get things started. As the ICT tools are concerned, results show that especially e-mail and the World Wide Web is used frequently. It could be interesting to find out how other areas such as videoconferencing or groupware can be stimulated among university staff. Another aspect in the survey is the role of the support institutions such as the library, the computing center and the educational center. There is a trend to integrate these support institutions to increase efficiency in universities. The rather equal distribution of how respondents perceive the value of the three institutions seem to support integration efforts but more research is needed to validate the impact. A final conclusion deals with the value of ICT for specific instructional activities. Results show a high score for ICT as to improve communication and interaction scenarios in course delivery. Especially the support of student groups by the use of ICT is perceived as being a valuable contribution and addition to traditional instruction.

Abstract: This paper will report on a pilot study which surveyed faculty to determine their attitudes towards WebCT during its first year of use at George Mason University. Faculty who responded to the survey seemed to be generally satisfied with both the WebCT tool and the WebCT support available on campus. However, faculty also reported barriers to WebCT usage, including difficulties using the designer interface and the amount of time involved in learning WebCT and setting up a WebCT folder.

Introduction

In January 1999, George Mason University began use of WebCT, an online course management system designed to facilitate the creation of web-based instructional material and instructional supports. Currently, WebCT is being used by some faculty and is considered to be in its early stages of implementation. Up to the present time, no systematic assessment of WebCT’s implementation has taken place. This paper presents a pilot study attempting such an assessment by looking at faculty satisfaction with WebCT. Data for the current study was gathered through surveys, and a large student including both surveys and interviews with selected faculty is planned. Before beginning a discussion of the data, a definition of an online course management system is provided.

What is WebCT?

WebCT is an on-line course management system that assists faculty in the creation of complex educational websites. It provides faculty with three types of tools: (1) an interface to help with aspects of page design and layout, (2) educational features such as a quiz-creation tool, a glossary, and a student presentation tool, and (3) a course management system to help instructors manage and distribute grades, and release course content according to grades, dates, and other related criteria. (Goldberg, 1997b)

Related Research

According to Phipps, R., & Merisotis, J. (1999) “There is a relative paucity of true, original research dedicated to explaining or predicting phenomena related to distance learning.” (Page 2). Much of the body of research that does exist dealing with on-line learning “are more anecdotal than systematically empirical or critical.” (Hara & Kling 1999). In addition Windschilt (1998, as quoted by Hara & Kling 1999) also notes that much of the published literature dealing with computer-mediated on-line instruction consists of descriptions of software or anecdotal accounts of how technology was integrated in a course or classroom.

To date, there has been virtual no research on faculty reaction to WebCT or other on-line course management software. The only article published dealing with faculty attitudes have been “testimonials” published by faculty on
their individual experiences with teaching on now (Ruth, Foreman, & Tschudy 1999, Goldberg 1996). Although these articles are usually positive, they are usually written by faculty who were previous technology (Phipps & Merisotis 1999) or even the developer of the software they are using in the course (Goldberg, 1996). Although their research focused primarily on students, Wernet & Oliges (1999) noted that learning curve was high for faculty learning WebCT. Pauley & Cunningham (1999) noted that faculty emphasized the importance of developing an understanding of the effects & implications of distance learning & needs of adult learner. They also noted that faculty emphasized the importance of the instructional support staff.

An investigation and review

The investigations were design to explore and gather information that could possibly be used to formulate a hypothesis to be tested. The following sections discuss the methodology used and threats to the validity and reliability of the data collected.

Faculty Survey Process

The faculty reaction survey consisted on 19 questions dealing with faculty reaction to the WebCT software as well as their judgment as to the quality of support provided by the university's Instructional Resource Center. Questions also included asking if they had ever used the Internet for instruction previously and how many WebCT workshops they participated in. The survey was then sent out on the university’s WebCT_users e-mail list, to which all faculty are added when they request their first WebCT course. The list usually serves as a forum for announcements concerning WebCT, discussion of problems with WebCT, and posts of upcoming WebCT related campus events. In addition to the WebCT_users list, the survey was also sent to all faculty and staff who had attended a WebCT workshop since March. An e-mail was sent out to all the above-mentioned faculty and staff containing the required cover letter for research projects exempt from Human Subjects Review. In the body of the e-mail below the cover letter information was the survey. Participants could complete the survey in one of three ways: (1) print out the e-mail, fill it out by hand, and send it back via intercampus mail, (2) reply to the e-mail and type their responses right in their reply, and (3) completing an on-line survey at a URL provided. Faculty were given 10 days to complete the survey. The multiple modes of completing the survey were designed to encourage participation and also to prevent the possibility of difficulty filling out the survey affecting the outcome of the study.

Threats to validity and reliability

As all faculty at the university involved in WebCT were surveyed, threats to validity due to selection were not relevant. However, as with all survey studies, results are based on those subjects who choose to participate and return the survey and who are therefore self-selected. Due to the desire of the Instructional Resource Center to gather data from as many faculty as possible and due to the short amount of time available for this study, this threat to internal validity was not compensated for and must be taken into account in our discussion of results. In addition, WebCT has only been used at George Mason University since January 1999, and most faculty who have been trained in WebCT and/ or decided to use this tool began only this past summer. Consequently, faculty attitudes may be tainted by a novelty affect, and a follow-up study after several more semesters of WebCT usage is planned.

Since this is the first known study of faculty reaction to WebCT, there currently exists no other surveys or research with which to compare either the instrument or results of this study. However, the survey was constructed in such a way that it would be easily adaptable to other institutions for future research. Most questions in the study were multiple choice, precluding the possibility that researcher bias could affect the results. In addition, there were a number of free response questions which will be discussed below.

Preliminary Survey Analysis

Survey response rate:

One hundred seven people received the request to complete the survey. Of those eleven were eliminated because they were staff members in the department running the survey rather than faculty. Of the 96 remaining, twenty-two
had completed the survey during the time period requested, a 23% response rate. A few additional surveys have been returned since the deadline, but they have not yet been added to the database yet.

Overall level of satisfaction:

As for WebCT itself, faculty rated it at an average of 2.05 on a scale of one (excellent) to four (very poor), with only 2 respondents saying that WebCT was either poor (3) or very poor (4). A large majority gave WebCT a rating of 2 (good). Faculty who have actually used WebCT with their students generally reported that their students level of satisfaction was good. In fact, faculty rated students as slightly more satisfied than the faculty, with an average rating of 1.9375.Faculty were then asked to rate the usefulness of particular WebCT tools on a scale of one (very useful) to four (very useless). Few faculty rated all tools, since they were asked to only rate the tools they had experience with. Ratings ranged from an average of 1.43 for the bulletin board to 2.22 for the White Board. Very few tools received scores of very useless, although ratings of useless were somewhat common.

Level of satisfaction w/ training & support:

Faculty who responded to the survey seemed to be generally satisfied with both the WebCT tool and the WebCT support available on campus. On a scale of one to four, with one being the best, faculty rated WebCT workshops as 1.47. While only approximately half of the respondents took advantage of opportunities for one-on-one help, those who did rated it very highly, with eleven respondents saying this help with excellent (1) and two replying that the one-on-one help was good (2) for an rating average of 1.15.

Best / Worst aspects of WebCT:

Faculty expressed the most satisfaction with the things that WebCT did to make their lives easier. These included the ability to post grades for students and to cut down on the number of paper copies that needed to be distributed, and the self-grading quizzes with automatic feedback.

Faculty thought the biggest drawback to WebCT was the “clunky interface.” It is “over-complication” with a “somewhat scattered and cumbersome array of elements.” Another big drawback was the time involved in learning WebCT and setting up a WebCT folder. “I still don’t know how to use most of the applications,” complained one, “That is, it is tremendously time-consuming to prepare course materials for on-line use and I just don't have much time.”

In fact, most of the faculty who are not using WebCT cited either the clumsy interface or their lack of time as their reason. “I haven't decided NOT to use it, but haven't had the time to get geared up yet,” said one. Another responded, “a program should not have to require so [many] workshops. We ought to be able to figure [it] out ourselves. . it made things a lot harder to do.”

Conclusions and future directions:

Although the data collected so far represent one of the few attempts to collect information on faculty reaction to WebCT, it is currently only skimming the surface. While faculty seem to be, by and large, satisfied with WebCT and with the WebCT support offered at George Mason University, it is also clear that they find some aspects of WebCT confusing and that many also find it difficult to set aside the time that they need to learn WebCT and design their WebCT folder. In order to get a clearer understanding of how faculty are using WebCT, how successful they feel that that use is, and how the university could best support WebCT course development, it will be necessary to do further research. Interviews with randomly selected WebCT faculty are planned. In addition, we plan to send a reminder to all faculty on the webct_users distribution list to attempt to get surveys from those who did not complete them by the initial deadline.

Abstract: The paper reviews the past uses of Virtual Reality (VR) applications for students with special needs. Although VR technology shows promise for helping these groups, applications have been slow to emerge. Reasons for the lag in development include the expense of VR components, special skills required to develop learning environments, and special challenges of educational applications. Research in the use of VR in physical rehabilitation and remediation for cognitive deficits are discussed. Design issues and variables are reviewed together with a description of new developments in the use of low-end VR systems and the Internet.

Background on Virtual Reality Applications for Special Needs Students: Potential vs. Performance

It is likely that no technology has created greater hope for improving the quality of life and learning for students with cognitive or physical disabilities than Virtual Reality (VR). Although VR environments for military training were first developed over 20 years ago, and applications in education have been in development since the early 1990's, VR applications to remedy or compensate for cognitive or physical disabilities have been much slower to emerge. Several reasons seem to account for this lag.

- **Expense of VR components** – Until recently, the software and devices required to develop and use VR environments were so expensive as to be prohibitive for schools, since they required well-funded research and development settings.

- **Special skills required** – Because of the expense and complexity of the systems, few educators have skills required to design virtual reality programs. Most environments have been developed in university labs or by special projects. Long term research and development efforts to address the needs of special populations have been rare.

- **Special challenges of educational applications** – Students with special needs usually cope with a combination of physical and cognitive problems that make learning in any environment problematic. VR environments can add another layer of required adaptation.
Difficulty of demonstrating need – The expense of VR systems in comparison to the small number of people in various special needs populations has made it difficult to justify extensive development in this area.

It is apparent that the relatively high costs of VR systems has been the single greatest obstacle to past progress in this area. However, recent developments in low-end VR systems may decrease the impact of all these factors. This paper describes examples of past work in this area and work currently under development by the authors. The presentation accompanying this paper will demonstrate sample VR systems that use either lower-end software or the Internet as a means of accessing virtual environments.

Research To Date

Descriptions of VR applications for students with special needs have appeared both in medical and education literature since around 1992. Environments in experimental phases have been described in two major areas:

- Physical rehabilitation - VR environments have been designed to restore skilled movement in students with physical disabilities resulting from various traumas and diseases (Andrae, 1996; Ira, 1997; Kuhlen & Doyle, 1994; Latash, 1998; Rose, Johnson, & Attree, 1997). Some systems have focused on the needs of people with motor problems due to cognitive processing difficulties. Krais, Kuhlen, and Friedewald (1993) reported on the use of systems to assess apraxias, loss of ability to organize and coordinate movement sequences spatially and/or chronologically. Molendi and Patriarca (1992) explored environments for helping people coping with ataxia, a condition in which visual stimuli are highly distorted. Stanton, Foreman, & Wilson, 1996; Stanton, Foreman, Martin, & Wilson, 1997) used VR to teach building navigation to students in wheelchairs, teaching them to locate and activate fire alarms and hoses and find exits from the building.

As recent reviews have noted (Cass & Roblyer, 1999; Roblyer & Cass, 1999), few of these reports include any actual research and data on the design problems and impact of VR environments. Interestingly, most of the research results come from two groups in England: research teams at the University of Nottingham and the University of Leicester. It is evident from the limited data available that students vary considerably in the length of time it takes them to adapt to this kind of environment. However, each of the R&D groups experimenting with this technology feel that their results to date encourage them to be optimistic about VR’s future impact.

Selecting VR Environments to Design

Even though VR costs are coming down, the complexity of these systems and the time and expense of designing them make it imperative that we assess carefully the reasons for choosing VR as an educational environment and the feasibility of implementing it in schools and classrooms. Two areas of criteria seem to emerge from past applications that can help us determine the future usefulness of VR.

- Safety concerns – When students need to acquire skills in areas that help them become functional, independent human beings (e.g., cooking, crossing streets), but learning these skills involves a degree of risk to their personal safety, VR seems to be the learning medium of choice.
• **Mobility issues** – Because of its capability to simulate real environments using varying degrees of real-life complexity, VR also seems the best choice for students who need to re-acquire physical or mental abilities lost due to illness or accident or to make up for physical limitations. Though it is not often recognized as a priority, some educators who work with students with physical disabilities have high hopes for improving the quality of life of these students through VR simulated participation in sports and games.

**Design Issues and Variables**

From the limited experience educators and trainers have had with designing VR learning environments, it is evident that this already-complex endeavor carries even more problems and issues when the target population is students with special needs. It is critically important that research studies help us address the design and implementation issues that have emerged from prior work.

• **Side effects from immersion environments** – Some studies have observed symptoms similar to motion sickness (Latash, 1998), and others (Strickland, Marcus, Mesibov, & Hogan, 1996) have noted difficulties adapting to headgear. These reports are rare, but cannot be ignored.

• **Transfer issues** – Several different kinds of challenges emerge in developing systems to teach skills that will transfer successfully to real life activities. Even fully immersive environments with goggles and data gloves do not provide perceptual experiences identical to real environments. There are differences, and the impact of differences on skill transfer are largely unknown.

• **False safety issues** – Another problem related to transfer of skills has been hypothesized but remains unexplored. Some students with mental deficits may learn to feel such confidence in their ability to operate in this less complex, simulated world that they achieve a "learned recklessness" in real environments. If this aspect is ignored, it has the potential to negate the benefits offered by VR systems.

**New VR Development Resources**

Recently, VR software systems have been developed that do not require the high-end computer systems of prior VR generations. Some of the groups that have developed these systems have found that completely immersive environments do not appear to be necessary to achieve the desire impact. Thus, rather than requiring headsets and data gloves, students can manipulate the environment using a 3D mouse and a standard monitor.

An added capability that makes these systems more feasible for implementation in schools is being able to access them over the Internet. One current example, *SuperScape* software (developed by SuperScape, Inc.), which was used by several of the R&D groups described in this paper, provides a plug-in that can be downloaded from their website and would allow schools to use the environments with a browser and a desktop computer. More such Internet-accessible VR environments are sure to follow in the near future.

**Conclusion**

As development continues, other issues may emerge that must be addressed before VR environments can be made functional components of educational plans for students with special needs. However, as one recent reviewer noted, VR represents "the new frontier for a field that represents perhaps the most exciting pioneering work in educational technology" (Roblyer & Cass, 1999, p. 53). Recent developments in VR software and Internet-access resources also may mean we are closer to closing the gap between potential and performance of VR for special needs students.

Implementing a 'Scaffolding by Design' Model in a WWW-based Course Considering Cost and Benefits

Contact author: winnips@edte.utwente.nl

Abstract: A model for 'scaffolding by design' is implemented in a course (called ISM-2) about the fundamentals of media design for education. This model tries to combine the focus on task-performance of cognitive-apprenticeship with the fading of support of scaffolding, and the flexibility of telelearning. To explore the impact of this model it is applied in the ISM-2 course. A scaffolded group (creators) is compared with a non-scaffolded group (reflectors). On a multiple-choice test for a knowledge and a transfer type of questions no significant difference was found between the two groups. The dropout rate for the scaffolded group was lower and their overall time-investment for the course was higher. It is concluded that the extra cost of using this approach of scaffolding can - at this moment - not be justified by the measured learning results.

Introduction

A scaffold is a support, such as the temporary framework that supports a building when it is built. When the building is finished, the support is removed and the building will stand on its own. In instruction scaffolding serves the same role as the scaffold for a builder (Wood, Bruner, & Ross, 1976):
1. It helps to ensure the learner's success.
2. It extends the learner's competency in a new territory.
3. It can be taken away as the learner becomes more responsible.

