What Tools for Adaptative Multimedia Telelearning

AJHOUN Rachida,
TALA, IERA, Morocco,
ajhoun@emi.ac.ma

BENKIRAN Amine,
département informatique, EMI, Morocco,
benkiran@emi.ac.ma

Abstract: In this paper we are mainly interested to present briefly a telelearning system where the learner is able to attend courses to his own rhythm and accesses only the elements of the course which relates to him. The power of our system is the use of widely available tools. This availability will guaranty a large opening and a larger audience. Our objective is to produce one generic course, which will be used to generate several specific courses according to the learner profiles.

Several telelearning applications were carried out to provide courses on the Internet (Harasim, 1999) (Padhye & al., 1999). Generally, the courses are hypertext documents. In this approach, a learner can access any sequence of a course without order constraints on these sequences and without having the necessary knowledge. Consequently, the teaching objectives (specialty, type of training...) aimed by the access to the course will not be reached. In our view and to ensure a pedagogical learning, the course must take account of the learner profile (capacities of training, previous knowledge, language...) and the learner evolution (prerequisite, speed...) (Fleury M.) (Bloom & al.).

In this paper, we are mainly interested to present techniques of adaptability of the courses in the SMART-Learning (System for Multimedia Adaptative and coopeRative Telelearning) project. The goal of our system is to allow a reliable adaptability of the courses to learners based on tools that are of a great availability and easy to use.

Functional model

The fundamental goal of SMART-Learning is to provide the learner with the sequences from the course which are adapted to his profile and according to the progress in the course. The profile changes are dynamically processed by the system. The author produces only one generic course and at the learning time, our system generates an individual course for each learner [Ajhoun & al. 2000].

To adapt a course to a given profile will recommend the author to take into account all various types of profiles as well as the pedagogic path to follow for each profile. To simplify the task of the course production, our system is conceived to guide the author by proposing some courses production models.

To make the courses evolutionary, the author uses the interactions of learners (questions, remarks, badly understood sequences...) with the system to improve his course. Using this feedback effect, the author will have the possibility of modifying the contents and improve its teaching techniques if necessary. This significant aspect is translated in the architecture of our system by a tight dependence between the phase of production and that of learning.

At the learning time, the profile changes with the advancement of the course. Every pedagogical sequence of the course should be generated in real time to take account of the new calculated profile. For this reason, our system proposes techniques of generation of the courses, based on the generic course produced by the author and the calculated profile of the learner.

Methodology of adaptability

In order to respect the adaptability objective, we have designed a model for the production of generic courses. This model provides the general structure of the course in accordance with the profiles of learners and the objectives aimed by this course. Our system integrates in the generated course the mechanisms to take account of the dynamic evolution of the profile during the learning (Benkiran & al. 2000).
At the end of each pedagogical sequence and if necessary, the learner make a self-evaluation test to control the knowledge obtained during this sequence. According to the test result, as well as other parameters based on the interaction with the system (e.g.: speed, spent time) and based on the educational graph, the system chooses the next pedagogical sequence to present to the learner. The educational graph represents the whole of the learning rules which control the succession of the different course sequences in order to achieve a teaching goal.

We applied this model using XML language, reputed by its facility to exchange complex document on the Internet, for courses production. This brings a double advantage:

1. The simplicity of production and updating of courses;
2. The ability to force the course structure and the links between the elements of the course.

To solve the problem of adaptability in its practical phase, we have defined an approach based on some XML specific tools (XSL, DOM...).

Why the Web

Make our system accessible to a large users require the choice of means and tools, which are available and known by great number of users. In our view, to provide courses to learners anywhere in the world, the use of Internet, is impossible to circumvent. Indeed, the number of users of Internet increases continuously (Bosak, 1997).

Designing software for the World Wide Web poses particular challenges to the design of user interfaces due in part to the limitation of bandwidth, and to the very nature of hypertext transfer protocol (HTTP) browsers as document retrieval systems.

The main disadvantages of the Web are bad interactivity, non-guaranteed quality of service, the difficult synchronization between the media and especially the structure of the HTML are opposed to some educational principles. This led us to find solutions at the design in order to avoid these problems.

The flow rate and the response time of the access to the Internet network depend mainly on the time and the place of access and can lead to bad performances to transfer the elements of the course which are multimedia documents, in particular in southern countries. To avoid this disadvantage, we propose several access modes to the courses. One of them, the off line mode consists in storing all the media elements of the course locally (e.g.: CD-ROM or disk). All the learning process is done remotely. To show a media element of the course to the learner the access is done locally instead of transferring the information from the server. This makes it possible to improve the quickness of the presentation and the interactivity with the system.

Conclusion

A prototype of our system was carried out and tested at our research unit with a great success and satisfaction. Furthermore, we underline the simplicity of the use of XML to provide adaptable courses on the Internet. Our approach has several advantages. We will mention its simplicity, the small data transfer between the learner and the course server – because only profile related data are transferred - as well as the negligible processing to adapt a course to each learner.

The Cosmos Web-based Explanatory Library (CosWbEL)

Saleh S H Al-Shidhani
School of Cognitive and Computer Sciences
University of Sussex, Falmer, Brighton, BN1 9QH, UK
+44 (0) 1273 678061, mapc0@sussex.ac.uk

Abstract: The Cosmic Explorer is a simulation-based interactive exploratory system aimed to provide an interactive means of simulating, exploring and studying cosmological models of the universe. This paper presents the web-based explanatory library of the system that takes into account the learner's difficulties in envisaging the cosmological concepts and adaptively presents the domain knowledge to match the learner's demands.

The Cosmic Explorer

Modern cosmology is an example of a complex dynamic conceptional domain and is best described by the General Theory of Einstein. The Cosmological Principle (CP) implies a homogenous and isotropic distribution of the matter in the Universe without giving an explicit definition nor sufficient distinctive description of what this mean in practice. Therefore, students face difficulties in grasping these concepts and their representations because their imaginary picture of the “big bang” event is often based on firework metaphor (Odenwald & Fienberg, 1993).

To tackle this situation we are developing the Cosmic Explorer that uses an N-body hydrodynamic cosmological simulator (namely Hydra by Couchman, et al. 1995) and a research-specific visualization utility (namely Tipsy by Katz and Quinn) to produce a realistic simulation of the real Universe and to provide scientific-class analysis tools. The system is aimed to promote conceptual understanding of the cosmological principle and confront several misconceptions associated with the expansion of the universe.

The practical goal of the CosWbEL is to support self-driven/distance learning, and to complement traditional learning settings. Here we adopt the view that Science teaching should reduce the emphasis on problem solving in favour of a clear and deeper understanding. One way to achieve this is by a heavy usage of visual illustrations of the concepts as well as comprehending its implication before concentrating on relevant problem solving skills. Consolidating the proper understanding can be helped by extracting several visual representations from real or simulated world(s) so the de-abstraction process will be easier. For example, the students can be shown visually the data form which the descriptive properties were extracted. Consequently, reversing the process will be easier for them, since they have visual images that go side-be-side with the description rather than purely theoretical imaginative thoughts.

During the process of refining the design, a preliminary study was devised to probe students understanding of a few key concepts. The study indicated a lack of proper understanding and incomplete background. The lack varied from one subject to another and seemed to depend on the speciality of the subject and on the relevance of his research project to the expansion of the universe and the large scale structure. Although this domain is addressed nicely in most of the recent astronomy introductory textbooks, a deeper understanding was not achieved probably because the students have taken few courses that cover the topic.

This situation set the rational for developing a web-based explanatory library tuned towards filling learners' understanding gaps. Providing the necessary coherent background is crucial since it is believed that this process is the most effective and efficient way to rectify several misconcepts specially naïve ones. Another valuable gain is comprehension of the current concepts as the next pivotal step towards providing a strong unfragmented foundation on which new concepts can be built. The ultimate goal of the research is "How the system can model the learner's reflections and provide dynamically generated meaningful choices.". The next section outlines the proposed library resources and the categorisation as initial attempt to grasp the nature of the problem and possible effective solution.

The Library Resources
The CosWbEL will consist of a comprehensive and structured database of the domain knowledge and a mapping of the relevant local and global resources. The knowledge database will consist of the following:

- Explanatory Text
- Illustrative Figures
- Interactive Diagrams
- Conceptual Maps
- Comparative Tables
- Associated Misconceptions
- Formula Sheets
- Units Listing Sheets
- Glossary Of Terminology.

As the above listing suggests, this section of the library will consist of online documents that present the cosmological concepts and their implications. The library will make use of a lot of visual illustrations that qualitatively show how these concepts apply in given situations as well as how they fit together as part of the whole picture. Furthermore, it will present examples of possible homogenous distributions and check for understanding and go deeper if necessary as a way of adaptive to the learner. Conceptual representations of the influencing factors have been prepared for five key concepts that are best supported by the simulation outputs.

Learners will be encouraged to adopt an exploratory learning methodology (Cox, 1992; al-Shidhani, 1999) since the dynamically constructed knowledge will be presented in a structured network. This mode focuses on synthesizing the applications of a certain concept from previously introduced cases. In addition, it emphasizes the generality by showing how linking between the concept abstractions and the specific cases has the same theme. The assumption here is that exploring such a conceptual network increases the understanding of the dynamics and the factors' interdependency. This approach adds elements of clarity to any explanatory text as well, it shows some implications of the concepts that are taught. In this way, the less complicated misconceptions can be pointed out and addressed easily at the appropriate place within the text, so building of new concepts goes step-by-step with comprehending and clarifying the current ones.

The mapping of relevant local and global resources will be aimed to associate the related resources to the constructed knowledge representation. The resources are classified as web resources, searchable databases and online discursive resources. This component will be an attempt to enrich the library resources by providing classified map to the diverse and vast resources available via the WWW and put the learners in control of their exploration and acquisition. The main distinction here is that learners are unlikely to get confused or lost in the huge web resources because most irrelevant pages are filtered out. The detail of the searching and filtering codes will be presented at the conference.

**Conclusion**

The CosWbEL is expected to facilitate the learning of complex and dynamic domains such as modern cosmology. The complementary approach of the knowledge representation has the potential to aid learners to build a coherent well structured conceptual understanding of the domain and enrich the subject teaching/learning experience and take advantage of the valuable www resources. Evaluation of its effectiveness helps to clarify the optimum utilization of the web in designing 21st century education.

Interactive Fiction: Model Development and an Example Created with DHTML and Microsoft Agent

Alan Amory and Devandran Govender
School of Life and Environmental Sciences
University of Natal
Durban 4041, South Africa
amory@nu.ac.za

Introduction
Interactive fiction (IF) appears to include both the adventure and role-playing games genres. However, Desilets (1999) defined interactive fiction as a "computer-based form of literature in which the reader plays the part of an important character, deciding, within limits, what action that character will take". That author argues that IF promotes student motivation, develops insights into elements of conventional literature, problem-solving skills, critical thinking and problem identification, and can be inexpensive to develop. McKee (1992) and Rieber (1996) agree that games can affect cognitive functions and motivation, and inherently stimulate curiosity (Thomas and Macredia, 1994) by including challenges and elements of fantasy, novelty and complexity (Malone, 1984; Malone and Lepper, 1987; Rivers, 1990). Educational researchers have investigated mainly two game types, simulation and adventure, as viable educational tools (Quinn, 1994, 1997; Roberts, 1976). Quinn (1994) proposed a model for the development of educationally sound games that attempted to integrate cognitive science, interface design and models of instruction. However, that theoretical model offers little practical help to guide game developers. In an attempt to formalize the relationship between educational theory, game design, play and development, we developed the Game Object Model (GOM) (Amory et al., 1999) (Fig. 1). While this model includes interfaces that create the ambiance of the game, Harrigan (1999) argues that dramatic theories (Laban, 1975; Stanislavski, 1976) could be incorporated into the design of educational software to heighten game play.

![Figure 1. Game object model (● - abstract interfaces, ○ - concrete interfaces). (From Amory et al., 1999)](image)

The primary objective of this study was to develop an interactive fiction prototype to evaluate the use of GOM and to extend this model to include an interactive actor. Secondary objectives were to teach young people basic astronomy and to evaluate the use of Dynamic Hypertext Markup Language (DHTML) as a viable authoring tool.

Materials and Methods
The basis of the interactive book is a story by Jenny Marais, a South African author of the book series for young people, Learning with Granny. Her stories attempt to integrate scientific knowledge into stories that stimulate and encourage scientific discovery in the reader. Two Microsoft® technologies were used to create the learning resource: Internet Explorer DHTML version 5 and Agent version 2 (http://msdn.microsoft.com/workshop/c-frame.htm#/workshop/imedia/agent/default.asp). The character selected for this project was Peedy, an animated parrot. While the development of the user-interface relied on VBScript, the puzzles were coded in JavaScript. Graphics were designed using Bryce (MetaCreations) and Photoshop (Adobe). The interactive book was created using DHTML embedded in a number of HTML frames (see Fig. 2). The pilot software was tested on two young people (a 10 year old girl and an 11 year old boy). An informal interview was held before and after the game was played.
Results and Discussion
Both participants were computer literate and had access to a computer at home that they used for recreation (playing games, drawing) and for school projects. They reported that they liked playing 'shoot-em-up' games and were familiar with Microsoft’s Encarta, WordPad, Paint and CorelDraw. Both reported that they used the Internet to find information, downloading computer games and looking at wildlife pictures and cartoons. Analyses of video recordings showed that participants used the interactive book in different ways: the girl spent more time carefully exploring and reading the information than did the boy, who spent more time solving puzzles. Klawe and Phillips (1995) reported similar results. Both players described Peedy as “cute” and commented on his friendliness and bright colours. However, they felt that younger children (8 year old) might find Peedy more appealing. When asked what type of a character they would have preferred, both agreed that an alien character or a parrot with a surfboard would have been better. The players enjoyed the interactions, collecting items and puzzle solving but did not enjoy reading all the text. They found the puzzle that required “matching the zodiac sign with its constellation” difficult and suggested that Peedy should help the user in such puzzle by providing clues about what to do. The participants thought that the story was a bit too simple, lacked a climax and did not support the complex ideas presented in the puzzles. At the end of the interview they commented that the interactive story was both fun and educational and would prefer other literature presented in this medium. Using DHTML to create an interactive story was fairly difficult to code but cheap to implement. The Common Object Model of Internet Explorer provided a framework for the development of this resource. The Agent and Speech components enriched the environment in that the inclusion of an interactive actor provided a focus for the player and made the interactions with the computer more meaningful. The inclusion of a virtual actor also adds an additional element of drama to the story and creates a more meaningful interaction with the player. Gestures made by the actor support the story line and provided additional information to the player. The Game Object Model and inclusion of virtual actors proved useful in the creation of the interactive story. However, DHTML is too difficult to use, as there are no software tools available to help in adding complex scripts to dynamic Web pages. The young players enjoyed interacting with the software and puzzles but thought that the story line should be more complex and felt that the interactive character was a bit too childish.

Abstract: This paper reports on the latest design updates and implementations of the task-based information support system AIMS. It emphasizes the visualization issues related to the overall system construction, implemented in the latest version of the AIMS prototype.

Background

AIMS stands for Agent-based Information Management System that aims at providing combined adaptive information support for students and instructors within the context of on-line course environments. AIMS helps students to get an overall conceptual view over the subject domain in which they work and to make a direct link with the course goals and assignments. They are also able to search for reference information and materials needed to perform a task as well as to explore the subject domain for better comprehension [Aroyo, Dicheva 99]. AIMS is built as an agent-oriented architecture, where agents' behavior is modeled in correspondence to the main activities involved in the process of task-based information retrieval. As a result of agents collaborative intelligent behavior, the system provides an intelligent user-oriented information support for learners and instructors.

What Do We Visualize and How Do We Realize it?

Main visualization target in AIMS is the presentation of the subject domain structure and the overlaying structures of the course and of the user model. As part of the supporting information search functionality AIMS proposes combined visualization of the search results. As the basic underlying mechanism for information structuring and presentation we use the concept mapping approach. Concept mapping allows the learners to connect new ideas to knowledge that they already have and to organize them in a logical structure. This way it allows them to see more complex relationships between ideas than just sequence and hierarchy. It is simple and intuitive visual form of knowledge representation well applicable for subject domain structuring and course tasks presentation. In this specific educational context, concept mapping appears to be a very useful technique for visual presentation of search results, domain and course structures. It is also used for course task and subtasks. The user model is build as an overlay model of the domain concept map. Search results are also partly presented with this graphical approach. The result documents are related to a result concept map of domain terms used in those documents. Documents are still organized in the traditional way of textual list-based presentation. Some metadata is also applied in order to support a better and quicker overall search result comprehension. Metadata in the form of short descriptive information and structured tags is also used in order to describe the context of the domain terms and links.

The visualization and domain navigation facilities help students to get orientated within the subject domain and to build up their own understanding and conceptual associations. It supports their visual thinking and imagination.
The GUI Issues in AIMS

**Student Support.** The student environment consists of a search facilitated with domain concept browser aimed at providing support to the student in the context of information search, domain exploration, and task comprehension. When the student logs in he or she can choose between working on a course assignment or exploring the subject domain and performing task independent search queries. The browser component visualizes a Concept Map of a set of domain terms and links in the context of the overall domain structure presentation, search results and course task presentation. Its functionality includes navigating (by shortcuts, history), bookmarking (terms, tasks, search results) and screen editing. The main AIMS functionality - searching for course related material is combined together with several options for refining search query and search results.

**Instructor Support.** Instructor support tools consist of domain, course, and library editors. The domain editor is aimed at providing support for the instructors to build and maintain the AIMS domain knowledge. Its functions cover building a new domain structure, that is, the domain concept map and the documents related to it, as well as editing and updating the existing domain structure, including terms, links, and documents. The concept map representing the subject domain knowledge is presented to the students to explore and is used to support their information search activities. The course editor is aimed at facilitating the instructor to build the structure of a specific course and organize along going tasks, course materials, and reference documents. Since the main goal of AIMS is to provide a task-based information support, a series of tasks are associated with each course. The main idea is that the system uses a task to constrain the information provided to the learner in support of his or her efforts to complete this task. Each course task is associated with a list of domain terms, which the student must know to perform successfully the task. Tasks are related also to course topics, which are automatically associated with the whole collection of domain terms included in each related task.

Understanding of Adults’ Metacognitive Knowledge about Information Seeking Skills via Internet

Petek A kar
Department of Computer Education and Instructional Technology
Hacettepe University
Ankara, 06532 Turkey
paskar@hacettepe.edu.tr

Serpil Yalcinalp
Information Technologies and Electronics Research Institute
ODTU TÜB TAK Ankara 06531 Turkey
serpil.yalcinalp@bilten.metu.edu.tr

Abstract: The purpose of this study is to understand the metacognitive awareness of variables that influence information seeking skills via internet among a group of university staff at Middle East Technical University, Turkey. Nine professors were answered the questions related to personal, task, and strategy categories. Most of the interviewers perceive the basic computer usage competence as a component of information seeking via Internet. Most of them complained about the bulk of search results, most of them are irrelevant which takes too much time. They indicated that goal and task definition is more important than to navigate through Internet. All of the interviewers indicated the importance of planning before starting to information seeking.

Metacognitive Knowledge

The general knowledge that guides effective selection and of task relevant skills has been referred as metacognition (Flavell, 1977, in Paris & Myres II, 1978). Metacognition has been used to describe our knowledge about how we perceive, remember, think, and act - that is, what we know about what we know. (Melcalfe & Shimamura, 1994)

Metacognitive knowledge consists primarily of knowledge or beliefs about what factors or variables act and interact in what ways to affect the course and outcome of cognitive enterprises (Nelson, 1992). There are three major categories of these factors or variables -person, task, and strategy. The personal category encompasses everything that you could come to believe about the nature of yourself and other people as cognitive processors. The task category concerns the information available to you during a cognitive enterprise. It could be abundant or meager, familiar or unfamiliar, redundant or densely packed, well or poorly organized, delivered in that manner or at that pace, interesting or dull, trustworthy or untrustworthy, and so on. The metacognitive knowledge in this category is an understanding of what such variations imply for how the cognitive enterprise should best be managed and how successful you are likely to be in achieving its goal. As for the strategy category, there is a great deal of knowledge that could be acquired concerning what strategies are likely to be effective in achieving what subclass and goals in what sorts of cognitive undertakings.

Information seeking is a kind of problem solving, which requires goal identification, task definition, search strategies, use of information, synthesis and evaluation. Internet and World Wide Web are changing our conceptions of information systems, which requires new search skills compared to the traditional environments, such as books and references. Open Ended Information Systems- OEISs differ from traditional systems in several aspects (Hill, J. R, 1999) which can be categorized as i. User orientation ii. System form and iii. Type of information retrieved. The user actively engages navigating and searching the system playing a primary role in processing the information retrieved. On the other hand, there are knowledge and skills, which are necessary for
problem solving and research independent of information system environment. In this study the metacognitive awareness about information seeking skills for Internet were investigated with respect to person, task and strategy variables.

**Personal Variables**

One relevant aspect of information seeking skills via Internet is the individuals’ s perception of the characteristics of good information searcher. All of the interviewers described the person who is good at information seeking via Internet as the person having information seeking skills that were gained at classic environments. Most of the interviewers perceive the basic computer usage competence as a component of information seeking via Internet. They indicated that the person who is good at using computers is the person who possesses the necessary skills for actualizing his purpose, is patient and knows the limitations of computers. More than half of them stressed the importance of using package programs. Interestingly, one interviewer responded that the person who's good at computers knows when to stop. On the other hand, two of them reported the importance of knowing English; since most of the information available on the Internet is English. Most of the interviewers reported that there is no difference on using computers regarding the gender. Persons stating the no differences, also proposed that success is related to the metacognitive skills. Two of the interviewers indicated that males are more successful while other two proposed that females are more successful. One of the interviewers stated that females are more successful since they are more patient.

**Task Variables**

Most of the interviewers complained about the bulk of search results, most of them are irrelevant which takes too much time. They indicated that goal and task definition is more important than to navigate through Internet. Therefore a person who will start to search on something need the necessary background and knowledge on the topic. In addition most of them indicated that open information systems don't provide them the articles that they need for their research study. However they responded that because of the interaction between the colleagues on the WEB, it is easy to access recent studies on one-to-one basis. One of the interviewers stressed the importance of how to perceive information on the Internet. He said, “If you perceive and regard the information as raw data which should be treated with suspicion and to be elaborated and validated then it will cause no problem. “ One of the difficulties with the task environment shared by most of the interviewers is the difficulty to follow and read the information on the screen. One of the problem that most of the interviewers stated that in open information environments it is not possible to see the whole and also it is not possible to see how much portion that you reach. This yields a very uncomfortable situation.

**Strategy Variables**

All of the interviewers indicated the importance of planning before starting to information seeking. More than half of them stressed the organization for efficient search. It is interested that interviewers from social sciences prefer to access reliable and well-known institutions, such as government bodies, universities and research institutions. On the other hand interviewers from science departments prefer keyword and author search using search engines. Most of the interviewers stated they prefer to read and analyze the material on paper rather than on screen. In addition more than half of the interviewers indicated that the people who are completing the search through shorter links are more successful than the others. This response is related to the planning and organization, which is stressed by most of them.

«Darwin’s World»: Hypermedia Technology to Enhance Scientific Thinking in the Kids

Michel Aubé

2500 Boulevard Université
Sherbrooke, Québec, Canada, J1K 2R1
maube@courrier.usherb.ca

Robert David
Université de Sherbrooke
2500 Boulevard Université
Sherbrooke, Québec, Canada, J1K 2R1
robert.david@cyberscol.qc.ca

Abstract: Scientific training requires much more than simply communicating content matter. In adult scientists, research activities involve complex collaborative work through which scientific rigor is achieved. This suggests that kids should best be trained into critical thinking by being immersed into real scientific communities wherein they could produce relevant knowledge and pursue significant exchanges with «real» experts. Hypermedia technologies now permit creating learning activities that meet such requirements.

Introduction

Within the typical school curriculum, scientific training is usually achieved through presenting the kids with the normative content of the discipline. More active and involving formulas also include laboratory work, field observations and personal research projects, yet most often rigorous and critical thinking still rely upon conformity with traditional material and examples, and upon applying logical or methodological rules. Moreover, even among scientists of the cognitivist tradition, there is still a clear emphasis on learning as basically an individual process, resting upon the learner’s past knowledge and acquired cognitive skills. But should this epistemological view be applied within the scientific community, not much progress could be made. Among «real researchers», collaborative work and mutual dependence are rather the rule: it is not just a matter of sharing knowledge and data, it is probably the essential way through which scientific rigor is achieved. Theories and data are thus compared and confronted, imaginative and provocative new ideas are generated and edited, and consensus in spite of the diversity of data sources and viewpoints provides the basis for critical thinking and solid theorizing. The question is then to engineer scientific curricula for the kids that would put them into the role of «real» researchers, interacting with «real» members of the scientific community, through activities that make sense for them. Moreover, these projects should constitute «real» knowledge contributions, and should by the same token attract expert scientists to interact imaginatively with the kids.

A Social Constructivist Perspective

«Darwin’s World» (Aubé, de la Chevrotière & David, 1999 – http://darwin.cyberscol.qc.ca) is an educational project using hypermedia technology so as to meet these goals with children from elementary and secondary schools all over the world. It is part of a larger project, «CyberScol» (http://cyberscol.qc.ca), aimed at providing school teachers with powerful tools, developed on the Internet, to help them meet the objectives stated within the governmental programs. Many disciplines are covered in CyberScol, from language skills to humanities, to physical sciences. Although more specifically concerned with activities from Biology and the natural sciences, «Darwin’s World» has been developed so as to foster and enhance rigorous thinking, along with the skills required to apply the scientific method. Hypermedia technology is used to enable and sustain articulate production and communication, and for inserting the youngsters into real scientific communities, as responsible peer researchers, interacting through electronic mail with a community of Biologists who act as consulting experts.
One typical example of a learning activity found in «Darwin’s World» consists in the adoption, by a whole classroom, of an animal species from the local surroundings. This choice has to be approved by the project team, and it involves a commitment to produce, on the project’s web site, the best card-file describing the identity and the ecology of the species. Only one class in the whole world could adopt a given animal, so as to promote responsible expertise for the research done. The scientific content has to be validated by at least one expert Biologist, most preferably a specialist on the adopted species. Moreover, all the texts written have to be validated as to their linguistic quality (composition as well as spelling). The kids’ commitment also includes constantly updating the card-file, and behaving as experts in case of public (or even expert) questions coming through the electronic mail. Computer forms are available on the web site, to guide the children into researching and selecting the relevant data, and the results are saved within a growing animal data base. The web site posting the card-file is automatically generated from these forms, and various multimedia elements (sounds, pictures, animations, hyperlinks…) could be inserted to enrich the ongoing description.

Two main objectives are characteristic of «Darwin’s World». First, kids have to build up their own knowledge, but this process has to be achieved through collaborative work, among the children themselves, but also with a large diversity of resources (books, web sites, CD, TV programs…), and with a few knowledgeable experts. They thus have to compare data, elucidate contradictions, raise new questions, and by doing so, to develop articulate thinking. Second, they have to become responsible for whatever knowledge they produce. Their work is to be posted on the web site; with the help of experts, they have to guarantee the scientific content of their research; they have to raise new, relevant and stimulating questions; their names and class photograph clearly associate them with their contribution. The approach advocated here stems from a socio-cognitive approach, and is strongly based upon empirical results about collaborative learning, the transfer of knowledge, science teaching and computer applications in education (Campione, Shapiro, & Brown, 1995; Palincsar, 1998). One central idea is that scientific attitudes might be acquired in a way similar to language skills, provided that the kids could be involved, as adult researchers most frequently are, in significant communication and exchange with other researchers. They could thus participate into building knew knowledge, for the value and utility of which they could truly be held responsible. Hypermedia technologies now permit such feats by combining many resources at once: accessing complex information distributed over a variety of web sites, producing and publishing complex information of high quality content, and communicating quickly with a community of experts, for discussion and validation.

Conclusion

Many objectives are reached by the same token. The kids are deeply motivated into serious work and rigorous verification of all kind of information to be posted. By requiring constant interaction with computers, the activity fosters computer literacy, yet it also incites to look for various sources of information, including books, journals, films, and other people. The complexity of the task also naturally leads to cooperation: individuals are not in competition and they need each other, which creates a positive climate in the classroom. The quality of the site also incites collaboration from the experts, and their comments motivate further the kids’ work. Finally, the approach is clearly project-based, creating learning opportunities through complex problem solving.

Training Students to Become Web Authors: Evaluation of a Training Methodology

Patricia Ryaby Backer
San Jose State University
Department of Technology, 1 Washington Square
San Jose, CA 95192-0061
pabacker@email.sjsu.edu

Abstract: This paper describes the development and evaluation of a training methodology to teach students how to create web pages. The training methodology evolved over two years and involved three stages of testing. The data from 1999 (current model) reveals two contradictory results. Approximately one-third of the student teams did worse than students from 1998 but half of the class received a better score than the previous year. Due to the small sample sizes and the results, it is impossible to state whether the new training model is superior to the previous two models.

Introduction

This research project built upon previous work on the nature of student use of computers for instruction (Backer 97). Backer (1997) analyzed student learning in constructing an electronic portfolio using computer-based multimedia development tools. The development of portfolios by students was not a cursory process. In order to be effective, portfolios require students to become self-reflective and view their work as a whole rather than as unrelated pieces. Electronic resumes, as natural technological outgrowths of portfolios, can expand this active process further by encouraging students to express themselves visually as well as in written form. In addition, this study showed that the use of electronic portfolios brought learning that is interactive and socially based.

The question then evolved for the investigation in this current project. Since students approach the design of multimedia in diverse ways and with varying results, how do they approach and learn how to create web pages? This question formed the basis of this qualitative study where the focus was on attempting to determine how students learn to use new tools rather than on the final projects.

Evolution of the WWW Training Methodology

The goal of the training was to teach students how to design web pages. The actual training methodology has evolved over the past two years. In Stage One (1998), the training model for web authoring was simplistic. The instructor made the assumption that the students, since they had experience in developing multimedia, would have little trouble developing their first web page. The training consisted of a presentation on HTML, a class exercise on HTML, and a demonstration of HTML editors.

Based upon the results of Stage One (see Backer 98), the training methodology was expanded in Stage Two and was more elaborate. Stage Two was done as a part of summer 1998 workshops on incorporating multimedia in education for K-12 teachers (see Backer & Saltmarch 99). These training workshops were organized by the Mathematics And Science Teacher Education Program (MASTEP), a five year NSF sponsored consortium to improve mathematics and science in the greater San Francisco Bay Area. The first two steps were the same as in Stage One, however, after these steps there were additions to the training methodology. The students were given a six-lesson, self-paced tutorial on how to complete a web page that they were required to complete. After the tutorial on HTML, there was a demonstration of Adobe Pagemill followed by a self-paced tutorial on Pagemill. Pagemill was used as the web editor as it had been donated to MASTEP by Adobe Systems as part of a software package for the students.

The quality of the web sites produced by students in Stage Two was significantly better than the quality of those produced in spring 1998 (Stage One). The simplistic error problems found in the first investigation were virtually
absent this time. In addition, the students appear to have the better grasp of the nature of web authoring than did the students in spring 1998.

The Stage Three model built upon the results of the previous two stages. For the Spring 1999 class, the training methodology differed slightly from stage two and was enhanced. Instead of starting the instruction by discussing HTML, a section on web design and web structure was added. In addition, the first day's lecture focused on design criteria for effective web pages. The next three steps were the same as in stage one and two. After this section, additional days were added to specifically address graphics, JAVA, and complicated HTML tags. The training model for Stage Three was as follows:

1. The instructor gave a web-based presentation on web structure and design criteria for effective web pages. This was done on day one.
2. The instructor gave a computer-based presentation on the structure of a web document and the basics of HTML. Then, the students were given handouts on basic HTML tags. This presentation was followed by a class exercise on coding a web page. For this exercise, students were given a screen shot of a web page along with the text present on the page. They were asked to add the correct HTML tags to make the basic text have the same format as the screen shot. After they finished, they were given a handout with the correct HTML code so they could compare it to their own coding. These steps were done on day two.
3. Next, the students were given a self-paced tutorial on how to complete a web page. The students were required to complete the six-part tutorial. The students were given the diskettes and asked to return them on day three.
4. Because of the problems with graphics evidenced in the summer workshops, one day was added to focus on using graphics on the web.
5. At this point, the instructor gave a computer-based presentation on Microsoft FrontPage to construct Web pages. After the presentation, the students were given self-paced tutorials on Microsoft FrontPage. They were required to complete this tutorial before beginning their own web design.
6. Three additional days were used to address specific web issues. The topics covered in these presentations included links, lists, tables, JAVA applets, and frames.

Results

The analysis of the outcomes (i.e., the web pages provided by the students) was done by reviewing the errors in the final web pages submitted by the student teams. The average grade for the final web project in 1999 was 75%; this compares to a class average of 77% from 1998. A t-test of the data shows there were no differences in the results from the two years although the variance for the second year was much higher than in 1998 (105.17 for 1999 versus 39.53 for 1998). More student teams received higher scores (50 and above) in 1999 as compared to 1998. However, in both years, there were some students who received very low scores: two students in 1998 received scores of 36/50 and three student teams received scores of 30/50 in 1999.

The data from 1999 reveals two contradictory results. Approximately one-third of the student teams did worse than students from 1998 but half of the class received a better score than the previous year. Due to the small sample sizes and the results, it is impossible to state whether the new training model is superior to the previous two models. The researcher is currently re-testing the third training model during the Spring 2000 semester in order to determine whether it provides a more effective method of training students to develop WWW materials.

Abstract: The leaders of 24 computer facilitated learning projects in higher education were interviewed about their educational beliefs and practices, and the transcripts and associated documents were coded on 16 belief and 16 practice dimensions. Shared patterns of beliefs and practices were sought by clustering the projects with the aid of hierarchical methods. Three example profiles are provided to illustrate the belief/practice connections which, although apparent, are not simply defined. Subsequent analyses will be based upon project narratives.

The impetus for the present work came from recent interest in the beliefs and understandings that academics bring to their teaching (Kember, 1997; Samuelowicz & Bain, 1992) including their use of educational technology (Bain & McNaught, 1996). There is some research suggesting that academics’ educational beliefs and practices are closely coupled (Bain 1998; Quinlan, 1999), but more work is needed to uncover the details of the relationships involved, particularly in relation to educational technology (Reeves 1992).

For this study we selected 24 university projects incorporating computer facilitated learning (CFL), based on documentary material provided by an Australian competitive granting agency. We conducted two detailed interviews with each project leader, each of about two hours duration. The first interview sought information about the academics' development and implementation of CFL, and the second probed their epistemological and educational beliefs. The semi-structured interviews were audio recorded and transcribed. Two interrelated analyses are being undertaken, one to result in detailed narratives of the cases, the other to provide an analysis of the patterns of belief and practice. A preliminary version of the second analysis is reported here.

The transcripts and documentary material were used to code academics/projects on 16 belief and 16 practice dimensions, with coding based on the full weight of evidence rather than localised interview comments or archival details. Some of the dimensions were drawn from published sources (Bain et al., 1998; Samuelowicz & Bain, 1992; Reeves 1992) and others from preliminary examination of the interview transcripts and project documentation. Most dimensions were five point bipolar rating scales (c.f., Reeves, 1992), but others involved qualitative differences that could be ordered from less to more sophisticated. Examples are presented in (Fig. 1).

A preliminary analysis of the data was undertaken by applying hierarchical clustering (using several methods and distance measures) to the full set of dimensions. The aim was to find similarities in the belief/practice profiles of the participants. Six clusters were tentatively identified, three of which are illustrated with individual cases in (Fig. 1), using 15 of the 32 dimensions. What is evident from (Fig. 1) is
that, although relationships between belief and practice profiles can be discerned, they are not simply defined. Some beliefs and practices seem to be interconnected in ways anticipated by Reeves (1992) and Bain et al. (1998) (e.g., beliefs concerning the origin of knowledge, the type of understanding and the role of discussion, and practices such as learning control, learning process and learning framework), but others are not.