Scaffolding is part of the cognitive-apprenticeship theory (Brown, Collins & Duguid, 1989), in which a student is modeled and coached to perform a specific task. Reflection, and articulation of reflection takes place, after which a -more free- phase may follow where students can self-reliantly explore, set their own subgoals and frame problems. In this way the student gradually becomes an expert in the performance of a specific task.

Nowadays, cognitive apprenticeship is being used in a number of telelearning settings (see for example: Guzdial & Kehoe, 1998; McLoughlin & Oliver, 1998, Suthers, 1998). Part of the appeal of using cognitive apprenticeship and thereby scaffolding in telelearning situations is its promise of flexibility. As the performance of the student, and not that of a lecturer is key (Pressley, Hogan, Wharton-McDonald, Mistretta, & Ettenberger, 1996), a lecturer does not always have to be present to support students. Students can work in their own time and place, and receive and ask for support from peers, or use support that is received in an a-synchronous fashion from an instructor.

Some other appealing factors of scaffolding are:
- Support at the level of the student, as stressed by Vygotsky (1978), attention is paid to the specific difficulties of a student when solving a problem.
- It's focus on the self-reliance of the student. When the level of the student rises, support is faded, so that the student learns to self-reliantly perform a task. This again is an advantage for telelearning situations where the continuous presence of the lecturer during learning is not possible.

When the aforementioned focuses on task-performance of cognitive apprenticeship, the fading of support, and the flexibility of telelearning are combined, the model seen in Figure 1 can be constructed. Performance has a main role in the model, fading is visualized by the decreasing part of the task that is performed by the instructor, and the increasing performance of the student. Using prototypes as a means of monitoring progress of students provides flexibility. In this model the prototypes provide proof of performance via which communication can be structured. The initial support provided is support that is already available in a learning environment. They can take the form of explanations provided, videoclips, process worksheets, or parts of the solution to a problem.
Scaffolding is a time-consuming and demanding form of instruction (Pressley, et. al., 1996). In order to scaffold students on their own level of development, and to scaffold students based on the progress they have made, much effort needs to be invested in monitoring or tracking of the progress of students. Therefore a part of the challenge of implementing this approach of scaffolding is a cost-effective application in telelearning environments.

In this paper an experiment is described whereby the model for 'scaffolding by design' is implemented in a course (called ISM-2) about the fundamentals of media design for education. More specifically the research questions for this experiment were:

- What impact does the implementation of this model for scaffolding have on students learning, measured by students course completion, study behaviors during the course, and student achievement on the final examination of the course?

- How much extra time is involved for students and instructors, for a scaffolded variant of the course compared to a variant of the course without WWW-supported scaffolding? If there is a difference in time investment, is this extra cost balanced by the benefits received?

Context: The course ISM-2, fundamentals of media design for education

The course ISM-2 is an obligatory course for second-year students in the Faculty of Educational Science and Technology. It is the second of a number of courses that introduce the student to the field of work of the Department of Educational Instrumentation (abbreviated ISM). The Department ISM focuses on the design, development, and use of technological tools and resources for learning-related purposes. While the first year course (ISM-1) provides a practical introduction to the work of the department, ISM-2 provides a more-theoretical perspective, especially focusing on human-computer interaction and the design base of the field. ISM-2 is worth 2 points of credit, representing 80 hours of study by the students.

Experimental design

To address the research questions, two experimental groups were formed. One group participated in a variety of required learning activities involving group collaboration and discussion, using a variety of WWW-based resources, participating in decision making and preparation of a summary of an article as an addition to the course study materials (therefore called creators), and interacting with the instructors in personalized and substantial scaffolding activities. The other group (called reflectors) had access to the same resources and activities, but not in a required way. Both groups attended the same four lectures; were responsible for reading the same set of study materials, and wrote the same final examination (worth 70% of the course mark).

A statement often referred to is that 'conditions of learning determine the learning effect' (Aronson & Briggs, 1983). In this case, the learning effect of the groups will be different, as the conditions, the WWW based learning environment and the interaction with instructors and peer-students are designed differently. As the creator group was making links outside of the initial course materials, by searching for articles for their summary, they were expected to better be able to use their knowledge in different contexts. So, at the final examination, they could also have a better score on a transfer type of questions, asking for application of a known concept in a new domain. The Reflectors were presented with the content of the course and did not have to find or contribute new materials to the course. So,
it was expected that they could spend more time studying, and reflecting on the materials presented, and have a better score on a retention type of questions, asking for definitions and direct recall of information. Participants were 29 second-year university students participating in the course ISM-2. From the students that were present in the first lecture of this course the creator and reflector groups were formed. Because there were six topics available (in three cycles) for contributing a summary to the course, students were assigned to the creator group first. The remaining students were assigned to the reflector group. The creator group consisted of 18 students, the reflector group consisted of 11 students. The creator group was divided into 6 subgroups of three students each. The course made use of the C@mpus+ course support environment developed at the Faculty of Educational Science and Technology (Tielemans & Collis, 1999). The two groups had access to their own version of this environment. They had however the same communication tools, instructor notes, and course information available, with only the roster (used for structuring information and providing forms and deadlines relating to the assignments in the course) being different for the groups.

To measure the time investment of both students and instructors, a time investment form was designed to be filled in with an estimate of the number of minutes spent on the different activities of the course. The final examination of the course consisted of a multiple-choice test, with a total of 36 questions covering all the objectives of the course. In this multiple choice test 18 knowledge type of questions were included, and 18 transfer type of questions. As a pretest, the results from the first year course ISM-1 were used in order to compensate for possible differences in ability between the two groups. The courses ISM-1 and ISM-2 can be compared, as there is continuity between them in content, nature of the examinations, and instructors.

Procedure

During the course the creators have actively constructed the knowledge that was used as study materials for the reflector group, thereby scaffolded by the instructors. As initial introduction to the topics of the course, three introductory lectures were given. In the week after the lectures the creators were asked to work with the materials presented in the lectures (and in the reader of the course), and find additional sources of information. This could be information from several sources, such as the WWW, staff members, CD-ROMs, etc. Each student had to find one source and submit some information about it, suitable for the topic. The sources were discussed in the groups, and one of the sources was selected. Of this source a summary was prepared as study materials for all students. The sources found, the choice for one of three sources, the group's motivation for this choice, and a draft and final version of the summary were all included in the WWW environment.

The instructors each gave careful feedback to the groups. The feedback was related to the choice of articles and the quality of the (draft) summary. The instructors gave personal comments to the group about the quality of the chosen articles and the suitability for their topic. The instructor could add personal feelings about a source, add some background information about the author of the source, suggest a different article, or add some information about the impact the chosen article had on the field. Typically, each of the feedback comments by the instructors were about one or two pages of typed text. The comments were uploaded to the WWW site and were only visible by the students of the creator groups.

In a face-to-face session following the posting of these comments, each group discussed the comments with an instructor, and revised their summary. When the final version of the summary was approved by one of the instructors, it was posted to the course WWW site as part of the study material. Also, the summaries were now available to the reflectors. By the end of the face-to-face session, the summaries should be posted, and the reflectors would have the whole week to read and study the materials posted. All of the creators' work, including draft submissions, and instructor feedback, can be viewed at the course WWW site, at http://education2.edu.utwente.nl/193032.nsf/guest?readform. (Most of the work and communication is in Dutch.) Students in the reflector group followed the same lectures as the students in the creator group. They studied the materials provided in the reader, and the summaries provided by the creator groups. Further, they individually prepared three essays around three topics of the course. They received feedback on these essays from the instructors, but did not have to improve the essays, nor were they used as study materials.

Results
All students in the creator group participating fully in the activities designed for them. All groups submitted the sources, draft summary, and final summary. On average the grade for the summaries was 8.25 on a 10-point scale. All students in the creator group participated in, and passed for the final exam.

Of the students in the reflector group 4 of the original 11 students failed to submit their essays and 4 out of 11 were not present at the final exam. The average mark for the essays was 7.55 on a 10-point scale.

Creators were more often present at the lectures than students in the reflector group. Of the creator group, 4 out of 18 creators attended all four lectures, 8 out of 18 attended three, and 6 out of 18 attended two or less. Of the reflector group, none of them attended all lectures, 2 attended three lectures, and 4 out of 7 attended two or less lectures.

**Results on the Final Examination**

The scores for the final examinations of the ISM-1 and ISM-2 are given in Figure 2. The scores for the creator and reflector groups are under the graph, with the standard deviation brackets.

There was no difference found between the based on the score of the previous course ISM-0.352, p=0.730). No significant difference was between the groups on the score of ISM-2 overall grade for the final examination is constant (t(22)=1.270, p=0.222). When the knowledge and the transfer items on the final examination considered separately, there remains no difference between the groups (t(22)=0.103, for knowledge questions, and (t(22)=2.083, for transfer questions).

**Time-investment by Students and Instructors**

Table 1 gives an overview of the time-investment of students for the course, split into creator and reflector groups. When an asterisk (*) is printed there was a significant difference between the groups.

Table 2. Tasks and time on task of instructors (in minutes)

Discussion

No significant differences were found when comparing the performance of the creator and reflector groups on the final examination of the course. The creator group however spent considerably more time on the course than did the reflector group (2,802 minutes compared to 1,932 minutes). So, the extra time spent by the creators in ISM-2 did not result in overall better performance on the final examination. However, the nearly significant difference on the transfer type of questions (p=0.054) suggests that there may be a significant difference when more-sensitive test questions are used. Further, the payoff may be more related to higher level insights than to knowledge level retention. There are some other indicators of differences between the groups. There were fewer dropouts in the creator group of the course, and as a result of this more students of the creator group finally passed the course.

With regard to the time-investment of students there were some interesting differences (Table 1). The time spent searching in journals and books was 337 minutes for the creators, while only 7 minutes for the reflectors. With the time spent searching for sources on the WWW there was less difference: 79 minutes for the creators, and 56 minutes for the reflectors. These results suggest that the WWW seems to invite students to search for additional materials to the course, much more than the library seems to invite our students to read additional materials.

Further, the creators spent nearly twice as much time studying the provided materials than did the reflectors (1,610 minutes compared to 872 minutes). It seems that the scaffolded approach used with the creators stimulated them not only to spend more time on the activities required for them, but also to spend more time on activities that were expected to be more important for the reflector group. This point is further illustrated by the total time investment of both groups, which was higher for the creators than for the reflectors (2,802 compared to 1,932 minutes). Time investment overall was lower than the expected 4,800 minutes (80 hours).

The instructor time spent was considerably higher than the time spent by the students of the course. A part of this invested time may be reduced next year, such as the time for redesign of the course and the course WWW site, time for discussing the new approach followed, time for designing the final examination questions, and time for redesign of the lectures. Another part of this invested time will remain, for example for giving elaborate feedback to students (total: 3,410 minutes). This time could however be reduced by using other forms of giving feedback, such as peer-feedback, and using other media, such as audio for giving feedback.

Conclusions

So, what has been the impact of applying this model for scaffolding on this course? The first research question (about the impact of implementing this model for scaffolding) is answered as follows: the impact of the model has not been expressed in a significant difference on the final examination favoring the creator, or reflector group. There was an impact however on the attendance at lectures, overall time spent for the course, and completion rate of the course.
The second research question (about the balance of extra cost with benefits) can now also be answered. Due to the lack of measureable differences found in the results, the extra cost, in terms of time-investment of both students and instructors, can at this moment not be justified.

Research on scaffolding does not stop here. First, the measurement of the results could be greatly improved. While the results point in the direction of a gain in transfer-type of knowledge. These skills may be more-sensitively measured with a different instrument than multiple-choice questions.

A second point is the improvement of efficiency. Not all aspects in a course need to be scaffolded. When an instructor knows what are the most important or hardest parts for the students, the scaffolding can be focussed on this part of the course. Further, scaffolding does not necessarily need to be done by writing elaborate feedback, but could also be done in the form of impersonal or general feedback remarks, as suggested in studies of Visser (1998) and Gordijn (1998).

The last point is related to the preference of the instructor. Instructors may believe that the changes occurring in the division of roles between student and teacher, with the student taking over the learning process as much as possible, collaborating with an instructor, and learning to regulate their own learning, may be important developments for the future. If instructors believe this, it is worth exploring scaffolding, and further improving the efficiency of scaffolding.

Abstract: The development of a Statistics 221 course at Brigham Young University required that a large number of multimedia objects (>800) be created in a relatively short period of time (<8 months) by over 20 employees, most of whom were students with varying schedules and abilities. As a means of providing a standard communication device in the development of the course, a storyboard was created in Microsoft PowerPoint. The effectiveness of the storyboard design was then evaluated by surveying all project participants. The results of the evaluation were used in redesigning the storyboard for use in the development of additional online courses.

Need Statement

The development of a Statistics 221 course at Brigham Young University required that a large number of multimedia objects (>800) be created in a relatively short period of time (<8 months) by over 20 employees, most of whom were students with varying schedules and abilities. These objects then needed to be inserted into web pages with other instructional elements (assignments and activities) to form the basis of the course. For the most part, these media objects are discrete multimedia objects embedded in instructional modules programmed in Macromedia Flash.

In a previous project, written and verbal descriptions of multimedia objects had been used to manage their production. However, our experience with that project provided insight about using written and verbal descriptions of media objects. The following weaknesses were observed:

1. Text descriptions of media objects are very time consuming to write.
2. Text descriptions never adequately convey what the designers want created.
3. Verbal descriptions required arranging expensive meeting times between designers, artists, and programmers.
4. Because verbal descriptions are not stored, they can be easily forgotten, misinterpreted or changed.
5. Verbal descriptions are also difficult to track.

The nature of these objects was part of the problem. Many of the objects, in addition to being very visual, were also designed to take advantage of Flash's highly interactive capability, making them difficult to describe.

Search for Existing Solutions

Various solutions to managing the output and quality of these kinds of multimedia objects were explored, but neither instructional design software (like Designer's Edge from Allen Communications) nor movie storyboarding software...
(such as Storyboard Artists from PowerProduction Software) filled the need. Problems encountered included the inability to print text and visual instructions on the same page and the inability to recognize a broad range of standard file types. A standard tool that content experts could learn quickly, and that adapted to our specific need was needed and existing solutions did not meet our needs.

Our Solution

The development of multimedia objects in Flash was actually the second phase of the course development project. An earlier version of the course had been created using PowerPoint. The purpose of migrating from PowerPoint to Flash was to take advantage of Flash's more robust animation and interactive capabilities and to make the discrete objects more suitable for the web. Yet, it was determined that the older, PowerPoint versions of the lessons could serve as the basis for the storyboards. Because the objects were going to be animated in Flash, it was decided that the content experts would not spend additional development time animating multimedia objects in PowerPoint. Rather, the slide layout feature of PowerPoint would be used to design the visual content of the course (see Fig. 1 Feature 2). Then, the "Notes" feature of PowerPoint was used to provide additional art and animation instructions to the artists and programmers developing the content (See Fig. 1, Feature 6).

This solution lent itself particularly well to the statistics course because so much of the preliminary work had already been done in PowerPoint and because there are many visual elements of the course that required statistical precision. These elements had to be specified by a content expert. The artist could then modify the statistical information to improve the aesthetic presentation to the degree that the statistical content remained accurate.

A design process was developed in which the content experts and instructional designers used PowerPoint as the medium through which the course content was developed. Statistical software such as Minitab was used to produce charts and graphs (see Fig. 1, Feature 4), which were then imported into PowerPoint. The content experts added textual instructions to the artists and programmers (see Fig. 1, Feature 6).

Once the storyboards were approved by the content experts, the Notes Template feature in PowerPoint was used to create a header on every page where the art director could indicate which art template would be used and which artist would be assigned to the project (see Fig. 1, Feature 1). Space was also provided at the bottom of the notes section for the art director to draw the layout that should be used and give other instructions to the artists (see Fig. 1, Feature 7). The ability to embed objects and add textual instructions in PowerPoint was useful. But allowing the art director to add freehand sketches allowed us to compensate for the limitations of the tool.
After the art director finished making comments on the storyboard, copies of the storyboard were made for each department participating in the project. These copies were bound and distributed to the Art Department, Instructional Designer, Statistics Department, Programming/Authoring Department, and Video Department. Additionally, the final electronic copy of the storyboard was distributed to the Art Department so that the Minitab graphs could be imported into Flash. The Art Department would create specific media objects while the programmers created the Flash file in which the text of the presentations and the media objects were embedded (see Fig. 1, Features 3 and 5). Once a produced, the instructional designer and content team reviewed the objects and requested revisions if necessary (compare Fig. 1 and Fig. 2).

![null and alternative hypotheses in symbols]

Fig. 2 Screenshot of a statistics lesson. End-product of the media objects requested in the storyboard above.

The hardcopy of the storyboard then served as the design document that all members of the party could reference.

**Results**

After using the storyboards for the statistics project, we conducted an evaluation of the storyboarding process as a means of determining whether or not it would be useful in additional course development projects and how it could be improved.

All the storyboard users who participated in the project were identified. This included the instructional designer, 6 members of the content team (1 faculty member content expert and 5 student content experts), 19 members of the art team (1 full-time senior production designer, 16 student artists, and 2 photographers), and 17 programmers (1 full-time lead programmer and 16 students).

Each type of storyboard user was asked how the storyboard was used, what elements of the storyboard were useful, and what elements of the storyboard were not useful. All storyboard users were contacted via email with the exception of the lead faculty content expert and the instructional designer. These two participants were interviewed in more detail.

The summary of the results follows in the detail given below.

**Content Team**

**How it was used**

The content experts used the storyboards as a basis of communication in the design process and during production. They compared the final product with what was requested in the storyboard to determine whether or not the media objects met the original specifications.
What worked
1. The storyboards were useful as a tool to compare the final product with the original production requests.
2. The storyboards provided a tool to help the content experts organize the logical flow of the lesson. As one student content expert reported, "The storyboards helped me organize the lesson in a logical flow, without being bogged down in the details of artistic content."
3. The storyboards a single point of reference for all participants of the project to communicate with.

What didn't work
1. The content experts felt that the animated nature of many of the objects was not adequately described on the static storyboards. He felt that when objects were designed, he could not visualize what they would look like when animated. This led him to desire revisions to the media object design after it was produced because he felt if reworked, they would work better in the classroom.
2. The content experts felt that artists took artistic license in revising objects that needed to be copied precisely. As a result, the statistical accuracy of some objects was altered, requiring additional revisions.

Instructional Designer

How it was used
The instructional designer used the storyboard as a means of communication while designing the content of the course with the content expert and his assistants. She then used it as tool to communicate production specifications to the artists and programmers. It was also used as the standard against which produced objects were checked for accuracy.

What worked
1. Useful as a single point of reference for all project participants.
2. Because of the large number of objects, it was helpful way of documenting design specifications.

What didn't work
1. The storyboard was intended to be used as a design document. It became obsolete when design changes were requested after objects were in production.
2. Many of the statistically accurate objects were embedded in the electronic version of the PowerPoint file that was distributed to the artists. When artists created objects from scratch instead of using the statistically accurate charts and graphs provided them, it became problematic.

Artists

How it was used
The artists used the storyboard as the design document. Essentially, it was their sole set of instructions for producing an object.

What worked
1. Useful as a single point of reference for all project participants.
2. The storyboards helped the artists understand what the content team wanted designed. For example, when student artist said, "They provided detailed directions of how to present the concept, making it possible for animators who have not taken the course yet to still know how to teach the concept."

What didn't work
1. Visual decisions were made by content experts rather than by artists. The artists viewed this as a problem for two reasons. First, the artists felt that many of the layout decisions were artistically inferior to what the artists could suggest. The result was decreased job satisfaction because artists were not allowed to be as creative as they would like.
2. Storyboard authors assumed their audience had a greater understanding of statistical audience than they really did. Problems incurred included confusing directions (because artists did not understand the terms); difficulties with accuracies of graphs because artists would make artistic changes to graphs, not realizing the changes made them statistically inaccurate; references to non-ascii characters were unclear (authors would refer to a spelled out version of a non-ascii character (i.e. “alpha” for α); the text references were spelled out and the visual storyboard used symbols; artists lacked the necessary knowledge to correctly identify them as the same character, making the instructions confusing.

3. Content experts requested additional design changes after storyboards were in production.

4. Storyboards were not thought-through enough. The artists felt that requests for design changes and misspellings in the storyboards were evidence of the content experts not thinking through their production requests thoroughly enough in the pre-production process.

By using PowerPoint to storyboard a Flash object, the capabilities of Flash were not maximized. The artists felt that more innovative animations could have been created in Flash. By using PowerPoint to design the storyboards, it limited the content experts to the technologies they were designing with.

Programmers

How it was used
The programmers used the storyboards for several purposes. First, the referenced the storyboard layouts to create the Flash file which contained the lecture and all embedded media objects. Second, once the media were produced, they would reference it to see where all the media objects needed to be inserted and how they should work. Finally, they referenced the storyboard for instructions on programming java applets.

What worked
1. Detailed instructions were useful.
2. A single point of reference for all participants in the project. For example, one programmer reported that, “The storyboards gave a common ground for everyone working on the stats lessons to work from.”

What didn’t work
1. Revisions made in the art process were not communicated effectively to programming. As a result, by the time the programmers were ready to insert media objects, their storyboard were often out-of-date.
2. Degree of detail and instructions led to decreased job satisfaction. Like the artists, the programmers felt that they were not able to fully utilize their programming skills.
3. The amount of revisions occurring in production was problematic. As one programmer stated, “We would make changes and then take them to the professor to approve and then we would make more changes and this would be repeated many times.”
4. Storyboarded objects sometimes didn’t take into account programming issues in Flash. Essentially, the design instructions presented to the artists and programmers did not reflect a consideration of how to best develop the objects given the selected technologies.

Conclusions and Recommendations
All project participants responded positively to having a single point of reference for all the objects being designed in the course. Most of the frustration identified by all participants of the project stemmed from the amount of revisions implemented after objects were produced. This frustration can be significantly reduced by helping content experts in the design process think understand that once the design stage ends and production begins, revisions can only be made when produced objects do not meet specifications rather than when a new idea for improving the object occurs. Such adherence to feature lock be understood by all parties in the project as well as the decision-making level of the organization.

Assuming that the revision process is decreased, the storyboard seemed to be quite useful. The storyboard is being used in the creation of an introductory biology course. In this case, a word processing tool is being used in place of
PowerPoint. The decision to not use PowerPoint was made for several reasons. First, the biology project is a self-contained, fully-online course rather than an in-class presentation. As a result, PowerPoint does not lend itself as well to the format of the course. Second, PowerPoint is a very time-consuming tool to storyboard in. It was selected for statistics since most of the content was in PowerPoint to begin with. But, in the case of the biology course, it is more time-efficient to use a word processor.

The biology course storyboard is divided into two sections, in attempt to address the needs of programmer and artists more specifically. The programming section includes a hardcopy of the entire script of a given biology lesson with instructions as to where to insert specific media objects. The art section details the instructional objective and production instructions for each object. Once again, space is provided for the art director to add addition comments, sketch layouts, etc. In addition to the programming and art sections, the front of the storyboard includes the specification for the navigation of a particular lesson as well as a Table of Contents listing each media object, the outline of the lesson, and the file names for each object in the lesson. As with the statistics storyboard, the biology storyboards are bound and distributed to all project participants.

The intent of the biology storyboard is to improve upon the features that worked in the statistics storyboard such as providing a single set of instructions to all participants. At this early stage, participants have indicated that the new-and-improved storyboard addresses most of the problems of the first type of storyboard and is much more useful.
Creating Multimedia Instructional Projects: Fun or Frustration?

C. James Wong

Abstract: The purpose of this case study is to investigate language teachers’ experiences in developing multimedia instructional projects. This paper reports two language teachers’ project development experiences, difficulties, successes, and concerns, and reflections. Implications and suggestions for technology training programs for language teachers are discussed.

INTRODUCTION

Media and technologies have had an inevitable impact on education. Multimedia software programs have been made available to teachers and students by commercial companies. Multimedia hardware and software are tools that offer possibilities for improving the learning process, but the teacher will have to integrate them into the curriculum in a way to facilitate teaching and learning (Heinich, Molenda, Russell, & Smaldino, 1999). In such integration process in language education, finding useful software applications can be a difficult task due to the following factors: (1) A large number of commercial applications are designed for personal use, not for classroom use. (2) Some applications might be useful, but too expensive to buy enough licenses for all the computers in a language learning lab (Aoki, 1996). Therefore, language teachers often need to create their own multimedia instructional materials customized for their instructional objectives and their students’ learning goals, in their specific teaching and learning contexts, and at their students’ language proficiency levels.

The purpose of this case study is to investigate language teachers’ experiences in developing multimedia instructional projects. The results of the study are expected to help teacher trainers discover and gain insights about language teachers’ experiences (such as successes, difficulties, and concerns) in creating multimedia projects. The understanding of such experiences is intended to (1) enhance teacher trainers’ facilitation in preparing language teachers (both pre-service and in-service) to develop multimedia instructional projects, (2) helps language teachers be informed of the possible difficulties they might encounter before attempting to start the multimedia development process, and (3) allow language teachers to reflect upon their own experiences in developing multimedia instructional materials and thus improve the development process in a more effective and efficient fashion.

BACKGROUND

More and more teacher education and professional development programs offer educational technology courses such as development of multimedia instructional programs to both pre-service and in-service teachers. Especially in the fields of science and math education, many teacher educators have been incorporating multimedia development training into their curriculum. In the meantime, this trend is being or will be soon adopted by language education programs. As Feyten, Taylor, and Nutta (1996) noted, "It is imperative, then, that our teacher preparation programs integrate instructional technology into their curriculum, to begin to correct this deficiency, and to produce future foreign language teachers who are comfortable with and adept at the implication of the media into their classrooms."
In the process of developing multimedia instructional projects, teachers' experiences might vary and depend upon a number of possible (or assumed) factors such as computer anxiety, previous computer experience, training, subject area, and creativity. However, these factors may or may not be applicable to every teacher, especially a language teacher. Thus, an understanding of language teachers' experiences in creating multimedia instructional projects may help teacher educators improve their educational technology programs based on various learner's needs and their individual differences. However, only a few studies (Mitchell & Hunt, 1997; Anderson et al., 1993; Tucker et al., 1990) have been conducted to explore the experiences of teachers in developing multimedia instructional materials. Research studies of such focusing on language teachers in particular are even rare.

LITERATURE REVIEW

In the research literature, studies on language teachers' experiences in developing multimedia instructional programs are rare. However, there are a few studies on multimedia development experiences of teachers of other subject matters.

Mitchell and Hunt (1997) state that higher education must train pre-service physical education (PE) teachers based on the requirements of more technologically literate students. In their study conducted at the University of Central Florida, an innovative way to develop lesson plans has been discovered by using multimedia authoring software, such as HyperStudio, that lets students integrate text, graphics, video, audio and digitized images into their lesson plans. They reported that a multimedia lesson plan can become a three-dimensional lesson plan that is advantageous in PE as it can show physical movements.

Hatfield (1996) describes a project that combines technology, teacher education, and the use of manipulatives for mathematics instruction to enhance the professional development of prospective teachers. The multimedia developed in the project are means of bringing the classroom environment to the university to facilitate discussions about prospective teachers' beliefs about mathematics teaching.

Another study (Anderson et al., 1993) was conducted in Scotland to determine whether untrained classroom teachers could learn HyperCard from a minimal manual and then create their own stacks. The development of the minimal manual is discussed, use of the manual and software is analyzed, and teachers' attitudes are examined.

In a 3-year project started in 1989 to train faculty in the College of Education to incorporate hypermedia into their curriculum at the University of South Alabama, Tucker et al. (1990) reported that evaluation of the program concentrated on program context, process, and product. Data sources included review of project proposals, analysis of internal evaluation data, visitation to field applications, interviews, and photo-interviews. Photography was chosen as an evaluation method because of its holistic quality, the volume of detail it provides, and the role it plays as a source of discussion. Results of the program evaluation reveal that: (1) most early adopters had prior experiences with technology; (2) HyperCard has been used by program participants in presentations, interactive video and animation projects, and reading analysis; (3) the biggest need cited for skills training was "time to practice"; (4) photo-interviews yielded rich data and provided a means to describe and explain the program and its consequences; and (5) photo-interviewing can serve as an instructional as well as an evaluative strategy given the projective nature of visual images.

According to another line of foreground research studies which concentrate on attitudinal effects, teachers' attitudes toward computers have significant impact on their decision to use specific instructional media including computers in the classroom and the curriculum (Dupagne & Krendl, 1992; Kluever, 1994; Pina &
Harris, 1993; Savenye, 1992). For instance, in a review of literature on teachers' attitudes toward computers, Dupagne and Krendl (1992) described that "early studies reported some resistance to computer implementation" (pp. 420-421), and this statement correlated with teachers' ambivalent attitudes toward computer technology revealed in the studies conducted in the 1970s and 1980s (Dupagne & Krendl, 1992). When teachers are found holding negative attitudes toward computer technology, their concerns about computer use in the school environment must be considered and pinpointed since there are a number of factors contributing to such attitudes. Some of the factors identified include computer anxiety, efficiency, liking, and instructional usefulness (Kluever, 1994). Furthermore, knowledge of and training on applications of computer in education and the actual limitations of the computer hardware and/or software may also be concerns of teachers (Dupagne & Krendl, 1992).

Due to the lack of research literature similar to the study, the literature review provided in this section might not be directly associated with the phenomenon to be discovered and addressed in the study. First, the research studies discussed above dealt with contexts different from those in the study, for example, the content areas of teaching in the literature review differ from that in the study. Second, the participants in the studies outlined above might also differ from those in the study who are teacher education students ranging from undergraduate to doctoral levels and who have or have not served as language teachers. Third, the most important aspect of the phenomenon considered as background, which is the whole phenomenon understood as a complex system that is more than the sum of its parts, is the whole experience of language teachers in developing multimedia instructional programs from a holistic perspective; nevertheless, no research evidence exists to help understand this aspect of the phenomenon.

METHOD

A semi-structured questionnaire was utilized in the study. With the voluntary permission of the participants, the responses were stored electronically and then analyzed. The participants were language teachers enrolled in a semester-long course, Seminar in Curriculum & Instruction: Introduction to Computer-Assisted Language Learning (CALL) at the University of Missouri-Columbia. Their participation was optional. Two individuals participated in the case study by completing a semi-structured questionnaire with a large number of open-ended questions. They were then asked to respond to follow-up questions via e-mail to clarify and confirm the accuracy of the interview interpretation made by the researcher, and the researcher also collected copies of their multimedia instructional project proposal, class reading journals, and other documents which illustrate their multimedia instructional project development activities.

RESULTS

The Chinese Language Teacher's Case

Minjuan, a doctoral student, has taught three levels of Chinese to undergraduate students for a year at a major public university in the United States. She rated her computer anxiety as "high" on a five-point scale. She has experience in "CALL courseware authoring" and HTML editing, also familiar with other "basic tools" such as word processing, spreadsheet, Internet applications, image manipulation, and audio editing. Minjuan hasn't utilized computers in her language classroom before but did provide a one-on-one tutorial with the use of a CD-ROM software. She has developed about four multimedia programs.

The Development Experience: Minjuan developed the "Practical Chinese Reader," a courseware designed for university level Elementary Chinese course. She stated that the guidelines provided by the instructor who is teaching this course set up an excellent beginning for this project. It took her about 4 weeks to develop a set of multimedia instructional programs supplementary to six
chapters of the textbook students are using. "The work was really time-consuming, but lots of fun," she summarized. "The final project works well," though there are "some problems in font-displaying" and in one of the chapters, "audio is not played well, due to the quality of the audio."