Although this profiling approach is useful as a preliminary way to compare and contrast projects, we are convinced that a full understanding of the connections between beliefs and practices awaits the writing of the academics' narratives, based on their detailed commentaries and our rich descriptions of the CFL and its educational context (c.f., Bain, 1998; Quinlan, 1999). We anticipate that, once the narratives are to hand, we will be able to group like projects more convincingly than the profiling and clustering methods allow.

**Figure 1: Profiles of three CFL projects on seven belief and eight practice dimensions**

Abstract: The Supporting Collaborative Community (SCC) model of instruction restructures learning environments to access the strengths of both individuals and the class as a whole by overtly emphasizing those moral relationships that define true community interaction. The SCC model creates this enriched environment through emphasis of four main features: support of clearly-articulated purposes or tasks, regard for each individual's unique worth and diversity, acknowledgment of one's responsibility to others, and a sense of obligation to share. Allowing students to "own" their experience and enabling the group to benefit from each individual's strengths and assets fosters a supportive community where members feel safe to take risks and collaboratively explore new learning experiences. The SCC model lends itself well to the dynamic nature of online/distance learning when diverse members must establish their learning environment without the usual interaction that occurs in traditional face-to-face settings. Because online/distance learning so often occurs asynchronously amid other priorities and commitments, a community providing dynamic social and collaborative support can motivate learners while providing the reinforcement necessary to take full advantage of the learning experience.

Introduction

The Supporting Collaborative Community (SCC) model of instruction restructures learning environments to access the strengths of both individuals and the class as a whole by overtly emphasizing those moral relationships that define true community interaction. Where traditional classroom models focus mainly on the relationship between the learner and instructor and test only individual accomplishment, the SCC model overtly emphasizes the positive dynamics created through community interaction. This model actively seeks to establish an environment with three elements: one, encouragement of exploration without ridicule for mistakes or shortcomings (support); two, emphasis on sharing previously and newly acquired knowledge (collaboration); three, a sense of belonging through participation and interaction with others (community). Within this environment learners are encouraged to take responsibility for creating and "owning" their educational experiences. In doing so they become co-instructors interested in making the experience valuable for themselves as well as others. Attainment of the group goals then becomes worthwhile to each individual.

The SCC model enhances learning in situations where there are multiple learners, where there is enough opportunity and time to establish a connected community, where interaction between participants is encouraged, and where learning is more than memorization and recall of facts. Although the specific structure of the model will be different for every instantiation, the appropriateness of using this model is not restricted by course content, type of knowledge, learners' ages, or proximity to other group members.
The SCC Model

The SCC model enriches learning by emphasizing four main features. The first is support of clearly-articulated purposes or tasks which help orient the learners and define the community. These must be considered important both to the community and its individuals so each group member will support them. The goals or tasks should address something the community sees as valuable rather than unimportant exercises. Learners must understand the purpose for any learning in which they engage. The second feature is regard for each individual's unique worth and diversity. Each member needs to feel that they are esteemed by others as a valuable person with individual skills and perspectives to contribute to the whole. Likewise, they must sincerely learn to perceive others as such. Establishing a pattern of valuing diverse opinions and perspectives encourages the community to seek participation from all members, including those who are infrequent contributors in more traditional settings. Though diversity often requires compromise and a willingness to think differently, articulating this as a group goal and explicitly emphasizing its importance helps alleviate some of the frictions that naturally occur when diverse opinions are expressed.

Third, community members need to acknowledge a responsibility to others, which is, fundamentally, a commitment of accountability to and for each other. This responsibility creates a relationship of support. When members agree to learn with and from each other they strengthen the power of their interaction. Fourth, when learners feel the obligation to share, they are prompted to enter into interchange and interaction with others. Sharing is an essential component that makes collaboration so effective. Without it, a community cannot determine its goals or come to know each other through anything but superficial stereotypes. Sharing, even when doing so may put one in a vulnerable position, provides both opportunities to define oneself and allows bonding relationships to form. Sharing also benefits the community by giving it access to everyone's resources.

Online Learning Implications

The SCC model lends itself well to the dynamic nature of online/distance learning where diverse members must create an environment with online's own unique methods of interactions. Lacking a well-known schema often supplied in traditional settings (classroom structure, nature of the instructor, etc.), purposes, tasks and even roles are often negotiated and must be clearly defined online. While virtual environments naturally allow participants the freedom to define themselves without as many physical or other identifying features affecting others' perceptions, care and sensitivity must be exercised so that exchange between learners fosters true relationships of trust where each individual's worth and diversity can safely be shared. Acknowledging a responsibility to others helps to ensure honest interaction takes place. It also encourages all learners to contribute what they can to the experience.

Additionally, a sense of community commitment helps bond its members. Online/distance learning often occurs asynchronously around other priorities, commitments, and time constraints. The SCC model of instruction can help form a community providing dynamic social and collaborative support that motivates learners while providing the reinforcement necessary to take full advantage of a rich learning experience.

Abstract: Rapid development in the field of Multimedia, Hypermedia and Telecommunication (MH&T) is continually providing new work, study and research areas. The authors are of the opinion that these trends have found their expression within the ED-MEDIA (EM), which has meanwhile become the most important conference in this field, and intend to prove this hypothesis by the evaluation and classification of the published papers presented at the conference. The study is based on the assessment and analysis of theme structures, technological backgrounds and questions of contents, beginning with the clarification of methodological questions. Due to this rapid development, prefabricated categories cannot encompass a change in trend, rather, the categories must be developed on the basis of the information at hand. The authors present the argument that the "grounded theory", a procedure developed in social science, is a suitable methodical tool for the building of these categories.

1. Methodological Approach

In 1999, 600 submissions from almost 50 different countries were presented in Seattle. For the purpose of our trend analysis, a methodological approach should include all papers submitted, since our analysis will only include the papers accepted for publication in Proceedings of EM 99, the discrepancy may be considered a significant intervening variable. We feel that exploring the trends in MH&T in detail could lead to a more active and therefore influential implementation. Previous studies of this subject were mainly cursory, the evaluation being based solely on the subject of the paper. In 1996, Jim Devines' (NDEC) evaluation of the EM papers from 1993-95 into didactic sub-categories showed an increase in the instructionist approach (cf. Devine (1996)). We intend a more rigorous evaluation of the texts contributed during 1999. Pre-definition of categories, which fails to recognize the continual fluctuation within the media, is unsuitable for our undertaking. We believe that the papers' contents are equally relevant to this study, not just the subject of the paper. It is of greater importance to explore the relationship between the two main reference points: Education and Media, is this instrumental or are there other connections to be considered - social, organizational or political?

In Montreal, we intent to exemplify our proposed Hypothesis and operationalize the resulting category construction. Using the material of the EM 99 in Seattle as a temporal slice we shall demonstrate and discuss the proportional distribution of the individual categories (representation in percentages). After this presentation, we intend to implement our theory with data from the complete volumes of the EM, for the EM 2001 in Amsterdam. The extensive data mining and evaluation will be carried out by students of Business Education, Innsbruck University, Austria. In spite of the relatively extensive effort required in this research we believe that the results are relevant to the scientific community - understanding the direction of the research in this comparatively new field is almost as important as the research itself.
2. Tools: The Grounded Theory

From the viewpoint of Constructivism it is appropriate to place emphasis on the fact that truth and reality does not have an existence independent of the subject. This should not be misunderstood as solipsism. If we arrange the available data according to pre-developed categories our preconceptions appear to be confirmed. Our failure to reflect the process of assignation, and our methods, preclude our awareness of the blocking and changing done to the material. These considerations caused us to choose an alternative: The Grounded Theory (cf. Glaser & Strauss (1967), Strauss (1987)), which aims at overcoming this methodological circular reasoning. In an iterative research process the universal should emerge from the individual through induction. Also in the Grounded Theory, inductive conclusions are not used for logical argumentation and, currently, have no empirical validity. They are merely heuristic instruments for the development of a theory. None the less, the validity of the inductive assumptions constructed still have to be checked. The theoretical assumptions still cannot be proved (verified) but only disproved (falsified). This falsification, as well as questions of actual data distribution, does not lie in the scope of the Grounded Theory, whose aim is the generation of new ideas, categories etc., but of other – more traditional – empirical research methods. To discover a theory from data systematically obtained from research means to "ground" the theory into empirical research, because the construction of the hypothesis is not based on the researchers preconceived ideas but on the data and material itself, the supporting, objective structures can be made visible. Examining the actual data, we designate codes as nominators for the incidencies of every interesting case to be investigated further (indices), reducing the endless complexity of the reality (lateral coding). Next, we compare the different nominators, the defining rule for this method is: "While coding an incident for a category, compare it with the previous incidents in the same and different groups coded in the same category (Glaser & Strauss 1967, p.106)". Slowly, the idea of a new concept emerges, which is able to catch the different features of some of the indices: A new category has appeared and is developed by the researcher. Whether the constructed category is actually relevant (theoretically "good") can only be confirmed by searching the data for further indications of the new category (axial coding). Closer consideration of the characteristics (dimensions) of the category indicate the suitability of further subdivision, or of generalization (construction of meta-categories). With this step we have arrived at the level of core categories. The description of the relation of these meta-categories will generate a special kind of theory called "Substantive Theory". In contrast to "Formal Theory" (Glaser/Strauss), this has a very close connection to the subject field. It is a kind of "thick description" as Clifford Geertz calls the construction of meaning in an anthropological description (Geertz 1973). Insert the Picture here: http://www-ang.kfunigraz.ac.at/~holzinge/edmedia/proposal.html

3. Theoretical Sampling:

Every category which has emerged is just a tentative, and temporary, hypotheses. It is therefore possible that for a specific category no appropriate passage can be found. In order to find the reason, we must investigate that section of our original data input that caused the construction of the new category and to look for other possibilities of building categories; the sample is extracted according to factors dictated by theory. This "Theoretical Sampling" (Glaser & Strauss) is not concerned either with chance or with statistically representative samples, since a single case is sufficient for both the construction and the interconnection. A research completed in the Grounded Theory style is therefore not concerned with the quantitative distribution of particular proportions but rather the discovery of categories where we can put the data in. We have to repeat this process from data to category and back, following a cyclic procedure until all our categories fit to the data and no further categories emerge. Glaser & Strauss call this the saturation of the sample.

Help in the Search for Information in Hypermedia Documents

Alain Beaufils, Francois-Marie Blondel
Institut National de Recherche Pedagogique, Departement Tecne
91, rue Gabriel Peri
92120 Montrouge France
alain.beaufils@inrp.fr, francois-marie.blondel@inrp.fr

Abstract: This paper presents a system of help for the exploitation of hypermedia documents. It was derived from a common type of educational CD-ROM in which we added search and note-taking tools. The evolving note-taking system interacts continuously with the document being explored, and allows the user to keep the explored sections in mind. A study on usability of the search tools showed that the students prefer the index or the table of contents and neglected the cross-reference links. The activity of note-taking at every stage of their search favored their planning of the search.

Introduction

The consultation of hypermedia documents can be easy and satisfying when it is simply a question of discovering an individual item of content, it can prove to be more complex when it is a question of in-depth research in the context of one particular project. In a previous study (Beaufils, 1998), we sought to identify certain difficulties encountered by secondary school students using a typical hypermedia (the CD-Rom encyclopedia which deals with ancient Greece) in order to respond to a series of questions on larger themes.

In this paper, we describe a prototype which includes specific tools for information seeking in a hypermedia; then we discuss the results of several investigations on the usability and the usage of these tools.

A prototype for information seeking

Although it conserved the content, the structure and the index of the original CD-ROM, the prototype includes several new tools for searching, selecting and note-taking.

The search tools, such as the index or semantic cross-references, function by interacting with the table of contents. Colored highlighting allows the student to use these tools in order to situate the pages that have been found within the hierarchical plan. Users also have the option of placing the headings of all the pages which interest them in their own personal area. The personal area can be divided into several compartments, allowing the students to organize the material they had selected into such categories as: pages to visit, pages already visited, pages corresponding to themes existing in the document, or pages corresponding to themes resulting from their personal research plans.

This workspace is intended to function by interacting with the selection system. Several different types of notes can feature on it: preparatory notes (clues, bookmarks, personal knowledge), personal comments and pieces of information gathered during the consultation. The notepad is structured by topics defined by the user. She can put together the heading of a page, some excerpts of a page and also personal comments, arrange them under a named topic or move them to another topic.

The usage of the search and note-taking tools

The study involved six students, all volunteers aged 16 and 17 coming from a high school in the suburb of Paris. Students spent three sessions working on three questions: (1) the image and place of women in Greece, (2) the importance of the body in Greek civilization, (3) the good and bad aspects of Athenian democracy.
In numerous cases, the students only used one search tool during any one session. They were tempted to repeat, in a somewhat systematic fashion, the strategies that had already succeeded, as Weyer has previously noticed about dynamic books (Weyer 1982). The index and the table of contents were the most commonly used tools. The index was often selected as the first tool and generally enabled a highly exhaustive search. The readability of the table of contents ensures the fruitfulness of searches conducted using this tool (Dee-Lucas, 1996). Few attempts to extend the search using semantic cross-references were noted, mostly during the last session. Linear exploration was only used by students as a complement of other consultation methods. The number of pertinent pages found during the three sessions was high (85% or higher) which shows the effectiveness of the strategies followed, whatever tools were used.

All the students used the selection tool but they usually inserted the page headings in a single compartment, limiting this tool to its "storage" function. The putting aside of page headings helped in consulting these pages and reduced the risk of forgetting about them. The loss of pertinent pages was moderate (less than 30% for the two first questions), which attests to a satisfactory command of the operations of consultation and exploitation. In few cases, the possibility of creating categories within the selection gave rise to diverse strategies: planning which sections to consult or structuring those categories that had already been consulted.

The number of notes produced by the students at the beginning of the session ranged between three and around ten. These notes essentially designated sections to explore. We noticed the strong influence the preliminary planning had on the search for information and on the organization of the final response. The production of an initial structured plan led to a precise but inflexible representation of the goal to be attained. During their consultations, students may discover pieces of information that do not figure in their preliminary evaluation of the question. Such discoveries can lead to modifications in the final plan with respect to the initial plan. Over the course of 75 operations of note-taking recorded, 17 corresponded to an event leading to a noticeable modification of the final plan. Our observations show that in the majority of cases, the representation of the response did not develop in any notable fashion. One might suppose that the more elaborate the representation, the harder the subject will try to preserve it intact (Rouet & Tricot, 1998).

Closing remarks

We observed that the activity of note-taking performed by the students at every stage of their search for information (evaluation, selection and treatment) unquestionably favored how they managed the search and the planning: (1) the initial notes stimulate the process of evaluating the task, giving the students points of reference and freeing their memories from certain work; (2) the workspace the students are able to use must be unified but with the constant possibility of being reorganized; its function is to put three types of notes in relation with each other: the preliminary search plan, a selection of pertinent pages, and a selection of information gathered from these pages; (3) some aspects of the process of note-taking are neither spontaneous nor common, thus it is desirable to give the students specific advice at the beginning of the session or to expose them to some prior training.

By using search mechanisms that are relatively independent of content, associated with an open, flexible and evolving note-taking system, students can have the possibility of constructing a personalized hypermedia system within the document they are exploring. We are now studying how such tools can be adapted to facilitate similar activities with web resources.

Assessing the Use of Technology to Enhance Learning in Higher Education.

Karen Belfer
Technical University of British Columbia
Belfer@techbc.ca

Abstract: The present paper reports on the development of an instrument called "The Use of Technology in the Classroom", that assesses the use, application and quality of technology to enhance education. A brief summary of statistical analysis of the reliability and validity of the instrument is presented.

Introduction

The process of integrating technology to enhance learning implies a change in the curriculum, which means a shift on the philosophy of teaching, every day classroom practices and reassessing the way we learn.

One of the responsibilities of the Academic Computing department in Mexico's Anahuac University is to work together with the faculty in determining needs and opportunities to introduce technology to enhance the curriculum or course content, and to facilitate the research, development and training to support educational technology.

A proposal was advanced to formally assess the projects that were generated and supported by the department.

The use of technology in higher education

With the arrival of the new Millennium the use of technology in higher education has become a "must have" rather than a "nice to have". And "... any institution that is not able to integrate elements of technology into their current offerings will find themselves at a competitive disadvantage with the virtual universities" (Rao & Rao, 1999).

The rapid changes in technology, the constant demand from the working environment to prepare professionals capable of using the new technology, the institutional to make decisions related to the acquisition of hardware and software, are some of the reasons that make the introduction of the use of technology so important in higher education.

Bennet (1987) described three different roles computers have in education: education with the computer, education about the computer and management of instruction.

The use of technology in education has advantages (Russell, 1999) and the diversity of ways it can be integrated and applied is immense.

Evaluation of the use and quality of educational technology has always been problematic because of the inherent diversity and complexity of the possible applications e.g. (Biermann, 1994; Doll 1987) created check lists that help teachers and administrators, assess different options for educational systems. Those lists are practical to evaluate independently of the classroom learning context. They are simple to use to assess if the system is user friendly, well designed, has no bugs and is well documented.

However more complete require an empirical evaluation, that may be time consuming and costly. Comparing a group of students with control groups is one way of doing this.

Both methods of evaluation reduce the learning process specific factors: list of criteria to assess a systems like if was never going to be used by students, and students that are consider like only receptors of knowledge.

The use of technology in education can be regarded as a social process in at least two ways (Baumgartner, Payr (1995):

a) It takes place in a social situation (classroom, work, home).
b) The goal of a learning process is to help us adapt with prevailing social conditions.

This report purposes the evaluation of the use of technology to enhance learning through the three social dimensions that the student perceives:
a) The Teaching Quality
b) The Classroom Climate
c) The Integration of Technology in the classroom.

Process:
The idea was to create an instrument that experiment the level of satisfaction that the students perceive from the integration of the technology (basically software) with the course content.

Based on the idea that student's satisfaction would derive from having a good instructor, being in a comfortable learning environment (climate) and good application of the technology.

</tr>
</tbody>
</table>

**Method**

An exploratory study of the psychometric properties of the instrument was carried out with students of undergraduate courses where using technology to enhance learning.

There were 490 participants from 34 courses, 224 male, 266 female; from the schools of Architecture, Social Communications, Design, Business & Economy, Engineering, Pedagogy and Psychology. 38% were in year one, 14% were in year two, 29% were in year three and 19% were in year four.

**Procedure:**

The project was an internal evaluation, created and applied by staff of the university.

One person, the author carried out the administration of the instrument giving any additional instructions needed beyond those printed on the questionnaire.

**Results:**

The following statistical treatments were applied:

A) To validate the internal structure of the instrument a factorial analysis: with a varimax rotation.

B) To validate the internal consistency of each scale a Cronbach's alpha coefficient was calculated for each item and scale. Alpha of the instrument = 0.9604

C) Discriminant validity of the scales was indicated by correlation analysis between scales: (using the mean correlation of a scale with the other five scales as a convenient index). All values are small enough to demonstrate that each scale has adequate discriminant validity, but the conceptual distinctions among scales are important enough to retain the six dimensions within the instrument.

D) We conducted an Analysis of Variance for items for each scale to demonstrate that there is significant difference between items within each scale. All values have \( p < 0.001 \).
e) Differences between classes were identified using an analysis of variance between different measures of groups, using the groups as the unit of analysis. The results showed that the instrument did significantly differentiate between the perceptions of the students of the classes.

f) A final ANOVA was calculated to demonstrate the independence of the scale. With an F= 64.55 p<0.001.

g) Multiple regression analysis was conducted to determine the relationships between variables.

h) Structural Analysis.

Conclusions

The instrument has proven to be reliable and valid.

The structural analysis showed the Teaching Quality (F1) as the center of the use of technology to enhance learning.

This means that the instructor has an influence in the way the student perceives the Equipment (F2), Use of the System in the Working Environment (F3), System as a Medium to Enhance Learning (F4), System Characteristics (F6) and all of this factors affect the students Satisfaction (F5). As a teacher or as a facilitator he has a great influence in the classroom climate, students satisfaction and the way they perceive the use and application of the technology.

The technology has advanced so much in the last two years since the data was gathered that some adjustments may be necessary especially integrating items related to the more advanced ways of using technology in education and considering some adaptation for online learning.

This instrument was created in Spanish and validation was based on the Spanish version. Future research has been done with translation and validation of the instrument in English.

A Learner Centred Assessment of Quality for Online Education:
Course Climate

Karen Belfer
Technical University of British Columbia
belfer@techbc.ca

Abstract: The Technical University of British Columbia is committed to the development and delivery learner centered courses that have an online component an emphasis on collaborative learning. Assessing the quality of these courses requires a new approach. The TQM theory suggests that providing the client with a high quality product at all times is a very important constituent of quality. The social environment "climate" has a positive effect on students satisfaction. This paper describes the development and adaptation of an instrument that measures climate for online courses and the importance of using the results of the applications as an important stage of the overall TQM process that includes an ongoing monitoring and modification of the learning environment based on climate assessment.

Introduction
The Technical University of British Columbia (TechBC), the newest university in Canada, has been created as a unique learning environment to educate the work force needed for high-growth advanced technology industries. Recognizing the rapid growth in information and knowledge, TechBC's programs will emphasize not only the acquisition of knowledge, but also the ability to utilize and apply knowledge appropriately, critically and creatively.

The university is implementing a learner-centered education (Bonk & Cummings, 1998), where students' cognitive, metacognitive, motivational, affective, developmental, and social needs are met. Although perhaps not unique, the creation of a new institution affords opportunity to more fully realize this approach in the learning process. All courses have an online component, and most courses (with the exception of the flexible learning) have an emphasis on collaborative learning.

Assessing the quality of courses delivered in a team-based, online learning environment

Total Quality Management for Education: Climate

In the last two decades there has been an emphasis on the importance of quality in higher education, with attention focusing first on the definition of quality and, more recently, on how to evaluate and measure it (Harvey, Green, Burrows, 1993; Brindley, 1995, Municio, 1995, Williams, Watson, 1995).

The increasing number, and demand for, distance education programs is prompting researchers to ask what constitutes a good distance learning course from the perspectives of both the institutions and client. Some, like Scriven (1995), have even provided indicators such as policy development and management, staff development, service provision, and processes of open learning. Certain levels on these indicators have been suggested as benchmarks for measuring quality in distance education.

Municio (1995), William & Watson (1995), Scriven (1995), and Brindley (1995) all mention that providing the client with a high quality product at all times is a very important constituent of quality. From the assertion by authors like Fernandez (1995) and Lampikoski (1995) that client satisfaction is a good indicator of quality, it follows that student satisfaction is a key criterion for institutions to determine quality in distance education.

Many researchers have talked about students' satisfaction, and the effect it has on academic achievement (Fraser & Deer, 1983; Fraser, Seddon & Eagleson, 1982; Muñoz, 1996). Peterson, et al. (1986) established that a good social environment or "climate" has a positive effect on students' satisfaction.

In Canada, the Ontario Ministry of Colleges and Universities prepared Vision 2000: Quality and Opportunity (1990) that emphasized the challenge of developing well-educated citizens for a culturally diverse society. As one possible answer to that challenge, Evans-Harvey (1995) proposed that administrators and teachers promote and develop of positive learning environments in which culturally diverse students work in harmony while meeting their personal aspirations.

Climate has an influence on behavior, and can determine educational outcomes such as cognitive achievement, satisfaction, motivation, and personal development (Fernández, Asensio, 1989, p. 2).
The definition of climate is abstract and its measurement is typically based on subjective self-reports. Mainly what we see is that the definitions of climate are limited to the instrument used to measure it (Anderson, 1982).

There have been many instruments created to measure classroom climate in higher education for a face-to-face environment. These include the Classroom Climate Scale (CES) (Moos & Trickett, 1974), the College and University Classroom Environmental Inventory (CUCEI) (Fraser & Treagust, 1986), the Science Laboratory Environmental Inventory (SLEI) (Fraser & Wilkinson, 1993), The College Classroom Environment Scales (CCES) (Winston, Vahala, Nichols, & Gillis, 1989). However, only the Distance and Open Learning Environment Scale (DOLES) has been created for the specific purpose of assessing climate in distance education.

**Procedure**

After reviewing the DOLES literature where the authors describe the choice of assessment method, criteria for method development and validation used, it was judged to be effective in assessing most aspects of climate for online learning.

For this instrument to work in our university the measure of climate has to integrate both online and face to face components, so we developed an adapted and augmented version of DOLES that consists of 8 scales. The descriptions of each scale are presented in Table 1.

<table>
<thead>
<tr>
<th>Scales</th>
<th>Description</th>
<th>Sample Item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Students Cohesiveness</td>
<td>Extend to which students know, help, work together and are friendly towards each other.</td>
<td>It is easy to organize a group for a project.</td>
</tr>
<tr>
<td>Teacher support</td>
<td>Extent to which the instructor befriends, trusts and is interested in students.</td>
<td>The instructor sends me comprehensive feedback on my assignment</td>
</tr>
<tr>
<td>Personal Involvement / Flexibility</td>
<td>Extend to which the students participate and independently decide individual ways to approach course discussions and activities</td>
<td>I get a chance to discuss my relevant personal experiences</td>
</tr>
<tr>
<td>Task Orientation / Material Environment</td>
<td>Extent to which activities are clear and well organized</td>
<td>Expectations of assignments are clear in this course.</td>
</tr>
<tr>
<td>Interaction</td>
<td>Extent to which the students interacts with the instructor, other students and the content.</td>
<td>The interaction between all participants is high</td>
</tr>
<tr>
<td>Learner centered</td>
<td>Extent to which the cognitive, motivational, developmental and individual needs of the students are satisfied</td>
<td>The course offers a variety of activities</td>
</tr>
<tr>
<td>Technology Resources</td>
<td>Extent to which the technology is used to enhance learning</td>
<td>The technology resources in this course allow interaction between instructor and student.</td>
</tr>
</tbody>
</table>

**Conclusion**

Revisiting connection between TQM and climate, the five areas of focus for the theory of TQM, suggested by Sherr and Lozier (1999), were mission and customer focus, systematic approach to operations, vigorous development of human resources, long-term thinking, commitment. These five points form a complete theoretical system, and one cannot fully understand any one point without the other four. Creating the instrument that measures climate in online learning was just the first stage of a larger process that includes an ongoing monitoring and modification of the learning environment based on climate assessment.

Assessing the Potential of Electronic Discussion Groups to Enhance Learning in a Classroom-based Course

John F. Bennett, Associate Professor of Marketing
School of Business and Professional Studies
Stephens College, Columbia, MO., USA
jbennett@wc.stephens.edu

Abstract:
Internet communication tools like Web sites, listservs, e-mail, newsgroups, bulletin boards, and real-time chat programs have been embraced by many educators for their potential to enhance traditional classroom instruction. Specifically, the use of these tools is believed to enhance the three major activities of all teachers: to counsel students individually, to deliver information, and to encourage classroom discussion. This paper reviews the findings from a study conducted by the author that measures the effectiveness of using electronic discussion groups to enhance teaching and learning.

Survey

Convinced of the value of electronic discussion groups in enhancing traditional classroom instruction, the author has been requiring each of the students in an upper-level, undergraduate marketing course to subscribe to a listserv set up specifically for the class. Students used the listserv to argue pro and con positions on statements posted to the discussion list by the instructor. Half of the students on the list argue the pro position and the other half argue the con position. Their responses are then posted to the list and critiqued by other students. A different statement is sent to the list every two weeks and is often related to a current news event related to the concepts being studied. When possible, students are sent links to Web sites that provide additional information about the topic being discussed.

To assess whether the electronic discussion groups were producing the desired student outcomes, the author conducted a survey of all students that had participated in the electronic discussion groups over a two semester time period. A total of 52 students were included in the survey and all responded.

Data were gathered from the students by means of a questionnaire that was distributed both by e-mail and in class. The evaluation instrument measured 1) the extent to which students had used or participated in e-mail discussions; 2) their opinions on the effect that the listserv assignments had on their learning of course content; 3) a self-assessment of their level of computer experience prior to the course; 4) a self-assessment of their level computer experience after the course; 5) their assessment of the negative features of electronic discussion groups, and 6) their assessment of the positive features of electronic discussion groups.

The results indicated that approximately 67% of the students surveyed participated in e-mail discussions on a weekly basis, 13% on a daily basis, and 7% on a monthly basis. 13% of the respondents reported that they did not participate in the e-mail discussions at all. Among those that participated in the electronic discussion groups on a weekly, daily or monthly basis, the majority, 70%, reported that e-mail discussions had a moderate influence on learning the course content. 15% reported that the e-mail discussions had very little influence on learning the course content with the remaining 15% indicating that e-mail discussions had a substantial influence on learning.

Among those students who participated in the e-mail discussions on a weekly basis, the majority, 70%, reported that the discussions had a moderate influence on learning. 20% reported that the discussions had a substantial influence on learning with the remaining 10% indicating that the discussions had very little influence on learning.

Among those students who participated in e-mail discussions on a daily basis, 50% indicated that the discussions had a substantial influence on learning the course content. The remaining 50% indicated that the discussions had a moderate influence on learning. In other words, all of the students in this group indicated that the discussions had at least a moderate degree of influence on learning.

All of the students who participated on a monthly basis indicated that the discussions had a moderate influence on learning the course content.
The students were asked some open-ended questions to assess their perceptions of the advantages and disadvantages of electronic discussion groups in the classroom. Inconvenient access to computers with Internet connections was the least liked aspect of using e-mail. Students also indicated that they felt overwhelmed by the number of e-mail messages they were receiving each week. This was particularly true among those students who were on several class lists. Some students noted that there was too little discussion of the pedagogical benefits of electronic discussion groups. Consequently, at the beginning of the semester they failed to understand why in-class discussions were being supplemented with e-mail discussions. It was only after participating in the electronic discussions for a few weeks that the students began to understand and appreciate their value. Finally, some students lacked experience using a listserv and expressed a fear of this technology. The students noted that their participation in e-mail discussions would have been greater if they had received some remedial assistance with the technology being used.

One benefit mentioned by several of the students was that electronic discussions provided a convenient means of interacting with peers as well as the instructor. They appreciated being able to send and reply to an e-mail message at a time of their choosing. Students also noted that it was easier to collaborate with their peers on group projects. The frustration caused by trying to arrange convenient meeting times for a group of students to physically meet and work on a project are largely eliminated with electronic discussion groups.

A few of the students commented that they were more comfortable with written rather than oral discourse. They stated that they felt more willing to make provocative assertions during e-mail discussions and to challenge the views of their peers and the instructor. In short, they felt liberated by this new medium. However, a couple of students did indicate that had they been able to maintain their anonymity they would have been more willing to challenge the viewpoints of their peers. This is consistent with research showing that people are more daring and confrontational regarding the expression of ideas when allowed to remain anonymous (Lauzon, 1992).

Conclusion

Based on the survey results, electronic discussion groups do appear to enhance learning of course content. This is especially true among those students who reported that they participated in e-mail discussions on a daily basis. Therefore, instructors should consider incorporating electronic discussion groups in their classes and using strategies for encouraging students to participate in the discussions on a regular basis. To avoid the problem of students feeling overwhelmed by the number of postings made to the list, a limit should be placed on the size of the discussion group. In large classes, several discussion groups could be used.

Critical to getting students to be active participants in electronic discussions is to provide them with an understanding of the pedagogical benefits of this learning tool. A few of the students surveyed indicated that they did not understand the need for the listserv, which may have resulted in a lower level of participation.

Consideration should be given to the students’ level of expertise with communication technologies. The survey found that several students were unfamiliar with listservs and would have appreciated some training in their use. Providing this training at the beginning of the course would help ease these students’ fear of these technologies and increase their level of participation in the electronic discussions.

Those considering incorporating communication technologies in their courses should also be mindful of the difficulty students may have getting access to computers connected to the Internet. Ideally, all students would have their own computers that would provide access to the Internet. However, it is more realistic to assume that at least a few students will be wholly dependent on the institution’s computer resources. Should access to computers on campus be a problem for students, it may not be possible to make participation in electronic discussions a requirement in the course.

Finally, in deciding whether to use electronic discussion groups it is important to: 1) identify the best teaching and learning strategies for the class, especially those that would not be feasible without electronic discussion groups, and 2) identify which technologies are best for supporting those strategies. It may be found that electronic discussion groups would be poorly suited to support the teaching strategies being used. There may be other technologies, even conventional ones, that would be better suited for carrying out a particular teaching task.
Introduction

"Emerging approaches to developing rich learning environments combine multimedia, computer mediated communication, and a host of interactive strategies to connect people in varied and robust ways.” (Schwier, 1999)

The virtual learning community can be the key to opening the door to the world for the learner. Instructional technology is a powerful tool for students to communicate within a global community and develop knowledge, skills and attitudes about the world. Students can electronic communication tools, Internet resources, and multimedia documents to research information, develop inquiry skills, or discuss diverse viewpoints. Communication tools can link professionals, educators, and students interested in social studies, art or music. Projects can be developed for students in different settings to work collaboratively and internationalize the curriculum. Designing global multimedia projects can enrich the art, music and social studies knowledge base and broaden their global perspective. Through global methods such as these and regular integration of technology a community of learners can be developed (White, 1996).

The Model

This web-based project was initiated in the fall of 1997 to meet the Principles and practices of the Undergraduate Teacher Development Center in the College of Education at the University of Missouri-Columbia framework for diversity and technology (1995). The technology benchmark is: “Effective teachers use technology to participate in a community for professional development, to engage in personally meaningful inquiry, and to support teaching, learning, and assessment.” The diversity benchmark is: “Effective teachers encourage students to value commonalities and differences of our pluralistic world.”

The project emphasizes promoting and facilitating internationalizing the curriculum and uses technology as an integral component in the learning process. This project is an effort to implement the college’s framework by designing undergraduate curriculum to increase global perspectives and technology as they relate to art, music and social studies. Each term approximately sixty prospective elementary teachers are enrolled in the elementary art, music, and social studies methods block in which this model is implemented.
The framework for the model includes:

- Using technology is an integrated component in internationalizing of the curriculum of art, music and social studies
- Developing Internet resources for internationalizing the in art, music and social studies curriculum
- Accessing electronic communication tools to discuss internationalizing the curriculum
- Infusing technology into internationalizing the assignments, class experiences and electronic portfolio in art, music and social studies

The performance expectations for students in the project are:

- Use their e-mail, a class discussion group, a newsgroup, and online forms. Each of these forums for communication, inquiry, and reflection support the articulation of ideas, diverse viewpoints, and creative problem solving.
- Design interdisciplinary units of study, lessons and children’s museums, which infuses technology into the internationalized curriculum. Within these assignments the students are designing multimedia projects and using interactive strategies for learning.
- Building a model for discovering quality Internet resources for internationalizing the art, music and social studies curriculum
- Disseminating the projects in local elementary schools

This report is on the development of the program and the delivery systems for the infusion of technology into the internationalizing of the curriculum. As an ongoing project, the curriculum is being refined based on feedback each semester from instructors and students.

Conclusions

This model will stimulate an awareness of possible means for delivering an integrated internationalized curriculum through technology. The world is at the fingertips of any learner when quality Internet sites are woven into the curriculum. In a virtual learning environment the learner can build a model of discovery to find exemplary resources. Students can develop international attitudes and views through online communication tools, collaborate with students around the world on projects, research new bodies of knowledge, and design global multimedia projects.

One student’s response represents an example of how students in the project make the transfer from the integration of technology and meeting the needs of diversity in an elementary school.

“I think as future teachers we need to know how to use the technology because many of our future students will be more knowledgeable about technology than me. Technology communication allows students to correspond with other children around the world. With the ever increasing diversity, children need to be able to talk with other students that are not exactly like themselves.”

As instructors and prospective teachers make use of technology as an integrated component of their daily life, then we can discover new methods for combining the art, music and social studies and infusing diversity and technology. The shift in the pedagogical infusion of technology and diversity are key to the success of teacher education.