**Difficulties, Successes, and Concerns:** As Minjuan described, "It took too much time. The biggest challenge is creating the glossary. I need to look up in the dictionary, to make sure all the words and phrases are correctly annotated." However, she exclaimed that "the success is to see the program works well after it is finished. All links are good, audio is well played, pictures are shown up." As a language teacher, Miss Chan's concern with developing her multimedia program is "how to integrate it into the classroom instruction."

**Reflections:** "It's a long process. But I enjoyed the creativity," Minjuan commented. She followed Philip Hubbard's design and development modules which have "given very good guidance on methodology." Both knowledge on the targeted language and skills in using the authoring software are most important. Her extrinsic motivation was to finish this project as a class assignment, and the intrinsic one was to present it at a conference related to language education.

**The ESL Teacher's Case**

Sheila, a master's degree program student, has taught English as a second language (ESL) for three years in junior high and senior high schools in Japan. She rated her computer anxiety as "none" on a five-point scale. Spending about two years using computers, she has learned word processing and basic HTML, computer art tools, and Macromedia Director at a major public university. She has used software such as word processing, spreadsheet, Internet applications, audio and video editing, image manipulation, HyperStudio, and HyperCard. Sheila has not utilized computers in a language classroom before. She developed two simple multimedia programs and thought that "both were interesting experiences, but a little frustrating given the amount of effort involved to produce a not very professional product."

**The Development Experience:** In commenting her experience in developing her multimedia instructional program, a web-based program for people learning Japanese, Sheila described it as "sometimes frustrating, but on the whole, a really enjoyable experience. I enjoyed practicing using new technology and being creative." She had problems with putting video on the web because the file size was too huge, and the end result was very disappointing. As she explained, "Planning first and keeping it simple (i.e., without too many bells and whistles) is what works. Aiming for too much (taking advantage of everything you can offer students on a web site) doesn't."

**Difficulties, Successes, and Concerns:** Sheila complained that her web space provided by the university was too small to accommodate all the sound files and movies she had, "things seemed to change a lot overnight, without having even touched them, and different browsers (even different computers) give different results in spite of following what a web development book said were standards." However, Sheila had some positive comments: "the sound files are great. I was really pleased to be able to put something worthwhile for Japanese learners on the web. Also, the quizzes (housed at the University of Hawaii) are a valuable, and enjoyable, in addition to the lesson. These features (along with the fact that anybody can access it free at any time), really made the web-based lesson far more valuable than a text version would have been." "Though worth it in the end," as a language teacher, Sheila's only concern was that the development process was "extremely time consuming."

**Reflections:** Sheila felt excited and challenged by the development process in which planning (storyboarding) was an essential stage because she had to "think first in terms of educational value rather than what's technologically possible." The "ability to honestly assess educational value of the multimedia project and a good sense of what's really practical and useful for students" were important, she explained.
"On the technical side, knowledge of how to create web pages is a must." Intrinsic motivation for Sheila was to get a good job that she enjoys doing, and she described, "personal work satisfaction which would be achieved by helping students (particularly disaffected ones) get motivated and interested in learning by/for themselves. The desire to create something worthwhile, be useful and productive, and make a difference is strong." She would not mind if someone is willing to pay her "lots of money for this."

DISCUSSION

Previous Computer Experience

The participants in this study are considered as intermediate to advanced users of the computer and multimedia production software. In the future, beginning users and non-users would be included in order to reveal their experiences which might be different from those described above, so the assumption about novice users tending to report more technical difficulties and higher frustration as well as anxiety level than experienced users will then be discovered.

Both participants emphasized that having the technical skills is crucial. An issue related to this is whether pre-service and in-service language teachers should take a series of technology courses prior to taking the CALL course which focuses on both theory and practice, or they should learn most of the technical skills like using multimedia production software in the CALL course. For this issue, two sides of the coin need to be examined. If novice users take a certain number of technology courses that are of interest to them first, they will have at least some good working knowledge about computers when they are taking the CALL course later. However, if they first take the CALL course partly as an introduction to software available to them; once they have a basic understanding of the technical functionality and feasibility of the software, they then can decide later which technology course(s) they would like to take in the future and utilize those skills acquired from such course(s) to create their multimedia instructional programs.

Difficulties and Concerns

Both participants reported that the development of their multimedia instructional programs required a tremendous amount of time although approximately one third of the class time was devoted to developing. In math and science education, lab and tutorial hours are supplementary to regular class meetings. Likewise, for a course in language education that has a multimedia development component, it might be adapted to the model used in math and science courses.

Technical difficulties are no surprises: just to name a few, limitation of web space and poor audio clip. Participants should be able to request a larger web space if they intend to create a complex multimedia web-based program. The computer lab should be equipped with acceptable quality of multimedia production and editing software and hardware. In terms of dealing file content instability on the web server, participants in a CALL course are advised to keep a master copy of the entire web-based program for recovery and a working copy for revision. Similarly, such dual copy approach can be adapted and adopted by participants creating other multimedia programs than a web site.

One of the participant's concerns was how to incorporate her multimedia program into the classroom. During the planning stage, it is essential to invite participants in a CALL course to conduct a user analysis of their multimedia program. A review of the target audience will help developers to focus on the content and interface of the multimedia program. Philip Hubbard's (1996) design module provides a concrete framework to guide developers building the ideas theoretically and practically. Besides, participants in a CALL course should strongly be encouraged to create something they will use in their own classrooms as an authentic learning and production experience.
Positive Comments

Though both participants encountered frustration, difficulties and challenges in the process of creating their multimedia programs, they agreed that it was an enjoyable experience after all, particularly the opportunity for them to express their creativity through the final product. When things have come to work, the degree of satisfaction and a sense of achievement are positive driving forces for these amateur multimedia developers.

IMPLICATIONS

More participants, especially those with various levels of computer literacy, will be needed to share their experiences for this on-going research study, so a larger scope of experiences can be documented and revealed. The researcher of the study has found the data collected so far very useful in refining the current CALL program designed for language teachers.

A Cognitive-Affective Framework for Instructional Interactivity: CAFI²

Michael Yacci
Associate Professor
Information Technology
Rochester Institute of Technology
Rochester, New York 14623 USA
may@it.rit.edu

Abstract: Interactivity is a popular, although little understood term. This paper provides a short definition of interactivity in instruction. It then proposes a framework to study interactivity that addresses both content learning and affective benefits that arise from instructional interactivity.

The Nature of Instructional Interactivity

The proclaimed educational benefits of the "new media" are their potential for increased and improved interactivity. However, the nature of interactivity is a conceptual area that has historically been poorly developed. This paper presents a cognitive-affective framework for instructional interactivity (CAFI²), and describes the general rationale for the framework. The CAFI² is currently being used as part of an ongoing cataloging and evaluation project, described later in the paper.

In his keynote address at AACE, Thomas Reeves (1999) suggested that we do not have a very good definition of interactivity in instruction, suggesting that "teacher-in-a box" has been the prevailing approach. The Institute for Higher Education Policy's recent review on distance learning (1999) cited the lack of a conceptual or theoretical framework as a major shortcoming in studying distance learning.

Research on various aspects of interactivity seems to focus on either the cognitive or affective aspects of interaction, but not both. For example, human-computer interaction studies generally concern themselves with the way that users understand computer systems, the mistakes that they make, and the previous knowledge that they bring into play, among other issues. These types of studies are generally cognitive in their concerns with a user's understanding of the principles and concepts of a system. On the other hand, affective issues are frequently brought to light in teacher training and educational literature as issues of motivation, group support, participation, collaboration, and attribution among others.

Therefore, a framework that describes both cognitive and affective interactivity within a single framework provides a mechanism for integrating past and future research. This framework would also become a structure by which evaluators could more thoroughly study distance delivered courses.

This paper describes the rationale behind the Cognitive-Affective Framework for Instructional Interactivity (CAFI²), an attempt to link previous research across the cognitive and affective domains into a contemporary framework for analyzing instruction. This framework has been initially intended to provide a map and a terminology by which designers can catalog and describe the components of distance learning courses. It is hoped that this framework can provide a mechanism for analysis of current instructional designs so that teachers and designers can ensure that courses are appropriately providing for cognitive aspects of instruction as well as affective aspects.

Interactivity Defined

The term interactivity is itself troubling. While the term is common in the literature, the exact meaning of interactivity is generally quite vague. We attempted to create a structural definition of interactivity that
The term affective benefits was selected because learning and growth in the affective domain is not as straight-forward as growth in the cognitive domain, where the principle of complexity (Krathwohl et al., 1964) is the primary organizational principle. It also would appear that affective growth is not the primary reason for including certain types of interaction. Motivational and social benefits as they relate directly to the student, independent of cognitive learning, seem to be the underlying results--not growth in a direct sense.

Previous research shows that affect is a significant contributor to academic achievement (Khan, 1969), but the area still has much that is unknown (Brophy, 1999). It is our belief that affective benefits provide value added beyond academic achievement. For example, it would seem that affective benefits can be reduced or eliminated (in a purely Spartan approach to content learning) but at the cost of lessened student satisfaction. Therefore, we believe that these affective benefits need to be examined outside of their role in academic achievement.

Krathwohl, Bloom, and Masia (1964) proposed their original taxonomy for the affective domain to "clarify and tighten the language" of instruction. In a similar manner, it is believed that the CAFI2 framework can help to link a variety of research interests in interactivity in instruction. The remainder of this paper sketches the three major areas of the framework.

1. Directive (learner-instructor) interaction.

This area represents the face-to-face, mediated real-time, and/or asynchronous contact that a student has with an instructor. In some cases, the instructor may be mediated, as in the case of videotapes, books, or computer-based training. In some circumstances, the instructor is "live" in the sense of being physically proximate to the student. An interesting hybrid is the "real-time teleconference" in which the teacher is not in physical proximity to the student, but is indeed in mental proximity--that is, the teacher and student are interacting in real time over distance.

The Directive interaction produces effects in two areas previously described: content learning and affective benefits. While an instructor is frequently a primary delivery mechanism for content, an instructor serves motivational roles as well.

The instructor as dispenser of information has often taken the form of teacher as lecturer or teacher as Socratic guide. The "lecture" is often a misnomer, as (in practice) it often allows for questions, answers, side conversations, and spur-of-the-moment inclusion and elimination of topics. So, while a lecture in its most extreme form is clearly one-way preaching, in practice the lecture tends to be a more interactive activity between teacher and student. In this interactive lecture form, the instructor provides content, remediation (in the form of alternative explanations and review) and clarifies relationships with other content.

The interactive lecture can take the form of computer based training, in which the student interacts with a computer-based instructor. In this tutorial format, the software often takes on the persona of a teacher, and the language that is used is frequently modeled after live instructors.

An important contributor to content learning is the instructor interaction that provides student feedback on performance. Mager (1988) suggests three types of feedback (adequacy, diagnostic, and corrective) that can be provided systematically. It is generally acknowledged that knowledge of results is one of the more critical contributors to content learning (Schimmel, 1988).

The teacher as motivator has been documented in many educational psychology texts. It may help to substitute other terms for instructor, such as facilitator or coach. For example, few would argue that a primary function of an athletic coach is to provide motivational support for players. It is from this direction that we ascribe affective benefits to an instructor. The qualitative evidence that a good instructor is motivational, inspirational, etc, is common. It is not likely that this motivating effect is related to actual physical presence; students can get motivated at a distance even if their contact with instructors is limited to
text interactions. Students may also find motivational benefits in the writing style of computer-based tutorials and textbooks that are written so as to foster motivation.

2. Experiential (learner-environment) interaction

The Experiential interaction should be thought of as a distinct type of interaction typified by a student's direct interaction with materials from the content domain. When a student works directly with the materials of the content area (or with simulations of these materials) we can say that the student is interacting directly with the content environment. In this type of interaction, there is not an instructor mediating the experience—that is, the feedback that the student receives comes directly from the environments (or its simulation).

Kolb (1984) called this type of world/person interaction grasping by apprehension. He describes this type of interactivity thusly:

"Apprehension of experience is a personal subjective process that cannot be known by others except by the communication to them of the comprehensions that we use to describe our immediate experience." (page 105).

An analogy that might clarify the differences between Directive and Experiential interactivity. The Directive (learner-instructor) interactivity is like a guided walk through the woods—the path has been well-paved and the guide protects the hikers from danger. The Experiential (learner-content) interactivity is like a visit to the untamed wilderness—there is no path provided, and the hiker faces the risks that an explorer faces—there is no certainty of success, but there may be a bigger personal reward when complete.

In like manner, the Experiential interaction provides students with the "raw materials" of instruction and allows students to explore and construct a path. It would seem that discovery learning techniques would be natural instructional methods to be used to foster this type of instructional interactivity.

Problem-based learning (Savery & Duffy, 1996) is the current categorical space that would include Experiential interactivity. Among other interactions, Experiential interactivity might include:

* checking for understanding (working with materials to test student hypotheses) and
* organizing raw data (creating cognitive structures for student-located data).

Kolb claims that there are affective benefits associated with this form of interactivity. We can surmise that certain students would greatly enjoy this type of interaction, while others might find it to be frustrating. Our own work (Yacci, 1994) shows that some students prefer the opportunity to explore for themselves, while others prefer to be "guided." Hence, some (but certainly not all) students are likely to find that there is an accompanying affective benefit to Experiential interactivity.

3. Coordinate (learner-learner) Interactivity

Coordinate interactivity occurs when students communicate with each other. Typically, students might exchange ideas, collaborate on projects, model strategies for success, or share "war" stories. These are generally used to provide content learning to students. Coordinate interactivity can also be a great source of affective benefits for students who enjoy working with other students. The opportunity to work with others is often desirable as a means of motivating students. Coordinate interactivity also allows "unvoiced" self-comparison between students. It allows them to get closer to others who are working towards the same goals and to "size up" work habits and methods of others.

Peer tutoring is (simply put) a method in which more able students teach less able students. This type of interactivity should produce content learning for the "learning student" and might provide affective benefits (friendship, a sense of involvement, greater self worth) to the "teaching student." Less formal mechanisms for student cooperation, such as team projects and work groups often provides peer modeling of strategies. As students work together to complete such projects, they provide insight into different ways of problems
solving, different mechanisms for approaching the unknown. Both the cognitive and affective benefits of work groups are often unstructured; there is no guarantee that peer modeling or friendship will occur.

When students communicate, the benefit can be seen in changes in motivation, as some students use the opportunity to compete against others as a motivator. Others students might use the communication channels for commiseration and support. Still others have subtle, hidden agendas that may exceed any given course, such as political leadership.

Abstract: The education arena in Singapore has seen very rapid pervasion of Information Technology (IT) and the World Wide Web (WWW). With the proliferation of courseware developed for the WWW, management of courseware development becomes an important issue that needs to be addressed for maintainability, efficiency and effectiveness. Even as the volume of WWW-based courseware development under Temasek Polytechnic's Online Learning Environment (OLE™) [3] grows, the Center for IT in Education and Learning [4] set out to develop a WWW-based Resource Management System (RMS) for the effective management of courseware development in three aspects, namely Documentation, Management and Standards. The objective of this paper is to discuss the plans and effort of Temasek Polytechnic in the development of RMS. The implementation of the completed Documentation module has improved our workflow and productivity in various areas including the reduction in paperwork, elimination of redundancy, and enhancement in the presentation of Temasek Polytechnic's OLETM courseware offerings. The expected benefits from the future development of the Management module include more effective management of courseware development in the areas of Project Tracking, Usage Tracking, and Electronic Commerce. Compliance to the Instructional Management System [9] from the future development of the Standards module is envisaged to make Temasek Polytechnic's courseware offerings more accessible worldwide.

1 Introduction

The education arena in Singapore has seen very rapid pervasion of Information Technology (IT) and the World Wide Web (WWW). The impetus is primarily fueled by the initiatives of the Singapore government, which has taken an aggressive and proactive approach in this area. For example, the Singapore government has various IT related masterplans, including a Masterplan for IT in Education [1] as a blueprint for the integration of IT in education as a strategy to meet the challenges of the 21st century.