Experiences with *The Universal Machine: A Multimedia Introduction to Computing*

Glenn D. Blank, EECS Department, Lehigh University, USA, glenn.blank@lehigh.edu
Robert F. Barnes, EECS Department, Lehigh University, USA, rfb1@lehigh.edu
(http://www.eecs.lehigh.edu/~glennb/um)

Abstract: There are a great many books introducing computer science, yet few use the computer itself as a dynamic instructional tool. Interactive multimedia opens a door for students whose learning styles lean more to the concrete, participative approach, rather than the typically more abstract, reflexive approach of most computer science textbooks. Our experience confirms our approach, by way of significantly improving final examination scores. We also introduce our plans for a more constructive, inquiry-based approach to multimedia education.

We have written yet another textbook for the first semester course on computer science (CS0 or CS1), which WCB/McGraw-Hill published in 1998. It is accompanied by a multimedia CD-ROM. Media-rich material makes computer science accessible to a broader audience and stretches what an introductory course can cover. There are still relatively few CS1 books that emphasize the breadth of computing as an *intellectual discipline*, rather than as just programming. Nevertheless, CS1 also requires programming in languages such as C++. Our multimedia presents the dynamic aspects of program structure and provides online help driven by a student's errors. Though C++ is now the most popular language for introductory courses, its complexity poses certain disadvantages as well. We have therefore focused on a subset of C++ (which we call C+++), together with an integrated programming environment catering to beginners. Finally, we believe it is essential to teach problem-solving strategies before taking up programming--especially before the student dives into a programming language as complex as C++!

The multimedia helps students visualize and experiment with analytical and analogical problem solving strategies. *The Universal Machine* therefore has three major goals, followed in the structure of both book and multimedia:

1. To emphasize the breadth of computing as a discipline. A narrow concentration on programming can lead to a misconception that computer science is little more than programming. True, computer scientists use programming as an experimental tool, but like other scientists, they emphasize *abstraction*. They also use mathematical techniques to study computing *theory* as well as engineering techniques to improve the *design* of effective systems. (Denning 1988 emphasized these three approaches to the study of computing: abstraction, theory, and design.) We follow the recommendations of Tucker 1991 by introducing a broad treatment of computing as an intellectual discipline, with topics ranging from computer architecture to artificial intelligence.

2. To encourage students to think about and practice programming as systematic problem solving. An early chapter examines three alternative approaches to problem solving: hacking (illustrating the difference between blind and informed hacking with the well-known fox-goose-corn problem), analytical (which includes top-down decomposition), and analogical (ranging from copy and paste to object-oriented reuse and inheritance). Early on, students practice these approaches with a simple programming environment called *Knobby's World*. “Knobby the Knowbot” is a simple agent that moves and picks up objects in a microworld. Using a graphical simulation program, students first learn to program Knobby by issuing simple commands, then by progressing to defining and calling macro-instructions, and finally by writing programs. Knobby is a relative of Karel the Robot (Pattis 1981). The purpose of Knobby is in part much the same as that of Karel--to serve as a “gentle introduction to the art of programming,” though Knobby is more oriented to teaching C++ than LISP. Later chapters studying the software life cycle emphasize the systematic use and reuse of functions and classes.

3. To provide an introduction to computer programming that gives an adequate background for a continuation to a second-semester course suitable for computer science majors, without disenfranchising those students without previous computer experience. Because C++ (unlike Pascal, BASIC or LOGO) was not intended as instructional language, it can be rather daunting for beginners. We therefore concentrate on a subset of this very rich language, which we dub C+++. The multimedia CD-ROM includes a tool called LOOKOUT which will “look out” for errors in C+++- programs. Beginners typically have difficulty understanding the error
messages that modern compilers emit. LOOKOUT provides detailed explanations of error messages. Moreover, the multimedia, after presenting expository and interactive material on C++, invites the student to invoke LOOKOUT to study sample programs and develop simple programs. Thus the student learns abstract presentation (in both text and audio mode) interactive exercises in the multimedia itself, then by example and problem solving in the integrated LOOKOUT environment. LOOKOUT also supports a small library of software "classes" which lets students solve a variety of problems (especially non-numerical ones) using simple graphical shapes, musical notes, external files, and strings and arrays that catch "out of bounds" errors. For those who want to go beyond the C++ subset, there are optional "Beyond C++" sections at the end of C++ chapters in the book.

Creating *The Universal Machine*, was, to put it mildly, a challenge. Early on, while writing proposals to publishers, talking to people with more experience than we then had in developing multimedia, we began to talk about our "Greek chorus." They warned us gloomily about the inevitable pitfalls and problems we would encounter and advised us to increase our budget. Sure enough, we did encounter many snafus, personnel changes, miscommunications, conflicting priorities, and learning curve issues. It took two and a half years to bring out the first edition of the book with multimedia. A year and a half later we released a second version of the CD-ROM, cleaning up many bugs, adding multimedia material for two chapters which we were not able to include in the first edition, and giving the user more control over the interface.

The initial user interface put the user at the console of a space ship and navigated into one of three galaxies (the three major themes) and thence into star systems or planets (chapters). The analogy of this interface is that exploring outer space is like exploring abstract problem space. As we expected, many beginning students enjoy this interface. However, many sophisticated students, instructors (who make textbook decisions) and our publisher's marketing staff (alas!) thought it was "juvenile," unfortunately misleading them about the level of most of the content. So we have developed an alternative interface, presenting themes and chapters in text rather than galactic graphics, with rollovers bringing up summaries of each chapters. The user can choose between either interface at installation and switch between them. The user can also choose to disable sound, have the presentation stop after each screen (by default it advances automatically, which most of our students seem to prefer), skip the opening and credit sequences, etc.

While developing *The Universal Machine*, the lead author taught CS I (to a mixed audience of majors and non-majors) at Lehigh University, about 70-80 students each year. From the first year, for which only the manuscript of the book was available, to the second, in which an incomplete version of the multimedia was introduced, mean final examination scores improved about six points. Improvements were especially notable in coverage of breadth topics. In the third year, once the complete first edition was available, the mean final examination scores improved another seven points. This time there was significant improvement in the programming problems, suggesting that integration of LOOKOUT with the multimedia was indeed crucial. We expect further improvement this year, with the introduction of two new chapters and many bug fixes.

We now envision an avatar-based model of learning, in which students would interact with multimedia personae modeling the experience of learning at different levels. *The Universal Machine* features a narrator, who speaks text in a professional voice, but otherwise has no identifiable persona, and also a cartoon-like character named "Knobby" who pops up from a pedestal to ask the user to do exercises or to dialog with the narrator in the role of a learner. A lesson learned from this first attempt is that while less sophisticated users enjoy interacting with Knobby, more sophisticated students find him juvenile. We envision designing several different characters, representing learners with whom a wider range of students can identify, as well as different teachers, such as a professor, graduate teaching assistant and undergraduate apprentice teachers. These avatars would model students and teachers studying expository multimedia material together, as well as guiding students through interactive exercises, ranging from point-and-click quizzes to exploratory research using online information, such as Compendex and INSPEC.

Meta Groupware Design for CSCL Environments

Grégory Bourguin, Alain Derycke
Laboratoire TRIGONE, Institut CUEEP,
University of Lille 59650, Villeneuve d'Ascq, France
gregory.bourguin@univ-lille1.fr

Abstract: In the last few years, many different research areas have raised from CSCW. However, we can notice a general goal shared by all of those domains: create more user centered groupware, i.e. design system better responding to user's needs. Our experience in CSCL system design teaches us that those needs cannot be totally pre-defined but seem to emerge from user's activity. This involves reformulating the problem: we have to design CSCL systems supporting non pre-defined but emerging user needs. Work based on Activity Theory helped us in creating a new CSCL environment called DARE (Distributed Activities in a Reflective Environment) designed for this dare.

Introduction

The observation of the evolution of real uses by advanced educational actors (pedagogical designers, tutors) shows that they have a light planning of the activities: they start with a pattern of proposed activities but, during the process, they have an opportunistic behavior, revising and evolving their instructional strategies and learning activities according to the learner population reactions and progresses. It appears clearly that they need more evolving CSCL systems. Below, we present the design properties of DARE (Distributed Activities in a Reflective Environment), an environment for groupware support. DARE emphasizes on co-construction and expansiveness (Kuutti 1991) (Bardram 1998) properties of activity. DARE is a meta groupware that takes elements coming from both social science and computer science for its design. Roots of this model are coming from Activity Theory.

Key Concepts for design

Activity Theory (AT) has been identified as a hot issue for HCI and CSCW over the 10 last years, due to contributions from (Engeström 1987), (Kuutti 1991) or (Bodkers 1991). We will not expose here all AT. However, we would like to present some elements we found essential to understand DARE’s philosophy. First and according to Kuutti (Kuutti 1991), we define activity as our basic unit of analysis. Secondly, activity is mediated by artifacts and we use Engeström's basic structure of activity (Engeström 1987) model to create our conceptual model. Finally, we accept that elements appearing in this model are creating a situation that influences activity and that they are subjects to modification because activity always modifies its situation in a reflective fashion.

The concepts we use for our conceptual model are the object (the motive of activity), the subject (or actor), the community (a set of subjects sharing the same object), the tool (mediating the subject and object relationship; anything used in the transformation process), the rules (mediating the subject-community relationship; explicit and implicit laws, accepted practices...) and the division of labor (mediating the community-object relationship; explicit and implicit organization of a community). We have decided to synthesize the two last concepts in only one named role. Rules it represents strongly influence actions that subject may perform during activity by defining an evolving set of rights. Role mediates the relationship between community and object by determining what each role existing in community has to do to reach the object of activity, this corresponding to the division of labor.

Bedny (Bedny & Meister 1997) mentions that task is the basic component of activity. According to (Leont'ev 1977), task is “a situation requiring realization of a goal in specific conditions”. AT argues that situation is never given in advance and is the result of interactions. Activity starts with an initial situation given in the task. This situation is shared by all subjects involved in activity; it is transformed by task performance and concludes with a final situation. For our design, we accept that activity is created according to a given task defining the object of activity, the tools to be used and the roles. However, activity tends to modify its task until the end.
Open Implementation

Usually, CSCW systems implement a specific task that has been constructed thanks to a task analysis. Unfortunately, breakdowns often appear generally due to a shift between system’s embedded task and user’s one (or the representation he has constructed). If user is unable to understand the task the system really implements, or to adapt it to its one, then appropriation does not happen. Our meaning is then to allow users to access to the task in order to help in understanding the real task behind the system and, if needed, to modify it. This corresponds to the Open Implementation approach described by (Kiczales 1996). An existing technique for Open Implementation is Meta Object Protocol (MOP) (Kiczales et al. 1991) that helps in providing system interfaces for examination and modification, in other words, providing a meta interface. We have used MOP technique to implement DARE. MOP defines a meta level description of the system that is accessible to users. It allows, through a meta application, the examination (introspection) and manipulation (intercession) of the system during its own execution while maintaining a causal connection between this execution and its meta level. Our meaning is to apply those concepts in order to create a reflective system based on task and activity.

In languages implementing MOP, the meta level corresponds to the classes and the execution to their instances. In DARE, that is realized in Distributed Smalltalk & Java, everything concerning task is traduced in term of class, and activity in term of instance. This correspondence takes advantages of reusing the reflective properties of the languages that are used. This allows to modify the task during the corresponding activity’s execution. Task itself is an artifact manipulated by subjects according to their role. Task is part of and is modified by activity it defines in a causally connection. Accessing to task is a meta activity in which subjects may modify their working situation in a cooperative way. This offers a support for activity implementing concepts and mechanisms as described in AT.

Conclusion

This paper has briefly presented how we have used a simple model and mechanisms coming from Activity Theory to design a meta groupware that helps users to define their own activities. This meta groupware is named DARE. However, Activity Theory teaches us that activity is reflective in the sense that it is co-constructed and expansive. This is why DARE is more than a meta groupware but a reflective groupware allowing users to access the meta level of their activity during its execution.

During the following months, DARE is going to be used for experimentation in CSCL domain. The main idea is to provide to users (students and teachers) a bootstrap CSCL activity and to study how they use DARE reflective properties to adapt, evolve and co-construct this CSCL environment. This possibility to allow self-organization inside a learner group and co-construction of the collaborative learning activities is seen for us as an important contribution to self reflection activities.

HAPTIC VIRTUAL REALITY FOR TRAINING VETERINARY STUDENTS

Stephen Brewster, Michelle Montgomery Masters, Aidan Glendye
Glasgow Interactive Systems Group, Department of Computing Science, University of Glasgow,
email: stephen@ecs.gla.ac.uk, michelle@ ecs.gla.ac.uk
Stuart Reid, Nik Kriz
Faculty of Veterinary Science, University of Glasgow

Abstract: This paper reports on an initial and on-going study into the use of haptic (Schiff & Foulke, 1982) technology in veterinary education. The University of Glasgow has a commitment to the implementation of non-invasive procedures for diagnostic and education purposes in Veterinary Medicine, wherever possible. As part of the continued development in the use of technology in veterinary education, Virtual Reality is now being explored as a possible aid to teaching and in particular to replace invasive examination procedures.

THE PROBLEMS

One major problem in the education of veterinary students is the danger faced by animals when being examined by inexperienced students. The students need to gain experience in internal examinations (a key method for diagnosing problems and diseases) but it can be dangerous. The animals may become stressed, be injured or may even die because of unskilled internal examinations. Large classes of students mean that each person may only get a very limited amount to time learn the practical examination skills required. Another problem is that the students must learn about a whole range of diseases and problems as part of their education. At the time during their training when they are learning about a particular disease there may be no animal available with the particular disease in question. This means that students may not be able to consolidate their learning with practical experience.

THE SOLUTIONS

We are investigating ways to solve these problems by using haptic devices that allow users to feel virtual objects. There are three main benefits from our solution:
Safety: The use of haptic models to simulate problems allows the students to learn in a safe environment. They can learn on the models without endangering any animals. Once they have gained sufficient skills on the models they can then move on to the live animals with much less chance of doing harm.
Cost: The cost of education is also reduced. A large number of students can interact with the haptic models very quickly and cheaply. They can also do this much more frequently than would be possible with live animals.
Flexibility: The flexibility of the models is great. It is possible to simulate a range of diseases that the students would not normally experience. Different stages in the progress of a disease or condition can also be simulated. This can be done at the time the students are learning, allowing them to try out their theoretical knowledge immediately in a practical setting.

THE TECHNOLOGY
The technology to feel virtual objects is just now becoming available (Massie & Salisbury, 1994, Bryson, 1995). It was first developed so that users could feel objects in virtual environments. Minsky (in Blattner & Dannenberg, 1992) describes the technology thus: "Force display technology works by using mechanical actuators to apply forces to the user. By simulating the physics of the user's virtual world, we can compute these forces in real-time, and then send them to the actuators so that the user feels them". The device used for the work described is a PHANToM. This is a very high resolution, six degrees-of-freedom device in which the user puts his/her finger in a thimble or holds a pen at the end of a motor-controlled, jointed arm. It provides a programmable sense of touch that allows users to feel textures and shapes of virtual objects, modulate and deform objects.

THE HAPTIC MODELS

As mentioned, we are developing haptic software models that will simulate the feel of parts of a horse under examination. This shows two horse ovaries. The ovaries feel correct and they move in appropriate ways (if pressure is applied they can be moved in three dimensions in a realistic way). Both ovaries have very smooth, taut surfaces. The left ovary is softer and slightly smaller than the right one. A follicle can be seen on the left ovary (indicating ovulation is about to take place). This sticks out from and is much softer than the rest of the surface. The visual representation of the ovaries is built in OpenGL. The haptic representation is built using the GHoST software toolkit from SensAble. When vets are doing internal examinations they cannot see the ovaries, so the visual images are mainly for illustrative purposes. However, a visual representation is beneficial when learning to use the system. Our software allows the visual representation to be removed as required. The PHANToM device only allows the user to feel with one finger, not the whole hand. This, however, is not a limitation as vets will only use their thumb when feeling the ovary in a real examination.

EVALUATION

The development of the models has been performed using an iterative, participatory approach. Computing scientists have been working closely with vets to ensure that the models are correct. This has involved the building of initial prototype models and their continual refinement via expert user evaluation. The next stage in our work is to carry out evaluations with vet students. We will discover if the models are usable: can the vet students interact with them, use the device, etc. We will also be able to find out how effective they are: can students correctly identify the particular diseases and conditions we have simulated in our models.

CONCLUSIONS

One problem in veterinary education is that students must learn how to do internal examinations of animals but in doing so can be dangerous for the animals. Another difficulty is that there may not be an animal available with a particular disease when the students are studying it. The availability of haptic devices means that these problems can now be overcome. We have developed a set of haptic models of horse ovaries that will allow students to learn in a safe, cheap and flexible environment. Once they have learned the necessary skills they can move to working with live animals with much less risk of danger.

Online Education in Schools: Expectations, Facts, and Fiction

Peter A. Bruck, Techno-Z FH Research & Development, Austria
Guntram Geser, Techno-Z FH Research & Development, Austria
Thomas Olesch, Techno-Z FH Research & Development, Austria

As institutions of knowledge transfer and know-how generation schools are particularly effected by the rapid spread and extended functionality of the new information and communication technologies. The expectations concerning the benefits of the integration of ICTs in schools are high. Yet, there are many obstacles for a sensible use of these technologies in schools which are not easy to overcome. The financial capacity of schools to make the necessary investments into hard- and software are restricted by severe budgetary constraints. Local networks and internet access have to be adjusted, which is often a delicate exercise with flexible costs. Much of the multimedia content available on the market fails to serve the pedagogical needs; and - maybe the biggest problem - the new learning tools cannot be integrated into teaching practices, unless the teachers themselves have been trained adequately and are ready to transform their established working habits.

The paper will address the bundle of expectations around the efforts schools are making in order to be part of, if not to say spearheading, the Information Society. These expectations are set in relation to available hard facts on the effects of ICT implementation in schools. What happens, if school classes are equipped with computers and get connected to the Internet? What is the impact on classes, how does this influence the roles of teachers and pupils, and what is the impact on teaching and learning processes? The paper will contrast expectations with empirical facts, whilst "fictions" will be singled out and realistic and manageable routes to effective online education in schools will be suggested.
A CD/Web-Based Team Project
For Undergraduate Business Ethics Students

Abstract: This article describes a case-based undergraduate business ethics team project that uses CD and web-based computer technologies to advance the moral decision-making skills of students.

Today, computer technologies are fairly well integrated in business school programs. They are not so firmly established, however, in the humanities and combination academic disciplines such as business ethics. The following describes one successful case-based team project that uses CD and web-based computer technologies in an undergraduate business ethics course. As does business ethics, this project co-joins academic disciplines. Unlike typical business ethics projects, however, it links computer technology with business management and ethics.

An Elementary Business Ethics Model

Although similar to other team projects in its attempt to teach students to describe, analyze, and resolve business ethics problems, this project is unusual for its concentration on a relatively young undergraduate population (first year/freshman and second year/sophomore students) having little or no previous formal ethics, business, or web design training. The project itself is simple. It merely has the students apply theory, principles, and select cases to a business ethics problem. Although this approach to moral problem solving is not as useful as a rich business-specific casuistry, it is helpful in educational settings to convey the underlying norms and issues at play in practical circumstances.¹

In essence, the project is a summary exercise introduced at the beginning of the course. Students are assigned to four or five member teams, encouraged to meet with the professor to discuss acceptable cases, and then sent off to work independently. Students design or select a case embodying a particular moral business problem. They then analyze the case using the theories and cases learned in class, produce a CD-ROM containing their analyses, and present their findings to the class at the end of the academic term.

Technology

Not surprisingly, the project has evolved over the course of its implementation. Early on, we used a series of linked web pages to describe it. These pages were to serve a dual purpose: they were to describe

¹ For more on this distinction, see Martin Calkins, S.J. “Casuistry and the Case Method.” Business Ethics Quarterly. Forthcoming.
the project to students and to be used as a template. Unfortunately, the template notion was lost on most of
the students. To rectify this problem, we introduced a simpler template containing a single sample image
and basic navigation and e-mail links. This seemed to work better. We also revised the description pages,
reducing multiple pages to a single page. This made the pages easier to read and revealed how web pages
can be simple, yet effective and user-friendly. For early and later versions of our project description pages,
see:

  Early version: http://www-acc.scu.edu/~mcalkins/BE10777Pg1.html
  Later version: http://www-acc.scu.edu/~mcalkins/BE14573Pg1.html
  Template: http://www-acc.scu.edu/~mcalkins/index.htm

From the beginning, we promoted the use of HTML because we believed that HTML allowed
students to create and distribute rich and easy-to-use multimedia presentations over a variety of computer
platforms (MAC or PC). We also chose Macromedia's Dreamweaver as our web-authoring tool because
Dreamweaver, unlike other web authoring tools, relies on traditional word processing functions already
familiar to students. Dreamweaver also lets more advanced users include visual page design, dynamic
HTML, and Java Script in pages relatively easily. In addition, we required that students place their work on
a CD-ROM. This was to avoid university server space problems, potential server inaccessibility, hassles
involving the promulgation of ftp software, possible copyright violations, the necessity to establish student
web accounts, and so forth. At presentation time then, students simply bring their CDs to class and flip
them into a laptop that is hooked up to a large screen projector.

Assessment

At present, we have conducted this project over three academic terms. Our students' work can be
viewed at:

  BE Team Projects Fall 1999: http://medialab.scu.edu/mcalkins/fall99/index.htm

It is our view that the project has many positive attributes. It is simple and forthright. It promotes
clear thinking and linear, deductive reasoning. It encourages students to reflect deeply on cases, to
concentrate on the gist of arguments, and to think creatively.

At the same time, it may be no more effective than traditional paper-based projects in teaching
business ethics and team participation. To date, it has always been implemented alongside a traditional,
paper-based project. Each time, paper and CD/web-based projects were of similar quality in terms of the
students' ability to apply theory and principles to situations. Interestingly, student evaluations reveal that
two out of three times students expend the same or less effort on CD/web-based projects than they do on
paper-based projects (see Table 1). This finding initially surprised us, but makes sense given some of
today's students' familiarity with computer technology.

Conclusion

In the end, we recommend this CD/web-based project because we believe that it successfully
integrates three factors essential to the success of technology-based learning projects. It (1) facilitates
cooperation between the course instructor and the technology specialist, (2) keeps course goals before those
associated with technology, and (3) fosters a supportive environment for student creativity. We recommend
it, too, for its ability to help students see how ethics, management, and computer technology are more
compatible than unrelated.
At our institution we have been designing and developing interactive courses and course modules for some time. For example, recently we converted twelve one-semester Distance Education courses from traditional paper, audio and video to online and we are scheduled to convert many more in the next few years. These online courses are each a one semester course (36 hours of instruction) containing various modules some of which are highly interactive and some of which are not highly interactive.

The highly interactive components, also called Multimedia Interactive Learning Environments (MILEs) (Plowman et al., 1999), that we have been building for these Distance Education courses and other courses typically cover 1-3 hours of the course instructional material. The components are addressing instructional bottlenecks — parts of the course which students have been struggling with year after year.

Our institution has been creating a development process for high quality MILES, which optimizes the use of faculty time, student engagement and instructional staff support. By structuring development around a set of incremental prototypes and instructional design tools, the 7 C'S Model insures that support resources are applied at the right time and in the right measure to sustain learnware development. We are currently scaling up this process for use across the university, and developing partnerships for sharing the products and the process with other institutions.

The 7 C'S Model has the following components: (a) Content bottleneck (b) Course prototype (c) Co-op project (d) Class pilot (e) Courseware Exchange (f) Commercial product (g) resource Centre. The process begins with (a) a content bottleneck identified by a faculty member. This is a part of the course that has students have had difficulty understanding year after year. The faculty member feels that technology may be useful in overcoming this bottleneck. The faculty member sponsors a team of four students who build and test a (b) prototype learnware solution for course credit in a third year project-based Independent Studies course called Designing Learning Activities with Interactive Multimedia. Successful prototypes are developed into (c) pilot systems by students on co-op work terms (normally with support from the university and government). The resulting product from the co-op work term is then (d) tested with pilot classes. The best of these learnware solutions are shared with other institutions, either as (f) commercial products or through a (e) courseware exchange where the market is limited. All of these activities are supported by a (g) central resource group: in our case it is the Centre for Learning and Teaching Through Technology.

Status

We have developed the 7 C'S Model through pilot studies with 14 teams of faculty, students and staff. Five systems have reached the class pilot stage, one is now ready for commercial productization, and others are working their way through this pipeline. The process has now been institutionalized in the undergraduate course, Designing Learning Activities with Interactive Multimedia, which is supported by a Web-based support tool, the Learner-Centred Design Idea Kit (Carey, Harrigan, Palmer & Swallow, 1999). Two of the main features of the kit are a detailed learner profile section and a visualization of the learning activities based on Laurillard’s Conversational Model (Laurillard, 1993). The design of the kit itself was informed by constructivist educational literature and thus the kit guides our novice designers through a design process which is based on the latest research.
An Example

Perhaps this process is best illustrated with an actual example. This representative 7 C's MODEL project originated in Fall'98 when an Environmental Studies professor identified an Instructional Bottleneck in that year after year his students had difficulties appreciating and understanding Life Tables. There seemed to be two main concerns. First, the students didn't seem to appreciate that life tables are important in many fields. Life tables are used in many fields to determine the life expectancy - in environmental studies they are often used for plants and animals, in accounting they are used by actuaries in evaluations, and in the insurance business they are used in determining policy premiums. Second, about half the students did not have the math background to easily understand the math used in calculating the columns in a life table.

Students in our course created a design and produced a very primitive prototype in Winter'99. The design was broken into three main parts the first two of which addressed the lack of appreciation of life tables and the last of which addressed the math issue. The first section was a relevance section where video was used to go and interview people who work with life tables to show students that people in industry do use life tables. The second part was field trips that used video to show people collecting data for life tables in the field - for example one was tagging birds and another was counting the survival rate of trees. The third section was really the core of the system that allowed students to actually build a life table. This section had a lot of feedback, examples, and assistance to help learners who were having difficulties understanding the math.

In Summer'99 one of the students from the class group and one other were hired to finish the project. The resulting application is being piloted in the Fall'99 semester with approximately 100 students who are currently taking the course. In is anticipated that because Life Tables are used in many disciplines this product will be a good candidate for the courseware exchange or commercialization. Even within our own institution we anticipate that other departments many adopt, or modify and adopt, this application for their use.

All throughout this process the Centre for Teaching and Learning Through Technology has provided assistance with things such as: selection of tools, project management, feedback at various stages in the design/implementation, and overall advise on issues such as how to perform the evaluation.

Conclusion

In presenting our model we are showing the model that seems to work at our institution. We are not suggesting at all that this exact model is the best one for any other institution. It is a model that works and thus others may gain by exploring the model and adapting all or parts of the model for their institution. Perhaps the main point is that institutions need some such model - good instructional material does not come out of thin air - it has to be well thought out, plan, and implemented using a defined process. Also, it should be grounded in the research and practice that is documented in the literature (and which our Kit supports).

WWW-based Tools to Manage Teaching Units in the PLAN-G Distance Learning Platform

Clara Inés Peña de Carrillo
Ramón Fabregat Gesa
José Luis Marzo Lázaro
BCDS-DEIA
University of Girona
Building PII, Avinguda de Luis Santaló, S/N, 17071
Gerona, Spain
{clarenes,ramon,marzo}@eia.udg.es

Abstract: This paper describes a set of tools to assist teachers to support open and distance learning by means of the PLAN-G\(^{1}\) hypermedia system, developed at the University of Girona with the aid of computer networks and, in particular, WWW technology. The web-based tools permit the creation and edition of didactic material, the transfer, organization and management of document contents files, the generation and management of different types of interactive exercises associated with a teaching unit, and the creation and management of a teaching unit. The current PLAN-G prototype has been successfully used on courses in different educational fields.

Introduction

At present, the PLAN-G is a hypermedia system that allows access to learning material in a static way (Marzo, 1998a, 1998b). We are currently working to include adaptivity in it for a specific student based on the knowledge of a student model (Peña, 1999). The teacher builds a linear navigational path by defining a directed graph (structure), using the contents stored in HTML page files (teaching contents), and linking them according to curriculum organization criteria. To make creation easy and to manage the teaching domain, we developed some useful web-based teaching contents authoring and managing tools (Fabregat, 1999) such as the contents generator JVS, the exercise generator, the contents organizer, publisher and searcher, and the teaching units editor. This set of applications is included in the PLAN-G platform environment. The PLAN-G system was designed as a learning platform, in which the teacher supplies the course contents and the students can navigate through them. Each course is called a “teaching unit” and is made up of a group of HTML page files structured by a directed graph. By means of the administration options of the graph, it is possible to create, modify and delete “teaching units”, so giving the possibility of changing navigation destinations or defining linear paths. The navigational structure is managed independently of the contents and is stored in a database. Only the user type “teacher” has the power to adjust the structure and unit contents, as required. Basically, the PLAN-G works around three concepts: users, teaching units and a performance level defined by certain languages (the platform is multilingual). The system gives a configuration and a group of sessions and visits (static and dynamic data) to each user. Each node of the teaching unit graph has an associated group of basic exercises or bibliography and a selected language to fix the contents.

PLAN-G Teaching Units Management

The PLAN-G architecture, as a hypermedia system, has general components of generic intelligent tutoring systems. It has a hypermedia component represented by an interface, a navigation control area (buttons) and a navigation space. The tutor’s component adds intelligent behaviour to the system based on the pedagogic organization of the

\(^{1}\) This research was supported by the CICYTTEL98-0408-C02-01 project: “Study and implementation of a New Generation Telematics Platform to Support Open and Distance Learning”
domain of learning and the student’s preferences and activities. The JVS Contents Generator Editor, enables the teacher to create didactic material without having to write a line of code and with use of only the mouse buttons or input of some data through the keyboard. With JVS, each didactic content is made by a photogram sequence or some screen displays related to each other, which should include texts, lines, arrows, squares, circles or images to create an interactive teaching content with graphic effects and animations. By creating interactive graphics, the teacher or the student can perform multiple activities from the interactive exposure of an image. To generate the exercise domain associated with teaching concepts, the Exercises Generator was developed as a user friendly tool that enables interactive closed-answer exercises such as multiple choice, gap-filling, associations drag & drop, selecting the correct answer, etc. to be created and managed. The exercise domain can be managed either by the teacher or by the platform administrator who can create, import, export or modify any exercise, create an HTML page with a particular execution exercise independently of the PLAN-G, move exercise parts from one exercise to another, ask for statistics of results, pre-watch the exercise and include multimedia files to complete the exercise. The exercise generator also acts in the navigation module of the PLAN-G structure by collecting, analyzing and evaluating the student’s activities over the proposed training or evaluation material, and storing this knowledge in the database. Once the teacher has defined and created the didactic material, it is ready to be managed (organized, classified and published) in the server. The teacher must use the Documentation Manager tool to fix the files in the server if he/she has used any standard HTML editor to make the didactic material, because, the files made using the JVS tool are organized directly in the server by the tool itself. All the essential information for the documentation manager like, file owners, folders and filenames, folder locations, HTML and reference document words, is stored in the PLAN-G relational database; in consequence, any action over any document file that will be used to build a teaching unit will be updated in the database in order to ensure data integrity. The documentation manager also allows users to publish HTML documents on the network without specialist knowledge and to define easy search spaces over them, without any maintenance tasks or software installation. By means of a web-browser, the user may utilize the documentation manager tool to interchange files, to classify them and to design query forms for different document ambit; this tool is useful when the user decides to publish a large volume of documents and a rapid search through their contents is needed. Once the didactic material exists in the server in its corresponding directory path, the teacher should proceed to create the teaching unit by means of the Teaching Units Editor that enables the structure of the learning domain (hyperspace or traversing structure) to be created, defined and managed. Currently, PLAN-G just allows navigation on static way, and so the teacher can only create a directed graph over the learning domain. However there are some projects under way on using a multi-agent system to improve PLAN-G adaptivity by means of the information stored in user models.

Evaluation of Web-Based Distributed Collaborative Learning Community Based on Knowledge Building of College Students

Chi-Cheng Chang
Department of Educational Technology
Tamkang University
Tamsui, Taipei, Taiwan
samchang@mail.tku.edu.tw

Abstract: A web-based distributed collaborative learning community based on knowledge building for academic growth of college students was implemented and evaluated. The evaluation results indicate that it provides college students with effective telecommunication and collaboration tools, and students' responses toward the WBDLC have been very positive and encouraging.

Learning Environment of WBDLC

Students may actively learn through participating in knowledge building and collaborative-based activities as a member of an online group (Brandon & Hollingshead, 1999). An evaluation by Scardamalia & Bereiter (1994) of the CSILE (Computer-Supported Intentional Learning Environment) project claimed that collaborative learning community formed by students facilitated knowledge building and generated positive learning outcomes with the use of telecommunication technologies.

Through the use of telecommunication technologies of the Web-Based Distributed Learning Community of Academic Growth (WBDLC, http://etwblic.et.tku.edu.tw), it is intended to transform traditional classroom learning to better enable college students to engage the virtual and social practice of learning. The WBDLC consists of various functional elements and interactive types of telecommunication tools, thus users may learn the content relating to the course and social interaction with peer at the same time. These include: asynchronous discussion board, online synchronous chat room, real-time call on line, desktop video teleconferencing, access to the learning resources on the Web, links to the relative Web sites, online multimedia materials, files for upload and download, e-mail listserv, online learning portfolio, and asynchronous advice through field experts.

Evaluation Results of WBDLC

User Evaluation

Resulting from the survey of students' satisfaction showed that in general, they rated their learning experiences in the web-based learning environment consistently higher than those in the instruction of traditional classrooms. Students indicated that they learned more, the class was more interesting, they were more motivated, and that they were more active to learn. They also reported that they had a greater opportunity to be heard by the teachers, they heard more from their peers, and that they gained more help from and interaction with their classmates. As far as the students' feedback on the satisfactions for the content, interface, and functions of WBDLC system reported that the system interface is easily accessible and usable to users. Comments from students showed that they liked having hands-on experiences with the web, they felt comfortable with the telecommunication capabilities provided by the WBDLC system, and that they would be willing to participate the learning activities of similar system to the WBDLC. The in-deep interviews of small-group were also conducted by group sampling based on students' performances on WBDLC. The student feedback from the small-group interviews formed by several deeper questions provided some insight into what needs to be taken into consideration when using the WBDLC. Interviewing comments from students also provided more deep insight into the advantages and disadvantages in the functions, uses and effectiveness of WBDLC system.

Although the majority of students offered a very positive response in the survey and small-group interviews on the functions and uses of WBDLC, the majority also offered anticipated disadvantages including not enough time to participate the web-based activities and insufficient feedback of field experts. The majority of the students indicated that knowledge building through the sharing of student work and idea was a great activity and was helpful to their learning outcomes. On-line activities like hands-on learning, resources hyperlink, synchronous chat, and asynchronous group discussion were common preference for the majority of the students. Moreover, students liked getting access to resources such as websites relevant to course and learning materials, to information such as course information and teacher notes, and to knowledge such as posting and replying ideas from peer in the Discussion Board.

Expert Evaluation

The teachers reported that additional time is required to prepare learning activity and make teaching
materials on the web, however it is well worth the effort doing that in terms of greater learning efficiency and make themselves growth on teaching experiences. Moreover teachers also encountered obstacles in developing web-based collaborative learning activities for online groups due to the lack of support of providing teaching resources, experience of using telecommunication technologies, and familiarity with preparing and managing online activities on a web environment. It reveals that online teaching assistants are needed for web-based learning to help teachers doing relevant teaching activity and making decision on web. Our key insight to the evaluation results of the WBDLC system is the verification of its design, creation and use experiences.

Conclusions and Future Work

We work continuously with teachers and students at the Tamkang University to develop new curricular as well as more proper teaching approaches and strategies that use project-based and problem-oriented learning activities. The critical challenges the WBDLC will face in the future are not simply technological uses, but also the challenges of social interaction, knowledge share, and creating online communities of learners. The WBDLC can be a base to inform educators and policy makers on the effective and sustainable application of social, distributed, and collaborative virtual community on Internet for college education.