With this backdrop, the educational institutions in Singapore, and in particular, the tertiary institutions are moving rapidly to adopt IT in teaching and learning, and to develop courseware for the WWW to harness the potential it offers. With the proliferation of courseware development for the WWW, courseware management becomes an important issue that needs to be addressed for maintainability, efficiency and effectiveness.

In Temasek Polytechnic, Singapore [2], even as the volume of WWW-based courseware development under the Online Learning Environment (OLE™) [3] grows, the Center for IT in Education and Learning (CITEL) [4] set out to develop a WWW-based Resource Management System (RMS).

(CITEL is a support centre that facilitates academic staff in harnessing information technology effectively in the teaching and learning environment so as to make the teaching/learning experience a creative, innovative and enjoyable one. CITEL initiated OLETM in 1997 as a service to offer computer-based learning courses for students of Temasek Polytechnic and the general public to develop work-place skills for the new millennium. It also offers useful resources for staff and students.)

The objective of RMS is to more effectively address what will be classified here as three main aspects pertaining the effective management of courseware development which is deemed important for CITEL's requirements. They are namely Documentation, Management and Standards.
The objective of this paper is to discuss the plans and effort of CITEL in the development of RMS to address the three aspects of courseware development highlighted. The RMS project is divided into three corresponding phases. The development platform used is PERL programming language and MS SQL database under the Windows NT operating system.

2 Documentation

As with MIS applications, documentation for WWW-based courseware is typically few and far between. If documentation does exist, it is usually not standardized and not kept up to date, and probably only the creator knows where to locate it. Furthermore, bits and pieces of such documentation are sometimes duplicated here and there, on an adhoc basis. This is not particularly effective, and it poses a challenge for attempts to update, as well as for maintaining information integrity.

Phase 1, the Documentation module (Courseware Information System [5]) designed to address these issues was completed in 1999, and is operational. Some of the objectives (features) of the Documentation module are:

1. To maintain a centralised database for online creation, updating, viewing and reporting of all courseware documentation.
2. To provide a standardised and consistent look-and-feel of all courseware documentation web pages generated on the fly.
3. To dynamically generate Temasek Polytechnic's OLETM User Interface [6] links for a one-stop access to all the available courseware and their respective documentation.

3 Management

Our plans for the future development of the Management module under phase 2 of the CMS project consists of three areas, namely Project Tracking, Usage Tracking and E-commerce.

3.1 Project Tracking

Many project-tracking tools exist in the market. However, for our intent and purposes, we integrated basic project-tracking information in CMS such as the stage of development of the project, and the respective time-line. This is useful for a number of areas in our environment.

For example, some of our OLETM projects received funding from the Infocomm Development Authority (IDA) [7] of Singapore. As such, we were required to update IDA on the progress of these projects on a regular basis. With basic project tracking integrated into CMS, we were able to issue IDA an access ID to CMS for real-time viewing of the summary of the projects' progress via the WWW, as and when needed, rather than manually preparing them, which can be both tedious and time-consuming.

Likewise, authorized users login to CMS to view reports on the status and progress of the courseware projects, again saving the effort for otherwise paper-based reports.

3.2 Usage Tracking

Usage tracking is typically managed by the courseware development tool itself such as CourseInfo, or programmed into the individual courseware as necessary if the tool used does not have such inherent features built-in.

Until there is a unified standard for exchanging such data among different software tools and courseware management systems, our plan for CMS at the moment is to just keep track of basic information like "when did who access or update the courseware and its documentation". This will provide some basic courseware access statistics for our internal use.
3.3 E-commerce

Currently, Temasek Polytechnic ties up with a commercial vendor for e-commerce subscription of our courseware offerings. When sufficient volume justifies, Temasek Polytechnic will examine the viability of managing this aspect by herself, with e-commerce functionality incorporated into CMS. The design and implementation will be decided upon at a later stage, depending on the state of the technology and available tools then.

4 Standards

The development and sharing of instructional courseware have been hampered by a lack of standards that enables sharing across institutions and across different technical platforms. While the World Wide Web has facilitated access to instructional contents, its effectiveness in this aspect is at best limited. Finding relevant and useful information on the web is likened unto finding a needle in a haystack because of a lack of existing structure or standards for documenting available content.

To address this, EDUCAUSE [8] launched an initiative called the National Learning Infrastructure Initiative in November 1994. The Instructional Management System (IMS) [9] was formed to address the following three obstacles for providing effective on-line materials and learning environments:

1. Lack of standards for locating and operating interactive platform-independent materials
2. Lack of support for the collaborative and dynamic nature of learning
3. Lack of incentives and structure for developing and sharing content

(The IMS Consortium is a member-supported, nonprofit, global organization that includes more than 200 campuses, university systems, tool vendors, system consultants and service providers, content developers, and U.S. and international governmental organizations committed to the development of timely, high-quality, practical open standards for interoperability of online learning and training tools, content and services.)

In collaboration with various institutions and organizations, IMS set out to address these obstacles via a set of higher-order standards and tools. These standards and tools will enable teachers, learners, software developers, content providers, and other parties involved in the learning process to create, manage and access the use of on-line learning materials and environments.

Realizing the potential merits of such an initiative, IDA of Singapore subscribed to IMS (1999) on behalf of the institutions of higher learning. Temasek Polytechnic, together with the various tertiary institutions in Singapore, and co-ordinated by Kent Ridge Digital Labs [10] actively worked with IMS to contribute towards the shaping of the set of standards and tools. IMS has since announced the release of various sets of specifications, namely Meta-Data, Enterprise, Content Packaging, and Question & Test specifications.

With the RMS infrastructure in place, CITEL is well positioned to adopt the standards when it takes off. Making Temasek Polytechnic's courseware IMS-compliant will be primarily what phase 3 of the RMS project targets to achieve. This will make our online courseware offerings more readily accessible globally. In addition, RMS can also be integrated with our organization's enterprise systems for greater synergy, and extended for uses with other resources such as CD-ROMs.

5 Conclusions

The development of RMS (and implementation of the completed modules so far) has significantly improved our workflow and productivity in the various areas discussed. Some of the benefits realized from the completed Documentation module include reduction in paperwork, elimination of redundancy, and enhancement in the presentation of our courseware offerings.
The expected benefits from the development of the Management module include more effective management of courseware development in the areas of Project Tracking, Usage Tracking, and E-commerce. Compliance to IMS for the Standards module is envisaged to make Temasek Polytechnic's courseware offerings more accessible worldwide.

The Effects of the L1 and L2 Caption Presentation Timing  
on Listening Comprehension

Abstract: Captions do not always facilitate listening comprehension; the degree of their effectiveness varies according to the amount of information that the individual can process in a limited period of time. In order to reduce the information that a learner processes at a time, the effective use of timing is considered to maximize listening comprehension. The results show that more information is memorized when L2 captions are presented before the corresponding L2 audio. It is suggested that this timing facilitates the listening comprehension of Japanese EFL students because they could concentrate on reading the captions and could prepare for the following audio. This effect was not seen with L1 captions and L2 audio; student performance was relatively independent of timing.

Introduction

Captions are used in second language (L2) classrooms as an effective aid for listening comprehension, and their effects have been examined in previous research and studies. Yoshino et al. (1997, 1998) studied Japanese university and college students with English as the foreign language (EFL), and found that both L1 and L2 captions facilitated listening comprehension. The effectiveness of the L1 and the L2 captioning varied with the difficulty level of the materials. The captions were more effective in aiding listening comprehension if the materials were relatively easy. Yoshino et al. argued that this might be due to the limitation of the student’s “processing capacity” (Just & Carpenter, 1992).

L1 and L2 captions differ in terms of learning support; more information was recalled correctly if L2 captions were used than L1 captions. L2 captions provide exactly the spoken words as while L1 captions provided the same information in a different (subjects’ native) language. With L1 captions, Japanese EFL students grasped the meaning by reading L1 captions, and simultaneously translated the L1 caption information for chunking the flow of L2 audio. This process of translation and chunking, if successful, allowed them to understand and recall what have been said. Because the translation process is rather difficult to manage, exceeding the learner’s processing capacity, say by increasing the presentation speed or raising the difficulty level of the text, may lower the effectiveness of L1 captioning.

From this point of view, the effective use of timing was considered to reduce the information that student had to handle at any one time and so increase caption effectiveness. By showing the captions in a audio dead period before the corresponding audio, viewers may be better able to process both tasks: understand the caption and understand the audio.

Yoshino, Kano & Akahori (1999) conducted preliminary research to examine the effects of caption presentation timing. In their experiment, L1 and L2 captions were presented either earlier or later than the corresponding audio, and words and phrases recalled by the subjects were counted. The results showed that recall was highest when the captions were provided prior to the audio. These results, however, were gained from thirty-two subjects watching five different sets of materials with five different caption presentation timing arrangements.
It is presumed that the difficulty level of the materials influenced the results to some extent. We decided to examine the effect of caption presentation timing by designing an experiment that used only one set of material. Because of the limited number of subjects, the effects of L1 and L2 captioning were examined in two discrete experiments.

**Experiment 1**

**Participants**

One hundred and ten Japanese junior college students, enrolled in the course “Language Laboratory I”, participated in this experiment. Based on the results of a listening comprehension test administered at the beginning of the semester, each student was assigned to one of the thirteen classes; the level of the students in each class was assumed to be equal. From these thirteen classes, five classes were selected and each class was randomly assigned to one of the five caption timing conditions.

**Material**

The materials used to measure the subjects’ listening comprehension were developed from a TV commercial presented by the US government. The commercial presented 68 words in 30 seconds; that is, the speech speed was 136 words per minute (wpm). The captions, which exactly matched with the corresponding spoken (audio) statements, were superimposed using the video edit software Media 100. The captions were presented completely on the black mask which appeared under part of the screen.

Five versions were developed from the same TV commercial video: 1) the captions appear on the screen two seconds prior to the corresponding audio (-2 Time Lag condition), 2) the captions are presented one second before the corresponding audio (-1 Time Lag condition), 3) the captions and the corresponding audio are simultaneously presented (0 Time Lag condition), 4) the captions appear one second after the corresponding audio (+1 Time Lag condition) and 5) the captions appear two seconds after the corresponding audio statement (+2 Time Lag condition).

The average length of pauses in the video material was about one second; that is, between every proposition (caption), there was a second audio dead period. When the captions appeared and disappeared simultaneously with the audio (0 Time Lag condition), the viewer must have read the visual verbal information (caption) and listen to the audio verbal information. Moreover, they have to decode the visual verbal information at the spoken speed of audio. However, when the caption projected in audio dead period before the corresponding audio (-1 Time Lag condition) - the caption appeared on the screen just after the forward audio was finished, the subjects might be able to read and prepare for the forthcoming audio statements. Likewise presenting the caption in no audio statements time after the corresponding audio (+1 Time Lag condition), the subjects were compliant what have been said with the caption remained on the screen one second after the corresponding audio was finished. Two other conditions (-2 Time Lag and +2 Time Lag condition) were arranged to compare with the -1 Time Lag and +1 Time Lag conditions. As the average length of audio dead period was one second, when the captions presented two seconds before the corresponding audio (-2 Time Lag), every caption were provided with the previous audio while a second. Contrary, in +2 Time Lag condition, the captions were always appeared two seconds after the corresponding audio was started. Then the captions overlapped with just after spoken statements while a second. Therefore, in these two conditions, the visual information and the verbal information were discordant. This discordance might cause the viewers’ confusion for understanding the contents.

**Procedure**

The subjects were instructed to watch the video twice with a thirty-second break, which is a common way of viewing English videos in Japanese EFL classrooms. They were asked to recall the video’s narration both in English and in Japanese after the second presentation. They were informed of the purpose of this study; that is, the experimenters were investigating the amount of information the subjects could remember with caption use. They knew that spelling and grammar would not be scored. The subjects were requested to write down every word, phrase, clause, or sentence that they could recall after each viewing.

**Scoring and Data Analysis**
Two measures - the number of recalled words and accuracy of recalled information - were used to examine the effect of caption presentation timing. The first, the number of recalled words, was number of words recalled correctly by the subjects. The second, accuracy of recalled information was needed since the number of recalled words does not confirm that the subjects understood the statement. The accuracy of recalled information was assessed by checking whether English (L2) recall matched Japanese (L1) recall in meaning. First, the English and Japanese statements made by the subjects were broken down into propositions; these were categorized as to either Correct (C) or Incorrect (I). Correct (C) propositions included only correct statements recalled by the subjects. Incorrect (I) propositions included both incomplete and false statements, however, the lacks of articles were disregarded. If there was no statement for a certain proposition in the statements, it was categorized as Incorrect (I). All the propositions recalled by the subjects were then categorized into four accuracy groups: 1) English-Correct and Japanese-Correct (EC-JC), 2) English-Correct and Japanese-Incorrect (EC-JI), 3) English-Incorrect and Japanese-Correct (EI-JC), and 4) English-Incorrect and Japanese-Incorrect (EI-JI). As if the subjects could listen the audio statements and understand the meanings, they could be able to recall both in English and in Japanese. In the four categories of accuracy, the number of propositions which were categorized as EC-JC was calculated for every caption presentation timing condition.

Separate one-way analyses of variance (ANOVA, 109 X 5 = subject by caption presentation timing) were utilized for the two measures. The main effect of caption timing was checked using ANOVA to test for differences among the five caption timing conditions.

Results

ANOVA results for the two measures are given below.

Number of Recalled Words

The ANOVA results showed that the caption presentation timing yielded significant effects (F(4,105)=15.31, p<.001). As shown in Figure 1, the number of recalled words decreased in the order -1 Time Lag condition, 0 Time Lag condition, +1 condition, -2 condition, and the +2 condition.

Since significant differences were found among the five conditions at the .001 level, the LSD multiple comparison method was employed to determine which conditions were statistically different. The LSD multiple comparison showed that the -1 Time Lag condition was significantly higher than the other conditions at least at the .05 level. There was a significant difference in the number of recalled words between the -1 Time Lag condition and the 0 Time Lag condition at the .05 level. In the second highest condition, the 0 Time Lag condition, the number of recalled words was significantly higher than those were in the +1, -2, and +2 conditions at the .01 level. No significant differences were found in the number of recalled words among the lowest three conditions - the +1 Time Lag, the -2 Time Lag, and the +2 Time Lag.

Accuracy of Recalled Information

Figure 1: Number of Recalled Words and Accuracy of Recalled Information by L2 Caption Presentation Timings
The accuracy of recalled information showed the same tendency as the number of recalled words (Fig. 1); that is, it decreased in the order -1 Time Lag condition, 0 Time Lag condition, and +1 Time Lag condition. The results of ANOVA showed significant difference at the .05 level among the caption presentation timing conditions (F(4,105)=2.42, p<.05). Since significant differences were found among the five caption presentation timing at the .05 level, the LSD multiple comparison method was employed to determine which conditions were statistically different. The LSD multiple comparison showed that the -1 Time Lag condition was significantly higher than -2 Time Lag condition and +2 Time Lag condition at the .05 level.

Summary and Discussion

The experiment showed that the number of the recalled words and the accuracy of the recalled information were high when the captions were presented one second prior to the audio. For more words were recalled in -1 Time Lag condition than the 0 Time Lag condition, it seemed that the subjects could manage with two types of information - visual and verbal - when these information provided with time lag than presented simultaneously. When the captions appear on the screen a second before the audio, the students could concentrate on the displayed text which led to better recall. The information gained from the captions may have functioned as prior knowledge about the information provided through audio. It might have helped the subjects to recognize the spoken statements, with which most Japanese students have more difficulties than with understanding written statements. The understanding gained from the written statements reinforced the recognition of the spoken statements. In the +1 Time Lag condition, however, failure to understand the spoken statements (which is highly possible for Japanese students) made it harder for the students to focus on and be more successful at reading the captions.