Assessing the Effects of Web-Based Interactive Learning Environment Based on Virtual Reality Simulation for Constructive Learning

Chi-Cheng Chang
Department of Educational Technology, Tamkang University
Tamsui, Taipei, Taiwan
samchang@mail.tku.edu.tw

ABSTRACT

Abstract: A VR-based interactive and simulated environment on web for constructive learning slide projector operation has been evaluated. The evaluation results report that this learning material has positive effects on students' learning outcomes. Finally some indication of further researches to be done will be given based on using the material developed in this study.

Learning Environment of WebVR

With the multimedia capacity such as 3D graphics and animation, Virtual Reality technology could dynamically simulate the manipulating processes of psychomotor skills for the goals of immersive learning and situated learning (Youngblut, 1997). Students could then manipulate the VR-based system dynamically and learn by their own hands-on experiences how slides are produced and a slide projector is operated that is impossible to observe in real situation (Moore, 1995). The types of activities supported by VR capability facilitate current educational application that students are better able to acquire, master, retain, transfer, and generalized new knowledge whenever they are actively engaged constructing their knowledge in a learning-by-doing situation (Youngblut, 1997).

In the VR-based learning world of operating slide projector on the Web (WebVR), students can easily move around within and freely navigate through the virtual worlds and do all kinds of actions, such as freely manipulating virtual objects in any degrees of freedom. Additional, students immersively existing in the 3D environment of WebVR may experience several degrees of freedom, including full freedom in navigation, the access to information through multiple interactions, and the capability to figure their own learning process.

Evaluation Methodologies and Results of WebVR

User-Based Evaluation

The survey was involved 35 undergraduate students in Teacher Preparation Program and undertaken by sending the post-course questionnaires to them. We evaluated the quality of the WebVR through doing qualitative study for mainly examining the functions, interface, content, and learning experiences by means of questionnaires that embrace specific questions. The results from the survey of students' feedback on the satisfactions for the WebVR reported that the system interface is easily accessible and usable to users. They also indicated that there are many learning materials that can be delivered more effectively by video and audio media that are not provided in the WebVR materials. Students reported that they liked having hands-on experiences with the virtual worlds, and they felt comfortable with the simulated capabilities provided by the WebVR material. The results from the survey of students' perceptions on their learning experiences showed that in general, they rated their learning experiences in the simulated VR-based learning environment consistently higher than those in the instructions of traditional classrooms. Students indicated that they learned more, the materials was more interesting, they were more motivated, and that they were more activate to learn. They also reported that they had a greater opportunity to be heard by the teachers, they heard more from their peers, and that they gained more help from and interaction with their peers.

Although the majority of students offered a very positive response in the survey on the functionality and usability of WebVR material, the majority also offered anticipated disadvantages. These disadvantages contained: not enough time to participate the web-based VR activities, low speed of system, insufficient realism of scene in the virtual worlds, and insufficient feedback of the materials, teacher and peers.

Expert-Based Evaluation

Three experts involved in the expert-based evaluation. The three experts consisted of a teacher as a subject matter expert in slide production, a field expert in web-based VR, and a field expert in computer-aided instruction and web-based learning. A teacher experienced slides production instructor who has been teaching "instruction media" for 3 years was invited to examine the correctness, appropriateness, and consistence of the learning content and objects. A field expert in VR experienced the design and development of web-based VR system was invited to check the functionality, usability, and interface of the
WebVR. A field expert in computer-aided instruction and web-based learning experienced the design and development of CAI and WBL was invited to provide opinions on the VR-based instructional design and learning strategies used in the WebVR.

Conclusions and Summary

Based upon the evaluation results of WebVR, it is a helpful tool both for students and teachers in the learning process. This is concerned about the experiences students gained from the free navigation and high interaction afforded to them, and from the exploration of basic skills of operating slide projector. As we have emphasized, WebVR is a learning tool that allows students to manipulate objects, navigate through the virtual worlds, and can stimulate them to construct their own knowledge.

E-mail: mars@mail.ncpes.edu.tw

Abstract: This article discussed the application of multimedia system to motor skills learning. First the authors reviewed motor learning theories. Then the development of application of information technology in physical education and sport learning in Taiwan was introduced. A specific study regarding the effect of multimedia computer-assisted learning in short service of badminton with forehand was described. According to the result, it is necessary that more efforts on design and development of the contents of multimedia that sufficiently represent the connection between cognition and skill performance on motor learning.

Introduction

Traditionally, motor skills learning proceeds the steps that include the learner observes, imitates the coach's modeling, refines his motor skills, and repeated practices. Diffusion of sports was limited by the lack of enough coaches, relative knowledge, and experiences. Information technology breaks through the obstacles of time and space, expands the approaches of learning, contribute to almost every part in contemporary human life and civilization. Therein, multimedia computer system condensing the necessary, versatile information on CD-ROM makes the diffusion of sports rapid, cheap, and efficient possibly. Motor skills learning, as a part of human life, was overlooked for a long period in my country, Taiwan. Therefore, trying to apply multimedia system to motor skills learning is being invoked because of the popularization of information technology.

Motor Learning Theories

Fitts and Posner (1967) have provided a model of motor learning that includes verbal-cognitive stage, associative stage, and autonomous stage. Jack Adams (1971) offered the verbal-motor and autonomous two-stage model. Schmidt (1975, 1982) proposed the schema theory of motor skill learning and emphasized learners to get sensory information before executing movement. Moreover, borrowed from Bandura's observation learning theory (1977), a notion was provided that the best situation for motor learning is to offer an appropriate model simulation (Iuppa 1984). In sum, observation of accurate motion demonstration and understanding cognitive activities behind motor skill performance will be helpful on learning motor skills. Many studies have showed that the cognitive effects of multimedia computer-assisted instruction are significant. Therefore, it is desirable that application of the features of multifunction and consistency of multimedia provide accurate modeling to help the sport learner acquire cognition and build up correct actions.

Research Tryout

The institute, which the authors belong to, has set up a particular section at graduate level to implement the information technology application in physical education and sport learning. Some projects involving in fitness, nutrition, health, and teaching in P. E. are in process. The following will introduce a study which researchers
developed a multimedia prototype on short serve of badminton and conducted an experimental research with this prototype to explore whether the multimedia material is a helpful tool. Subjects participating in this study were 111 sixth-graders from three classes in an elementary school. Each one of three classes received a specific one of three teaching methods: multimedia computer-assisted learning (MCAL), multimedia computer-assisted instruction (MCAI), and traditional instruction (TI).

The whole teaching procedure included three sessions. In each session divided into three segments. During the second and the third segments, subjects received the same kind of activities in separate class at gymnasium. The first segment taking about five minutes was the three different treatments for respective groups. According to the results showed on the cognitive test, providing accurate video demonstration plus teacher’s explanation and demonstration had significantly better effect than those of traditional instruction. The results indicated that presentation of image, video, sound, and related text explanation (MCAL group) indeed generated more efficient cognitive learning. Adding a human teacher’s interpretation (MCAI group) could yield better learning. Performance test evaluated the students’ posture, standard, pace, coordination, and stability while they performed. The results of analysis of variance on the performance test revealed the MCAI group had significantly better performance than that of the TI group. Result of analysis of variance on skill test failed to yield main effect. The result had the same finding as Ross (1994) did. But, it is different from Stiffen and Hansen’s (1987) research finding that showed the CAI group had better skill test scores than those of the traditional instruction group. Because motor ability and practice affect sport skill learning, the reason of no difference might be that short serve of badminton is not so complicated to need more strength and endurance. Therefore, we suggest the continued research on other type of sports, time arrangement of practice, or different age learners to explore the appropriate explanation.

**Conclusion**

Motor skill learning has its own features that emphasize physical execution and practice. Furthermore, motor skill learning involves different response types that are either open or closed and either rapid or slow (Poulton, 1957). In other words, different sport type probably needs very different motor skills to perform. To a specific sport type, from the sensory stimuli, perception, memory, to movement, it could have its own particular cognitive process. From the study of short serve of badminton we can only assure the effect of multimedia application on cognitive learning of motor skill. However, mental training and mental rehearsal have showed effects in sport psychological research recently. Apparently, we need to make more efforts on design and development of the contents of multimedia that sufficiently represent the connection between cognition and skill performance on motor learning.

Instructional Technology in the Classroom: New Directions for Foreign Language Faculty

Jessamine Cooke-Plagwitz
Mimms Foreign Language Learning Center
University of South Carolina
Columbia, SC 29208
jplagwitz@sc.edu

Abstract: This short paper is a report on efforts at the University of South Carolina to encourage and train foreign language faculty to be literate and enthusiastic in the area of instructional technology. The creation of a new position for the Academic Director of the Foreign Language Learning Center illustrates the school’s belief in the importance of instructional technology and its dedication to ensuring that faculty in all of its departments be given the opportunity to incorporate it into their curricula.

Introduction

An increasingly “wired” learning environment compels faculty in foreign languages to learn and use a variety of new technologies. To that end, the University of South Carolina has created a new role for the Academic Director of its Foreign Language Learning Center. The position bundles administrative duties (including the daily operations of the Center) with teaching foreign language (in this case, German), and directing faculty development in the area of instructional technology.

Faculty Development Opportunities

According to the Department of Education’s 1993 paper, “Using Technology to Support Education Reform”, the challenges faced by today’s faculty include:

- Learning to use a variety of technology applications;
- Using, adapting, and designing technology-enhanced curricula to meet students (sic) needs;
- Expanding content knowledge;
- Taking on new roles; and
- Responding to individual students.

Furthermore, Kassen and Higgins (1997) include the following necessities in their list of requirements for faculty development programs:

- Establishing a comfort level with technology;
- Integrating technology into the curriculum;
- Developing the critical skills to use technology effectively. (p.264)

One key aspect of the new directorship entails creating and overseeing a Faculty Development Center for foreign-language faculty interested in increasing their employment of instructional technology. The Center provides an area where faculty can develop multimedia courseware, design and maintain Web pages, work with audio and video materials, and experiment with instructional technology in a non-threatening environment.
The Workshop Series

Included in the faculty development package is a series of instructional technology workshops designed specifically with foreign-language faculty in mind. Some of the topics covered in the workshop series include: using Microsoft PowerPoint in the language classroom (especially as it applies to distance learning), hypermedia in foreign language instruction, the hyper-syllabus and online course delivery, creation of CD-ROMs, courseware authoring and authoring software, and orientations to commercially available language-learning software packages.

Workshop participants are asked to arrive with a didactic project in mind that they can complete during the course of the meeting. Most workshops are two hours in length, with the first half consisting primarily of hands-on instruction, and the second half being set aside for participants to work on their own, ask questions, and get better acquainted with the application being covered.

At present, the workshop schedule is such that one workshop is offered each month. I anticipate, however, an increase in the frequency of workshops as demand has been steadily increasing.

Evaluation

Any new undertaking must be evaluated in order to ascertain whether it represents an improvement over past conditions. Thus, at the close of each workshop, participants are asked to fill out a short questionnaire. The results are compiled and will be presented as part of the Language Center’s annual report, as well as becoming part of the Director’s own research on faculty development. An additional aspect of this training is determining if the material covered is actually learned, and, in the case of faculty development, subsequently utilized by instructors in their classrooms. In order to measure these criteria, a second set of questionnaires will be distributed to workshop participants at the end of the semester following their workshop attendance, with the ultimate goal of establishing whether the workshops have encouraged increased use of technology in the foreign-language classroom.

As the workshop series has only been ongoing for one semester, questionnaire B has not yet been distributed to foreign language faculty. Initial results of questionnaire A are promising, however, and workshop attendance has progressively increased throughout the course of the semester.

Conclusion

Foreign-language faculty must be given the opportunity to develop their teaching skills in a non-threatening environment where support is available if it is necessary, and where creativity is encouraged and appreciated. A program like that currently in place at the University of South Carolina removes some of the unknowns that prevent many instructors from introducing technology into their courses by letting them take the technology for a “test drive” ahead of time. Ultimately, I hope that all foreign language faculty at the University of South Carolina will feel comfortable enough with instructional technology to make it a part of their courses. In the meantime, it is encouraging to see language professors attending the workshops, working in the faculty development center, and taking an interest in what they can do with technology in the classroom, as well as what technology in the classroom can do for them.

Remote Controlled Teaching Experiments, in Science and Engineering Subjects, Accessible over the World-Wide-Web: the PEARL project

M. Cooper  
Institute of Educational Technology / Knowledge Media Institute  
Open University  
Milton Keynes, UK  
m.cooper@open.ac.uk

Abstract: This paper introduces a major European collaborative project, PEARL, that is developing a system to enable "real world" teaching experiments to be undertaken by students working collaboratively over the Internet. The paper outlines issues in university level education that led to the project's definition, summarizes its pedagogic foundations, and highlights the emphasis on making the science and engineering curricular accessible for students with disabilities.

Introduction to the PEARL project

The PEARL (Practical Experimentation by Accessible Remote Learning) is researching and developing a system to enable students to conduct real-world experiments as an extension of computer based learning (CBL) and distance learning systems. The objectives being to give high quality learning experiences in science and engineering education by bringing the teaching lab to the students; offering flexibility in terms of time, location and special needs. This will extend Internet course delivery to accommodate collaborative working in practical experimentation. The project is developing a modular system for flexibly creating diverse remotely controlled experiments, integrating this with a collaborative working environment and accessible user interfaces. The project will research the pedagogic impact of this approach, validating its developments in different educational contexts and subject areas. These include: foundation level physical sciences (as part of an open & distance learning introductory course); cell biology (as part of a final year undergraduate course); manufacturing engineering (postgraduate training) and digital electronics (as part of undergraduate courses in design and testing).

Educational Issues

Experimental work is a vital part of science and engineering teaching at all levels. There is an increasing trend to use multimedia science education packages and "virtual science" in both school and university level education. These approaches have great value and if done well, however they generally focus on the teaching of science facts and principles and not the teaching of the process of scientific enquiry or engineering practice. A key objective in PEARL is to create a (CBL) facility for learning science and engineering as a process.

Access to experimental work in distance education has traditionally been achieved by including simple home experiment kits or intensive residential schools as part of the course. The project is seeking to facilitate a wider participation in experimental work in distance learning courses and to make this available throughout the course. For campus based universities, the expansion of student numbers has put increasing strain on facilities and has made it difficult to provide adequate access to teaching laboratories. By making these facilities remotely accessible they, can be offered to students at different times and with less space demands on the teaching laboratory.

Increasingly there are demands on universities to teach their students the use of complex technical equipment. This pressure comes both from the need to introduce the students to state of the art practices in their subject and to fulfil the expectations of future employers or industrial purchasers of university education. By providing remote access to experimental work involving expensive and sometimes safety critical equipment, the widespread use of such equipment by undergraduates and industrial clients becomes feasible. Further it becomes possible to share the use of key teaching facilities with other universities with inherent economies of scale.
The distinction between distance learning and traditional university learning is blurring with the rapid increase in Internet course delivery. However there is widespread concern about the quality of the educational experience offered in some current Internet based courses. The PEARL system supports high quality science and engineering courses by enabling practical work to be integrated with other Web/multimedia based teaching material.

Pedagogic Foundations

Much educational research has shown that a key factor in the pedagogic advantage of practical work is that it is normally undertaken by pairs or groups of students. This facilitates the development of the students' ideas in conversation with their peers (Scanlon, et. al. 1993). The practical work provides the focus for peer-to-peer interchange normally supported by the tutor. Important motivational gains for collaborative working have also been frequently demonstrated (e.g. Issroff 1993). Hence it is vital that the PEARL system facilitates such collaborative working at a distance.

Contemporary accounts of student learning accept that it is an active process and depends on interaction. Laurillard (see Laurillard 1993) offers a model of student / tutor / courseware interaction. She considers the learning process as a kind of conversation, and asserts that this process 'must be constituted as a dialogue between teacher and student (or student and student), operating at the level of description of actions in the world'. She classifies the types of interaction between instructor and student as being discursive, adaptive, interactive or reflective. In the PEARL system the teacher can implement a wide range of learning modes. It facilitates the exchange and discussion of knowledge; reflection (by student and tutor); interaction at the level of the real world experiments; construction of and subsequent adaptation the experiments, by either the student or the tutor. There is thus a multiplicity of "conversations" envisaged in a PEARL practical session through which the learning objectives are achieved.

Science learning should also be an introduction to a community of practice (Lave and Wegner 1991), and this means that science learners need to be involved in the type of activities that real scientists perform. Therefore, all students need to experience practical work and all students need to experience collaborative working mediated by information and communications technologies, as these are the contemporary experiences of working scientists.

Access for Students with Disabilities

The PEARL project also seeks to make experimental work in science and engineering accessible to students with a wide range of disabilities. Indeed the project was originally conceived in to achieve this. Disabled students are grossly underrepresented in the science and engineering subjects at higher education. The reasons for this are complex, however access to experimental work is often cited as a key barrier. Much work has been done over the past 20 years to make computers accessible to people with all kinds of disabilities and a high degree of success has been achieved. Hence the tactic for the PEARL project is to firstly to make practical work computer controlled and then to ensure that the software and interface design follow well-established design for accessibility principles and that they are compatible with the available access technologies.

Acknowledgments

The PEARL project is funded by the European Commission's Information Society Technologies program (Project reference IST-1999-12550). Partners in the project with the Open University are University of Dundee, Trinity College - Dublin, Faculty of Engineering at the University of Porto and Zenon SA - Athens.

SOS (SUBJECT ONLINE SURVEY) : AN ONLINE TOOL TO SUPPORT IMPROVEMENT IN TEACHING AND LEARNING.

Robert M. Corderoy1, Ray Stace1, Sandra Wills1 and Albert Ip2
1Centre for Educational Development and Interactive Resources. University of Wollongong. Australia.
bob_corderoy@uow.edu.au, ray_stace@uow.edu.au, sandra_wills@uow.edu.au
2Multimedia Education Unit. University of Melbourne. Australia
a.ip@meu.unimelb.edu.au

ABSTRACT: Traditionally, data relating to the conduct of subjects at the University of Wollongong has been collected for teachers with one main purpose in mind: to provide the teacher with supporting information as to their teaching ability for the purposes of promotion.

SOS is a web based system which teachers can use to author customised surveys to collect information about the subject they teach. These surveys are completed anonymously by the students via the web (using randomly generated, survey specific numeric tokens) and the data is automatically collated and returned to the teacher. The teacher may also produce the surveys in hard copy, for manual distribution and collation.

The system provides a ‘non-threatening’ and ‘informal’ mechanism by which teachers can obtain useful information about the subjects they develop and teach in terms of subject based criteria rather than the ‘teacher based criteria’ of formal Teaching Surveys. In this time of declining University budgets, SOS provides a very cost efficient solution to the collection of this data.

This paper provides a background to the development of SOS in the context of the needs of the University of Wollongong and its teachers. It briefly outlines the main features of the system, new features being added to Version 2 and reports on the outcomes for the early adopters.

BACKGROUND

In 1998, the Director of CEDIR, Associate Professor Sandra Wills, secured funding to conduct research on the development of an ‘informal’ online survey system. The goal of this system was to provide teachers with personal formative data on the success of their subjects from a student’s perception, allowing them to improve teaching and learning outcomes for students without the need to resort to numerous and expensive formal Teaching Surveys. The research working party examined the online methods used to conduct teaching surveys by 15 Australian universities including the Subject Evaluation kit developed by the Griffith Institute for Higher Education (GIHE) at Griffith University [1]. In summary the findings included:

- most existing web-sites were highly University specific
- none were using the web exclusively to distribute and collate the data
- most surveys seemed to consist of set questions plus some optional ones selected from item banks.

From this research the working party made several recommendations which later formed the basis of the development specifications for Subject OnLine Survey (SOS). These included:

- the tool should be totally web based and should require minimum web skills to operate it;
- there should be an item bank of ‘standard questions’ and the ability to author individual questions;
- there should be a variety of questions types available such as Likert scale, True and False, Yes and No
- there would need to be a concurrent staff development program

During the research phase, a generic evaluation tool LEO [2] or Learning Evaluation Online, which is a template based in the as OXYGEN (Object eXtensible analySis and Generation of Education coNtent) software engine developed by Albert Ip [3] was identified as a possible engine and later implemented.

SUBJECT ONLINE SURVEY (SOS)

SOS is a web based system which provides a simple and intuitive interface through which teachers can construct
and author customised surveys designed to collect information about the success or otherwise of the subjects and/or subject components that they provide for their students. These surveys and the returned data are password secure and student access is anonymous, survey specific and controlled via 'tokens'. The data is auto-collated and is made available through a data collection site and/or via automatic email posting.

DEVELOPING A QUESTION DATABASE

The Teaching Survey database previously in use within the university contained many hundreds of questions which were either directly suited or with modification could be used successfully. Many additional questions have been added to take account of a wider range of delivery options than the traditional lectures, tutorials, and laboratories including flexible and online delivery.

EVALUATION

Version 1 of the system was made available to three faculties within the university: Engineering, Commerce and Public Health. Over a period of approximately 6 months a total of almost 1000 students were surveyed using SOS. In 2000, the University has launched two new remote centres at which two full degree programs are being offered flexibly including online. SOS will be used as part of the evaluation strategy for this initiative.

Much of the evaluative data collected so far is in the form of comments and suggestions from users. The most common responses include
- the simplicity of the authoring interface and low level of computer skills needed to operate it;
- the ease and speed of survey and the quick turn around compared to paper based surveys;
- the ease of customisation for a variety of different student groups and needs.

Teachers using the system to date have identified the following possible weaknesses of the current version:
- the 'set' 7 point Likert scale, possibility of others being available;
- no mechanism for students to see aggregated results, and;
- the need to manually modify the data collected before exporting to a spreadsheet.

FUTURE DIRECTIONS

User feedback over the trial 6 months period has given us direction in further development into version two, greatly expanding the applicability of the system to all campus teaching and learning. Some of these include:

- The existing databases will be greatly expanded to incorporate all questions currently in use at UOW.
- Question categories will be expanded and current question categorisation will be re-assessed.
- Sets of faculty based "Standard Surveys" will be built up and provided at the top level of authoring.
- In the longer term, normative data on each question in the database will be collected, collated and analysed.
- Preliminary data analysis by teachers will be supported by a downloadable Excel macro which will have built-in frequency counts, bar chart generation and cross-tabulation.
- Finally, the program of staff training needs to be extended to include developing an understanding of the application of the survey results to teaching.

Learning Object Containers: 
A suggested method of transporting metadata with a learning object 

Duane Currie, AITT, Acadia University, Canada, duane.currie@acadiau.ca 
Craig Place, AITT, Acadia University, Canada, craig.place@acadiau.ca 

Abstract: Learning Objects have the potential to revolutionize the delivery of technology enhanced courses. To realize this potential, standards for the production and transmission of learning objects must be developed and adopted. The IEEE and IMS have made a large effort in producing standards for describing meta-data, but there has been little work in producing standards for reliably connecting the learning object and its related meta-data. In this paper, we will describe an enhancement of an existing standard which allows effective encapsulation of both the learning object and meta-data in a single container.

The IEEE Learning Object Meta-data Working Group defines a learning object as “any entity, digital or non-digital, which can be used, re-used, or referenced during technology supported learning.” For the purposes of this paper, we will limit our scope to defining a learning object as any digital entity that can be used or referenced during technology supported learning. Currently, there is much existing work, by groups such as IEEE and IMS, on developing standards for the meta-data used to describe learning objects. However, less attention has been paid to the binding between the meta-data describing the learning object and the object itself.

Without some means of reliably storing and transferring the data and meta-data as a single entity, two problems easily occur. First, if the learning object is not packaged or appropriately connected with its descriptive meta-data, it retains little information about the appropriate use of the learning object, reducing its usefulness to the educator. The second problem is that of possessing meta-data which describes and links to a learning object which either no longer exists or has moved elsewhere, making the learning object useless to the educator. Unfortunately, both problems currently exist.

Binding the two (or “Ensuring the twain shall meet”) 

Currently, the IMS Meta-data specification, based on the IEEE specification, describes a large amount of standardized meta-data to be used in describing a learning object. As well, they provide a proposed XML binding for this meta-data.

With little effort, this XML binding for learning object meta-data may be extended to include the associated data. All that is required is a few additional XML tags, and a data encoding scheme. The first tag to introduce would be a pair of tags to delimit the block(s) which contains the data files (“sub-objects”). Keeping it simple, we could use <DATA> and </DATA> tags for this purpose. This data block could adequately be placed within the record block, as described in the IMS XML bindings specification. Within this data block, specific files must be enclosed. For this purpose, additional tags may be used: <FILE name="filename"> and </FILE>.

Now, the problem of conflicts between the XML allowed character limitations, and the contents of the data arises. This is easily remedied by using a base64 encoding scheme for files contained within the XML document. This format uses only characters which are valid for inclusion in XML fields.

As an illustrative example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE RECORD SYSTEM "http://www.imsproject.org/XML/IMS-MD01.dtd">
<RECORD xmlns="http://www.imsproject.org/metadata"/>
```
Linking the meta-data and data (or “Letting the left hand know what the right hand is doing”)

Allowing more powerful connection between the meta-data and data is the XLink specification, currently under development by the W3C. The XLink specification allows for linking between XML documents, and linking within XML documents. This allows for a more natural connection between the meta-data and data, and even allows for more powerful learning objects.

For example, in the meta-data, you may wish to identify which concepts are required in order to gain most benefit from the learning object. With the use of these XLinks, you may explicitly link to learning objects which instruct the required concepts. Also, the sub-object you use to demonstrate the concept to be learned, may be a different sub-object from that which you would use to test or exercise the student’s learning of the concept. This linking specification provides a means of using other applications to describe the particular metadata element, and through the use of multiple sub-objects, provide a more complete educational experience for the learner.

Developing a solution

Currently, an application for using learning objects of this style is under development. It uses a small Java based web server as an intermediary between a web browser client and the XML files containing the learning objects. This is intended to be able to run on personal systems as well, using any web browser as the primary user interface for accessing the learning objects. More information is available at http://aitt.acadiau.ca/research/lo, and an example implementation should be available in late April for download.

Preparing our Teachers for Distance Education

Christina Dehler and Christina De Simone
Centre for the Study of Learning and Performance
Department of Education, Concordia University
Montreal, QC Canada H3G 1M8
cdehler@education.concordia.ca
cds@alcor.concordia.ca

Introduction

Much of the focus in the distance education (DE) literature centers around the learner and learning, almost to the exclusion of the teacher and teaching. Consequently, instructors of DE courses have been left suspended in virtual space. This paper focuses on the teachers' position in the DE course context, especially with respect to the type of training they receive. An example of an alternate mode of teacher preparation is presented and suggestions for further improvement in DE teacher training are discussed.

The Challenge of Providing Adequate DE Preparation

The majority of faculty have little knowledge about what DE is, what it entails, and how it is successfully taught (Moore & Kearsley, 1996). Yet instructors receive little or no training prior to being assigned a DE course (Dooley, 1995; Gehlauf, Shatz & Frye, 1991) which leads to teachers being under-prepared, frustrated, isolated, and disillusioned. Teaching at a distance requires methods of instructional delivery that are different from the strategies and approaches commonly used in a traditional classroom setting (Northrup 1998, Moore & Kearsley, 1996) because the structure of the teaching is changed. Rather than being the typical source of information, the instructor assumes the role of facilitator, monitor and peer collaborator, engaged in creating discourse with students (Shedletsky, 1997). DE teachers must be willing and able to develop new methodologies of teaching that re-distribute power, roles, and responsibility within the learning community. Therefore, to ensure the success of learning activities carried out at a distance, DE faculty must not only develop the necessary competencies to do their work but must also develop a clear understanding of their re-defined roles and responsibilities.

The Training Strategy

While the importance of technical training for distance educators is well documented (see Hiltz, 1986; Schutloffel, 1998), it is often the only type of training offered to faculty, in insufficient amounts and using inappropriate techniques (Schutloffel, 1998). Northrup (1998) argues that additional training on new instructional techniques and strategies for promoting interactivity and for providing adequate and timely feedback may promote a DE environment more conducive to learning. Teachers need to extend their learning to beyond how they will use the technology. They also need to understand how the technology enables and affects their pedagogy and need to be given the time to digest and accommodate this new knowledge.

In our situation, the teacher training differed from the traditional DE training described above in the following ways: a) it was designed to take place over the summer months prior to the course implementation; b) the teacher (second author) worked in collaboration with a Ph.D. student in Educational Technology (first author) who assumed the roles of pedagogical technology consultant and teaching assistant; c) in contrast to a "just in time" training approach, the instruction was structured over a period of several weeks, building in time for practice and reflection; d) the training program was experiential in that the teacher was able to acquire technological skills within the context that she would be later teaching; e) training was carried out in close proximity to course implementation so that skills and knowledge were retained, practiced, discussed and
contemplated upon, in relation to the DE environment; and, f) the training focused on helping the teacher to
understand and become familiar with her new role as a DE teacher. More specifically, the teacher created a
metaphor which helped the instructor to deal with her own feelings of isolation, especially from her students
and from colleagues who had no experience with the DE environment.

Future Implications for DE Teacher Training

Presently, adequate training and support for distance teachers remains piece-meal and strongly associated
with the efforts of key individuals, not with the university community. Bringing about large institutional
reform, however, is no easy feat and certainly not accomplished in a short period of time. As DE increases in
popularity, teachers will need to be prepared for new distance teaching assignments. Below are some
strategies that can help DE teachers develop the skills and knowledge required to comfortably grow into their
new roles.

With respect to faculty development, it is important to institute a training program for initial preparation and
ongoing support that is sensitive to the needs of the teacher and the learning goals. Such a program should
recognize that teachers need time to become familiar with the technology, their pedagogy in the DE
environment and their role as DE teachers. If DE faculty training continues to focus only on technological
skills, at best what is addressed is something akin to what Abhram Maslow (1987) refers to as teachers' basic
needs. Therefore, it is critical that training of DE teachers evolve and expand to incorporate issues such as
defining one's role as teacher in a virtual learning environment, building interactive learning communities of
responsible learners, and creating a supportive collegial infrastructure so as to minimize not only isolation
but increase feelings of belonging to a community of scholars, learners, and compassionate individuals. An
effective training program should foster a community of resources (i.e., people, materials, technology) so that
faculty can share knowledge and expertise as well as stories of successes and failures. This will not only help
distance teachers overcome feelings of detachment from their peers but also build a strong collective
knowledge of what teaching methodologies are most effective in DE environments.

Architectural Aspects of an Interactive Multimedia Environment for Training Employees in Internet/Intranet Technologies

Gregory Derekenaris, John Garofalakis, Jim Prentzas, Spyros Sioutas, Athanassios Tsakalidis
Computer Engineering and Informatics Department
University of Patras, 26500 Patras Greece
and
Computer Technology Institute, Research Unit 5
P.O. Box 1122, 26110 Patras, Greece

Abstract: In this paper, we present a multimedia-based system facilitating the training of an organization's employees in Internet/Intranet technologies over a LAN connected to Internet. The system uses several types of multimedia educational patterns, such as hyperlinked text and images, special sounds, animations, interactive simulations demonstrating the use of various Internet tools, e.t.c. It contains several training courses, depending on each trainee's background in using Internet/Intranet technologies. All the multimedia material is stored in a multimedia database, which can be accessed and updated by the trainer through a user-friendly interface consisting of forms.

1. Introduction

The use of multimedia technology has given a great impetus to the training evolution. Multimedia systems provide an integrated environment for the creation, storage and presentation of a variety of media types enabling the development of a great number of successful prototype educational applications (Faconti 1994). This paper presents the architecture of an interactive multimedia-based environment as an assistant for training an organization's employees in Internet/Intranet technologies over a LAN connected to Internet. The environment incorporates a multimedia interface, and a multimedia database for storing and organizing all the multimedia assets. The information presented to the trainees via the multimedia interface during a course is dynamically accessed from the multimedia database. This feature facilitates the modification of the multimedia database's contents by the trainer through a user-friendly interface.

2. The Front-End Component

The main issue was to develop an interactionally rich system that would support user functionality efficiently and effectively, taking advantage of the new infrastructures currently available. The functionality concerns both training activities and navigational ones, like moving through hypermedia objects and browsing large multimedia structures (Schnaze 1993).

The information provided by the system is presented in a variety of ways, such as interactive simulations demonstrating the use of various Internet tools (e.g. Internet browser), hypertext, special sounds, appropriate images and animations, hypermedia object, educational games. Certain hyperlinks correspond to URLs of WWW servers. Therefore, from within the multimedia system the trainee can start his/her computer's default Internet browser and thus, put everything he learns in the specific section into practice. The content is distributed in sections, subsections and topics. Each topic comprises a series of educational screens. The user determines the presentation flow, by using hot area selections as well as buttons. On-line help is available, usually via messages at the bottom of the active screen, where necessary. Furthermore, the user can consult a glossary of primary Internet terms in order to enrich his/her knowledge.

There are different components of the system interface (front-end), related to the user views, described in section 4. One of the distinctive features of our approach is dynamic linking to the various multimedia assets (e.g. images, audio and video tracks, text files, animation files) by submitting queries to the multimedia database. This means that the contents of the multimedia interface are established dynamically, at run-time,
since the information is structured appropriately in the database. This minimizes the cost of the system's maintenance, results in consistent presentations and ease of tailoring. In addition, the data modification effort is reduced.

3. The Back-End Component

The back-end component consists of the SQL components, ODBC software and a multimedia database. The multimedia database is used to store and organize all the multimedia assets of the system. The SQL components contain the SQL statements used to access the multimedia database through the ODBC software. The two SQL components related to the user views (section 4) are as follows:

1) SQL component for the trainer: This component enables the trainer to access and update the multimedia database keeping thus, all the multimedia material up-to-date with advances in the Internet/Intranet technologies. Furthermore, it enables the trainer to establish login names and passwords for the trainers which are stored in the database.

2) SQL component for the trainees: This component is responsible for validating the trainee's login name and password and accessing the system's multimedia assets.

4. User Views

The user interface is unified offering different view to different users. We can distinguish three basic views as far as the users are concerned corresponding to the components of the system's user interface:

1) General view: In the general view, the user can access all available information regarding Internet/Intranet technologies by navigating through the sections, subsections and the topics of the multimedia application.

2) Trainer view: In the trainer view, the user is able to modify the contents of the multimedia database with a user-friendly interface consisting mainly of forms and establish login names and passwords for the trainees.

3) Trainee view: In the trainee view, the user identifies himself/herself to the system.

The trainees can use the general and the trainee view whereas the trainer all the views.

5. Implementation Aspects

The system, in the form of an advanced prototype, has been developed under the Windows 98 and Windows NT operating systems. The multimedia interface (front-end) was developed using the Macromedia Authorware 5.0 and Macromedia Afterburner authoring tools. Additional code was written using Visual Basic. The multimedia database application was developed using the Microsoft SQL Server on Windows NT 4.0 Server operating system. The application handling the communication between the user interface and the database is comprised of a number of SQL components using Authorware's ODBC functions. These functions are called via calculated icons. Dynamic linking is implemented by connecting Authorware parameters to database items.

Navigating Scholarship: A Study of Discipline-Based Web Gateways in Large Research Libraries

Barbara I. Dewey
University Libraries
University of Iowa
United States
barbara-dewey@uiowa.edu

Abstract: Research libraries have always built and organized authoritative discipline-based collections. This short paper provides a preliminary look at the state of discipline or subject-based web gateways to so-called authoritative scholarly works in large research libraries. The study is based on an in-depth analysis of the 30 largest academic research libraries (based in universities) as defined by the Association for Research Libraries' index ranking. The study also draws upon the results of a survey to each library revealing comparative data on gateway content decision-making and application of learning technologies to promote gateway usage within the universities’ respective curricula. Gateway content is examined in terms of subjects covered, methods of content selection, formats pointed to, and integrative features with “traditional” online catalogs of the libraries’ owned physical and electronic holdings. Goals for the study are two-fold: a) obtaining a profile of subject-based gateway development, structure, and maintenance practices, and b) seeking models for effective subject gateway development in light of efforts to improve aggregation of web resources with online library catalogs.

Introduction

The explosion of information resources available on the web has driven many research libraries to develop a subject-based gateway to selected sites deemed particularly useful for the scholarly community. The labor intensive nature of developing, maintaining, and updating these gateways provides motivation to identify best practices which can be applied successfully to other institutions. This analysis is also important given the growing number of web-wide search engines available to the user (Yahoo, Alta Vista, etc.) as well as software to apply to a more selective group of sites chosen by research library subject specialists. Boundary crossing between institutionally created subject gateways, library catalogs, commercial indexes, and other sites on the libraries’ web presence is becoming more essential for comprehensive navigation of scholarship. Another factor is the emerging ease by which library users can create and customized their own gateways.

Methodology

The target population for this study are the 30 largest Association of Research Libraries (ARL) academic research libraries based on the ARL membership criteria index. The large academic research libraries were examined in two ways: 1) an examination by the author of the libraries’ Web presence in terms of gateway existence, and 2) administration of a questionnaire to each library to self-identify their gateways and answer specific questions regarding the creation, content, and maintenance of the site. These include existence of a locally maintained subject gateway, its name, description of search engine, selection information, comprehensiveness and depth, type of resources included, maintenance procedures, and prominence factors within the library website.

An Example -- Iowa's Gateway to Online Resources

As with most research libraries the University of Iowa's efforts in developing an internal subject-based gateway are continually evolving. The goal of the Gateway to Online Resources is to allow users to find high quality sources quickly and efficiently. The resources in the Gateway have been selected by the Libraries' bibliographers and reference librarians, who use their knowledge of faculty research interests and class assignments to select the most reliable and well-designed electronic resources. These resources include authoritative Web sites maintained by professional societies or leading faculty as well as databases licensed by the Libraries from reputable publishers. It
also includes databases and reference to materials in the online catalog. The Gateway (http://www.lib.uiowa.edu/gw/) consists of two sections: 1) reference categories including links to dictionaries, style manuals, encyclopedias, etc. and 2) subject headings including links to 57 subject areas at this writing. The Gateway holds a prominent place within the Libraries' web presence and uses FileMakerPro as its search engine. At this point in time Iowa's Gateway does not feature automated web checking and links are corrected as errors are reported.

**Preliminary Survey Results**

Preliminary results of the survey are trickling in at this writing but of 10 respondents eight report having gateways. Of these eight, two are unnamed. One of the two responding in the negative did indicate they had separate pages with subject access to areas such as electronic journals, indexes, reference links, and bibliographer pages. Seven report having search engines for their gateways including WWW wais, htdig, InfoSeek, Index Servicer, Filemaker Pro, Glimpse, and MySQL. Most of the respondents indicate their gateways are somewhat selective. Respondents with gateways indicate that they include links to resources on the web, in the catalog, databases, electronic journals, and references to print materials. None indicated specializing in a particular subject area. The majority of respondents indicated that their gateway holds a prominent place within the library website. Three institutions used a software program to check links while the rest used staff. Software included Linkchecker, MySQL, and Linklint.

**Conclusion**

Best practices among the research libraries' gateways to scholarship will inform next steps in individualized and collaborative development to improve web-based navigation of scholarship (regardless of format), gateway placement, maintenance and long-term viability. New developments and trends in commercial browser development will impact in a variety of ways on the structure and proliferation of individually crafted gateways. At the same time more and more individual scholars are building their own customized gateways. These factors, along with the implementation of new web-based automated catalog systems in research libraries, will affect future subject gateway development and architecture.

---

[1] Based on the 1997-98 ARL membership criteria index and index formula. The index is a summary measure of relative size among the university members of the association. The index is calculated using five data elements including number of volumes held, number of volumes added, number of current serials received, total operating expenses, and number of professional and support staff.

Abstract: The University of Iowa Libraries recently received a two-year $270,000 grant from the Roy J. Carver Charitable Trust to develop a new program called the Science Information Literacy Initiative (http://sciencelit.lib.uiowa.edu/), which is designed to help University of Iowa undergraduates taking courses or majoring in the sciences to develop skills in locating, critically analyzing, organizing, and applying scientific information. Participating academic departments include Biological Sciences, Chemistry, Geology, Mathematical Sciences, Psychology, Science Education, and Engineering. This paper will describe the steps taken with the College of Liberal Arts prior to receipt of the grant to launch the more general, UIII (University of Iowa Information Literacy Initiative) (http://www.lib.uiowa.edu/user-ed/uiii/index.html). Concepts behind planning and implementing the Science project will then be examined. Project staff, science librarians, and faculty design discipline-specific components and assignments to meet a set of learning objectives. Faculty and librarians test these components in actual courses and present them in a variety of formats depending on the course requirements, needs, and structure. Information literacy components deemed successful will be further developed into what is hoped to be an easily adaptable program for widespread use throughout the sciences. Issues and challenges faced in launching the Science Information Literacy Initiative will also be featured.

Why Science Information Literacy?

The ability to locate, critically analyze, organize and apply scientific information is an important skill for University of Iowa science and technology graduates. On a daily basis students preparing for professional and academic careers in science and technology will need, to correctly locate, evaluate, and apply science information from the constantly growing and rapidly changing universe of print, electronic, multimedia, and web-based sources.

Advancing information literacy in the sciences and technology is of major importance at the highest levels of national policy. Albert Henderson writes that “an ideal vision of science requires goals and strategies to deal directly with the growth of new information. “Information Age” science policy fails to do this. By ignoring the study of science communications, it fosters a policy vacuum on information.” Although the more general concept of “science literacy” has been recognized as a concern and challenge in the U.S., particularly since the post-Sputnik era, proponents have focused primarily on recruiting students into the sciences and heightening the public’s understanding of science issues rather than on addressing effective scientific information seeking. Academic libraries have not developed comprehensive science-based literacy programs although many science librarians have been successful in promoting certain information seeking skills such as specific database manipulation and web searching. For example, a widely cited College & Research Libraries article reviewing the advances of information literacy efforts by librarians made no mention of specific applications in science or technology. The University of Iowa Science Information Literacy Initiative seeks to address this void for the campus and as a potential model for other institutions.

The Roy J. Carver Charitable Trust

A major factor in the development of the Science Information Literacy initiative was the interest and subsequent funding of the project by the Roy J. Carver Charitable Trust. The Carver Trust had funded the successful Information Arcade, the Information Commons, TWIST, and a new Biological Sciences Library, a total of $2.13 million in awards. Senior library staff developed a prospectus and presentation for Carver and were then
encouraged to submit a formal grant proposal. Funding of $270,000 was recently received for the two-year project. Funding supports a coordinator, an instructional designer, and two graduate assistants.

**University of Iowa Information Literacy Initiative (UIII)**

Both the UIII and the Science Information Literacy Initiative are based on the University of Iowa Libraries' philosophy that integrated curriculum-based user education in the most effective and scaleable approach for developing students' portfolio of information literacy skills. An important outgrowth of the information literacy programs will be development of alternative methods for faculty to incorporate into their courses for each component including web-based methods, in class presentations, use of existing library web tutorials, and other means since librarians are not numerous enough to appear in every introductory class at a university of Iowa's size.

**Student Learning Objectives**

Development of relevant student learning objectives in partnership with faculty is an essential part of the Science Information Literacy Initiative. Below are examples of objectives likely to be included in the program:

- Identify problems that require solutions based on scientific information
- Identify appropriate scientific information sources and execute effective search strategies
- Interpret and analyze search results
- Critically evaluate scientific information retrieved
- Organize, synthesize, and apply scientific information
- Understand the structure of the information environment and the process by which scholarly and other information in the science and technology fields are produced and disseminated
- Understand the ethical issues related to access and use of scientific information.

**Methodology and Project Evaluation**

Science Information Literacy project staff and science librarians are working directly with select faculty in each science discipline to customize curriculum components which meet the student learning objectives. Faculty and librarians will test these curriculum components in actual courses and may present them as web-based instruction, in-class instruction or some other format depending on course requirements, needs, and structure. Evaluation of the project will be accomplished using appropriate tools to measure students' acquisition of the learning objectives. Information literacy components deemed successful on the basis of student outcomes will be developed into an easily adaptable program for widespread use throughout the science and technology curriculum.

Initial Projects. Besides enhancing course assignments, the University of Iowa plans to develop an easier interface for beginning level students in the sciences who need to access various science information databases. This part of the project is currently in the initial development stage, but will include examination of various basic science databases to determine how beginners might best choose which database to use in response to particular needs.

**Conclusion**

Gradually integrating new initiatives into the existing framework is sometimes a slower process than we might like, but patience developing the collaborative process often pays off in the final outcome. We have at this point laid the groundwork for successful implementation of our project goals and hope to report on our further progress at a later date.

---

Abstract. Visualization of computational models is at the heart of educational software for computer science and related fields. In this paper we look at how generation of such visualizations and the visualization of the generation process itself increase explorativity. Four approaches of increased explorativity are introduced.

1 Introduction

Educational software mostly aims at the width of knowledge (facts) and is not able to teach complex processes. The majority of systems are intrinsic electronic books, encyclopaedias and dictionaries. Process-oriented systems exist mostly for physics. In the area of computer science tutorials of programming languages prevail. Particularly in computer science and compiler design the theory and algorithms are very abstract and usually complex. Therefore visualizations are appropriate for computer science instruction. Although compiler design is often considered a practical field within computer science, most of its techniques are based on work in theoretical computer science, e.g. formal languages, automata theory and formal semantics. In recent years we have developed several educational software systems for topics in compiler design and theoretical computer science. These systems have in common that they teach computational models by animating computations of instances of these models with example inputs. But they differ in the level of explorativity.

<table>
<thead>
<tr>
<th>Approach</th>
<th>Input</th>
<th>Computational Model</th>
<th>Generator</th>

<td>user</td>
<td>user</td>
<td>yes</td>
</tr>
<tr>
<td>Second-order generative</td>
<td>user</td>
<td>user</td>
<td>yes/visualized</td>
</tr>
</tbody>
</table>

Table 1. Levels of explorativity

Table 1 not only reflects the increased flexibility of the software developed, but also the chronological development of software in our group. Higher levels of explorativity demand more prerequisites and self-control by the learner. Thus, in the educational software the learner should start with static examples and as the user advances the level of explorativity should be increased. Exercises and textual hints in the educational software should guide the learner, to make sure he/she doesn’t miss the important issues.

2 Approaches

Static Approach In the static approach the execution of an instance of a computational model is animated for a given, fixed input. The educational software "Animation of Lexical Analysis" [Braune et al. 99] is an example for this approach (http://www.cs.uni-sb.de/RW/anim/animcomp.e.html).

Interactive Approach In the interactive approach an instance of a computational model is animated for an example entered by the user/learner. An example for this approach is our application "Animation of Semantical Analysis" [Kerren 99] (http://www.cs.uni-sb.de/RW/anim/animcomp.e.html).

First-Order Generative Approach In the first-order generative approach the user enters the specification of an instance of a given computational model. Then an interactive visualization of this instance is generated and the user can enter an example input as in the interactive approach. As an example of the first-order generative approach we present GANIMAM [Diehl et al. 99], our web-based generator for interactive animations of abstract machines (Fig. 1 and http://www.cs.uni-sb.de/RW/users/ganimal/GANIMAM/).
Second-Order Generative Approach  As in the first-order generative approach the user enters a specification of an instance of a given computational model. But in the second-order generative approach in addition to visualizing the computation also the generation process is shown as an interactive visualization. An example of this approach is our application GANIFA, a web-based generator for animated finite automata (http://www.cs.uni-sb.de/RW/users/ganimal/GANIFA/).

3 Explorativity and Learner Control

In conventional educational software answers of an exercise are checked for correctness. Unfortunately such correctness checking is not possible in most interesting cases. In computer science, many properties of computational models can not be checked because of the halting problem. As a consequence we need alternative ways to provide feedback for the learner.

In the generative approaches an interactive animation is produced from the response (specification) of the learner. Then the learner can test it on the basis of own examples. In this way he/she can detect errors. The generative approach offers a way for explorative, self-controlled learning. The learner can focus on certain aspects in the generated, interactive animation and see what effects small modifications in the specification have. With the help of such observations he/she formulates hypotheses and checks these empirically. In the interactive approach such checkable hypotheses are restricted to the instance of the computational model. In the first-order generative approach also hypotheses about the computational model and in the second-order generative approach about the generation process itself can be checked.

Abstract: New technology – Microcomputer Based Lab (MBL) in particular – was beneficially used to support Mechanics teaching at Junior High School students. Two series of seven experiments each were developed and implemented at five schools, including control and experimental groups of approximately two hundred students in total. The experiments focused on linear motion, Newton laws and conservation laws. The students of the experimental group demonstrated a significantly more successful ability of distinguishing among position, velocity and acceleration versus time graphs. Furthermore, they appeared to better understand the proportional relation between force and acceleration, the equality between action and reaction, as well as momentum conservation and mechanical energy conservation laws. In conclusion, new technology enables students to build scientific concepts taking profit of their own experience of real world.

Introduction.

As we approach the new millenium, a general attitude is developed towards the improvement of quality and effectiveness of the provided education, regarding Natural Sciences, which has two objects. The scientific and technological "literacy" of the average citizen, on one hand, and on the other, the preparation of future scientists and instructors so as to utilize the outcomes of the rapid scientific and technological developments of our times. Since the beginning of our decade, an intense concern has been created among the natural sciences education researchers about the effectiveness of the traditional instructive system as far as the understanding of the natural world on behalf of the students is concerned. Almost everybody seems to agree that listening to someone talking about the natural phenomena does not constitute a productive way of understanding the laws and concepts of nature. Students of all ages approach science better by actively participating in the examination and the interpretation of the natural phenomena (1).

Subject/problem.

Many researchers hold the view that the use of new technologies will supply students with the ability to successfully take in concepts of physics by putting to use their own experiences from the natural world. One of the interactive educational technologies is the real - time, computer-based data-logging tools (often called microcomputer-based laboratory or MBL). These new methods using the L were implemented for teaching the Newtonian Mechanics to first-year students and schoolchildren of the last classes of senior high school in the USA, leading to particularly positive results (2,3). Up until now and to our knowledge, no attempt has been made towards the utilization of new technologies regarding the teaching of Physics to students of younger age. The Greek syllabus does not give such an opportunity, since it provides the teaching of the elementary concepts of the Newtonian Mechanics in Grammar school (age 13-15).

Design and procedure.

In order to investigate the effectiveness of the new teaching methods of Physics in the low secondary education we put to practice a project with the general title «Physics and New Technologies». The chapters of Heat and
Mechanics were chosen based on the criterion of their position in the Greek curriculum and their suitability for the development of laboratory experiments in an MBL environment. The part of the suggestion, which is related to Mechanics, is presented in this paper. Two series of 7 experiments were designed: one for the groups of control classes and one for the classes of experimental application. The duration of every laboratory experiment was the same for both classes. The experiments included all the basic topics of Mechanics at this level: linear motions, Newton's laws and conservation of momentum. The design of the experiment for the control classes was based on the electrical ticker-timer and the cart that comes along with it. The experimental application classes used various simple means (their hands, little wagons, toys etc.) as mobiles, and worked in MBL environment, which disposed a computer, proper software, a printer, a projection screen, a video projector, sensors of position and force, as well as an interface for the sensors and the computers. Five grammar schools in Athens were selected to be school units of application, so that the sample would represent the average Greek student. The experiment and control classes operated equally in every school unit, on every aspect. The teachers were the same for both classes. Students in both classes worked under the supervision of two teachers and they filled in worksheets. The efficiency of each teaching intervention was evaluated through a questionnaire, common for both classes. (The filling in of the questionnaires was conducted a week after every laboratory experiment).

Results.

The results presented here concern concepts of kinematics motion and immobility, velocity, acceleration, gravity acceleration while research related to dynamics is in progress. As a sample of the experiment we mention the following: One out of two students of the experimental group E G (48,5%) and one out of five of the control group C G (20,3%) recognized motion with uniform velocity in a position/time diagram. The difference is more striking in the identification of the immobile condition: E G (68,7%), C G (25,2%); as well as the backward motion: E G (67,7%) and C G (13,1%). At this point we should mention that the electrical ticker-timer or every other «typical» means cannot register the motion backwards. At a linear motion with constant acceleration, 80% of the E G and about 55% of the C G understood the concept of velocity, while for the acceleration the results were: E G (65%) and C G (50%). Finally, for the case of the free fall of a rubber ball and a metal sphere, 60% of the E G and 40% of the C G understood that the two bodies have the same acceleration.

Conclusions.

Based on these results, it becomes obvious that the use of new technologies in the Physics laboratory offers the possibility of a simultaneous supervision of motion and of the model of its representation (diagram). This activity supported, interactive learning environment helps students of this age:

1. To identify the trajectory of a motion from the depicting motion diagram. Not to confuse the position, velocity and acceleration diagrams in relation to time. To discern the analogy of force - acceleration. To comprehend the third law of Newton and the conservation of momentum, which derives from it.

2. To acquire the ability to describe the behavior of a natural system based on the model it depicts.

Abstract: The University of Colorado at Denver, Indiana University, Western Governors University, Educause/IMS and Phi Delta Kappa are working on a five year FIPSE (Fund for the Improvement of Post-secondary Education) grant to develop the Learning to Teach with Technology Studio (LTTS). The LTTS is an Internet-based, anywhere, anytime learning environment designed to help K12 teachers integrate technology into their instruction. The instruction in the LTTS is designed from an inquiry based learning model. A key objective of this project is to ensure that it is replicable and self-sustaining. The strategy for achieving this goal is to develop an initial set of modules and then invite other professionals in the field (teachers, university faculty, technology coordinators) to contribute modules. Thus, it is critical to provide strong support for the multitude of authors that may contribute to this project. The Design Strategy Environment (DSE) provides this support; it is a resource-rich environment that helps developers create high quality, self-contained, problem-centered learning modules.

Background

The National Center for Education Statistics (1999) found that 80% of K12 teachers do not believe they are prepared to integrate technology into their curricula and the Milken Exchange (Solmon, 1998) found that teachers do not model the integration of IT skills in their teaching. One of the reasons for this ill-preparedness is a lack of relevant instruction for both pre-service and in-service teachers.

To meet this need, the University of Colorado at Denver (UCD), Indiana University (IU), Western Governors University (WGU), Educause/IMS and Phi Delta Kappa began work in September, 1999 on the Learning to Teach with Technology Studio (LTTS), an Internet-based, anywhere, anytime learning environment. The LTTS will provide self-paced instruction in the following six content areas: (1) design of learning environments, (2) measurement and evaluation, (3) technology and production proficiency, (4) project management, (5) leadership, and (6) applied research. This work is funded by a five-year, FIPSE grant.
The instruction in the LTTS uses an inquiry based learning (IBL) model; each instructional unit is structured around a problem-based case. While many potential developers probably have prepared materials for information transmission-based online courses, few have experience in preparing inquiry-based online activities. Shifting to an inquiry-based mode of instruction is a difficult process for many educators, a fact confirmed by the professional development literature (e.g., Richardson, 1998). In our extensive experience offering problem-based learning workshops, we have found that nearly all educators willingly accept the idea that students must learn to solve problems, work with others, and create meaningful products. However, we have also found that they are reluctant to change their teaching methods, believing that their students need to know “stuff.” Unfortunately, the information transmission model of learning conflicts with the inquiry approach to instruction.

The change to an inquiry based learning model is even more complicated on the LTTS project because the instruction is self-paced and web-based. Most of the literature and guidelines for developing inquiry based learning are designed for group-paced, classroom-based instruction. Further, in addition to developers from Indiana University and the University of Colorado at Denver, we will invite other professionals in the field, e.g., teachers, university faculty and technology coordinators, to contribute modules to the LTTS. Thus, we anticipate the possibility of having hundreds of developers contribute instructional material to the LTTS.

**Design Strategy Environment**

To assist and support those who are developing instruction for the LTTS, we are creating the Design Strategy Environment (DSE). The DSE is a resource-rich, performance support site, which provides instructional guidance, templates, and examples for developers. Our goal for the DSE is to make the work of our developers as efficient as possible, and to insure a consistent look and feel of the interface. In order to achieve this goal, the DSE uses forms, templates and other automated techniques.

We provide a Developer Notes Worksheet which developers can use as they review the DSE site. The purpose of the worksheet is for developers to record their ideas, notes, reflections and concerns as they research and review the information in the DSE. This worksheet is divided into four sections that correspond to the four-step development process: (1) Describe the problem, (2) Describe and define the resources, (3) Describe the learning activities, and (4) Describe the assessment criteria.

For each of these four steps, the DSE provides the following information:

- A brief description (50-100 words) of that component of the inquiry based instruction. For example, the brief description of the first step (Define the problem), indicates that a good IBL problem is ill-structured, situated, authentic and complex.
- Links to our examples. These examples are other LTTS modules that contain comments and notes. That is, for the first step (Define the problem), an example problem is displayed in the first column of a two-column table. The second column contains comments, notes and explanations about how this problem exemplifies the critical characteristics of a good problem.
- Link to detailed explanation. This information is essentially an elaboration on the brief description (a. above). It contains not only a full description of the topic, but also provides a reference list and links to LTTS examples.
- Link to necessary features. This is a checklist developers can use to evaluate their work. It is a list of the necessary features each of the four components of their module must contain.

Accessing Advocacy Training Virtually and Physically

Dr. Tanis Doe
Computer Master/ Canadian Association of Independent Living Centres
6 1261 Goldstream Ave
Victoria BC V9B 2Y9
techolt@home.com

Abstract: This is a research project conducting a comparison of traditional classroom instruction and self-paced multimedia training in "advocacy" for people with disabilities. The three main populations are Deaf sign language users, blind users who do not read print, and people using alternative input, such as Dragon Dictate or puff and sip switches. Technical specifications for access to html using WWW3 universal design standards will be discussed. Advantages and disadvantages to both classroom and virtual training will be compared using evaluation data.

Comparing Methods for Delivering Advocacy Training

Advocacy is a skill required for navigating life as a person with a disability. The Canadian Association of Independent Living Centres was funded by the Office of Learning Technologies to conduct a research and demonstration project to understand the differential impacts of learning technologies on people with disabilities.

Traditional Classroom Delivery

The advantage of classroom delivery is the interactivity and direct feedback available in real time. Students may ask questions, have them answered and participate in group activities. For Deaf students, another advantage is that the course content is delivered directly in sign language. Although handouts and exercises are in written English, there is an opportunity to ask directly for clarification and access new concepts in sign language. Students who do not read print, and who process information aurally, are able to benefit also from spoken discussions, role plays and interactivity. No reading or print processing is required in a traditional classroom situation. The provision of handouts in alternate formats- such as in Braille, diskette or on audiotape, also enables learners to access material after the class is completed. Because the classroom course delivery involves other peers, similarly situated blind people, the participants directly benefit from experiences of others. This is a key in the process of adult learning. For students who cannot use text input due to physical limitations or learning disabilities classroom participation can be very enabling. The verbal participation and support given by human staff in a classroom situation may enable learners to avoid some of the limitations that their disabilities create when interacting with text or technology. For example, even turning a page of a workbook may require a technical aid for a quadriplegic and a person with a learning disability may need a screen reader to process assignments in writing. Having a human instructor also provides the flexibility of gearing the course to the topical and learning needs of participants.

Virtual Training Delivery

This project was designed to test virtually learning in comparison to classroom learning. Realizing that private citizens have a wide range of access to computers and the internet, the "lowest" common denominator was selected for delivery. (Cantor 1998) CD technology using html allowed any one with basic internet software and NO connection to the internet to take the course. Students would be able to email, phone, fax or even write to instructors. (Burgstahler 1995) By providing OFF line access, students without fast modems, students with time limited access and people who have CDROM drives but no internet access can still benefit from the course material. This is particularly important for disabled learners who use augmentative technology that slows down participation and interaction. (Coombs 1999) Participation in the on-line version of the course (same content) will only be different because it allows direct emailing to the instructor and potentially a response within a very short time. There will be on interaction with other learners in this project, but students will be asked at the end of the project if that was something they would be interested in. A bulletin board style notebook will be used for students to post their comments about the course and any suggestions- either anonymously or through their own email address. (Brooks
1997) The text only version of the course will enable blind users to access the text and exercises through both screen readers and audio files without navigating through frames. The deaf users and the people using alternative input will benefit from the enhanced visual navigation and easy to use self-pacing. Interactive exercises, sign language video and audio files will be available on demand. The advantages of these processes include a slower or more individualized pace of learning, opportunity to repeat and review more frequently, a chance to complete exercises before and after course work, and the ability to stop the process and return to it at any time. Classroom teaching doesn't allow this flexibility and the presence of other students often reduces the opportunity to individual the steps to learning achievement.

Training Design Standards

While WWW standards for accessibility do exist, and the WWW consortium has an ongoing list of requirements, (Web Accessibility Initiative 1999) html is not always used to deliver training. Other sources of accessibility design standards will also be used to inform the training design standards. (Waddell 1998; Vanderheim, Chisholm & Ewers 1996) This project seeks to combine accessibility standards with training design standards to ensure that web/on line training is as flexible and accessible as possible for diverse learners. This project is still in progress but the following technical specifications have been used to implement the project. The starting point for the content was the pre-post test which would be used to measure achievement of skills and knowledge about advocacy. The contents of the in class instruction and the multi-media instruction had to be compatible so we began with the text and graphical content. Images were imported from Clip Art and custom drawn by an artist. All images have alt-tags but the html text-only site does not rely on graphics for navigation. (Khan 1997) In addition, we provided sign language versions of instructions and difficult vocabulary which was accessible by clicking a particular location identified by signing hands. In addition, the "hot spots" or links in the software were made to work without timing limits and through keystrokes so that people using Dragon Dictate and alternative input switches did not always need to move the "mouse" but could directly control the navigation. By building in accessibility at the design stage, more flexibility for consumers is achieved. (Waddell 1999) Evaluation to date has shown that disabled participants benefit from both in class and on-line delivery methods. Different individual preferences, access to technology and learning needs help determine which suits each student. Design standards will be developed as a result of this project to increase access to future training initiatives.

Abstract: In this text, we explore the similarities between engineering and instructional design, in terms of methodology, tools used and emerging trends (growing consideration for the client, research of quality, prototyping, concurrent approach). We conclude that the expression “instructional engineering” is amply justified.

Introduction

In recent years, instructional design (ID) is more and more often equated with instructional engineering (Paquette, Crevier and Aubin, 1999). Engineering is a process covering the whole life-cycle of a product. The engineering process is generic as it is applied in all fields where one has to image a solution that will satisfy the needs of potential customers whether those needs be educational, financial, medical, etc. When this process is put to use to solve a problem industrial in nature, it is said to be applied to the field of engineering. Similarly, the ID process has been traditionally defined as this whole cycle of analysing, designing, producing (or developing), evaluating, implementing and revising a learning system. In this sense, the expression “instructional engineering” is well justified. As we will see throughout this presentation, it is not the only reason.

Tools

In both fields, engineering and education, introduction of computers has greatly increased the productivity of the designers by easing the creative process, by facilitating modifications, by performing simulations more rapidly. But what about supporting decision making within the engineering process?