In the 0 Time Lag condition, the captions and audio were presented simultaneously. As it was expected, the viewer had to read the visual verbal information (caption) and listen to the audio verbal information at the same time which might cause overflow of learners’ processing capacity. Two other conditions (-2 Time Lag and +2 Time Lag condition), each caption was overlapped with the previous or the forthcoming audio for a second. That is, they have to handle two different verbal contents - one from audio and another from captions, which might cause the confusion of the subjects understanding the contents.

Experiment 2

The effects of L1 caption presentation timing was investigated. The experiment used the same procedure as Experiment 1.

Participants

Forty-three Japanese university students participated in Experiment 2. They were freshmen or sophomores, their average of TOEFL score was 444, and all were non-English major students. They were randomly assigned to one of the five caption timing conditions.

Instruments

The same material was used. Five versions, for the five caption timing conditions were developed.

Scoring and Data Analysis

The TOEFL scores of the five subject groups were statistically different (F(4,38)=2.77, p<.05), separate one-way analyses of variance (ANCOVA, 43 X 5 = subject by caption presentation timing) were utilized for the two measures of the number of recalled words and the accuracy of recalled information. The main effect of caption timing was checked using ANCOVA to examin for differences among five caption timing conditions in the recall of EFL university students.

Results

Number of Recalled Words
The number of the recalled words and the accuracy of recalled information by the five caption presentation timings were shown in Figure 2. The results of ANCOVA presented no significant effects of the caption presentation timing ($F(4,38)=2.18$, $p=.09$).

![Figure 2: Number of Recalled Words and Accuracy of Recalled Information by LI Caption Presentation Timings](image)

**Accuracy of Recalled Information**

The results of ANCOVA showed no significant difference ($F(4,43)=.91$, $p=.47$) among the caption presentation timing conditions.

**Summary and Discussion**

In this experiment, the result showed the LI caption presentation timing provided no effect on both the number of recalled words and the accuracy of recalled information of the Japanese university students. This result suggested the Japanese captions information and the English audio information would be managed without overflowing individual's processing capacity.

**Conclusions**

The purpose of this study was to investigate the best presentation timing of L1 and L2 captions. When the information provided in a certain period of time exceeded one's capacity, there would have a possibility that the captions no longer work as an effective device for listening comprehension. In this study, therefore, the effective use of timing was considered to diminish the information presented at a time and to maximize the caption effects. It was expected that the Japanese EFL students had a difficulty to read the L2 captions presented on the screen simultaneously with the audio at the spoken speed. However, when the caption presented prior to the corresponding audio among the audio dead period, they could read the English captions and grasp the spoken words effectively. The result of the experiments followed this expectation; the L2 captions supplied one second prior to the audio contributed better listening comprehension of the Japanese EFL learners.

It was also predicted when the L1 caption which provided the same meaning in the different language presented before the audio would be more helpful because the viewers could translate the L1 caption information and prepare for the forthcoming L2 audio. The contradictory result was found from the experiment; the subjects' listening comprehension was independent of the L1 caption presentation timing. It was suggested that in this experiment, the L1 captions and the L2 audio were managed without exceeding the capacity of the Japanese university subjects even if these two different information presented simultaneously.

The result of L1 caption presentation timing is differed from the preliminary research by Yoshino et al. (1999). It was unclear what causes this contradict findings- difficulty levels of the materials or difference of the subjects including the processing capacity or translation ability. If the Japanese captions were always handle with the English audio without any difficulty by Japanese EFL students, the reason that explains the lower effects of L1
caption would not the exceeding of viewers' processing capacity by an additional process of translation. More research to conduct the L1 caption presentation timing may be needed.

Looking, Looking, Looking:  
Students' search strategies using an encyclopedia CDROM program

Katina Zammit
University of Western Sydney, Macarthur

Email: k.zammit@uws.edu.au

Abstract: In elementary schools there is increasing use of computer-based environments as information sources. Information is hot-linked creating a hypertext environment. CDROM programs are closed hypertext environments with limited links between nodes and they present a unique way of locating information with no print-based equal. As students use CDROM programs they need to employ search strategies relevant to hypertext and the program. This study investigated the search patterns of 10 - 12 years old students using a commercially produced encyclopedia-based CDROM. Each group of students was given the same task, which was set in context, by the classroom teacher. Students using the encyclopedia CDROM set up mental maps and predictions based on a print equivalent. The success and search patterns across groups varied according to the search strategy employed and the user orientation to the program and the task. The effectiveness also depended on the group's knowledge of the topic, knowledge of the program and their mental map of the program's construction.

Introduction

Within the education system knowledge is gained from a variety of sources. In elementary schools computer-based technology in the form of CDROMs (Compact Disk- Read Only Memory) and the Internet are being used more often as information sources. CDROMs are closed hypertext environments; the links between nodes of information is limited. While the Internet can be considered an open hypertext environment, as there are innumerable links to be made to a large number of sites. The very nature of these resources means students have to access information from a more complex multimedia source.

CDROM programs are not as easily accessible as other resources used in classrooms. They store a large volume of information and can also be a form of entertainment - 'edutainment' or 'infotainment'. CDROM programs are non-linear, unlike books (Slatin 1990; Lawless & Kulikowich 1998). The user cannot 'see' the information contained in the program by flicking through the pages or turning to the index at the back. Users may not be aware of the extent of the information or that they are taking a wrong path (Edwards & Hardman 1989; Slatin 1990). Navigation becomes a critical tool in a student's learning. As a result, CDROM resources create a learning environment dependent on students' effective information retrieval (search) strategies.

Learning in a hypertext environment also involves a high degree of learner control. This can be seen as either beneficial to students or a constraint. Students using CD-ROMs tend to wander around, interacting with the most entertaining parts from the offerings available (Russell 1994). This wandering can be construed as developing children's metacognitive skills (McAleese 1989) or simply as an inefficient method of finding information with the learner expending a lot of time trying to find their way around (Russell 1994; Marchionini 1989).

Studies in the use and retrieval of information from multimedia sources have found that students have little difficulty using and finding information though students' search strategies and their methods of retrieving information were restricted (Marchionini 1989; Oliver & Perzylo 1994). The degree of success or effective use of the CDROM was influenced by the students' understandings of the system, the system itself and students' use of search strategies and retrieval techniques. However the issue of how effective students' information seeking methods were when using multimedia needs further investigation (Oliver & Oliver 1996).
Users of CDROM programs employ a variety of strategies to find information. McAleese (1989) presents a number of studies that classify these strategies, termed "browsing". Canter et al. (1985) based their categories on the way users navigated through a database, obtaining a graphic representation of their pathways. They found 5 distinct search strategies -

- **Scanning**: covering a large area without depth
- **Browsing**: following a path until a goal is achieved
- **Searching**: striving to find an explicit goal
- **Exploring**: finding out the extent of the information given
- **Wandering**: purposeless and unstructured globetrotting. (p. 100)

Lawless & Kulikowich (1996; 1998) have proposed a different classification. Their categories incorporate the users’ orientation and control over the environment, as well as addressing the range of special features within a program. They identified 3 types of common navigational profiles:

- **Knowledge seekers (also known as book lovers)**: those readers who pursue information related to the content of the hypertext; navigate to screens that contain information needed to enhance comprehension; strategic in selection of screens; acquire information in a systematic manner.
- **Feature explorers (also known as resource junkies)**: those readers who spend a lot of time interacting with the movies, graphics sound & visual effects; invest more time in understanding how the hypertext works and what kind of screens it contains than gathering important information.
- **Apathetic hypertext users**: those readers do not appear to care about using the hypertext either to gather information or to explore its features; characterized by short intervals interacting with the text; navigation paths reveal no logical order. (Lawless & Kulikowich, 1998, p 52)

The provision of multimedia resources does not by itself increase the learning outcomes of students (Saga 1992). One has to look at the strategies employed by students, consider the construction of the multimedia programs and the teaching and learning or "training" of skills required in the classroom. Knowledge of these skills and the ability to work in a hypertext CDROM environment may also have implications for students' effective use of the Internet. As electronic and digital texts are becoming the ‘new’ sources of information in education and the workplace, the development of students' information retrieval skills using information technologies is critical. They will assist in providing the background for the essential literacy skills for the information age - critical literacy, visual literacy and digital literacy skills (Burbules 1997; Lankshear et al. 1997).

This paper will present preliminary findings about the search strategies used by 10-12 year old students working in cooperative groups using an encyclopedia CDROM program on a set task based on the class's current theme.

**The Investigation of Students' Search Strategies**

**The Program**

The CDROM Program was a commercially produced program entitled ENCARTA 96 (Microsoft 1993-1996). It was part of an Apple Macintosh hardware/software package purchased by the school in 1997. The program uses an encyclopedia metaphor to frame its information and the layout of the screens. However unlike a print-based encyclopedia it does not contain a range of information on a huge number of topics. The program is produced in the United States and contains limited information on Australia, in particular Australian history.

**The Students**

Students were aged between 10 and 12 years. They all had used the program before in a previous unit of work on "Rainforests". The majority of the students had access to a computer outside the school. The class teacher allocated the thirteen students, who took part, to a group. Each member was assigned according to their different role: recorder, reader, reporter and gopher. Groups ranged in size from 3 to 5 students. Four groups were observed using the program.

**The Task**

Students were asked to obtain information on the lifestyle of Australian Aborigines prior to European Settlement. The task was introduced to students by the class teacher as the initial session of a historical theme on Early Australian history. The teacher scaffolded students' investigation by having a discussion with the class about
what areas to investigate, writing these as headings and sub-headings on the blackboard. This provided students with possible key words to use as students searched any of the resources.

Methodology

A naturalistic form of data gathering was employed (Oliver & Perzylo 1994). Field notes were kept as well as a video recording of each session to document the pathways taken by each group. The video-recordings provided detailed information about the interactions and pathways of each group. This has become a useful data collection technique for computer-based information-seeking studies (Oliver & Perzylo 1994; Edwards & Hardman 1989). The class teacher and students were interviewed to obtain information about students' sociocultural and computing background. During the session, students were asked to articulate the reasons they chose specific paths or navigation tools - a procedure adapted from the 'Think-aloud' technique (Afflerbach & Johnson 1984). There was no time constraint and each group pursued their searches until satisfied they had found all they could from the program.

Results

The breadth of each search, was obtained by tabulating the number of different nodes visited (NV), the number of nodes visited and the most frequently visited nodes (Tab. 1). In addition, the researcher assessed the quality of the searches in relation to location of relevant information and the types of sources used to gather information. Relevant information was defined as any source (section of written text, image, caption for image, sound) containing either specific information on Aboriginal people before the Europeans, as well as general information about Aboriginal Art or Culture, for example Didjeridu (Tab. 2).

*This session was extremely short with only 8 screens being visited. Hence, comparison with the written descriptive instead of the graphic representation was used.

**Table 3: Search Strategies and User Orientation**

**Group 1**
This group visited the least number of nodes within the program (Tab. 1) and spent the least amount of time searching for information. They found relevant information during their initial search using the FIND tool. The information was obtained from the caption under the 'Aboriginal Music of Australia' image and sound file (Tab. 2) on the 'Aborigines' screen. When unsuccessful in further searches using the same technique they chose to finish their search session. The diagrammatic representation of their search could be equated with Wandering but the group visited so few screens (nodes) and this categorization is inconclusive. They did exhibit characteristics of apathetic hypertext users.

**Group 2**
Group 2 chose to investigate each section of the program as listed on the Main Menu screen. They were the only group that did not begin their search using the FIND tool, choosing the LOOK & LISTEN section for their initial search. They found useful information but did not take notes on any of this information for the task, preferring to talk about the sound file accompanying the 'Aboriginal Music of Australia' image in the Media Gallery, accessed via the LOOK & LISTEN section. They visited a high number of different nodes, with a medium NV/NS score. The diagrammatic of their search and the medium NV/NS score are features of Browsing. Their user orientation can be classified as Feature Explorers.

**Group 3**
Group 3 visited a variety of nodes, revisiting six (half of the number of different nodes visited) more than once (Tab. 1). They located useful information on their initial search using the FIND tool and were unsuccessful with subsequent searches using the same technique. The information extracted was from the image, caption and sound file (Tab. 2) entitles 'Aboriginal Music of Australia' on the 'Aborigines' screen. They also located information about Aboriginal populations, which they deemed to be important but did not infer that this information was recent not historical data. The diagrammatic of their search was similar to Scanning. This group was the only one that exhibited behavior similar to Knowledge Seekers. Towards the end they moved into Feature Explorer behaviors.

**Group 4**
Group 4 visited the largest number of nodes of all the groups. They revisited 5 nodes frequently, these being the core or base nodes (Tab. 1). The FIND tool was revisited the most (18 times) as they used this node to frame their search. Hence the lower NV/NS ratio in comparison to the other groups. Although the group visited relevant nodes they did not write any useful information from any of these texts, nor did they talk about this information. They believed the information about the population of Aborigines was important and recorded notes from this. Unique was their investigation of each section of a node (Weapons) which contained only a list of hotlinked words. This group visited 2 screens not found by any of the other groups: Didgeridu and Boomerang. However, they did not explore the "Related Articles" sections nor consider any of the information relevant. This may be due to locating them at the end of the session. The group lost focus and interest due to lack of success with their searches. They used hotlinked words more often than the other groups. The diagrammatic of their search demonstrated similarities to Browsing. Their orientation was equivalent to Feature Explorers.

No group located the written text with specific information about Aboriginal people prior to European settlement, which was on the 'Australia' node. Students did not use the 'View: Outline' strategy to locate this text.

1 This is the spelling used in ENCARTA96 (Microsoft, 1993-1996). Students used 'didgeridoo'.
information, preferring to scroll down the text box when in the 'Australia' node. As this node is extremely long, this was not an effective method for locating this section of text. Students did not understand how to use this section of the program. This is evidenced by 3 of the four groups locating this section of the screen, 'reading' the options but not clicking on any of the alternative views.

Discussion

The information the groups found was obtained from the sound and visual texts of the program. But this was not consistent for all groups and all relevant information was not extracted. This reinforces the need for students to be given experiences on how to extract information from non-verbal texts (Oliver & Perzylo 1994). The written text was not helpful, and for some proved to be a distraction as they lost sight of the objective of the task and were consumed by the special features of the program (Russell 1994).

Effective search strategies rely heavily on the background knowledge of the topic by the searcher whether they use print-based or computer-based texts. In a computer-based environment, this knowledge becomes a crucial aspect if the user is to locate relevant information using the search tools of the program (Lawless & Kulikowich 1998). Group 4 located two information nodes (boomerang and didjeridu) at the end of their search but did not explore any of the related articles (key words), take notes or consider them important. The information did not specifically mention early Aboriginals or pre-European settlement.

The most relevant information was to be found in three sections of written text on the 'Australia' node. However, this screen contained a very long piece of text and students did not use 'View Outline' as a strategy for locating information within the screen. Students obviously did not know about this organisational feature of the program. An orientation for the user to the program, its sections, ideology, authorship, limits of information need to be covered prior to use. During the use of the programs, the imperative is to provide scaffolding for students, for example guided question proforma or key words guide (Zammit 1999).

One of the reasons for the use of the 'FIND' tool and lack of use of the 'View Outline' tool can be explained by the students' orientation to program. The first strategy is one used primarily in print-based encyclopedias; the latter is an example from a hypertext environment. Students' mental model of how to access an encyclopedia, what an encyclopedia should and would contain was based on print equivalents. As a result they did not locate all the information in the program. The construction of the program influences the strategies chosen by the user.

Even though graphical representation of navigation patterns do not seem to identify individual differences with the same precision as cluster analysis (Lawless & Kulikowich 1998: 397), they do provide a visual overview of a distinguishable search pattern. When Canter et al.'s (1985) categories of browsing are used in conjunction with Lawless & Kulikowich's (1998; 1996) types of users, one can gain an indication as to why some students are more successful than others at locating information using closed hypertext CDROM programs.