In 1992, Spector and his colleagues predicted that the automation of the instructional engineering process (through the use of expert systems) would evolve in much the same way as word processors have. Unfortunately, the passage of time has not proven them right. The use of expert and other knowledge-based systems is much more frequent in engineering. This may be explained by the fact that a large portion of the body of knowledge is rooted in “hard” science as opposed to “soft” science, much more open to debate, in the field of education. Furthermore, the rules included in educational expert systems are much more difficult to formulate.

Quality

One usually associates quality with a lack of defects, with reliability. In engineering, nowadays, a quality product is one that responds to the needs of the customer. One can therefore never overemphasize the importance of the first phase of the engineering process: problem definition. This is true irrespective of the field.
Traditionally, problem definition has been performed through analysis. A growing number of companies developing new engineering products rely on Quality Functional Deployment (QFD), a method devised to clearly identify customer needs. The method rests on a graphical tool called the House of Quality. While developing a technology-enriched course, we used this tool and found it to be a highly effective communication and design tool.

Another mean of achieving quality in engineering is through a prototyping approach as proposed by Smith (1991), which is also an emerging trend in education (Moonen, 1996; Tripp and Bichelmeyer, 1990). Needs and requirements are no longer viewed as input but as output of the design phase. The goals of the prototypes are to solicit, to elucidate, to define customer needs and requirements. The method is useful if a prototype can be easily and quickly produced, thus the expression “rapid prototyping”. In general, the more specific the tool used (from general programming languages to learning systems shells), the more quickly the prototype is produced. Merrill (1996) does warn however that education authoring tools do require some type of programming, that they are not neutral with regard to instructional theory and that the user must have some knowledge of ID. Ignoring these warnings may result in an inadequate product, that is one that lacks quality!

**Concurrent engineering**

The classical work organization is sequential. This type of organization is often referred to as “over-the-wall” or “waterfall” since each team works independently of one another, with minimal communication. This lack of true communication results in multiple errors, increase in development time and cost. Concurrent engineering was devised to overcome these shortcomings. The proposed solution is simple: create a single multidisciplinary team, whose members work concurrently on different aspects of the product. A mounting body of literature is available to document the effectiveness of the concurrent engineering process when applied to the field of engineering. Meanwhile timid incursions are observed in the field of education. Most classical ID models have a bias for sequential engineering with numerous feedback loops providing for iterations, very few incorporate task parallelism. However, there exists a few attempts to embed concurrent engineering in ID (Paquette, Crevier and Aubin, 1999).

**Conclusion**

Our analysis shows that the expression “instructional engineering” in amply justified. The similarities between engineering and ID, in terms of methodology, tools used and emerging trends (growing consideration for the client, research of quality, prototyping, concurrent approach) are quite amazing. Up to now, there have been very few occurrences of borrowing engineering principles to shed new light in the field of ID (Teslow, 1997; Yang, Moore and Burton, 1995). Our own experience of combining ID and engineering expertise to the task of developing a computerized learning environment and to reflect together on the theoretical underpinnings of both fields has been an experience which gains to be repeated by others and become a practice more widely spread.

Technology Across the Curriculum

Gerald W. Drake
George Mason University
4400 University Drive
Fairfax, Virginia 22030-4444
gdrake@gmu.edu

Abstract: The College of Arts and Sciences (CAS) at George Mason University has launched a program - Technology Across the Curriculum (TAC) - to promote student use of information technology. The TAC initiative supports faculty to develop technology-enhanced course assignments with funding provided by the Vice-President for Information Technology. Through their work to promote these innovations, faculty have opportunities to take a deeper look at their teaching and scholarship. Students who enroll in TAC courses are not only empowered with advanced tools for problem solving, they also acquire a conceptual understanding of "applied" technology so that the utility of these tools can be transferred to different domains over time.

The College of Arts and Sciences (CAS) at George Mason University has launched a program - Technology Across the Curriculum (TAC) - to promote student use of information technology. The TAC initiative supports faculty to develop technology-enhanced course assignments with funding provided by the Vice-President for Information Technology. Through their work to promote these innovations, faculty have opportunities to take a deeper look at their teaching and scholarship. Students who enroll in TAC courses are not only empowered with advanced tools for problem solving, they also acquire a conceptual understanding of "applied" technology so that the utility of these tools can be transferred to different domains over time. With this extensive exposure to a wide range of information technologies, CAS students graduating from George Mason will have an education that is both grounded in the critical perspective of the liberal arts and bolstered by new ways of thinking for the digital age. The broader community served by the University is the ultimate beneficiary of the TAC program. Present and future generations of students will enter the region's workforce confidant in their ability to master new technologies and therefore better prepared to face the challenges of a rapidly changing global economy.

The TAC program has identified three basic types of technology competencies that would have practical value in the classroom as well as the workplace: information management, electronic collaboration, digital authoring. Each is supported by a subset of specific tools and activities that will be an integral part of course assignments and the learning outcomes intended for TAC courses.

1. Information Management
   Students will collect, organize, evaluate, and analyze different types of data. They will conduct research using web-based directories and search engines or on-line library catalogs. They will evaluate digital archives using sources and citations. They will use databases to create relational data structures that are the basis for queries and reports. They will use spreadsheets for data entry, plotting and graphing charts, and for descriptive statistics. They will use geographical information systems(GIS) for spatial analysis for descriptive statistics, economic geography, and environmental data.

2. Electronic Collaboration
   Students will engage in online collaboration for learning and to produce knowledge. They will communicate using, e-mail, listserves, and asynchronous conferences. The will exchange documents and other materials using e-mail attachments, FTP, and netware. They will collaborate on group projects and organize workflow using online tools that permit conferencing and the posting of documents.

3. Digital Authoring
   Students will be able to present information in an engaging, effective manner using digital authoring tools. They will design, develop and maintain websites using an HTML editor. They will learn visual principles of
communication (effective color and graphics, text treatment, and audience targeting) using *PowerPoint* to create a technology-enhanced presentations.
ITBeankit: An Educational Middleware Framework for Bridging Software Technology and Education

{Abdulmotaleb.El-Saddik,Stephan.Fischer,Ralf.Steinmetz}@kom.tu-darmstadt.de

Overview: In this paper we describe a layered approach, which allows the adaptation of the visualization content according to the user's needs using meta-data. In contrast to existing approaches, the educator can adjust both the level of explanation and the level of interactivity of an animation, thus influencing the presentation and the results of the algorithms being illustrated according to a desired level of functionality and appearance, suitable for the specific needs of the learner. Our approach is similar to a middleware approach. In this three-tier model, the lowest layer of this paradigm suits the programmer. On the middle layer, which is composed of various services common to all educational animations, such as management of data, control, interaction level and presentation, acts the educator. The user interface of the current educational visualization is the top-layer medium with which the end-user (learner) interacts.

Meta-Data within Algorithmic Animations

One way in which software evolves is to push a configuration out onto the user and to make the program as interactive as possible. An alternative way is to defer such decisions until runtime, or to push configuration decisions out into the data. Data itself become more universal and reusable when it is accompanied by meta-data. As meta-data we define data that describe other data, rather than aspects of the application domain itself. These data may become even more general and independent when they are integrated into the code, which may be transferred over the Internet. Using the object-oriented language Java to implement data to be described, the use of meta-data or code descriptions as objects has great advantages. Instead of using meta-data in its general term and traditional role, to create universal descriptions of objects (for example in digital library systems) these meta-data are used instead to describe properties. Runtime mechanisms for accessing, altering, adding and removing meta-data or properties at runtime should be provided by the programmer in order to integrate data with meta-data seamlessly.

Several works have dealt with classifications of meta-data, for example [Bohm et al. 94] or [InfoQuilt]. InfoQuilt classified meta-data into two categories: content-dependent and content-independent meta-data. All of the methods used to classify meta-data make use of meta-data in its traditional sense of describing data to facilitate search activities of the data (in general the documents) they describe. That is, the meta-data descriptors are associated in a fixed way with the data sets and as granular as defined initially. However, meta-data can also be seen as parameters that are passed to some object of a system in order to change its behaviour as well as providing information, which will help search engines. In order to change the behaviour (dynamic property of a resource allowing it to be integrated into a desirable context) of an object, it should be possible to change parameters on the fly. For this purpose dynamic meta-data are needed, extending the static nature of meta-data in the traditional sense.

- **Static Meta-data**
  Static meta-data are meta-data that are used to create universal and widely applicable descriptions of objects, which may not change the behavior of the described object. Examples are [IEEE-LOM] and [DC].

- **Dynamic meta-data**
  We suggest the use of the new term "dynamic meta-data", describing the possibility to adapt the content of an object according to the value given in the description and the ability to change the value of a parameter of a given object in order to change its behaviour. As an example of dynamic meta-data we examined the Ethernet protocol. In the visualization of this protocol, changing the value of the meta-data field “PROBLEM” (being represented in the program as a property) from “Collision” to “Shortframe”, may change the whole behavior of
the algorithm to be visualized. Dynamic meta-data can in its turn be divided into the following two categories. We further subdivide into horizontal and vertical dynamic meta-data. *Horizontal meta-data* contain information that does not depend on the content of the algorithm to be visualized. The meta-data fields defined within this category are common for all visualization units, and thus can be applied to all animations. *Vertical meta-data* are used when the decision of changing the value of a field is up to the user. Parameter panel is an adequate representation of these meta-data.

**itBeanKit**

We use the itBeanKit (interactive teaching Bean Kit) to develop animation chains consisting of modular animations visualizing the steps of an algorithm. The itBeanKit comprises the following levels:

- **Programmer**
  - First, the programmer identifies animation objects that visualize the steps of an algorithm. He defines the smallest entities of the algorithm and develops them as black-box software components, which may be re-used for the development of other algorithms. The programmer specifies animation actions at particular points in the algorithm chain according to a predefined set of meta-data. The programmer’s view has been described in detail in [Elsaddik et al. 99].

- **Educator**
  - As a middleware actor, according to the needs of the end-user, the educator may convert an algorithm developed by the programmer to a series of animation sequences by mapping algorithm variables, specifying animation actions, and associating execution points in the algorithmic chain to perform the desired animation. He uses dynamic meta-data, which have been pre-defined by the programmer.

- **Learner**
  - For the learner, a visualization window is divided into three areas: an animation pane, an explanation area, and a parameter pane. The animation pane displays the resulting animation envisioned by the educator. The explanation area displays some hints and information concerning the visualized algorithm. The parameter pane is divided into two parts: interactive utilities and a VCR, allowing the learner to control the progress of the animation. The interactive utilities pane depends on the algorithm and on the topic, defined by the programmer and customized by the educator. The animation may request intermediate input from the learner, allowing him to control the path of the algorithm.

**CONCLUSION AND OUTLOOK**

The itBeanKit provides an environment in which an educator, without conventional programming skills, can build an interactive visualization of an algorithm. We currently extend the itBeanKit, particularly by increasing the available choice of components. As a prototype, we implemented animations, for example “Ethernet” or “JPEG”. Details can be found under the URL http://www.korn.e-technik.tu-darmstadt.de/projects/iteach/itbeankit/applets/paradelektion/index.html.

Evaluation of a Systematic Tele-Tutor Training

Bruno Emans, Noor Christoph, Jacobijn Sandberg
Department of Social Science Informatics
University of Amsterdam
The Netherlands
emans@swi.psy.uva.nl

Introduction
The Lilienthal project is a collaboration of 5 European flight schools (Lufthansa, KLM, EPAG, IAJM and HORIZON), and the universities of Berlin, Stuttgart and Amsterdam. Within this project a Distance Learning Platform (DLP) for pilot training is developed. Students can study 250+ modules and they can communicate with their tutor and peer-students via e-mail, chat, discussion groups and bulletin boards. In a distance learning environment, the role of the tutor is different from the role of a classroom teacher. Traditional teachers from the flight schools now had to learn to become a successful distance tutor. A Tele-Tutor Training has been set-up to provide for this need. This paper describes the systematic set-up and the evaluation of this Tele-Tutor Training.

Systematic set-up of Training Tele-Tutors
From the early beginnings of the project it was considered necessary that the classroom teachers would be trained for their role as distance tutors. Since communication between students and teacher is of vital importance for the learning process (see for example Laurillard, 1993), the DLP was designed with much possibilities for interaction (e-mail, chat, bulletin board and discussion groups). Now the teachers had to be trained to work with these communication tools. They need both practical knowledge of how to use the tools and strategic knowledge about when to use the communication tools.

For the training program a user-driven approach was chosen. The (future) tutors were asked to fill in (part) of the training objectives. They were provided with an electronic template, which they could use to describe the requirements and skills that they would need while teaching with the DLP. The basis of this approach was formed by the activity template provided in Barnard and Sandberg (1994) which links activity descriptions to technical support that is required for facilitating or enabling the performance of activities (Sandberg, Christoph and Emans, 1999). This inventory formed the basis of a list of six main categories of requirements for distance tutors on the DLP (see table 1).

<table>
<thead>
<tr>
<th>Requirement categories</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Background in distance learning and the DLP</td>
</tr>
<tr>
<td>2. Communication requirements</td>
</tr>
<tr>
<td>3. Information storage and retrieval requirements</td>
</tr>
<tr>
<td>4. Adaptation requirements</td>
</tr>
<tr>
<td>5. Administrative and management requirements</td>
</tr>
<tr>
<td>6. Coping with difficult situations</td>
</tr>
</tbody>
</table>

Table 1: Six main categories of requirements for distance tutors.

Categories 1 and 2 contain mainly basic requirements and skills in the field of distance learning, the DLP itself and the communication tools. Categories 3 to 6 contain the more advanced requirements and skills for being a distance tutor.

Description of the training
The different requirements and skills were trained in three phases. First a two-day seminar was organised to teach the tutors the basic skills of the communication tools and the DLP. Then a simulation program was set up. During two weeks, the tutors had the opportunity to practice these skills in a real distance education simulation. Each tutor was assigned a class of students. The tutor never lived in the same city as his/her students, so no other than distance communication was possible. Before this simulation the teachers were
asked to formulate their own learning goals, besides getting practical experience with the DLP. (For example “To be able to interest students”)

The Tele-Tutor Training concluded with another two-day seminar. During this seminar the experiences of the simulation program were discussed. Furthermore the advanced skills and requirements like time-management and the strategic use of communication tools were trained.

**Evaluation Results**

The three parts of the Tele-Tutor Training were evaluated separately, and one over-all evaluation was performed. The evaluations focused on the actual skills the tutors gained during the different parts of the training, and on the confidence and motivation of the teachers to become distance tutors.

After the first Tele-Tutor Training seminar, all tutors mastered the basic skills for using the DLP. This was a good result, since some teachers that had never used e-mail before now were able to use the different communication tools on the DLP swiftly. And more important, the motivation and confidence of most teachers to become distance tutors grew during the seminar. The simulation program resulted in 82% of the teachers achieving (partly) their learning goal. Furthermore, experience with the ‘real situation’ was of great value.

All subjects in the last Tele-Tutor Training was reported to be useful. The tutors were asked for their opinion on the usefulness of the different parts of the training and of the complete training as a whole. These overall figures can be found in figure 1.

![Figure 1: Mean answers to the question on the usefulness of different training parts. (1 = strongly disagree, 6 = strongly agree)](image)

**Conclusion**

We tried to set up a Tele-Tutor Training that trained all skills and requirements needed to become good distance tutors. The requirements where gathered by the (future) tutors themselves, giving them influence in their own learning process. The first skills and requirements that were trained were the basic skills for handling distance communication and the practical and technical knowledge for working with the DLP. The training seminar for this purpose was successful, since the confidence of the tutors grew, and they were all able to handle the communication tools and DLP on a basic level.

The follow up training would involve more advanced skills. It was felt that these could only be trained in a real distance course simulation. It turns out that this feeling was correct. Real problems only come up in a simulation as we performed it. And in a simulation as we set up, the tutors finally got an idea of what it would be like being a distance tutor. The set-up was such that every tutor could individually train on his own personal learning goals, while all the tutors were forced to train the essential skills, and build up experience with the DLP.

We strongly advise everyone to incorporate a simulation in a distance tutor course. Distance tutoring only can be taught over a distance. During the presentation I would like to illustrate this with some more examples and evaluation results.

Perceptions of a Fearless Experimenter:  
Student Perceptions of Creating Electronic Portfolios

Dr. Susan Eskridge, Benerd School of Education, University of the Pacific, USA,  
HYPERLINK mailto:seskridge@uop.edu seskridge@uop.edu

Ray Posey, Benerd School of Education, University of the Pacific, USA,   email:  
rposey@uop.edu

A simple definition of a portfolio is "a container of collected evidence with  
a purpose" (Collins, 1992). Many schools of education across the country ask  
students who are entering the teaching profession to create these "containers" and  
provide evidence of their successful completion of their preservice experience. Some of these schools have offered students the opportunity to  
create their portfolios through the use of technology. Rather than creating a binder with a collection of artifacts, students who use a technological approach to create a multimedia presentation of their preservice experience. It seems that the purpose of most portfolios completed by preservice students is to exhibit their performance during course work and student teaching. Electronic portfolios seem to have a secondary purpose: they communicate an expertise and enthusiasm for the use of technology on the part of the student. Our study considers this secondary purpose from the students' viewpoint.

The National Council for Accreditation of Teacher Education (NCATE) issued a report called "Technology and the New Professional Teacher: Preparing for the 21st Century Classroom" in 1997. The NCATE technology task force suggests that perhaps the best way teacher education faculty can inspire future teachers to use technology is "to cast themselves as learners and to experiment fearlessly in the applications of technology," making themselves "role models of lifelong learning" (p. 9). The U.S. Department of Education states that technology offers "numerous possibilities for integrating assessment into the daily life of the classroom" (1997, April, p. 6). This study asked students to reflect upon their experiences and perceptions as "fearless experimenters" with electronic portfolios.

This study asked students from a small California university to reflect upon the process of creating multimedia portfolios during their teacher education program. This study considers student perceptions of electronic portfolios during four stages of their teacher preparation program; 1) during the very first course in education, 2) at the end of their teacher education course work, 3) during student teaching, and 4) after completing the education program and obtaining a teaching position. Students in each of these categories were interviewed to gain insight into the experience of collecting and preserving artifacts electronically. From these interviews with students, their perceptions evolved into themes that focused on issues such as the experiences of creating
the portfolio, the students' personal reflections during the portfolio process, the manner in which students selected particular artifacts, and the usefulness of the electronic portfolio once it was completed. The students' insight was significant and may have an impact upon other schools of education as they consider embarking upon the electronic portfolio process.

Some of the emerging themes mentioned by the students included 1) time constraints and issues, 2) familiarity with software used to create electronic portfolios, 3) the need for guidance and support from those with expertise in creating these portfolios, and 4) the opportunity to manipulate, experiment, and create by themselves, rather than having the "expert" provide short cuts by pushing the student through the process more quickly than their current knowledge would allow.

Students expressed that the most pressing need for creating an electronic portfolio is the issue of time. Within a hectic schedule, students found that when asked to create an electronic portfolio, they were overwhelmed by the process. Some indicated that they had no understanding of the time commitment needed to create this type of document. They also expressed that the concern about time was very individualized. Some students needed time to become familiar with the software program while others, who already had experience with the program, needed time to push themselves beyond their current level of understanding.

Familiarity with the software was a concern for some students who wished to create a portfolio. They believed that it was a great burden to become familiar with the software at the same time as they tried to create their portfolio. Prior working knowledge of the software was seen as crucial by these students. A third concern expressed by the experimenting students was that they needed access to individuals who had some expertise either with the software, with creating portfolios, or with creating actual electronic portfolios in the past. The students did not care whether the "expert" was a faculty member or simply another student. They seemed to be very comfortable with learning from their peers. Some students expressed that other technology-using students were often more understandable than technology faculty because their level of expertise was more comparable to that of the novice student.

Another concern expressed by students focused on the nature of the help they received from "experts". Students mentioned that often, the expert "grabbed the mouse and sped through the process" rather than guiding the students and allowing them to experience the process for themselves. The students felt that once the "expert" left them to work on their own, their understanding was not enhanced by the assistance. The students expressed frustration that they were often left to work their way through the process alone. Because the "expert" had by-passed the student's involvement rather than serving as a guide in the process, their assistance was not seen as helpful.
In conclusion, if faculty members in schools of education continue to encourage students to create an electronic portfolio of their college and/or student teaching experience, they must remember that the students have concerns about the process of creating such a document. As stated previously, the issues found in the study focused on time, software knowledge, and the helpfulness of those with expertise in the area of technology. As students work through the process of creating electronic documents, faculty members need to listen to and compile their concerns in order to better meet the needs of future students. Through a deliberate conversation with student experimenters, those interested in promoting technology among preservice teachers may obtain valuable insights that will assist students in the creation of creative, organized and frustration-free projects.
Helping K-12 Teachers Integrate Internet Technology in their Classrooms

Christopher Essex
Instructional Systems Technology
Indiana University
United States
cessex@indiana.edu

Abstract: This paper describes the design, development, evaluation and revision of an online course over the six semesters that it has been offered. The course is designed for K-12 teachers and librarians interested in integrating Internet technology into their teaching. In this course, students research educational resources on the Internet, design their own educational websites, and develop educational activities that utilize the Internet. Recommendations for others teaching similar courses are offered.

Introduction

According to the National Center for Education Statistics (1999), in the Fall of 1998, 89% of public schools were connected to the Internet. But do our K-12 teachers know how to use this new technology? The same study states that “teachers commonly report that they have not received adequate preparation in the effective use of computers within the classroom.” Throughout the nation, K-12 teachers are feeling pressure to integrate Internet technology into their teaching, but even if the hardware and technical support is available, pedagogical support is often lacking or totally unavailable. Now that the classroom is wired, how can the elementary and secondary educational process benefit from the availability of the Internet? This online course was developed for K-12 teachers who are not finding much support locally in answering this crucial question.

Description of Course

My decision to offer this course came out of experiences I had in the real world of K-12 education. While teaching a summer computer course at a local elementary school, I introduced my students, fourth through eighth graders, to the wealth of educational resources available on the Internet, and I gave them the opportunity to practice their research skills and explore their creativity through creating their own websites. The other teachers at the school were intrigued by our use of the Internet and wanted to learn more about how they could integrate this new technology into their teaching practice. Because of this experience, I decided to develop an online course on the topic.

The audience for this course is, as I have stated, K-12 teachers; however, I was pleasantly surprised to discover that K-12 librarians were also interested in the course. I have had students from all over the US in the course, as well as from as far away as the Philippines and Colombia. The course is a graduate-level, one-credit-hour course offered for credit by the School of Education at a leading Midwestern state university. The course delivery is 100% online (the students and instructor never meet face-to-face), though the students still are assigned a print textbook (though this may change in the future). The course was first offered in the summer of 1998, and has been offered every semester since then.

My initial design for the course was based on my own experience as a teacher, both at the K-12 and the postsecondary level, and an instructional designer, having spent four years working with instructors to develop other online courses. After reviewing other courses and textbooks on this integrating technology into the K-12 classroom, I decided on the following objectives for the course.

In this course, the students will gain experience in:

• Using email for contacting outside experts and other students
• Utilizing an online, asynchronous bulletin board system for class discussion
• Communicating with other students and the instructor via a live, synchronous chat program
• Evaluating existing online resources for educational value
• Using HTML to create web pages

But above and beyond the above technology-related goals stated above, the students will also gain experience in:
• Designing lesson plans that integrate Internet usage into the curriculum
• Sharing their experiences with, and concerns about, using the Internet in their classroom with fellow teachers
• Dealing with issues of Internet safety and student use of Internet resources
• Reviewing current research on teaching with Internet technology

Changes in the Design of the Course

Over the six semesters that the course has been offered, I have made many changes to the course design, both for technological and pedagogical reasons. In terms of the technology-related changes that were made, it is obvious to even a casual observer that computer hardware and Internet software have changed enormously since Summer 1998. Faster computer processors, increases in modem speed, more advanced browsers, and improved email and synchronous and asynchronous conferencing programs have all influenced the design of the course, and they will continue to do so as Internet technology continues to develop.

Pedagogical changes that occurred over the six semesters were primarily related to my interest in improving the quantity and quality of our online class discussion. Feenberg (1993) described the role of the instructor teaching through computer-mediated communication technology as having three roles: that of providing context, monitoring, and meta-commenting. Feenberg’s three roles provided me with a useful framework for thinking about my activities within our online conferencing forum. In terms of my contextualizing function, I would open discussion, generally by posting a question to respond to, or by giving them a task to perform. Early on in the semester, it is important to set the norms of the conversation by making a few postings which will serve as models for the students, in terms of the language and tone and level of formality that our conversation should have. I also provided context by providing the schedule and an overall agenda for our discussions over the semester. My monitoring functions included welcoming students, assigning them to teams, and nagging them when they weren’t posting enough. Finally, my metacommenting included providing students with summaries of what we had accomplished in the discussion up to that point, and working with students to resolve any problems in communication or misunderstandings of the context of our communication that occurred.

Conclusion

If our nation’s classrooms are to truly benefit from the sudden infusion of Internet technology that the latter half of this decade has witnessed, teachers must be given both technological and pedagogical support as they begin to integrate this technology into their teaching. It is my belief that online courses such as the one described in this paper are an important way to address this need, especially for teachers who find it difficult to attend on-campus courses.

"NEXT STEPS"

Dr. Josephine Ferazzoli Farrell
State University of New York at Oswego
Oswego, New York 13126
jfarrell@oswego.edu

Abstract: The education of preservice K-12 teachers in using communications technologies has not kept pace with the technologies themselves. Consequently, when new teachers enter the classroom, they routinely limit their use of technologies to add-ons and skill/drill exercises rather than integrating those technologies into their lessons to create optimal learning environments for students. A consortium of Central New York educators, led by the State University of New York College at Oswego, along with both rural and urban K-12 school districts, will remedy this situation by implementing a program to provide preservice teachers, teacher educators, and K-12 teachers with improved access to and support with technology. The plan also provides preservice teachers the opportunity to model teachers who are experienced in infusing technology into the New York State Standards-based curriculum.

NEED FOR PROJECT

Educators have seen a recent proliferation of initiatives aimed at infusing technology into Teacher Education Programs. Current conditions contributing to this effort are:

1. Recent standards developed by the International Society for Technology in Education (ISTE) and adopted by the National Council for the Accreditation of Teacher Education (NCATE).
2. The NCATE Task Force on Technology in Teacher Education's recommendation that schools of education have a technology infusion plan (NCATE, 1997).
4. The availability of federal funds from several sources, as well as,
5. The demand of the K-12 schools for technologically sophisticated teachers.

With all of these initiatives, why haven't teacher education programs kept up with these crucial technology requirements? We all know that generally change is a slow process. It is time that helps change take place. Already over-scheduled educators with full class loads are reluctant to spend time on initiatives that take time away from tried and true programs and curricula. Of course, times change and educators must change from what worked well or adequately in the 50's and 60's, and maybe up until recent years, to what our children need to function optimally in the global marketplace of today. The major effect of the multimedia emplacement may be in adapting students for the technological world they are soon to enter as productive society members. Additionally, the traditional methodology is no longer suitable for preparing preservice teachers for dealing with the complex demographics of the schools (Allen, 1997); they can easily communicate with people around the world, and the schools no longer have to rely on outdated texts to deliver this information to them.

Clearly our K-16 schools have not kept up-to-date with what is happening with regard to technological advances. The millennium is upon us, and our teachers are not prepared to teach the children in a manner that will help to insure their future success. Although e-mail is a word that is on the lips of most people today, whether or not they use it themselves, some educators do not use it, even when they have access to it. Access to new technologies will not by itself solve this problem because it is two-fold: educators need to have access, but they also need confidence and knowledge about the pedagogical potential of the new technologies. Preservice teachers need to experience ways in which new technologies can be integrated seamlessly into lessons in order to make active and pedagogically sound use of technology.

A key element in promoting a natural integration of technology into lessons is an opportunity to model excellent classroom use of technology. One can lecture about how a unit plan is created, BUT it is not until a preservice teacher actually creates a unit plan that real learning and understanding about unit planning takes place. The same is true for teaching with technology. Preservice teachers can know about technology, word processing, e-mail, and the World Wide Web; however, one cannot conclude that they will be able to utilize technology appropriately in the K-12 classroom to enhance the teaching/learning process. In fact, the opposite is the case; preservice teachers who are technologically literate have indicated that they had false notions about what you would do with technology in a K-12 classroom before they were exposed to methods courses where their instructors served as models for technology infusion; had field

1334
experiences in classrooms with master teachers who integrated technology into their curriculum and used it as a tool, instead of an add-on or skill/drill; and watched excellent (model) teachers via videoconferencing (Vannatta, 1999). Preservice teachers need technology to get a glimpse of real-world contexts and to connect to practitioners in the real world (Jonassen, 1995).

Current practice, however, provides too few opportunities for preservice students to model after others. A consortium of schools including the State University of New York at Oswego and partner K-12 schools will continue its efforts to remedy this problem by building on lessons learned in an earlier effort to infuse new technologies into teacher education. Specifically, through the establishment of a plan that is inclusive of more teacher educators than are presently included through our Goals 2000 Grant, we will provide technology, technological support, and mobile teacher stations that include the ability to do desktop-to-desktop videoconferences with partner schools. Overall, we will improve preservice teachers access to observing and modeling "real classroom" uses of technology.

Gaps and Weaknesses in Current Practice--Project 2000

The consortium's participation in a project funded by a Goals 2000 Grant has allowed us to see first hand the weaknesses in current practice and the ways they can be remedied. The Goals 2000 technology infusion project began in 1997 with the purpose of increasing preservice teachers' proficiency in classrooms through videoconferencing and technology infusion. The effort was supported theoretically by a constructivist view of learning, which identifies three essential elements as contributors to preservice teachers learning how to teach: reflection, active student involvement, and development of a community of learners (White, 1996). All of these elements can be enhanced through the use of computer-mediated instruction (Ford, et al, 1999).

The Goals 2000 project involved partnering college faculty from the School of Arts and Sciences and the School of Education with K-12 teachers to infuse technology in preservice education. The project supported a continued revision of education courses, implementation of an integrated MST course at one of the partner high schools, ongoing training and mentoring of faculty and inservice teachers, and infusion of technologies into science foundations, general methods, special education methods, and reading methods courses. A key component of these activities was the targeting of methods courses offered each semester for enhanced infusion of technology. Enhancements were chosen or developed in partnership with Arts and Sciences faculty and K-12 partners during a summer workshop and subsequent team meetings. Among other activities in these methods courses, there was also a concerted effort at modeling integrated classroom uses of technology. Methods classes used the School of Education’s computer lab and the Goals 2000 Project’s "technology” classroom. There, instead of using computer- aided instruction as add-ons to lessons, or sending preservice students to the computer for additional research, a methods faculty member would link writing assignments to her web page, provide a link to a group unit assignment and then to hyperlinks on related topics. Research assignments seamlessly lead to the use of web technologies to enhance research and encourage group interaction. In addition, students in methods courses were periodically linked via videoconferencing to K-12 project partners in order to observe the technology at work in real classrooms.

These activities provided students with experiences that would increase their confidence with the technology, permit them to model imaginative uses, and forestall the tendency to use the technologies merely as add-ons. Moreover, and importantly, the videoconferencing provided them with an early and real-time experience in the potential use of technologies in teaching specific subject matters.

Formal evaluation after the second year of the Goals 2000 Project, as well as formative focus group feedback, testified to the success of the project. Pre- and post-tests indicated that the technology infusions did, in fact, significantly increase preservice teachers' proficiency in integrating technologies. After preservice students completed their practicum experiences, supervising teachers indicated their significant approval of the students; they were seen as "heads and shoulders" above earlier practicum students in their ability to infuse technology into the New York State Standards-based curriculum.

So what is the problem? If we know what our preservice teachers need to develop into the teachers that we need for tomorrow, why haven’t we restructured our teacher preparation programs to reflect those necessary changes? The answer to that question is not a simple one; it is complex and multi-faceted. It has to do with change, human nature, knowledge, money, and much more. It is indeed a dilemma. How does one accomplish teaching a new group of teachers to be technologically prepared for a technological environment if they are not prepared themselves? One can compare it to trying to teach someone to fly an airplane, when they are not truly comfortable with flying an airplane themselves! A whole generation of teachers needs to learn new tools, new approaches, and new skills. This will be a
challenge, not just because of the slow moving wheels of the change process, but because of financial
cutbacks, low teacher morale, increased workloads, and reduced retraining budgets (Tapscott, 1999).

User Studies: Evaluating the Use of EPSS Tools for Self-Management by Children

Overview of the Presentation

The presenters will report the results of a research project designed to evaluate the effectiveness of new EPSS software created for children to provide them tools for managing their personal behaviors in classroom settings. The presenters will demonstrate the EPSS software and an online resource infobase that supports teachers' use of the software tools. Methodology for the user studies will be explained. These include the use of a behavior rating scale by teachers, perceptions of locus of control by children, software audit trail logs, an examination of artifacts created by children, and results of interviews with teachers. This research study is underway during the 1999-2000 school year and results will be available for presentation at Ed-Media.

Theoretical Base for the Use of EPSS with Children

Computer-based training and support mechanisms are an innovative approach for helping children gain control over personal behaviors. Although there are limited data on the use of computer-based instruction to support behavior change in children to date, research results are promising. Fitzgerald and Werner (1996) reported success with a computerized verbal mediation essay as a cognitive retraining procedure to assist a student with significant behavioral disorders in changing his behavior; the computerized essay provided consistent practice and focused the child's attention and thoughts on behavioral choices and consequences. In another case study, the same researchers reported a procedure in which software templates were developed for a student to create self-monitoring materials. This study was the pre-cursor to this work to develop and investigate the use of EPSS tools with children and their teachers as part of a federally-funded initiative focusing on children with classroom behavior problems (Fitzgerald & Semrau, 1998-2001).

The Two Components of the EPSS System

1. KidTools

KidTools is a software program designed as easy-to-use templates that can be individualized by children and/or their teachers. The software is kid-friendly with colorful graphics, text-with-audio directions, and simple formats. KidTools has undergone usability testing with children ages 7-10 to ensure literacy is appropriate for young children (Fitzgerald & Lynch, 1999). The text and audio in KidTools utilize natural language of children, graphic characters serve as “guides” to the different tools, and audio directions are provided to supplement the simplified text instructions.

KidTools is designed for children to use independently on classroom computers. To use the templates, the child simply clicks on “hot words” on the template form to enter personalized content and then prints the completed form for use in the classroom. The
program automatically enters the child’s name, date, and establishes an audit trail for recordkeeping purposes and user studies.

2. Teacher Resource Infobase

The online resource infobase provides adults with information to assist children in using KidTools. The tools in the program are grouped into six types of self-management procedures: point cards, countoons, self-monitoring cards, STAR (Stop-Think-Act-Results) cards, make-a-plan procedures, and contracting. The infobase includes descriptive information for each type of procedure, steps for implementation, a variety of examples for students, troubleshooting tips, and recommended resources. It is expected that teachers introduce children to effective use of KidTools and troubleshoot the procedures as they are implemented in classrooms. This information resource component has been developed in conjunction with KidTools for teachers and is available on CDROM as well as online for easy access.

Participants

The research project is underway in three elementary schools in two states. The participants are children, ages 7-10, whose teachers nominate them for inclusion. Children selected to participate are those either (a) showing behavioral difficulties in classroom settings, or (b) having personal habits that can be improved through a self-management process. Participants can be attending general and/or special education programs and there are no disability requirements. To be eligible, each child and his/her parent must voluntarily agree to participate and the teacher must attend an orientation session.

Methodology

Each child utilizes KidTools under the guidance of the classroom teacher for a four-month period. The process of identifying behaviors and selecting the tools for self-management is negotiated between the child and the teacher. Implementation decisions also include length of time for use of each tool and positive outcomes for success with the tools. Parents may be involved in daily communication regarding use of the tools at school. It is anticipated that tools will be used for a wide variety of behaviors and that tool usage will change as the child demonstrates progress. These kinds of unique applications that will be examined through the audit trail data and tool artifacts.

Data Collection

2. Comprehensive Behavior Rating Scale for Children: The primary teacher who nominates the child completes a normed, objective rating scale on 45 behavior items.
3. The audit trails stored on the computer disks will be analyzed for tool selection, content entered into the tools, and frequency of use by each participant.

4. Artifacts created by the participants and saved by the teachers will be collected and analyzed for indicators of success and actual use by the children.

5. Teachers will be interviewed at the close of the project regarding use of the tools, perceived impact on children's behavior, usability of the resource infobase, satisfaction with the software tools, and recommendations for improvement.

Data Analysis and Interpretation

Results from the locus of control questionnaire, behavior rating scale, and usage data will be entered into a computer file for statistical analysis. These data will be linked to qualitative information derived from audit trail data, artifacts, and teacher interviews. The interpretation will include: (a) an examination of the behavior characteristics of the participants (Comprehensive Behavior Rating Scale for Children), (b) an examination of the beliefs children have about behavior control in the classroom (Gruen, Korte, Stephens Internal-External Scale for Children), (c) descriptive data on frequency of use and content entered into the tools by children grouped by age and locus of control, and (d) qualitative analysis of artifacts and teacher perceptions.

The results from these user studies will allow developers to improve future design and development of EPSS software for children. Interview responses will help define the need and use of supports for teachers who implement EPSS procedures with young children. Finally, the approaches utilized in these user studies may provide guidance to other researchers who conduct usability tests with young children.

Distance Learning Development Teams

Anthony J Frisby, PhD
Thomas Jefferson University
1020 Walnut Street
Philadelphia, PA 19107
Tony.Frisby@mail.tju.edu

Abstract: Thomas Jefferson University, an urban health sciences university located in downtown Philadelphia, Pennsylvania, has produced and evaluated two very different distance learning format courses. Each course was a partnership between TJU’s Academic Information Services and Research (AISR) division and the College of Health Professions' Nursing Department. The Nursing Department was concerned about local competition for students and wanted to attract potential program candidates for its graduate degree program unable, or unwilling, to avail themselves of the traditional campus-based course schedule. This short paper describes the development team approach used to produce each course and presents descriptive and anecdotal feedback from students.

Development Team

The literature in software development and distance learning indicates considerable benefits in using a team approach. As Ramesh Rao, associate dean of the Graduate Business School at the University of Texas-Austin states, "From the standpoint of development, creating courses in a new medium such as the Internet can be very exciting. Very often, however, the faculty member, well-versed in his or her own subject area, does not possess sufficient knowledge in the areas of technology or instructional design." (Jeff Cobb, 1999) AISR has effectively used development teams in designing and producing high quality instructional material. The team contributes qualities no one person can master. Development team roles are outlined below.

Subject Matter Expert (SME) is the primary content person and responsible for writing, or identifying an existing source of course content, determining appropriate exercises, and reviewing all material for accuracy.

Course Editor is responsible for keeping the group organized and on schedule, as well as reviewing material for consistency. The role of editor is similar to that in the print industry and a project manager.

Instructional Designer works closely with the programmer and artist to develop the user interface for the course, identify appropriate learning technology tools for the course, and converts the content supplied by course faculty into storyboards. The instructional designer analyzes the educational goals and determines the best activities to allow learners to reach those goals.

Programmer uses the supplied storyboards, text, and graphics to code the online course using a combination of HTML, Flash Shockwave files, JavaScript, and PL/SQL commands. At Jefferson, we use a number of programming tools to facilitate production and improve the level of interactivity with the content.

Graphic Artist works closely with the SME and instructional designer to produce graphics and animations that engage the learner with the content.

Database Administrator is responsible for developing the database tables and access procedures, and for creating routines to record the students' progress through the material and responses to questions. At this time Jefferson is using Oracle as its database allowing considerable customization to meet both instructional and faculty needs.
Course Design and Production

**Epidemiology**, a graduate course for advance practice nurses, was selected as the first course to produce in this format. A web-based version of the course was developed over a nine-month schedule. The distance learning course covered the identical content as the campus-based course, but substituted alternative activities for those in the classroom. Online course materials included graphics, animation, over 1200 information "pages," a search utility, glossary, self-assessment practice quizzes, exercises, discussion boards, and case studies.

The second course, **Health Policy, Ethical and Legal Dimensions of Care**, was developed soon afterwards using a very different, much less labor intensive, approach to distance learning. Whereas the Epidemiology course produced a completely self-contained learning environment and used standard examination techniques, Health Policy used an existing, print-based textbook and online group work for evaluation.

These two courses (in either campus-based or distance-learning format) are required of all matriculating graduate nursing students. However, non-matriculating students may take these courses as well, allowing interested candidates the option to experience the curriculum before committing to a degree program. Current plans include developing online versions of all core courses in the graduate nursing program, with the goal of reaching a wider pool of students from which to recruit.

Course Results and Comparison to Campus Group

Quantitatively there was no significant difference between the distance learning and campus-based groups. The no-significant difference result is not unusual in alternative education programs. Years of research studies designed to compare traditional instruction and different computer-based learning models have suggested that the actual method of delivery may matter very little in the final outcome of student learning. Perhaps the most reliable variable for predicting student results is their involvement with the content. Time involved with the content or time interacting with the content seems most related to student success. On a subjective measure, students in the online Epidemiology course reported greater satisfaction with the course overall, and rated the course as more relevant to nursing practice than did the campus-based group.

Summary

Faculty and most students expressed their satisfaction with the distance learning format. It should be noted that distance learning is not suitable for every student. Distance learning requires a largely self-directed learner, with a fair amount of self-discipline to regularly interact with the content. Some students enrolled in the distance learning format course expecting it to be easier or require less work than the traditional course. They were surprised by the amount of effort required. As universities learn more about the needs of distance education students, new tools will be developed to meet these needs. A larger instructional design toolbox will allow developers to include an increasing variety of interactive exercises and make learning more meaningful for all students.

Our foray into distance learning was very successful. We are pleased to report that not only did the majority of students say they would take additional distance learning courses, several have. Since the first course was offered in 1998 two additional courses have been released and course enrollment has increased with each semester.

Virtual Reality Simulation of Reovirus

Denis Gadbois, David Rittenhouse, Dave Goulden
University of Calgary
2500 University Drive N.W.
Calgary, Alberta, Canada, T2N 1N4
dgadbois@ucalgary.ca

Abstract: There is an increasing role for 3D imaging and animation in clinical medicine and in scientific and educational visualization in recent years. Indeed, it is evident that computer graphics are poised to replace hand-painted textbook illustrations to become the main vehicle through which complex scientific phenomena are visually expressed. This paper describes steps taken to help visualize and popularize the research done by the Cancer Biology Research Group of the University of Calgary on the reovirus (Dr. Patrick Lee, Dr. P. Forsyth, Dr. M. Coffey and Dr. P. Strong).

Introduction

Generally speaking, our survey has found that medical animation are used for: 1) demonstrating and popularizing surgical procedures and biological processes; 2) simulating surgical procedures; 3) educating, students, patients and healthcare professionals; 4) visualizing macroscopic and microscopic anatomical structures; 5) introducing new products to physicians or consumers. In the field of medical animation, popularization can be described as the breakdown of the seemingly impenetrable wall that sometimes stands between hard medicine, student and the public. The focus of this work is to render any discovery in a visually arresting manner without sacrificing the clarity of message. The goal is to represent complex phenomena as understandable and plausible animations.

The reovirus (reo is an acronym for respiratory enteric orphan) is a naturally occurring virus that is believed to cause mild infections of the upper respiratory and gastrointestinal tract of humans (2). Preliminary research shows that the reovirus is a potent killer of cancer cells and can selectively kill cells with an hyperactivated Ras biochemical pathway (2). The Ras pathway normally regulates cell growth but becomes highly active in about 75% of tumors (including breast, pancreatic and brain cancers). Infection of a single cancer cell by a single reovirus particle can generate a thousand progeny reovirus particles, which in turn infect and destroy neighboring cancer cells. This cycle continues until all cancer cells are eliminated. Throughout this process, normal cells are spared. Tested on mice only at this point, this approach could have a tremendous implication for the treatment of cancer in humans.

The Method

An animation was developed to illustrate the research work and educate the student about how reovirus kills cancer cells. Our animation team chose SOFTIMAGE | 3D. Softimage is well designed for scientific visualization where the goal is not solely to represent scientific data, but to also tell a story. To represent these complex events (the processes of initiation, infection and replication), we used the following steps to achieve our goals:

a) Storyboarding

Several meetings were held with the research team to discuss the purpose of the animation, the intended audience and the level of detail required. Several two-dimensional illustrations were provided for the animation team to work from. The sketches and eventual storyboards for the animation were planned using these reference materials and related literature in molecular biology. One of the first facts that became evident in the planning period was the varied levels of scale that would have to be represented. A way had to be found that would enable the story to move from a macro scale (the mouse), to a cellular scale, and finally to a biochemical scale. These scale jumps had to be seamless enough to prevent the viewer from becoming disoriented about what was being shown. One way this was achieved, for example, was zooming into the cancerous tissue on the mouse and then fading into a scene showing the cellular surface. In addition, aesthetic choices about how the environments would look had to be made. It was decided that monochromatic tones would be used to de-emphasize often complex background scenes. Elements that needed to be highlighted against this background would be given different colours to bring them to the viewer’s attention.

b) Model Building

1) The Mouse

To design the mouse we used photographs of mice taken from a top, side and front views. The pictures were scanned and converted into tiff format. The scans were then imported into SOFTIMAGE | 3D. Using both the autotrace and the rotoscope option, the mouse was designed with nurbs (Non-Uniform Rational B-Splines). The
tumor location on the hind flank of the mouse was based on actual experimental protocols used by the research team. The final stage involved placing and positioning fur as a two-dimensional (2D) texture map.

2) Cell Surfaces and Proteins
The plasma membrane of each cell was modeled from a primitive two-dimensional grid. An earth tone was given to the outer surface of the cell, while the inside surface was given a water tone. Various surface proteins and receptors were created from other primitives and revolved two-dimensional profiles, and attached to the plasma membrane model using constraints. To conserve disk space, instances of these proteins and receptors were duplicated over the surface of the plasma membrane model. This made the editing of hundreds of these shapes simple and screen refresh rates much faster. A cyclic wave deformation was assigned to the plasma membrane to help create a dynamic, “living” environment. Special attention was given to the proteins and receptors of the Ras biochemical pathway, in lieu of its importance to the story being told. These models were built in consideration of their affinity to the plasma membrane and to each other. Plausible structural details were created on each model to illustrate its binding specificity to the next and previous proteins in the chain. To emphasize their importance, the proteins of the Ras pathway were given contrasting textures to the blue and purple-shaded elements comprising the background.

3) The Reovirus
A detailed model of the reovirus was created based on the structure of the actual virus as determined from electron and cryoelectron micrographs, and image reconstructions (4,6). The ultrastructure of the reovirus consists of a non-enveloped double shell of inner and outer capsids which enclose several proteins which aid in its replication, as well as a genome of double-stranded RNA (3). The components of the capsids were modeled with extruded polygons and circles, the proteins with metaballs, and the RNA stands with simple paired spheres. Where possible, instances of these models were used in place of actual geometry to reduce the model’s polygon count. This detailed model was used in those scenes where the virus was disassembling, replicating and assembling itself. A simple dodecahedron was substituted in those animation sequences which called for multiple instances of the virus. In both cases, a green texture map was applied to the models to accentuate its foreign nature within the cell.

C) The Animation
The main purpose of the animation was to explain how the reovirus kills cancer cells. Accomplishing this meant showing what normal cells look like, comparing normal cell growth to that in cancerous cells, and finally demonstrating how the reovirus interacts with cancer cells to ultimately destroy them. This task involved the visualization of a complex series of biochemical interactions to simulate both an active and a hyperactive Ras pathway, some of which were simplified to preserve the clarity of the story. The storyboards for the animation composed five sequences: 1) an introduction, 2) a depiction of normal cell growth via the Ras pathway, 3) uncontrolled cellular growth in a cancer cell, 4) the introduction and replication of the reovirus in a cancer cell, and 5) cell lysis (disintegration) and tumor regression. The narrative was added to simplify and reinforce concepts that were visually being presented.

D) Rendering
Approximately 1000 hours were used to construct the models and render the resulting five minute animation within SOFTIMAGE | 3D version 3.8SP1. The animation sequences were rendered using the Softimage rendering algorithm on 10 Intergraph workstations and one SGI Octane workstation at a resolution of 640 by 480 pixels. The five sequences were then composited and rendered with the narration using Adobe Premiere 5.1.

Conclusion
In the end, Dr. Lee and his research teams were exuberant in their praise of this project. The animation was selected for the prestigious SIGGRAPH 1999 computer animation festival and a frame from one sequence has appeared in Computer Graphic’s World (August 99).

Orienting Tasks to Enable Hypertext Learning

James E. Gall
Department of Educational Technology
University of Northern Colorado
United States
gall@edtech.unco.edu

Abstract: This paper is a report on the findings of a study conducted with a hypertext learning system used in a sophomore history class. The participants were given an orienting task (browsing, searching, connecting) to guide their use of the system. The connecters performed the best on conceptual understanding of the material, followed by the searchers with the browsers performing the worst. A number of en-route indicators also showed similar patterns of access by all three groups, including access to articles directly related to items of the posttest measures. Connecters also reported the highest levels of database utility for completing their task and the posttest. These findings demonstrate positive effects for both learning and attitudes when students are given a conceptual orienting task in the use of a hypertext system.

Introduction

Hypertext is a method for organizing information that allows meaningful, non-linear access to text-oriented resources. Unlike traditional computer-based instruction and databases, hypertext systems allow the user to access information by “jumping around” via a series of electronic links, whether in encyclopedias, textbooks, magazines, journals, databases, knowledge bases or other resources. Although the concept of hypertext can be traced back at least 50 years (Bush, 1945), it’s “practical” history has unfolded over the past ten years. Personal computer software, such as HyperCard and Toolbook, have allowed the most novice computer user to create hypertext. The emergence of the the World Wide Web in the past few years has pushed the concept of hypertext into popular usage.

The ease in both producing hypertext environments and providing access to students has created considerable research opportunities. Gall and Hannafin (1994) outlined a framework for the study of hypertext. Within this framework, they suggested examining hypertext from the perspective of a learning environment, consisting of the hypertext learning system, learner attributes, the learning task, and educational setting. More recently, Ayersman (1996) has summarized a number of research studies on hypermedia-based learning. He has organized this review into categories based on the main focus of each study (perceptual/attitudinal, individual differences, systems analyses, and performance). In short, the careful analysis of hypertext from a number of perspectives is a timely and important topic for educators and researchers in the field of educational technology.

At a surface level the concept of hypertext is appealing for education due to its flexibility and degree of learner control. However, past research on learner control with other media has led educators to be wary of the effectiveness of giving learners too much responsibility for managing their learning. Unless they are highly experienced or dealing with familiar content, this additional management chore can easily detract from the learning.

This presentation reports the results of a study conducted on the use of external orienting tasks to facilitate learning. Within the context of a learning environment, it was proposed that providing learners with goals in the form of conceptual questions would allow them to better manage their use of a hypertext system. Many of the advantages of hypertext, such as flexibility and non-linear access, would still be available to the student. However, the conceptual questions would foster better understanding of the material with corresponding positive attitudes towards the use of hypertext. Whether differences in these measures existed or not, it was also important to record the en-route behaviors of learners to better understand the way in which this flexible medium was used. This insight came from critiques of earlier learner control research.
The Study

The purpose of this study was to determine the effects of various external orienting tasks on learning, learner attitudes, and en-route behaviors in the use of an educational hypertext system. Thirty-one sophomore students enrolled in three honors sections of an introductory military history course at a major service academy served as participants in this study. During three 50-minute class periods, the participants used a hypertext database containing approximately 200 articles on World War I. To examine the efficacy of the hypertext, it was important to conduct the study within the context of an authentic learning environment. The content was both relevant, and with regard to the structure of the course, timely for the participating students. The prior knowledge and experience of the students suggested that they would be likely to be able to successfully manage their learning even when presented with a novel delivery method.

Each section was given one of three orienting tasks—one in which they were asked to browse the database to learn about airpower in World War I (browsing condition), a second in which they were required to answer factual questions about the material in the database (searching condition), or a third in which they were required to answer conceptual questions (connecting condition). These tasks were chosen as representative of the types of activities (except for the creation of links) with which hypertext users are typically involved (Gall & Hannafin, 1994).

Findings

The results indicated that the connecters performed the best on conceptual understanding of the material, followed by the searchers with the browsers performing the worst. It would follow that those pursuing the answers to conceptual questions about the material in the database (searching condition), or a third in which they were required to answer conceptual questions (connecting condition). These tasks were chosen as representative of the types of activities (except for the creation of links) with which hypertext users are typically involved (Gall & Hannafin, 1994).

Conclusions

These findings demonstrate positive effects for both learning and attitudes when students are given a conceptual orienting task in the use of a hypertext system. These findings do not discount the value of searching or browsing. However, they do suggest that these activities may limit understanding when they serve as the primary mode of interaction. Further research could focus on having students develop their own goals or questions for exploration in addition to other types of self-monitoring activity.

A Split-Brain Human Computer Interface

Gregory P. Garvey
Quinnipiac University
275 Mount Carmel Avenue
Hamden, CT 06518 USA
greg.garvey@quinnipiac.edu

Abstract: This paper describes the prototype design of a split-brain user interface which delivers two independent audio-visual streams simultaneously to each hemisphere of the brain. Users view digitized C-SPAN Archival Video of the emotionally charged testimony of Clarence Thomas and Anita Hill from the 1991 United States Senate Supreme Court Nomination Hearings. This interface presents these two diametrically opposed versions of events to each hemisphere of the brain creating a kind of artificial cognitive dissonance.

Introduction

This paper describes the prototype design of a split-brain human computer user interface. Like research in augmented virtual reality, augmented interaction and wearable computers [Mann 1998] this approach seeks to extend, enhance and augment natural intelligence by matching the innate capacity to process and understand parallel streams of dynamic audio-visual data with a new interface. Inspired by the split brain research this interface delivers dynamic audio-visual data independently to each hemisphere of the normal brain.

The initial prototype was tested with the Virtual Research Systems V-6 Head Mounted Display which supports two 640X480 60Hz VGA Active Matrix Liquid Crystal Displays. A split-brain human computer interface permits the user to comfortably watch one digital video delivered to the left eye while watching a different digital video delivered to the right eye. Simultaneously the user hears different speakers in the right and left ears. By restricting the resolution and position to one half of the raster graphic liquid crystal display the left or right hemisphere can be targeted. The interface permits the user to fluently control playback by pushing buttons or turning control handles.

Background

This "split-brain" approach to user interface design was inspired the "split-brain" research conducted by Roger Sperry and Ronald Meyers, J.E.Bogen and Michael Gazzaniga (Sperry et al. 1969). Gazzaniga along with others tested 'split-brain' patients who have undergone the surgical procedure of commissurotomy in order to limit the spread of an epileptic seizure from one hemisphere to the other. Gazzaniga's research in particular suggested the feasibility of a split-brain interface.

In a study of a split-brain patient who developed a capacity for speech in the right hemisphere, Gazzaniga presented two stories separately to the left and right hemisphere. When read by a normal subject these two stories would be read as one complete story. The split-brain patient first reports only what the left or normally verbal hemisphere sees. Then the right hemisphere reports what it read and when the patient is asked a third time to explain what was read, a third story is told made up of what was read by both hemispheres and embellished by items not contained in either source story (Gazzaniga, 1985). Gazzaniga attributes to the left hemisphere a "creative narrative talent" which he calls "the interpreter mechanism" which "is constantly looking for order and reason, even when there is none--which leads it continually to make mistakes. It tends to overgeneralize, frequently constructing a potential past as opposed to a true one." (Gazzaniga 1998)
Splitting the Brain

The split-brain effect requires matching the visible image to the nasal (closest to the nose) or temporal half of the retina. As the optic nerve leaves the eye, fibers from the nasal half of the retinas cross at the optic chiasma and continue along the optic track to opposite side brain hemisphere. The fibers from the temporal half of the retinas do not cross but continue to the same side hemisphere (Swanston & Wade 1991). The view of the world seen by each eye can be divided in half by a line at the nose. The left and right field of view are referred to as the left and right hemifields. The light coming from each hemifield is refracted and inverted through the lens of the eye to the opposite side retina. The temporal retina of the left eye together with the nasal retina of the right eye see the right hemifield of the visual world while the temporal retina of the right eye together with the nasal retina of the left eye see the left hemifield. The hemifields overlap which is essential to providing the stereo depth perception of binocular vision.

Because the resolution of the digital video was selected to be less than half the display resolution the digital video image could be registered along the inside (nasal edge) or the outside (temporal edge) of each LCD. Two placements of the digital video afforded two viewing modes which I term Convergence and Divergence Mode. The user can choose either Viewing Mode and switch them at will.

Divergence Mode delivers the digital video to each nasal retina and therefore to the opposite side hemisphere of the brain. With Divergence Mode the majority of first time users-viewers can quickly and comfortably view both digital videos as separate images. With Convergence Mode the digital video is seen only by the temporal half of the retinas of each eye and is routed to the same side hemisphere. With Convergence Mode the two image appear to be superimposed and overlap. At least a third of the users experienced difficulty in fusing the images.

Conclusion

This ‘split-brain’ interface does seek to induce in the ‘normal’ person the strange behavior and experience of split-brain patients. Rather it is intended to create a new and different kind of viewing experience. Additional research is required to unravel how the normally connected brain filters and apportions attentional focus when two parallel audio-visual data streams are presented independently to each hemisphere. The results of such experiments may yield additional insights that can be applied to the design of a split-brain interface.

BIDACI: Modeling Agents for a Learning Environment based on a Digital Library

Gerardo Ayala, Felipe Coc6n & Layda Agosto
Universidad de las Americas-Puebla
Sta. Catarina Mártir, Cholula, Puebla, MEXICO 72820
ayalasan@mail.udlap.mx

Abstract: Currently, in the area of computer aided learning, the field of Computer Supported Collaborative Learning (CSCL) presents research opportunities. Of special interest of our group has been the development of a CSCL environment based on a Digital Library. In this context, we have been working on the modeling of software agents that assist the participants in the establishment of virtual communities of practice and locate easily the knowledge considered of their interest, making a digital library a source for a more adaptive and collaborative learning environment.

Introduction

Digital libraries are repositories developed in order to collect and organize knowledge and information, making them easily accessible to users [Fox, 98]. At the Centro de Investigacion en Tecnol Automatización (CENTIA) of the Universidad de las Americas, we have been developing BIDACI (Biblioteca Digital para el Aprendizaje Colaborativo en Informática), a collaborative learning environment based on a digital library in computer science.

Digital Libraries in Education

Digital libraries in education offer opportunities to provide access to resources beyond the school and establish distributed learning communities, increasing the integration of formal learning and informal learning at the workspace or home [Marchionini, 97]. In this perspective, we consider digital libraries as the fundamental repositories for CSCL environments and lifelong learning environments.

The objective of this project has been the research and development of software components that allow the distributed, continuous and organized construction of educational material in computer science by academics from diverse institutions in Mexico. The idea was to develop a digital library that allow the exploration, construction and presentation of the material. The project has been supported by the Informatics Research & Development Network (REDII) of the CONACYT, the Mexican National Council of Science and Technology. The central objective is to increase the quality of education in computer science and information technologies in Mexican universities. For the development of BIDACI we considered three primary roles for digital libraries in education [Maly, 98]:

1) Course-related information and course materials for asynchronous distance learning.
2) Tools for constructing and organizing materials. The processes for construction must be easy for authors (technical skills and motivation).
3) Tools for an active virtual session. It must support active learning, where learners construct their own knowledge through resource discovery.

Software Agents in BIDACI

The first version of BIDACI allow the users to organize and locate easily the material, as well as communicate, cooperate and collaborate using groupware tools. For the next version we proposed the development of three software agents in order to increase the adaptiveness with the users and facilitate the maintenance and location of material in BIDACI. Based on previous work on agents, digital libraries and learning environments [Sánchez, 98] we modeled and developed:

1) A user agent.
2) An information agent.
3) A management agent.
BIDACI's User Agent

The user agent in BIDACI allows it to be an adaptive environment. The agent holds a user model [Ayala, 96] which represents the user's preferences, being a representation of her/his interests about the material. Based on this information and data from other user agents, it autonomously proposes the configuration of discussion groups, helping in the commitment of a chat session among possible participants in the virtual community. The user agent proposes a discussion group when there are potential participants in BIDACI's community. A user is considered a potential participant when s/he has shown interest in a given topic or area, which is supported by the data of the user model provided by her/his user agent. Once a group has been proposed the potential participants are notified. At any time a learner can manually make a subscription to a given discussion group, or remove her/his name from the list. The user agent notifies the elimination of a discussion group where only one member remains.

BIDACI's Information Agent

The user must be aware of the changes of the dynamic repository of distributed educational material. S/he must be aware of the material that is considered relevant and popular by the community and the new members who show interest in the same topics or areas. The information agent has been developed in order to keep the user informed of:

a) new educational material considered of her/his interest.

b) updated educational material considered of her/his interest.

c) educational material considered popular (and therefore relevant) by the community.

d) chat sessions established related to the discussion of a topic considered of her/his interest.

BIDACI's Management Agent

The management agent is designed in order to provide information to the manager of BIDACI concerning the status of the educational material. Periodically it autonomously checks the material and obtains information about:

a) the web sites that have not become accessible.

b) the material that have not been updated in a given period of time.

The management agent sends warning e-mail messages to the authors, with a copy to the manager. It constructs also a report for a given period. Here is convenient to mention the commitment of the authors of provide to BIDACI educational material every year, and keep it accessible and updated.

Conclusions

We have been working on the modeling and development of software agents that assist the participants in the establishment of virtual communities of practice, and locate easily the knowledge considered of their interest, making a digital library a more adaptive and collaborative learning environment. We believe that software agent modeling, from the perspective of learning environments, will make digital libraries the fundamental repositories for CSCL environments and lifelong learning environments.

Abstract: The University of Western Ontario (UWO) is a large, research-intensive university (equivalent to a Class I institution in the US) with a traditional undergraduate curriculum as well as a number of professional schools. As a regional institution, UWO is situated in the centre of the southwestern Ontario industrial and agricultural heartland. This presentation will describe the ongoing evolutionary process that has given rise to a centralized facility, the Instructional Technology Resource Centre (ITRC), that supports faculty in the development of on-line curriculum and course materials. Issues that are relevant to this process touch on the very core of the educational enterprise in an institution of higher learning.

The Instructional Technology Resource Centre (ITRC) at the University of Western Ontario

The Present

The ITRC was born in November of 1998 when the Vice-President, Academic allocated targeted funds for the creation of a central support area dedicated to supporting faculty in the development and use of computer-based instructional materials. The ITRC is administratively located within the central unit that supports all computational activity on campus, the Information Technology Services (ITS) unit. The ITRC mandate states, “The Instructional Technology Resource Centre is a multi-media support facility for faculty who wish to integrate technology into their courses.”

ITRC is managed by an Advisory Board composed of the Directors of the Ancillary Academic units (Libraries, the Educational Development Office, the Western Centre for Continuing Studies, ITS, the Coordinator of Summer and Distance Studies) and a faculty member from each of the 12 Faculties selected by the Dean. Logistical support is provided by ITS.

ITRC is fundamentally an instructor driven enterprise in that it functions as a resource centre for those who have the interest in the development and use of computer-based teaching and learning materials. ITRC is managed on a day-to-day basis by a full-time Coordinator who has a strong background in both information technology and educational practice. As well, two part-time ITS staff provide technical support and assistance in high-end content development for specific projects. Student developers are hired from the undergraduate population, and all have skills in the production of on-line curriculum materials.

BEST COPY AVAILABLE

1350
The ITRC operates in two main modes: first, as a drop-in centre where faculty can make use of the human, hardware and software resources. Secondly, ITRC issues requests for proposals to the campus community twice yearly. Faculty and professional librarians submit proposals to the Advisory Board where they are reviewed according to established criteria and voted upon for support. Supported projects are assigned a student developer who then works with the faculty member to develop the project from concept to product under the supervision and advice of the Coordinator. Although faculty are encouraged to acquire themselves the skills needed to develop their project, this is not an absolute requirement. The ITRC student developer is considered to be the technical “hands-on” individual.

The Past

The ITRC represents the most recent iteration of central support for instructional technology at the University of Western Ontario. In 1992, the so-called “multi-media” studio was established and operated for four years on grant funds that were used to “buy” faculty from a half-course teaching load allowing them to spend the time in the studio acquiring the necessary technical skills and developing their projects. The studio was located within one of the 12 Faculties and did not have a high profile on campus.

This model proved to be relatively unsuccessful in that faculty were unable in most instances to develop the depth of necessary skills and create their products in the time available. Only a very few of the projects that were completed ever did see use in the classroom or computer lab. However, the studio did serve very effectively as a pilot project and contributed greatly to the design and concept of the ITRC.

The Future

The University of Western Ontario is currently developing an institutional strategic plan for instructional technology (IT). IT has become a very visible issue with the Faculty Association, with academic departments, with the Distance Studies operation and with the central administration. The planning process is affected by both internal and external factors: educational quality, demand, opportunity and alternative sources of instruction. The universal input from faculty members to this process has been to support an expanded version of the ITRC with additional professional staff and financial resources.

The goals of the planning process will be to maintain the current philosophy of the ITRC as an instructor-led as opposed to top-down operation and to respond to the needs of both instructors and students. Consideration of how to arrive at these goals has touched on the very core of the university’s mandate; issues such as the role and place of teaching at a research-intensive university, the promotion and tenure process as it relates to teaching as a scholarly activity, the role of part-time faculty, the perceived versus actual demands from students for flexible learning opportunities and the financial implications of technology-based teaching and learning.
A New Education Framework within IMS-Specifications

Antonio Gómez Skarmeta, Eduardo Martínez Graciá, Pedro García López

Facultad de Informática. Campus de Espinardo.
Universidad de Murcia. 30071 Murcia, España
{skarmeta,edumart,pedro}@dif.um.es

Abstract: Educational Institutions have been using the World Wide Web for a long time in the provision of education. Currently we can observe a growing knowledge complexity and a widening variety of backgrounds and qualifications. As a consequence, we need modularly structured contents, which are linkable across subject domains and support different kinds of usages. However, the demanding requirements for comprehensive and flexible educational services clash with the complexity of its development. To alleviate this tension, the IMS Project proposes a generic architecture for online learning based on extensibility and composability of its components.

WWW and University Education

People from all corners of the university community now have the ability to create Web pages and make them available to the world. While the benefits of HTML-based documents are clear, it is also evident that this use has some deficiencies: there is no interactivity, the concept of role is not included, it does not take into account the state of the learning process, it is restricted to a few information formats and there is no quantitative measure of student performance or the effectiveness of teaching. There are several technologies that overcome the HTML limitations (Allen 1998): interactivity can be achieved with Java applets embedded in HTML pages, or JavaScript combined with HTML forms; with VRML, teachers can create virtual environments where students are invited to deal with realistic situations; XML—a system for defining, validating, and sharing document formats on the Web, appropriate for separating user interface behaviour and the semantic content of information; SMIL—an application of XML to coordinate a streaming multimedia presentation with more than one type of media file.

However, we cannot talk only about technologies, there is also a new learning style and it is necessary to design tools that support it (Schlichter 1998). In this way it is common that students work in groups to write and submit reports, or debate alternative perspectives and solutions on a common problem. Tools to engage this collaborative work in a distributed way are needed, like discussion forums, chats, whiteboards and collaborative authoring tools. This leads to the creation of new powerful learning environments, which are not adaptations from classical teaching and training, able to produce high quality multimedia education material, learner-centered and network-based. To show our work in this line, in the next section we present one of the main standardisation effort in the educational environment the IMS project.

The IMS System of the University of Murcia

The Instructional Management Systems (IMS) project (http://www.imsproject.com) is a partnership of academic, commercial and government organisations to cooperate in the definition of an Internet architecture for instructional systems and learning content, with a primary objective: enable an open architecture for online learning in all sectors of lifelong learning. Learning materials are collected in IMS containers, which include a unique identifier and metadata that describes the container and its contents to facilitate search, storage, retrieval and use rights. Learning materials can be web pages, interactive content or collaboration tools. Containers can be aggregated or nested, and the contents of a container may be sequenced according to different rules. IMS environments are software developments that implement the IMS Specification. The IMS environment extracts the contents from IMS containers and delivers them to users, normally with a Web server.
The next figure shows the components of the IMS System and the relations between them. The central element is the Management System, the component that provides the interface to access or administer learning materials. It identifies users, creates sessions to facilitate a uniform mechanism of access control and supervises the actions that users can perform, according to their roles. Through the Management System, an administrator can install new content packages, and perhaps create new users or groups and edit access rights. A student also uses the Management System to operate with content.

The Content Server (there would be more than one) stores the learning materials and their metadata, and provides the IMS CORBA interfaces to access those materials. A Search Engine can use those interfaces to perform intelligent searches. As a first prototype, our IMS System will use already created html-based documents as learning-material, with associated XML files to describe them. The Management System also uses Content Servers to get the materials requested by users. User profiles are stored on the Profile Server, which also provides a special interface to access this information.

The University of Murcia, like other Spanish universities – UNED, UOC – has a clear interest in the use of new technologies applied to higher education as a way to improve the quality of the learning process. This interest took shape last year in a project called SUMA – Servicios Universidad de Murcia Abierta. SUMA affects two main fields: network infrastructure, that will be scaled to support 10,000 users and 1,000 concurrent connections, and telematic services. We are designing the new architecture of the SUMA framework taking into account the ideas defined in IMS, and considering CORBA and XML as fundamental elements of the learning support. We are also working in the introduction of videoconference tools and security elements in this system. There is a PKI based on the use of X509 certificates that has been completed successfully with the development of a PKCS11 module that lets students use web-based services securely with HTTPS. Each student and teacher has his/her private key stored on a smartcard protected by a PIN. When the user connects to a secure web server, the Netscape browser activates the PKCS11 module, which performs cryptographic operations with the smartcard. SUMA project of the University of Murcia represents one step in the development of an Open University, based on the used of the WWW technologies. In order to be successfully implemented, it is necessary not only to create innovative collaborative tools that support the active learning, but also to design the whole system under the light of open specifications like the one proposed by IMS.

Art and Technology in the Classroom: The Activities and Impact of a National Project.

"The Community Discovered: The Search for Meaning Through the Integration of Art and Technology in K-12 Education" is now in its final year of its five years of funding, and is being conducted by Westside Community Schools in Omaha, Nebraska. The major focus of The Community Discovered project is represented by its five goals, which are carefully integrated into the objectives undertaken in the project. These five goals, and brief examples of activities within the project, consist of the following:

Goal 1: To enable students to achieve high academic standards by integration of the arts and technology into core subject areas

Goal 1 Example Activities: The project has developed a web based curriculum unit structure by which teachers document developing curriculum units which target the effective integration and technology into core subject areas. In addition, teachers complete electronic growth plans which describe this ongoing effort and focus within the project to actively engage students in discipline based art activities using technology, and resources available over the Internet.

Goal 2: To provide students and educators equity in access to information and museum resources at the state and national levels

Goal 2 Example Activities: The project has developed a model web site for convenient access of the information and museum resources developed by all of the project partners. This web site can be accessed at:

http://communitydisc.wst.esu3.k12.ne.us.

Goal 3: To enable educators to effectively use appropriate technologies for constructivist teaching and learning across the curriculum

Goal 3 Example Activities: Educators within the project have participated in extensive inservice activities targeted at constructivist learning and interdisciplinary teaching across the curriculum. These have entailed summer institutes, periodic inservices during the regular year, and a variety of local efforts, such as "curriculum street fairs" within the schools.

Goal 4: To enable educators to implement effective curricula incorporating the arts and technology in core subject areas

Goal 4 Example Activities: Participating educators have also engaged in considerable inservice efforts related to the use of technology in teaching and learning, with a focus on the integration of the arts into core disciplines. A particular innovative example during this last year was a national ConferNet effort, which was a model on-line student conference offered for participating classes of K-12 students and teachers. A second academic on-line conference for students is being planned for the Spring of 2000.

Goal 5: To create a national network of educators to support the development and implementation of appropriate learning strategies integrating technology, and the arts with other core subject areas.

Goal 5 Example Activities: The project has been highly successful in creating a network of individuals assisting with the project. In particular, an extensive
listerv process, special interest groups, and a three level national advisory board is in operation and is being utilized throughout the project. The members of the advisory boards are often asked to interact with project staff for the purpose of guiding the evolution of the project and providing feedback regarding the outcomes.

THE IMPACT:
The Community Discovered Project has had considerable success with both students and teachers in the project, and is evolving into a national model for the effective integration of technology and art into education. The ongoing evaluation process of the project uses multiple sources of information, and includes a comprehensive approach to data collection that is targeting information related to each project goal and objective. These data types include: 1) teacher survey data, 2) electronic data, such as listserv participation and electronic logs, 3) classroom observations, 4) teacher and student interviews, 5) student projects and portfolios, 6) teacher growth plans, 7) focus groups, 8) stakeholder surveys, and 9) teacher based classroom research initiatives.

All data is summarized and placed within a World Wide Web page format that is available for review by anyone interested, and especially project staff, participants, and stakeholders. The web site representing the evaluation portfolio is:

http://ois.unomaha.edu/cdeval/

The evaluation web site is fairly comprehensive and is organized using a variety of themes and graphics in order to present the evaluation information clearly. The evaluation team, composed of three education professors from the University of Nebraska at Omaha, and two assessment specialists from WestEd Laboratories, has documented the impact of the CD project within this web site. Some of this impact has included:

1) In-depth Participation: The project has already successfully involved over 300 teachers, 300 teacher partners, and 24,000 students, with in-depth technology and art integration experiences within the project.

2) An Impact on Student Achievement: The project has resulted in enhanced student achievement as documented by carefully controlled classroom studies involving over 600 students. These studies have demonstrated significant project impact through improved reading scores, mathematical patterning skills, writing fundamentals, art interpretation skills, and general attendance of the students.

3) An Excellence in Student Products: The project has collected a wide range of innovative student products which show the power of students working within technology based environments, including projects involving hypermedia, the World Wide Web, and virtual reality.

4) An Impact on Teaching Knowledge and Skills: Teacher knowledge has greatly improved within the project. Through surveys and interviews, 96% of the teachers report improvement in technology, 99% report improvement in art integration, 85% report improvement in interdisciplinary teaching, and 90% report improvement in constructivism. In addition, a careful analysis of the teaching process through formal classroom observations, has documented that teachers are indeed involved in effective instructional techniques related to these four areas.
5) An Extensive Contribution to the Professional Literature: The Community Discovered Project has been aggressive in its contribution to the professional literature, and has already resulted in 6 professional refereed articles/papers, 2 graduate theses, and more than 20 refereed presentations at national conferences including well respected conferences such as the National Educational Computing Conference (NECC), the Society for Information Technology in Education (SITE) annual conference, the American Education Research Association conference (AERA).

6) A Model Web Based Environment: The project has developed an impressive presence and use of the World Wide Web. As mentioned, this presence is accessible at http://communitydisc.wst.esu3.k12.ne.us, and includes an extensive project web site, an on-line evaluation portfolio, databased curriculum units, and substantial listserv and conferencing. The project has also conducted the well respected ConferNet 99, the first ever national student conference conducted on the Internet. Museum partners also maintain impressive project related web sites, which include a variety of digitized works, virtual museum tours, on-line magazines, and a wide range of Internet based curriculum support materials.

A FINAL THOUGHT:
It is said that a good project will always continue to grow and evolve, and "The Community Discovered: The Search for Meaning Through the Integration of Art and Technology in K-12 Education" is now well established, growing systematically, and evolving fully in its final year of formal activities. The project has embraced advanced information-based technologies and has refined its plans as technology-based applications continue to evolve with emerging capabilities, such as new capabilities on the World Wide Web. The project is building upon its earlier successes, upon a strong organizational foundation, and with an aggressive commitment by its many partners. As The Community Discovered project moves forward, perhaps most importantly, there continues to be a real team effort underway by all stakeholders in the project to positively effect the learning environment for all students. This teamwork is growing and becomes more solid during each successive year of the project. As any project desiring to stay on the "cutting edge", it is expected that The Community Discovered project will continue to evolve as new educational technologies and understandings become available. The project is a comprehensive one, and its use of a systematic implementation process and the incorporation of a careful evaluation plan are no doubt critical components in its effectiveness to date and promise of effectiveness in the future. The strong and full commitment by all partners to contribute to the overall success of the project will no doubt continue to provide a natural catalyst for success as the project strives to implement its very aggressive set of goals and objectives.
A Comparison of Static and Dynamic Media Types for Process Oriented Learning Tasks

Guttormsen Schär, S., Zuberdübler, H.J., Krueger, H.
Institute of Hygiene and Applied Physiology
Swiss Federal Institute of Technology, Zurich, Switzerland
e-mail: guttormsen@iha.bepr.ethz.ch

Abstract: This paper presents an overview over an experiment, which investigated the effect of dynamic (e.g., animations) and static (e.g., pictures) media types for process oriented learning content. Teachers who want to apply new technology in education need guidelines in order to develop the presentations themselves, supervise programmers or to know what to buy. Many fragments for such guidelines do exist, our experiment is a contribution to build a consistent empirically based knowledge base in this area. A small advantage of animations for pictures was found, more attention should be given to the design of such presentations.