Those students, who were Browsing, were also Feature Explorers and they were absorbed by the program. These students did not take notice of relevant information nor appear to know what was relevant. It is also possible they did not have the skills to extract the information when it was located or how to take notes. As a result they 'lost' track of the task, being more interested in using the program's tools. Those students who were Knowledge Seekers used Scanning and covered a wide area of the program. They discussed information located, assessed the value of the information and took notes from a range of sources. This group gained some information for the task they were set. For Group 1 (the Apathetic Hypertext Users) the data is not as conclusive, given the short amount of time they spent interacting with the program. They went in, got some information and left. Their success was related to the quality of the moves made not to the quantity. (Marchioninni 1989)

From this information, two searcher orientations are proposed:

Voyeurs: they are like tourists in a new country. They have difficulty reading the visual and written signs; locate sources but have difficulty understanding what is relevant; have limited discussion of content; and are more interested in clicking and acting on the hypertext environment than negotiating meaning. They are not very successful with their search; they may locate the information but not recognize its value or use it for notes.

Investigators: they are like detectives looking for clues. They are focused in their exploration; cover a wide area within the program; discuss the value of the information located; negotiate meaning with the program; and use a range of sources for their note taking. They are successful with their search, locating information relevant to their search.

Just as two people negotiate meaning when they speak to each other, the user negotiates meanings with the computer as the other interactant. These types of negotiation or engagement are a more refined ways to consider the
search strategies of users and may be more useful than the broad categories and types of users. Further research into these orientations with consideration of the types of engagement and the influence on learning in a hypertext environment is required. Perhaps certain types of users have a preference for certain types of interaction and avoid others. Some students may be better negotiators in a hypertext 'conversation' similar to those who are better talkers. In addition to this area, there is a need for more work on information retrieval using a range of commercial products in classrooms.

Conclusion

The engagement of young students during information seeking tasks is influenced by their orientation to the program and their knowledge of the topic. These in turn influences the search strategies students select when given a task and hence the effectiveness of their search. Students are drawn to the image and sound texts of a program but are not necessarily skilled in extracting information from these. In addition it is the opaqueness of the extent of programs and their construction that constrains students' effective searching. How to open up these resources for young children as effective learning environments needs conscientious efforts by educators.

Abstract: On-line learning for undergraduate students is being embraced by higher education institutions as they adapt and react to the changing circumstances of student expectations, societal demands and available funding. Students' perceptions of learning on-line must be considered if their learning needs are to be met and best practice is to be achieved. Over the 1998-1999 period, an undergraduate teacher education subject, convened by the first author has included an on-line component in the delivery and assessment. Rather than replacing existing practices with on-line teaching and learning, lecturers working in this subject used mixed mode delivery to develop students' understandings and skills. They encouraged students' independent learning through on-line modules, computer based assessment tasks and presentation of subject content via the Internet, lectures and tutorials. From the students' evaluations of the subject, the mixed mode of delivery including independent learning, the use of technology, and on-line tasks were favorably received and had positive affects on the students' learning in the subject.

Changing Practices and Relationships in Universities

The advent of Information Technologies (IT) in affluent countries has changed, fundamentally, the nature of communication and learning within those societies. As a result, society is moving away from a print based to an information technology based society (Spender 1995; Negroponte 1995). The medium of exchange in society has moved from physical things represented as atoms to network based information represented as electronic bits. Higher education is especially affected by these changes and those involved in this enterprise must adapt to take advantage of the opportunities offered by the emerging technologies.

Universities will have "to change their purposes and their practices. Scholarship, knowledge, research and teaching are significantly different when done electronically" (Spender 1995, p. xxiii). Universities also operate within a political and economic climate. There is an increasing need for university qualifications in order to gain paid employment and a need for life long learning in order to maintain credentials in a rapidly changing employment environment. As a result, the numbers of students attending university has increased dramatically. These students come increasingly from a diverse population and have changing aspirations (Le Grew and Calvert 1998).

Within Australia, relatively few universities are "as yet taking a whole-of-institution approach to ... flexible delivery" (Latchem and Moran 1998, p.67). Lewis and Merton quoted in Lewis (1998) suggest that the application of technology to flexible delivery of instruction in universities has been "patchy" in that it has met with mixed results. This is especially true in the field of Initial Teacher Education (Hacker and Sova 1998).

One important dimension for university based flexible delivery is a move "from a teacher-dominated, transmission-based process to a learner centred, constructivist process" (Latchem and Moran 1998, p.67) with the use technology to maintain contact between students and tutors. Technology in flexible delivery can support students by providing;

"Information on the curriculum,
Recognition for existing achievements and advice on appropriate learning routes,
Flexible access to resources, facilities, and program content,
Opportunities to practice and apply learning." (Lewis 1998, p.27).
Innovation and change in practice comes about from what has gone before: it is not entirely 'new'. Branch and Tonkin's (1997) case study of the trial of multi-campus video on demand illustrates this principle. New learning environments grow out of old learning infrastructure when innovation has an opportunity to flourish.

Methodological Principles

Evaluation is a continuous process that is an interaction between the internal and external learning processes of students and teachers. The purpose of evaluation is to determine the value of a particular learning experience for the students who are engaged in it. There are two aspects to developing such understanding. The first is to identify what is not working for a particular student or group of students. These elements of the experience need to be changed to create the conditions for positive outcome for learners. The second aspect is to find and retain what is helping students to learn what it is they need to know.

Learning is an internal process for which learners are individually responsible. Teaching is an external process in which teachers are responsible to their students. However teachers must collect information from their students (external process) and reflect on the implications of this information (internal process) for the learning environments that they have provided for those students. Kirkpatrick, quoted in Alexander, McKenzie and Geissinger (1998), provides a four level framework for organising the collection of evaluation information. These principles have guided the examination of the subject that is the focus of this paper. The levels parallel the integrated approach suggested by Alexander and Hedberg (1994). The levels are:

- reaction to the innovation;
- achievement of learning objectives;
- transfer of new skills to the job or task;

The Subject - Curriculum Studies 6: English and Science & Technology

A site for the subject Curriculum Studies 6: English and Science & Technology (CS6) was developed containing on-line Internet resources organised around nodes, which included information and activities (Zammit, Nanlohy & Corrigan 1998; 1999). The nodes were Your Concept; Factual Genres; Learning and Teaching; Programming and Planning; Assignments and Tasks. The website demonstrated the integration of the two subject areas via hotlinks between content nodes. Each node was broken into sections; each of these varied in length depending on the content. Where a section was a long page, the parts were identified at the top and internal navigation used. It was attempted to keep the amount of information to a screen-size, but this was not always successful and different computers varied the display of the information.

The subject presentation consisted of three lectures; eight x two-hour tutorials in both the English and the Science & Technology strands interspersed with five independent study weeks. On-line tasks were developed for students to complete during independent weeks. In 1998 the Science tasks were compulsory, the English tasks were not and no grade was attached to the completion of tasks. In response to students' evaluations in 1998 and further investigation of students' completion of on-line tasks (see Alexander, McKenzie & Gessinger 1998, p.234) the 1999 tasks and the web page construction assessment item were refined.

The tasks were intended to assist students in the completion of their final assignment - an integrated program for a grade of their choice, and covered topics not addressed during lectures or tutorials. The Science tasks extended students conceptual development within a selected concept area and the use of outcomes in Science. The English tasks were designed to extend students knowledge about language, factual genres, information skills and critical literacy. In 1999, one of the tasks was the annotation of a text written in a self-selected genre relevant to the concept being investigated by students. Students had to write the text, annotate the text with the structure and 2 key language features (grammatical). In 1998, this task was part of the web page assignment. The number of overall on-line tasks decreased from eight to six. All six on-line tasks were compulsory and a pass/fail grade assigned to their completion. Students were asked to submit the tasks via email.
The Students

All the students (1998: 153 students; 1999: 126 students) were in the second year of their three-year Bachelor of Teaching (Primary) degree. Students voluntarily participated in the evaluation and hence the numbers of participants varied across evaluation forms. Most students' previous computing experience was limited to word processing. They had limited knowledge and experience of the Internet. The 1999 cohort reported an increased familiarity with the Internet. In a preliminary survey, the students' initially rated using information and receiving instructions from computers as one of their least preferred mediums.

Students Opinion of Learning in a Mixed Mode of Delivery and On-line

In both years, students mid semester completed an open-ended evaluation. The end of semester evaluation instrument combined Lickert scale responses and open-ended written replies. Students also completed a pre-subject questionnaire to ascertain their use, comfort and knowledge of computers and the Internet.

The subject's web site

The subject's site was well received by the students in both years (Tab. 1). In 1999, however it was rated more highly than in 1998. This may be because students have become more comfortable with the Internet and learning with computers than they perceived themselves to be in the preliminary survey. It may also be because students had to access the site to locate tasks, to complete tasks and find information to assist with tasks and assignments. A few students completed the subject on-line and did not attend classes. These were mainly students who were repeating the subject.

Table 2: Frequency of use of Website: end of semester

The frequency of use by students did not vary over the two years (Tab. 2). This is an interesting result given that the 1999 English and Science on-line tasks were compulsory and the content of these was not covered in tutorials or lectures. This required more independent learning by students but the results suggest that they used the site and the information more effectively than the 1998 cohort did. It is also important to note that 3% did not use the site at all. The completion of on-line tasks could be done with a partner, in a small group or individually. These people may have opted to work in with other students, who did the actual 'looking up' and using of the site, while they assisted in the completion of the tasks. They may also have been able to obtain enough information about tasks and content from students, books, journals or other sources.

In both years, the site was mostly used for accessing information. It was also used to get help with assignments, to access the lecturers and obtain clarification about the content.

On-line Tasks

Between 1998 and 1999 there has been a significant change in students opinion of the on-line tasks (Tab. 3). The on-line tasks in 1999 were more favorably rated than in 1998, in relation to increasing students' learning in the subject. The most significant change occurred for the English on-line tasks. This can be related to the compulsory completion of these tasks in 1999. However it may also provide a better reflection on the quality of the on-line tasks as all students completed them and could evaluate them more effectively than the 1998 cohort.

1 In all tables the numbers are in %, rounded to nearest whole.
1998 - voluntary: English
1998 - compulsory: Science
1999 - compulsory + graded: English
1999 - compulsory + graded: Science

Table 3: Rating of on-line tasks: end of semester

In 1998, students who did not attempt the English on-line tasks may have rated them of no or little help in their learning because they didn’t have to complete them. Students in 1999 also rated the Science on-line tasks higher than in 1998. This may be due to the decreased number of on-line tasks in Science. It may also reflect on the different learning styles, perceptions of the 1999 cohort of students, and their increasing familiarity and comfort in learning independently and in learning with this medium (Tab. 4).

Table 4: Influence of Independent study weeks on learning in subject: end of semester

Students found the presentation mode of the subject useful to their learning (Tab. 4 & Tab. 5). In 1998 this subject was the only undergraduate subject with a different pattern of attendance and on-line tasks. For 1998 cohort it was a unique and challenging experience. In 1999, the subject is only one of a number of undergraduate subjects with unusual attendance patterns, combining a range of delivery modes. Hence 1999 students may have had previous experience or other subjects where they had to keep track of their attendance for other subjects as well as Curriculum Studies 6. When read in conjunction with Table 4, the results also show that students can learn and appreciate learning from a range of mediums and modes, including an on-line medium and an independent mode.

Using Computers

Students developed a lot of confidence in using computers as a result of this subject (Tab. 6). Their experiences working with computers were commented on favorably mid-semester and at the end of semester (Tab. 7). Again the difference between 1998 and 1999 cohorts' negative opinion may be due to the changing nature of the student population in regards to use and exposure to computers. The more negative comments in 1999 about ‘using computers’ were related to lack access.

Table 6: Working with computers: end of semester

Technical difficulties and access to computers were the most frequently reported problems students encountered. The authoring software, although different in each year, was a problem and the problems with email
preferences in the computing laboratories meant students in 1999 couldn't email directly from the Internet browser. This required students to print out or send tasks as attachments using their personal email accounts.

Students' opinion of the construction of a web page assignment changed over the 2 years (see Tab. 7). The 1999 cohort commented most favorably about this assignment in the formative mid-semester evaluation. There is also a decrease in the negative comments about this assignment in 1999. Students' comfort at using computers may account for this. Also students can see the benefit in learning about web page construction as future educators of children living in a digital world.

Table 7: Mid-semester evaluation

Face-to-Face Content

The largest number of mid-semester negative comments related to the face-to-face content (Tab. 7). What was remarkable was one of the two content areas received the majority of unfavorable comments over both years. Even with changes made to the Science subject content, it was still not well received.

Discussion

Two trends are clear from the CS6 initiative. The first is that students are increasingly comfortable with on-line delivery of aspects of undergraduate subjects. The second is that, the on-line component of a subject can become increasingly supportive of students' learning given appropriate evaluation and subject design changes.

Simply participating in a university course increases students' experiences with Information Technologies (IT). They need to use IT for research, information collection and production of assignments. In this subject, the use of IT was required for participation and for the production of assessment items. A third dimension was added in that this subject also studied the place of IT in children's learning. Thus the use of the on-line resources were linked to the students' future professional roles. Significant assistance was given to students by their peers, by the lecturers and by the technical staff of the computing center.

It is important to note that comfort increased in the second year of the subject when there was a grade attached to the completion of on-line tasks. This is a form of compulsion and as such needs to be backed by support for those students who find the use of IT a challenge. From the student evaluations obtained it seems that the central importance of the tasks and the support provided mitigated the compulsory nature of the on-line tasks.

The second trend that these evaluations highlight is the need for continuous monitoring and improvement in the on-line learning experiences offered to the students. The lecturers responsible for the delivery of this subject responded to students' evaluations by redesigning the number and nature of the on-line tasks. They made changes that were designed to assist students to be more independent in their learning.

In addition, the responses to the face-to-face delivery indicate that lecturers also need to evaluate the content and presentation of the face-to-face lessons if using a mixed-mode presentation for a subject. It is essential to meet the needs of students, consider what they have learnt before the subject and extend this knowledge.

Conclusion
The design of the subject and the improvements made were part of an attempt to develop a more "learner centred constructivist" learning environment (Latchem & Moran 1998, p.67). The students approved this philosophical approach.

The success if this subject is a significant component of organisational change within the Faculty's pre-service teacher education program. Indicators of organisational change since the inception of this initiative has been the interest of other lecturers in doing on-line work; involvement in Flexible delivery projects funded by the university; knowledge sharing and collaborative learning of lecturers; the use of an integration approach to on-line learning in subjects; and the modification of subject presentation formats.

Abstract This paper reports our work towards the development of an authoring system for automating the instructional design for teaching procedural knowledge. The core of our work is the design of a set of instructional events for teaching procedural knowledge, Introduction, Presentation, Demonstration, Exploration, Practice, and Test, and the development of corresponding instructional event shells and an instructional simulation tool. An instructional event shell is a piece of program code that executes an instructional event. Demonstration, Exploration, Practice, and Test event shells are built upon the instructional simulation tool. The instructional simulation tool provides an environment for creating simulations of procedural knowledge. These simulations may be used for Demonstration, Exploration, Practice, or Test. The focus of this paper is a description of these instructional events and the instructional simulation tool.

Introduction

With the rapid advances of computer network and multimedia technologies, the use of interactive instructional technologies has been experiencing a dramatic increase in recent years. However, development of high quality computer-based courseware is both time consuming and labor intensive. Therefore, only the best funded training programs can afford to be computer-based. Many organizations that are attracted to the concept of computer-based training have to give up when they discover the cost and the time to implement computer-based courseware.

A traditional computer-based courseware development team involves subject matter experts, instructional designers, and programmers. The subject matter expert determines what to teach and provides subject matter knowledge. The instructional designer together with the subject matter expert determines how to teach and designs the instructional treatments for subject matter knowledge to be taught. The programmer generates computer code to implement the instructional treatments for the delivery of the instructional material. The development processes of both instructional design and programming are very long and labor intensive even for some simple training programs.

To reduce the time and cost spent in programming, authoring systems have been developed and used widely. The goal of existing authoring systems is to eliminate programming in the courseware development process and lift the expensive burden from the course developer’s shoulders. Solving the programming problem for course developers with authoring systems has greatly influenced the productivity of development of computer-based instruction, and the number of interactive instructional software products has increased geometrically.

However, the current conception of authoring systems has not solved the cost and time problem to a sufficient degree. The quality of many current instructional products still appears to be far below the potential promised by the current computer technology. Even though the expensive programming burden has been lifted from the course developer’s shoulders, there remains a equally cost and unnecessarily repetitive instructional design process burden which still rests on the developer (Merrill, 1985).
Merrill and his colleagues (Merrill, Li, & Jones, 1991) introduced the instructional transaction theory that maintains that the basic building block of instruction should be the instructional transaction. This principle applies particularly to the highly interactive medium of computer-based instruction, in which the most powerful vehicle for learning is the pattern of interactions between the student and the computer. Based on the instructional transaction theory, a simple prototype named ID Expert (Merrill & Li, 1989) was developed. ID Expert was intended for use by both novice subject matter experts and experienced instructional designers and provides instructional design and templates for courseware developers. The instructional transaction theory provides a theoretical foundation for the development of authoring systems that automate the instructional design of computer-based instruction (Zhang, et al., 1997). Recently, a few commercial authoring systems such as ToolBook and Authorware included some templates or widgets that speed up the courseware development process.

Instructional simulation is an important instructional design technology, especially for teaching procedural knowledge. A simulation is any attempt to mimic a real or imaginary environment or system (Alessi, & Trollip, 1991; Reigeluth & Schwartz, 1989; Thurman, 1993). A simulation is often used for one of two purposes: scientific or instructional. The reasons for using simulations instead of real systems are cost, danger, inaccessibility, or time. Instructional simulations are designed to teach the student about the system by observing the effects of actions or decisions. Instructional simulations are different from scientific simulations in that it should provide guidance, explanations, hints, and feedback for actions, decisions, or results.

Computer-based simulation has been recognized as having cost benefits, safety benefits and security advantages in teaching procedural knowledge. Three barriers to the effective use of simulations in education and training have been identified (Leston Drake, 1997). First, developing simulations is extremely expensive. Second, once a simulation is completed, maintenance and modifications to the simulation are difficult and costly. Finally, not all simulations are instructional.

This paper reports our work towards the development of an authoring system for automating the instructional design for teaching procedural knowledge. The core of our work is the design of a set of instructional events for procedural knowledge teaching, Introduction, Presentation, Demonstration, Exploration, Practice, and Test, (Merrill, et al., 1992) and the development of corresponding instructional event shells and an instructional simulation tool. An instructional event shell is a piece of program code that executes an instructional event. The ideas introduced in this paper have been implemented in a prototype named PKAuthor using Visual C++ and the Access database system.

Teaching Procedural Knowledge

Course Structure

Authoring a course using KPAuthor is to create a course structure, provide content material, and create instructional simulations. The course structure, the content materials, and simulations are stored in a database.

A course structure is a tree of course units. The root of the tree is the course and the leaves are instructional events. A course may consist of a set of events and a set of lessons. Instructional events of a course may be a pre-test, a post-test, a course introduction, a course summary, and a comprehensive practice.

A lesson may be composed of a lesson introduction, a lesson summary, a comprehensive practice, a test, and one or more instructional sessions. An instructional session may consist of a set of instructional events and zero or more other instructional sessions. A session may teach one or more procedures.

Instructional Events

Procedural knowledge may be taught using six instructional events: Introduction, Presentation, Demonstration, exploration, Practice, and Test (Merill, et al., 1992). These six instructional events may be used repeatedly. In PKAuthor, six corresponding instructional event shells are implemented to execute these six events.

Introduction. It informs the student of the learning objective: what the student can do after he/she completes the learning of the procedural knowledge. In addition to the learning objective, the student is also informed of the prerequisites: what the student must know before he/she can start learning the procedural
knowledge. It also briefly describes the tasks to be completed and the goal to be achieved. All materials may be presented using different media such as text (rich text format), pictures, still images, animations, audio, and videos. All materials may be presented in one or more pages. Hyperlinks are allowed.

**Presentation.** It displays all the material for mastery of the procedural knowledge to be taught. Presentation presents the task to be accomplished with a text or audio description of all steps to be performed in order to complete the task.

**Demonstration.** It uses examples to illustrate the material presented in *presentation* in a simulated environment. Each step is demonstrated by showing the student how to perform the step. The consequence of each step is also demonstrated by showing the student the state of the device or system following the execution of each step.

**Exploration.** It provides the student with an opportunity to "play with" in a simulated environment. This "play" allows the student to explore "what happens if ..." type questions by actually trying out a variety of actions and observing the consequences of these actions. Exploration is the mode of learning by discovery.

**Practice.** It assigns some problems to the student and then the student solves these problems in a simulated environment. Problems can be solved with or without guidance. With guidance, the system shows the student what to do at each step. Without guidance, the student solves problems on his/her own. Hints for solving a problem are always available upon the request of the student. Both intrinsic feedback, observing the consequences of a given action or set of actions, and extrinsic feedback, informing the student about the appropriateness of a given action or set of actions, are available.

**Test.** It checks the level of mastery the student has attained and determines if the student passes a session/lesson/course. Test questions may be performance questions or concept questions. A performance question is similar to the problem in practice. Neither hints nor feedback is provided in test. Only the score is given to the student. Concept questions are multiple questions, true/false questions, matching questions, sequencing questions, and fill-in-blank questions. The student is informed if he/she passes or not.

**Instructional Simulation Tool**

A simulation provides a controlled learning environment that attempts to replicate key elements of the real world. Simulations allow the learner to act and then provide appropriate outcomes or consequences. Simulations can best serve procedural knowledge teaching. Four of the six instructional events for procedural knowledge teaching need to use simulations.

**Simulation Components**

Components of an instructional simulation are objects, states, actions, tasks, and rules. Creating a simulation is to create these components. A simulation of a system consists of a space of states, a set of actions, and a set of tasks.

**Objects.** Simulation objects represent entities in the real world. They can be physical objects or conceptual objects. They are the basic components of a simulation. A simulation object is composed of two parts: internal and external representations. The internal representation is a set of attribute value pairs, which represents the internal status of an object. The external representation is a set of graphic images.

**States.** State is one of the most important components used in the instructional simulation. A state represents the status of the current world. A state consists of a set of objects and relationships between these objects. A change of an attribute value of a state or a change of a relationship between two objects changes the current state to a new state.

**Actions.** An action changes the state of current world whenever it is executed. Teaching procedural knowledge is to teach how to choose a sequence of actions under various conditions in order to achieve a goal state from an initial state. An action consists of three parts: precondition, consequence, and an external action. The precondition of an action specifies the conditions under which the action can be executed, the consequence specifies the effect of the action. The external actions specify how to execute the actions and include mouse and keyboard actions. An action moves one state to another by changing some attribute values of some objects or some relationships between objects. Each action is also associated with some instructional materials. The instructional materials teach the student what is the action, when to apply the action, how to perform the action,
and what is the effect of the action. An action may be taught explicitly or taught implicitly using the exploration instructional event.

**Tasks.** A task defines a problem. A task may be used as a demonstration example, a practice problem, or a test problem. A task contains one initial state, one goal state, and sequences of actions. The problem is how to apply actions to achieve the goal state from the initial state. The sequences of actions are the solutions of the problem.

A complex task may be divided into a few subtasks, each of which has its own initial and goal states. It makes the complex task easier to learn.

Each task is associated with some instructional materials. The instructional materials include instructions for the student how to solve the problem, hints at each step, and feedback at each step. The feedback can be simply right or wrong for an action or detailed explanations of why the action is correct or incorrect. Feedback may be immediate feedback or delayed feedback. Immediate feedback is given immediately after each action. Delayed feedback is given after a sequence of actions is performed.

**Rules.** Rules are represented as IF-THEN rules. The IF part is a conjunction of conditions and the THEN part is a conjunction of consequences. A condition is either an attribute value pair or a relationship and a consequence is either an attribute value pair or a relationship. Whenever all conditions in the IF part are satisfied, all consequences in the THEN part become true.

An action changes the state of the world. These changes may cause a sequence of changes of states. Rules are used to determine this kind of changes of states.

### Creating A Simulation

Creating a simulation is to construct objects, states, actions, tasks, and rules. The simulation authoring tool is composed of a set of editors: Property Editor, Object Editor, Attribute Editor, Action Editor, State Editor, Task Editor, and Rule Editor. Fig. 1 show the screen of the dialog box of Action Editor, respectively.

![Action Editor Dialog Box](image)

**Property Editor.** A property is an attribute. The Property Editor is used to define properties of objects and relationships among objects. A property may have four types of values: enumerated, numeric, set, or string. To define a property, one needs to specify the name of the property, the value type, and the legal values. Fig. 2 shows the screen of the dialog box for editing value type and values of a property.

**Object Editor.** The Object Editor is used to collect the necessary information for creating an object. The information includes the name of the object, the type of the object, the list of properties, and the media representation.
**Action Editor.** The author defines actions through Action Editor. Action Editor allows the author to specify the name of an action, the preconditions, the consequence, and the mouse and keyboard action.

![Fig. 2 Dialog box for editing value type and values of a property](image)

**State Editor.** The author creates, renames, and removes states using the State Editor. To create a state, the author only needs to give a name to the new state, specifies the property values of objects, the relationships among objects.

**Task Editor.** The author makes use of the Task Editor to create and edit tasks. A task is one of the most complicated simulation components. The author defines initial and goal states using the state editor. A graphic editor is provided for the author to specify the solutions (sequences of actions). Detailed feedback may be constructed using the graphic editor.

**Rule Editor (Process Editor).** Rule Editor allows the author to define the conditions and consequences of a rule. It consists of a condition editor and a consequence editor. Fig. 3 is the screen of the dialog box of the condition editor.

**Authoring A Course Using Instructional Event Shells**

Authoring a course using PKAuthor consists of the following three phases.

- Content Knowledge Acquisition
- Simulation Development
- Course structure construction
- Instructional event configuration

Content knowledge acquisition is to create instructional materials for courses, lessons, sessions, and instructional events.

Simulation development is to construct one or more simulations. A simulation consists of a set of tasks for demonstration, practice, and test and/or an exploration environment for exploration.

Course structure construction is to create the tree structure of a course and define all course units including instructional events.

Instructional event configuration is to associate instructional event with the content knowledge, simulation tasks, and simulated exploration environments.

Conclusion

In this paper, we reported the work we conducted in development of a procedural knowledge teaching authoring system, PKAuthor. This work is a part of a larger project. One of the major objectives of development of PKAuthor is to explore the methods for developing authoring systems to support automated instructional design. PKAuthor is implemented on Windows 95 in Visual C++ and the Access database system.

In the current version of PKAuthor, only a subset of the features described above has been implemented. In the future, we will add more features into the system. PKAuthor has only been tested on computer literacy courseware. PKAuthor needs to be tested on more applications. A more user friendly GUI interface needs to be designed and implemented in PKAuthor. In the future, we plan to implement a web-based version of PKAuthor.

SHORT PAPERS
Creation of a Simple Intranet for University Educational Use

Dr. Hassan Ahmadi Torshizi,
Faculty Member, Computer Science Department,
Islamic Azad University, Mashhad, Iran

Mr. Bagher Azghandi,
Faculty Member, Computer Science Department,
Islamic Azad University, Mashhad, Iran

Abstract: This article describes and presents the results of an 18 month project by faculty members and students of the Computer Science Department of the Azad University in Mashhad, Iran, at an approximate cost of $10,000. The result was the creation of a simple Intranet which employs eight phone lines and makes it possible for faculty members, students, and university employees to access information by only dialing up. Although not complex, this Intranet does provide information services through the use of Microsoft Information Internet Services (Internet Information Server - IIS) and NT Information Systems support software packages (such as Back Office), which offer users ready pages in static or dynamic form via ASP (Active Server Page). This Intranet system also features E-mail service to facilitate the communication between and among students and faculty. In addition, users may conduct direct conversations on Web pages (Net chatting) and participate in network conferences (Net meetings) while conveniently using the local language, Farsi.

Introduction

Today there is no doubt that information systems play an important role in the development of the remote education culture. From remote sites, via telephone lines and satellites, computer users can now access different kinds of hypertext information data bases that specialize in scientific, commercial, artistic and other areas with multimedia user friendly formats. Actually, this scenario is the basic working principle of remote education. However, the problem remains that information is too widely scattered, with no dedicated organization, fixed protocol or rules, for guiding the user in efficiently locating and utilizing these valuable educational resources in an optimum way and format. This is indeed a universal problem, not just isolated to the specialized academic environment. One possible solution for resolving this dilemma is the creation of local Intranets in educational institutions and their departments. With proper planning and organization, direct and indirect communication between users and access to the data they need can be realized. This would also make possible scientific conferences and other direct and indirect means of conversation between educators and students, information providers and searchers. However, because of the high expense and technical expertise entailed in establishing a comprehensive information system with state-of-the-art information technology, Intranet systems such as these are not yet common. This simple Intranet provides the following services:

1. Access to data about different university departments, including information on:
   1.1 University departments: Campus locations and addresses, the geographical and historical development of the departments, their academic goals, along with related pictures.
   1.2 Class schedules: Current semester schedule along with instructors’ names, class times, classroom locations and other information.
   1.3 Faculty members: Campus addresses, phone numbers, E-mail addresses, academic experience, qualifications, classes taught and now teaching, research work, scientific articles and books published.
1.4 Students: Majors, E-mail addresses, projects interested in.

1.5 Academic courses: Curriculum, university departments, number of units, pre-requisites, course resources and references, short descriptions of how the course will be conducted including laboratory requirements, projects, exam materials, exercises related to each course are provided.

1.6 Laboratories, workshops, practical courses, hardware and software workshops: Along with a calendar showing schedules and work to be accomplished, suggestions are included on how these special classes can be taken advantage of.

1.7 Publications: Articles published by faculty and students and where the abstracts are kept.

1.8 Books: List of existing books within the different university departments.

2. E-mail, on-line conversations and Net Meetings:

Provided are E-mail access, on-line conversations through the Web (Web chatting), and network conferences (Net Meetings). All of these facilities are available for those having User I.D.'s and E-mail accounts. In on-line conversations, it is possible for users to communicate in either English or the local language, Farsi. In the case where users have a CCD camera and sound card connected to their computers, they will also be able to see and hear each other.

3. Software bank at the university computer center and the possibility of transferring files to and from remote sites (File Transfer Protocol, FTP).

Study and Investigations Performed in this Project

This project's main functions covered six areas:

1. Design and implementation of hypertext pages along with the scripts needed in the database. This was accomplished using software packages such as Home Site, Front Page, VB and Java.

2. Design and implementation of Access software for university departments which store information obtained from the University Information and Statistics Center and which is updated by the Computer Service Department of the university.

3. Creation of dynamic Web pages (ASP) for accessing related information on departments, students and the software information bank. With the help of these pages, users can access databases of the server environment.

4. Creation and use of E-mail by users from within the internal pages of the database with the help of the software called Exchange Server.

5. Creation of Net chatting with the use of Web pages.

6. Creation of Net conferences through the server with the use of Net Meeting software.
Conclusion

The development of a simple Intranet can provide essential information for faculty and students, plus the advantages of electronic communication in the forms of correspondence, conversation and network conferencing. The use of the Intranet offers endless possibilities in the development and progress of the remote education culture.

This article outlines the conditions, requirements and actions that were taken to establish a simple Intranet. One must consider that the work was performed under limited conditions, by faculty members and students from the Computer Science Department at an overall low cost. This should be compared to the unlimited current and future possibilities in the development of remote education that the Intranet and the use of computers provide to the University. It naturally follows that, as a result of this project, university departments will take more advantage of this and related projects.

The following outlines other areas that can be explored to make this Intranet more profitable and successful:

1. Separation of E-mail servers and the transferring of files from other system information servers so as to increase the number of users and the speed of services.