Introduction

Multimedia is a challenge for the educational field, insofar as consistent guidelines for how to apply the different media types for the presentation of learning materials are lacking. The tools for developing multimedia presentations are still not easily applicable for teachers. Hence, teachers may have the choice between not applying new technology, learning how to implement presentations themselves or organise the necessary productions with external resources. Whenever the two latter options are chosen guidelines about how to make high quality presentations are needed, either for supporting own development, to supervise a programmer or to know what to buy. This paper presents an experiment in which features relevant for the presentation of dynamic learning contents (processes) were compared. A former experiment investigated how to present static learning contents (principles) (Guttormsen Schär, Kaiser, & Krueger, 1999). We have taken a task dependent approach to media allocation, based on a general categorisation of the learning content as concepts, principles, facts and processes (Merrill, 1983). In the multimedia context, dynamic features could be animation, film, voice or simulation. Empirical guidelines for the implementation of multimedia for dynamic learning material are only slowly approaching. The reason is, on the one hand, that the tools and technical resources for the production of dynamic presentations are only recently easy to apply. On the other hand, the design of experiments in this area requires much effort, because the production of unique test material (e.g., animations) is both time and resource demanding. Nevertheless, to realise the pedagogical potential of multimedia, there is a great need for such research.

Experiment

The general hypothesis was that process oriented learning material is better learned with dynamic presentations, in this case operational defined as animations. The experimental conditions are shown in Table 1. Unique animations of 5 different processes were produced; the static presentations were derived from the animations. The experimental situation was fully computerised and all the data was registered in a log-file. Operational definitions of learning performance are given below:

Visual: The recognition of logically correct pictures, under a selection of similar pictures with small errors.
Active: Complete incomplete sentences in which essential concepts or expressions were missing.
Passive: Choosing correct statements from a collection of both wrong and correct examples from the tasks.
Preferences: "Which of the presentation forms (/tasks) did you like most?"

Table 2: Effects of Presentation Forms

Discussion and Conclusion

The benefit of dynamic presentation was smaller than expected. However, the fact that we found no difference between presentations with animation (without voice) and picture + text shows that movement possesses basic informational quality. The hypothesis is further supported in that the best learning effect was achieved with presentation forms including a dynamic factor (animation and voice). The pictures were carefully produced to represent the same information as the animations (e.g. movements were indicated with arrows). Hence, the relative good effect of pictorial information may reflect good picture quality more than low importance of animation. In conclusion, animations alone are no guarantee of good learning performance when pictures and voice can be produced with high information quality. Still, animated presentations were preferred by the subjects.

Time-Expanded Audio For Learning

Kevin Harrigan
Centre for Learning and Teaching Through Technology
University of Waterloo, Canada
kevinh@uwaterloo.ca

Research has been conducted on building tools that allow users to control the speed of audio when playing audio on a computer and some commercial products are beginning to appear on the market (Eloguent, 1999). The research to date has focused exclusively on time-compressed (i.e. speeded-up) audio with an emphasis on improving the user interface (Arons, 1997) and improving learning efficiency (i.e. learning per unit of time) (Harrigan, 1995a; Harrigan, 1999). The research has shown that audio can be time-compressed by approximately 50% without any loss of comprehension or retention and that learners do use the time-compressed audio if given the controls in the user interface. The research has also shown that using a known technique, called SOLA (Roucos & Wilgus, 1985), speech can be time-compressed without any significant change of pitch which is much preferred by learners over simply playing the audio faster which producing a change in pitch and what is often referred to as the “Mickey Mouse” effect.

This paper reports on the first experiments that have been conducted using SOLA to time-expand (i.e. slow down) audio without any significant pitch change. These preliminary experiments used subjects who had no special needs but the end use of this technique is envisioned to be for people with special needs such as those with acquired brain injuries.

Research Questions

The two questions we addressed were:
1) When time-expanded audio is played to learners at what point will they notice that the audio has been time-expanded? In other words, what is the Just Noticeable Difference (JND) of time-expanded audio.
   A) When the audio has been time-expanded simply by playing the audio.
   B) When the audio has been time-expanded using the SOLA technique.

2) What is the time-expansion percentage at which learners will not be able to understand the audio. In other words, the intelligibility level. This has typically been measured by playing speech segments to subjects at an accelerated rate and determining the point at which the subject cannot understand 50% of the speech segments (Harrigan, 1995b).

The Experiments

As stated, we intend to use time-expanded audio with people with special needs. However, in these initial experiments we used subjects who had no special needs as we felt we could gain two things (a) we could ensure that our software worked properly and (b) we could address some fundamental questions that may shed some light on issues related to time-expanded audio and may help us calibrate our future experiment. We were successful on both counts.

Experiments One: We had a speech file on our computer that was a help file from an application. We used the SOLA technique to create versions time-expanded by 5%, 10%, 15%, 20%, and 25% for a total of six files including the original. We then created a screen with thirty buttons labelled 1-30. As each button was selected one of the six speech files was played with each speech file being played five times in total. After selecting each button, the learner had to circle on a piece of paper whether the speech sounded normal or time-expanded. The results from the seven learners (N=7) showed that the average JND was 5.4 % with a SD of 3.9.
Experiment Two: Experiment two was identical to experiment one except that the audio files were created by simply playing the audio slower with a resulting change in pitch. The six learners (N=6) had an average JND of 9.2% with a SD of 2.6.

Experiment Three: In this experiment we had five files time-expanded using the SOLA technique by 38%, 58%, 84%, 100%, and 121%. Some calibration was done prior to the experiment in order to choose the appropriate compression levels. We had 25 continuous speech segments from a file in an educational multimedia CD that we had created. Segments were about six words each. As an example, the first speech segment was “it was important to open my mouth”. We created a screen with 25 buttons. The six learner’s (N=6) task was to click on each button in sequence, listen to the speech segment, and then write down the phrase that had been spoken. After the experiment the two investigators read each response and made a judgement as to whether they understood the phrase. The results showed an intelligibility level of 92% with a SD of zero. This means that all subjects understood the audio at 84% but not at 100%. The intelligibility is calculated as the middle point between these two levels (i.e. ((84+100)/2)=92). An intelligibility level of 92% means that a one minute file plays in 1.92 minutes (1 minute 55.2 seconds) which is almost twice the length of the original file.

Conclusion and Future Work

The results of the first two experiments clearly indicate that the SOLA technique is superior to simply playing the audio slower because when using the SOLA technique learners don’t realize the audio is time-expanded until a higher time-compression percentage is used.

The results from the third experiment are close to what we expected. When audio is speeded-up it can be speeded-up by double (i.e. played twice as fast) before intelligibility begins to drop (Foulke & Sticht, 1969) and with this experiment we show that it can be slowed by almost double before intelligibility begins to drop. Since people normally speak at 150 words per minute (wpm) this means people can listen at rates up to 300 wpm and as low as almost 75 wpm. The results of this experiment confirm that using time-expanded audio has the potential to be used to half the speaking rate and thus time-compressed audio may be useful for people with certain special needs.

We now plan to continue our work with the following initiatives: (a) produce a system that can be used by the learners to control the speed of audio and test it with learners, (b) test our system with learners with special needs who might benefit from this system that supports time-expanded audio and (c) build a system that includes audio as well as video and test it with learners.

Project DEED, Distance Education for Education Diagnosticians. Putting Available Technology to Work via Internet for Rural, Bilingual Sites Along the Texas/Mexico “Border Corridor.”

Ralph M. Hausman, Ph.D.
The University of Texas at Brownsville & Texas Southmost College (UTB/TSC)
80 Fort Brown, School of Education, School Specialties Department
Brownsville, TX, USA 78520
rhausman@utbl.utb.edu

Abstract: Project DEED is a four-year internet based special education personnel preparation program funded by the U.S. Dept. of Education, Office of Special Education Programs (OSEP) as located at UTB/TSC. The project involves the preparation of practicing, bilingual teachers located in 8 rural sites to become educational diagnosticians, assessing students with possible disabilities. Instruction is accomplished through a combination of available resources, i.e., multimedia modules in synchronous format with videoconferencing, CD-ROMs, email, chat rooms and local mentors. Extensive time was required for the initial videoconference setup between all nine distal sites. Although there remain a variety of ongoing, technology related problems, evaluative data available on completion of the second year of the project supports the use of multimedia modules in conjunction with videoconferencing in the preparation of rural, special education diagnosticians.

Overview

Use of the internet for one-way instruction is not particularly new, neither has it been actively employed in an interactive manner to deliver multiple-course programs. However, it would seem to hold promise for content delivery in a manner acceptable to, if not preferred by, consumers in rural, geographically isolated areas. With the advent of T-1 fiber-optic lines connecting the local school systems throughout South and South West Texas in the past few years, the internet has been made available as a vehicle for distal instruction. The project to be described herein is considered innovative in that it is new to the geographical area and combines a variety of available, relatively inexpensive technological resources in a manner directly relating to the learning styles of the targeted population. The intent of the project is the production of a cohort of bilingual educational diagnosticians in an area in which there is a serious dearth (Hausman, 1997).

Project DEED, Distance Education for Educational Diagnosticians

Federal legislation (IDEA, 1990, 1997) mandates the comprehensive individual assessment of school age students, i.e., from three through 21 years of age, to establish eligibility for special services. A variety of school-based personnel have been developed in response to these mandates, among them educational diagnosticians. The diagnostician's certificate involves specialty training on a graduate level in a wide range of areas related to assessment. IDEA also mandates nondiscriminatory evaluation in the students’ native language. This poses a problem in that of the 3,748,167 students enrolled in Texas schools, 46.4% were White (not of Hispanic origin), 36.7% were Hispanic, 16.9% were other minorities. Thus, minorities comprised 53.6% of the student population in Texas public schools with Hispanics as the largest minority group. Yet, only 10% of the active diagnosticians had Hispanic surnames (and not all were bilingual). Along the Texas/Mexico Border Corridor, i.e., an area extending 50 to 70 miles North of the border along the nearly 900 miles of its length, the proportion of Hispanic youth soars to a significant majority of students, particularly in the Rio Grande Valley (Texas Education Agency, 1996).

Project DEED was designed to connect the UTB/TSC site, via the internet, with 8 distal-based school systems located in the Border Corridor up to 400 miles distant. The cohort consists of 20 certified bilingual individuals (2 males and 18 females) currently employed with the public school chosen as a site. Program delivery involves
specially designed interactive multimedia modules (based on the QUEST utility package). The overall program was structured with reported preferred learning styles characteristics of Hispanic students in mind (e.g., Griggs & Dunn, 1995). For example, videoconferencing among all 9 sites during scheduled classes each week was selected to appeal to the traditional conceptualization of formal instruction, respect for authority, and need for cooperative or peer-based learning activities. The QUEST-based multimedia, interactive modules were also included to fit reported preferences for structure, vivid stimulus displays, variety and kinesthetic instructional approaches.

The QUEST utilities package (Allen Communication, 1998) was selected as the basis of module development in that it permits the combination of video clips, various illustration types, graphics animation, audio overlays, and text, all with preprogrammed instructions, into interactive modules designed for use over the internet. The modules consists of a compilation of frames containing color-coded text with specific concepts illustrated, and popup insets triggered to key underlined words or to provide in-text references. Extensive use of 'side bars' and animations has also found favor with the cohort members. Thus far, the module format that has been received most positively has included a brief overview of the focal topic, followed by simulation activities to allow learners to experience a variety of difficulties that, hypothetically, are experienced by students with disabilities. In addition, the content includes definitions (federal and state), terminology, student eligibility requirements, categories, history, legislation, and services associated with the specific topical area. Interspersed throughout the modules will be case studies or scenarios with questions similar to those included on the state mandated, certification examination. CD-ROMs mailed to the sites remain the preferred delivery system for high-security items such as test kit training units.

A variety of potentially useful videoconferencing systems were reviewed. The CU-SeeMe (1995) based ClassPoint and MeetingPoint software packages were selected due to the need for multipoint connections and as they were the most economical at the time. The primary problems we have experienced this first year of online classes have included (a) broaching a regional firewall (surrounding 5 of our 8 sites), (b) fine tuning the instructor (oncampus) setup (e.g., software as well as hardware), (c) arranging for site-based, site-supported technical staff to work together with the other schools systems technical staff members and (d) interconnecting differing computers and computer systems to function as an extended network. The forces of nature, including the effects of a hurricane also contributed challenges. Then, fine-tuning intersite connectivity is required to adjust to each of our university system’s internet access upgrades, requiring extensive, readily available support from our Academic Computing department. Yet, the student’s grades remain high, as does their reported sense of accomplishment.

Throughout the Fall, 1999, semester offering of the first online course (an introduction to special education), the sites used a conference telephone call and oncampus audio bridge to supplement the videoconferencing. Since March, however, our transmission delay time has significantly reduced as has the number of ‘hops’ reported between connections, and our audio quality has improved to the point that the conference telephone line serves only as a backup system.

Abstract: DHTML (Dynamic HTML) has the potential to deliver interactive hypermedia cheaply from a CD, without the courseware developer having to cook up solutions for all the cross-platform, rendering or navigation problems that the browser resolves. Visual, extensible HTML editors, and the talented group of people developing extensions for them, are building a development environment that might just make the HTML editor/browser combo a workable substitute for older Hypermedia authoring environments.

Educator’s Dilemmas
The limited budget and political surroundings of educational researchers and developers often require us to do our own software engineering, or at least to know what we’re asking a contractor to provide. This paper outlines some of the technical and pedagogical issues involved in this endeavor.

Design Methodology
We have found that a sound theoretical background and curricular analysis are essential to a worthwhile educational effort. We started with a modified implementation of Rand Spiro’s Cognitive Flexibility Theory and soon incorporated elements from other Constructivist and Situativist learning theories. This paper will not attempt to summarize those theories, but merely to point out that we have not simply let the available technology shape our designs.

To CD or not to CD

Custom Browsers
Netscape and Microsoft both provide free customizing kits: NS-CCK and MSIE-IEAK (modifying a browser may be too involved to be practical, but often 3rd party vendors will do it for you). Information is available at:

CD Production
Major browsers cannot run off a CD; browsers that are able to do so are usually not very good at Javascript or DHTML support. Therefore, your CD should include an option to install the browser of choice on the learner’s computer. The many issues of providing multimedia content on CD-ROM are nicely summarized at this Web address:
http://www.phdcc.com/helpindex/cdroms.html
Persistent Storage
Cookies- Most browsers make something like this available, and it's the most obvious way you can put semi-
permanent information on a computer (test scores, student info, learner-selections), but users also have the option of
turning cookies off, and the learner might change computers.

Parent page globals-- If you declare a variable on a page that remains open but opens other pages in front of it, that
variable remains useable by any of the other pages. This is a valid technique in some situations, and we use it at:
http://www.bonfils.org/courseware/

Hidden form fields in frames-- If a standard frame appears beside your other pages, that frame can contain hidden
fields with information generated by the learner's interactions. See the article at this Web address:

Strings appended to link addresses-- Another possible technique, described in detail in the article at:

CD as Server
CD speed equivalents
(this information was gleaned from various sources and is not authoritative; the point is that even the slowest CD is
faster than the fastest modem.)
1x: 150 Kbytes per second (about three times faster than the fastest modem).
2x: 300 KBPS
8x: 1,200 KBPS
16x: 2,200 KBPS (comparable with a slow hard drive)
24x: 3,600 KBPS
Check this Web address for details: http://webopedia.internet.com/TERM/C/CD_ROM.html
Compare the T1 rate: http://www.ora.com/reference/dictionary/terms/D/Digital_Transmission_Rate_1.htm

Browser Wars
DOMinance
The Document Object Model is a way to categorize everything on a web page as a part of one big hierarchy of
objects (like tables or lines of text). These program items can be given specific names and attributes. By referring to
these items by name, and by responding to events (like 'mouseover' or 'dragdrop'), a program can make a web page
interactive or "dynamic."
For more about the DOM, go to: http://webopedia.internet.com/TERM/D/DOM.html

Standards? We don't need no stinkin' standards!
The group that first designed and enabled the Web now calls itself the W3C, and it noticed that scriptable browsers
used DOMs that bore only a passing resemblance to one another. So, in association with the ISO, an official,
detailed, standard DOM has been prepared. MSIE 5.0 and Netscape 5 (as yet unreleased, but available in
development form as Mozilla), both claim to use "most" of the W3C DOM.

Platform Issues
Rendering, type size
A difference in the way Windows and Macintosh machines draw text on the screen often results in Macs displaying
type smaller than Windows machines.

Debugging the browser
Once a company feels it's Windows version is ready for release, it seems that, whatever shape the current Mac
software is in, the Mac version goes out the door too. We have found that some functions that are fully implemented
in the Windows version of a browser are not quite as well handled in the Mac version of that same browser.

Browser Plug-ins: Authorware, Shockwave, VRML, etc.
At the student's end, most major multimedia producers provide extensions to the browser that allow the student to
view your web page's content from within their browser. However, you must be sure your server (not just their
browser) can handle the files that contain the multimedia content.
Abstract: Learning objects are rapidly finding a place among the standard teaching tools upon which educators depend. Although they have the potential to enhance student learning, this potential may not be realized unless standards are developed to communicate information about the learning object and its educational role. In this paper, we will discuss a way that the educational role of learning objects could be communicated to educators who are considering its use in instruction. We propose a format that describes four key features of the learning objects relationship to the instructional context. The four categories of information are entitled concept, context, instruction and activity. Including this instructional information will facilitate the incorporation of learning objects into instructional contexts.

The IEEE Learning Object Metadata Working Group (1999) defines a learning object as any entity, digital or non-digital, that can be used, re-used or referenced during technology supported learning. This definition is broad, demonstrating that learning objects still tend to be ill defined and lack standards (Cox, 1999). For the purposes of this paper we will be defining them as digital media, designed to be used by educators and learners to achieve particular learning outcomes. Part of the reason for the increased interest in learning objects is that greater numbers of people are able to create them, as applications that were once the sole domain of multimedia experts become more accessible. While, on the one hand, the proliferation of learning objects is a positive development for education, on the other, the existence of large numbers of learning objects, created many different people using various development tools may result in mass confusion. Finding, assessing, and using a learning object may become so difficult and time consuming that few educators would see the value in doing so. The development of learning objects needs to be accompanied by a standard way of communicating information about them (metadata) so that they can be easily found, assessed and used. Part of what needs to be communicated needs to refer specifically to the ways in which the learning object can be incorporated into instructional contexts.

An example of a learning object could be “Strike Lines”, a fundamental concept in the discipline of geology required to fully understand geology maps, mining and oil geology. The learning object would include a description of the significance of strike lines, put them in context relative to rocks, geology maps, contours and other related concepts or learning objects.

The instructional context

All educational media, digital or not, is best judged upon its ability to support student learning. For that reason, it is necessary to embed any discussion of learning objects within the language and conceptual framework of current learning theory. Constructivism (Cobb, 1994; von Glasersfeld, 1989) has been the most influential theory of learning in recent years. In addition to having been prominent in educational literature, it
has become the standard perspective on learning put forth in many curriculum documents. Constructivist views on learning recognize that students are active constructors of their own knowledge. Students enter a learning situation with prior knowledge. It is upon this prior knowledge that new constructs are acquired by the learner. Sometimes the construction process is one of simply relating new constructs to existing ones, while at other times acquiring new constructs requires that existing ones be altered or replaced. Recognizing and facilitating the construction process is the work of the teacher.

When a learning object is used in the classroom it is important that the idea or concept that the learning object is intended to support be seen in relation to other related concepts. This provides a teacher with the conceptual landscape in which the learning object is located. Knowing the conceptual landscape helps the teacher appreciate the context in which the instruction takes place and the sort of linkages students need to make. Planning instruction requires this appreciation be used to in the development of instructional strategies aimed help students achieve the desired cognitive goals. Even when a good instructional plan is created and enacted, students frequently have difficulty constructing new understandings, especially when they conflict with their prior understandings. For this reason, learning activities for practice and follow-up must be carefully developed and administered.

Communicating the Potential

We suggest that measures be taken at the time when learning objects are produced to ensure that they are easily used in instruction. Part of the information given should refer to the instructional role of the learning object, taking into account many of the issues highlighted by a constructivist perspective on learning. Specifically, we propose that four categories of information accompany learning objects:

1. concept - a description of what the student will be learning from the learning object.
2. context - information on expected prior knowledge and links to other concepts and/or learning objects. The context may also describe applications of the concept.
3. instruction - details the way(s) that the learning object could be used in instruction.
4. activity - describes or includes activities in which a student could use the learning object to practice and perfect the concept as well as to assess their progress.

On the basis of this information, we believe an educator would be able to make a decision about the ways in which any particular learning object could be incorporated into instruction. This information would support the usage of the the learning object for concept introduction, practice, and/or review. In addition to being informed of the educational role of a particular learning object, educators will be able to consider the relationships between various learning objects available for instruction. Conceivably, a web of learning objects could be designed to support students as they learn complex, interrelated concepts.

My presentation is about supervising students on their terms of probation abroad. For this aim I have developed several years ago an internet site in HTML. We have tested this site in co-operating with our students abroad. To improve this application I have developed a new tool in Lotus Notes/Learning Space. During the presentation I want to show and discuss the results and our experiences. With this presentation I hope to achieve the following aims:

1. To show how useful the Internet can be in education particularly to supervise the students on their terms of probation.
2. To get feedback and critics on our product.
3. To establish contacts with other colleagues in case of this subject.

Today’s Situation
- All our students abroad have to send their reports to the supervisors.
- Nowadays they use the postal service or send a fax. Sometimes the documents Don’t arrive at the workplace/office.
- When they are in trouble, they use the telephone for the communication with their supervisor. This method is very expensive.

Vision Statement
Students and supervisors need a good tool for their communication. Using the Internet is the solution.

Goal
To create a possibility for the communication between students abroad and their supervisors at the university.

The solution
- First we have created a website with all the possibilities available for the students and their supervisors.
- Nowadays we are working with Lotus Notes/Learning Space

Perspective

In a time when modern culture is linked by telecommunications technologies in ways never before possible, people transmit and process information, conduct business, collaborate in research, and engage in social and political discourse in dramatic new ways (Kapor, 1998, Wriston, 1996). Amidst this context, many educators search for a cost-effective way to develop a technological infrastructure that can effectively serve the needs of their students. When their searches yield promising results, educators who attempt to initiate such infrastructures can become stifled by bureaucratic norms and historical values, or thwarted by political and economic crosscurrents within their institutions. Furthermore, the implementation of new technologies within higher education institutions—environments almost perpetually preoccupied with finances and funding—must be done with utmost economic efficiency. The development of new technologies must also support the diverse needs of student populations whose characteristics are continually transforming beyond those of the traditional student (Dalziel, 1997). For example, many contemporary students need flexible scheduling of classes and alternative ways to access and distribute information because they work and attend school. For these students, distance education is often heralded as an excellent way to help them obtain the benefits of higher education while balancing their non-traditional roles and responsibilities. Yet, ironically, the potential benefits offered by something as non-traditional and futuristic as distance education classes may be undermined by their incorporation of pedagogical techniques and traditions that are not consistent with the changing educational needs of society. If distance education classes merely entail the uploading and distribution of didactic lectures, quizzes and paper assignments, then they may be falling far short of their potential to serve contemporary students who want—and need—to become successful members of modern society. Today's highly interactive society demands that its citizens think critically, problem-solve, and see outside traditional paradigmatic structures (Cox, 1997, Frazier, 1997, and Boetcher, 1997), and educators should be preparing students in a manner consistent with the needs and demands of their society. Distance education in particular needs to provide the types and extent of interactivity consistent with the new global society. But the question is: Can distance education courses actually be aligned to pedagogical practices which serve the needs of a rapidly-evolving, technology-assisted, information-driven society?

Purpose of the Study

The purpose of this case study was to analyze a distance learning program designed to align technological methods and pedagogical practices to better meet the needs of its students. This study focuses on a block of secondary teacher education methods courses that employed web-based distance education. The methods courses were taught at a mid-size state university to sixteen post-baccalaureate students who were teaching in grades 7-12 on emergency certification during the 1998-99 school year. Strategies implemented to support the program’s goal were:

- Professors created problem-posing curriculum that required students to assimilate information presented in their methods courses, synthesize it, and apply it within the context of
their own school or classroom.

- Professors created public cyber spaces for students to publish their work and to react to the work of their peers.
- Professors created public cyber spaces for students to debate, solve problems, and dialogue about current issues and concepts associated with the courses and their work.
- Professors’ modeling of meaningfully integrated technology in order to support a problem-posing curriculum.
- Students’ learning of requisite technological skills for engaging in class activities.
- Students’ reflection on their learning through journals, conversations, and electronic portfolios.

Methodology

Informants for this study included sixteen post-baccalaureate university students teaching on emergency certification, two professors, and one graduate student/instructor. The students' electronically posted papers, projects, field notes, response logs, and forum responses were analyzed qualitatively looking for evidence of theory-to-practice connections reflective of the changing pedagogy. Course syllabi and instructors’ field notes were analyzed qualitatively for evidence of professors’ reflection about their own theory-to-practice. Sixteen end-of-course evaluations were examined for student satisfaction in meeting their learning needs according to the traditional university evaluation rubric.

Findings

Formative evaluations made at the close of Fall 1998 indicated student, instructor, and supervisor satisfaction with the methods' block. Students reported a high correlation between material studied and its relevance to their classroom practice. Students, professors and supervisors also addressed areas of concern and recommendations for improvement. The professors for the methods-on-line class published web pages to deliver information about the structure and content of the course, but the threaded message boards became the forum for students to interact with the class community, professors, and other students in the class. Threaded message boards served multiple instructional purposes in the Spring 1999 component of the block. They provided a mechanism for the professors and students to:

- Deliver information about the structure and content of lessons,
- Post expository assignments discussing the application of theory to classroom practice,
- Report primary data collected,
- Post lesson plans and construct instructional strategies,
- Summarize, evaluate, and reflect upon assigned readings from texts and journals,
- Present persuasive arguments on educational issues,
- Analyze educational issues and current events, and
- Simulate classroom practices through role play.

In a typical lesson, a professor posted:

- Information about the dates and times the assignments were due for any particular class meeting,
- Questions which guided student inquiry into the lesson,
- Introductory information about the topic and supporting links to sites on the web, which provided a basis for linking student prior knowledge to the topic to be studied, and
- Threaded message boards for students to respond to the readings, discuss their responses with each other, or post other instructional activities products.

Recommendations

- Educators must place learning within a problem-solving framework that compels students to synthesize the information acquired in their courses and apply it to real world scenarios.
- Educators must facilitate virtual communities of learners who work in small, collaborative
- Educators must create public cyber-spaces for students to debate, solve problems, and dialogue about current issues and concepts associated with their courses and their work environment.
- Educators must model how to meaningfully integrate technology to support a problem-posing curriculum.
- Students should learn technological skills as they are engaging in class activities.
- Students should have opportunities to reflect about their learning through authentic means such as journals, conversations, and electronic portfolios.

Abstract: We are developing an online interactive Web-Based instructional module, which provides our user community with basic tools to understand microarray technology. Additionally, providing basic theories associated with microarray technology may allow the user community the necessary means to appropriately and innovatively apply the technology. We describe a longitudinal learning environment designed to educate the novice undergraduate and practiced researcher. Preliminary studies of senior level undergraduate students suggests that such a system will enhance the learning experience of current technologies as they move from development in the lab to useful research tools. This case study, exemplifies a novel use of the web to expeditiously disseminate information and training in emerging technologies.
Graphical Representations of Convergence in Web-based Educational Computer Conferencing: A Prototype

L. Hopperton, R. Rupp, M. Campos, B. Fisher, L. Harasim, M. Luk, C. Ostler, & C. Xin
Virtual-U, Simon Fraser University

Introduction

Graphical representations of the structure of information are not uncommon on large, World Wide Web sites. But because of the continued addition of notes in evolving computer conferencing, coupled with the labour intensive activity of continually creating and updating these navigational, conceptual maps, these site maps have not been adapted to evolving, computer supported discussions. These systems actively support idea divergence but are limited in providing hypertextual tools that support idea convergence and structuring (Harasim, 1990). This limits their ability to scaffold the development of mental models of a domain of inquiry based upon progressive reconsideration and synthesis of content.

The research and development team of the Virtual-U project has developed a prototype of a graphical representation of convergence, VU-ROC, for online learning environments. The prototype shows promising results for the construction of an active, message mapping system for online learning. It is designed to be an external support tool that will encourage reflective thinking by illustrating the structures of existing knowledge and the dominant hubs and conceptual triggers over time within the corpus of information. While computationally based and dependent upon user-specified categories, it is relatively user passive, requiring only reflection upon the nature of a note after it is written. It is intended to scaffold the developing mental models of students by mapping the relationships between notes as they are entered thereby illustrating and stimulating convergent thinking.

The VU-ROC model used 27 actual notes from a college seminar on two poems by Blake, “The Lamb” and “The Tyger”, which present complementary visions of the nature of God and creation. Figure 1 presents a full message map of the Blake seminar. By clicking on any node within the message map, the full note text is brought onto the screen along with a small representation of the notes to which it directly refers. This allows students to browse through hubs of information in a simple, intuitive manner.

The legend for notes appears on the left-hand side of the screen. This acts as a reminder to students about the nature of any given entry. In the visual window, a selection box indicates the note that a student has selected by pointing and clicking. The visual relationship of this note to its referents is highlighted using darker lines. Unread notes are solid colours while read notes are in outlined colours. The text of the selected note appears at the bottom of the screen. Tabs allow users to manipulate the representation in the graphical display window.
Using Groc

Following the writing of a note, when the student is ready to post their entry, they are required to specify the note categories using a simple drop-down box in which students point and click their choices. Drop-down boxes contain optional reminders of literary periods and note types that are pre-set by the course instructor.

![Graph View](image)

Figure 1: Full message map of the Blake seminar

Discussion

Current development is focused on the full semester conference, and this will be followed with full field tests. It is anticipated that a beta test version of the prototype will be ready for these field tests by 2001.

The application of computer generated, graphical information management and structuring tools are positive and useful additions to educational computer conferencing systems. These tools facilitate the process of progressive reconsideration of course-based ideas, and, potentially, support the inclusion of external resources such as web pages. Knowledge synthesis, as demonstrated through the linking of conference entries, can be brought to bear upon multiple domains of inquiry, and so requires successive re-juxtaposition, re-examination, and re-interpretation of ideas by students.

Teaching and Learning with STYLE
(Situated Technology Yielding Learning Enhancement)

Barbara K. Iverson
Columbia College Chicago
Journalism (New Media)
600 S. Michigan
Chicago, IL 60605
Biverson@popmail.colum.edu

Abstract: The paper discusses the STYLE (Situated Technology Yielding Learning Enhancement) program where unique on-the-job faculty development in technology skills, integrating technology into post-secondary classes, and promoting learning-centered classrooms in one logical, easy to implement and assess innovation. Currently, STYLE is a FIPSE-sponsored program at Columbia College Chicago. We discuss qualitative and quantitative evidence of program success. The model can be adapted across a continuum of existing technology configurations that exist in post-secondary education settings today.

The Teaching with STYLE Model
At the heart of STYLE is a faculty developed interactive, non-linear collaborative project to be created by two different classes according to a flexible plan created by the faculty involved in the paired collaboration aimed at the transformation of the learning environment (Tinto, 1998.) Instead of following the familiar form of learning communities wherein the same students take two concurrent classes taught by different teachers who communicate about their learning objectives and teaching in general, STYLE is a loosely coupled simulation of the modern workplace (Iverson & Torriera, 1999.) The learning community formed in STYLE collaborations is made up of a pair of classes with different students and teachers. One is a traditional class, such as a liberal arts class, where lecture is a prevalent teaching method, and there is little, if any integration of technology into the classes. The other is a technology -oriented class, such as New Media projects, or Multimedia Producer that are "technology heavy" and "content light." The technology teacher serves as a leader in using tech to collaborate, and as a research tool in the classrooms. Often the content teacher has many ideas about what they want to do with tech in the classroom, they simply lack experience and expertise. Experience has shown that the tech teacher comes to the collaboration believing they are using tech fully in their teaching, but they may discover from their teaching collaborator new ways tech facilitates learning and communication beyond its uses as a production tool (Iverson, 1999.)

STYLE synthesizes several simple but important ideas about learning, pedagogy, and technology into an easy to implement model that introduces project-based collaboration across departments and disciplines. A benevolent "Trojan Horse" approach is used to get faculty to use various digital tools and technologies by focusing on teaching tasks, not skills learning per se. The model improves learning, increases faculty digital skills, and helps integrate technology into the fabric of teaching, avoiding the less effective "bolt on" approach to technological integration in post-secondary settings.

STYLE is based on an emergent understanding of human learning (Schank, 1992; 1994) and of what works (Jonnessen, et. al, 1999), that is "praxis" (theory in practice) in higher education. Its simple premises are:
1. Learning is more meaningful if learners are engaged. Active learning is more engaging than passive learning.
2. Time on task is a potent predictor of achievement.
2. Learning is a social activity for students and faculty alike. Communication, collaboration and teamwork provide an effective setting for teaching and learning.

3. Situated learning about any subject, including learning to use technology, is more effective for faculty as well as students.

4. Technology enables us to provide necessary passive learning (formerly transmitted via lecture) outside the classroom (via on-line technologies) and to use in-class, face-to-face for communication and active learning activities. Witnessing knowledge in action, and working as knowledge organizers, rather than being passive knowledge consumers makes students better learners.

5. Encouraging students in sustained perspective taking (as in creating interactive, non-linear versions of their work) promotes higher order thinking and learning, as well as fostering the appreciation of diversity of opinion.

Implementation

Teaching with STYLE collaborations retain a set of objective unique to the content class, a set unique to the technology class but include a shared set of learning objectives that involve teamwork and communication centered around the collaborative project. The shared objectives, scope, and form of the project are designed by the participating faculty with input from participating students. They vary from semester to semester. Each class also engages in a variety of other assignments related to and separate from the shared projects.

In some institions it is difficult to add new classes to the curriculum. The STYLE approach allows updating of existing courses and integrating facilitating technologies into these classes. It avoids proliferation of new courses and the "bolt-on" technology syndrome that results from mandates to use tech in teaching.

The ease with which web sites can be created using modern WYSIWG HTML editors makes projects like this possible in a range of institutions that may not have high-end technology classes. Through FTP, use of a project site, and other facilitating technologies that encourage asynchronous communication, new forms of information and virtual collaboration are possible. The inter-class communication requirements of STYLE can be met with the use of a range of tools, from simple and ubiquitous shareware to high-end proprietary packages, as suits a given setting. Faculty seeking to implement STYLE can begin with a shared set of PowerPoint-like presentations and e-mail and evolve to the use of GroupWare, DHTML, and more sophisticated tools as suits their needs. The point of STYLE intervention is not the product, but the process.

The faculty in the collaborations differ in their skills with digital technology. Generally one faculty is more technologically savvy than the other is. This is where the "Trojan Horse" approach comes in. It is in the interest of both faculty that they can communicate easily and conveniently. They help each other in using specific software and hardware in specific settings to accomplish their shared tasks and goals. Results of a digital skills survey given before and after project participation shows that faculty develop their skills as a result of the project. This is more effective in encouraging the transfer and retention of learning than the pullout workshop model.

There is flexibility built into STYLE collaborations because institutional and bureaucratic impediments to collaborations like this include scheduling issues, length of classes, and resource issues, etc. The ideal collaboration involves classes that have overlapping meeting times so as to provide for face-to-face meetings. This is preferred in every evaluation we have conducted. However, STYLE can work even if the classes meet on different days because of its reliance on simple electronic collaboration tools (e-mail, FTP directories, project web sites, and threaded discussions.)

Results

It is often problematic, to compare achievement between the STYLE program and traditional classes. In order to look at the effectiveness of the model as a method of improving teaching, we use the whole class as a unit of analysis, and focus on changes in the psycho-social learning environment of the classroom that result from collaborative learning strategies. We look for changes in the class' sense of cohesiveness, cooperativeness, democracy, diversity, and satisfaction. These factors are stable and robust in large-scale research studies of cooperative and collaborative learning in pre-computer times, and are correlated with academic achievement (Fraser & Walberg, 1984.) Faculty significantly enhance these aspects of the classroom learning environment through instructional grouping, project-based assignments, and an increase in student participation, communication and collaboration, in the projects, and our quantitative and qualitative results show this. This signals success for the teaching with STYLE model.
The exciting thing about STYLE collaborations is that we document program effects from anecdotal and open-ended questionnaire data but we triangulate from data based on assessing the classroom learning climate, and by assessing the project products as well. Summary data is viewable at http://acweb.colum.edu/users/biverson/ed_media2000/. The projects themselves are viewable at http://digdesign.colum.edu/fipse.

In conclusion, we discuss how to match up the current hardware and software and expertise available with the kind of projects that can be best accomplished in any setting. The key point is that the collaboration learning objectives and the five premises of STYLE listed in the beginning of the paper are most important. Fit the project-based collaboration to the tools at hand. Using e-mail and threaded discussion, and having a website or even a simple networked and thus accessible site where you post work for clients to observe will put you on the road to success. Faculty using the "each one, teach one" method to work together, and modeling this kind of on-going learning for students set the process in motion. Process is what should be emphasized in adopting STYLE in your teaching, not products, either the technical ones used for making work, nor the outcome project of the collaboration. Our evaluation results, pulling from what participants say, and what they do show the program is effective and holds promise for promoting active learning, providing effective on-the-job faculty development, and in integrating a range of technologies as tools to facilitate learning and communication into classroom practice.

Designing a Media Management System to Match Your Needs:  
A Systematic Approach

John M. Jackson, M.Ed.  
Office of Medical Education  
University of Virginia School of Medicine  
United States  
j.jackson@virginia.edu

Abstract: This paper describes the reasons to consider developing a customized media management system, along with the disadvantages of these systems. A step-by-step system for designing, developing and evaluating a customized media management system is described.

Overview

Most web based educational systems develop begin with a single project in mind. As new projects evolve, bits and pieces are borrowed from previous projects, and over time the overall system can become quite complex, and difficult to maintain. At a certain point a critical mass is reached: either more resources have to be allocated to maintain the current way of doing things, or a more efficient system must be developed. The goal of this paper is to describe a way of systematically choosing and developing an efficient database-web resource management system to meet your specific needs.

A web-database resource management system offers several advantages of "hard coded" HTML pages. Resources such as pictures, sounds, movies and teaching cases can be indexed with metadata so that they may be easily searched and reused in multiple projects. Web based forms can be developed so that textual content can be easily edited, separating the creation of content from design and delivery, allowing authors to focus on content, not technology. Sites can easily have a consistent look and feel through the use of templates, with content being served up dynamically via a database. Updating a single template can then update an entire site. E-commerce and other transactional system can be implemented. Faculty can track student progress and performance through a series of exercises. Correspondence between faculty and students can be facilitated and archived for later analysis. Some off-the-shelf systems offer these features as pre-designed widgets that can be customized with a minimum of programming, or a custom system can be built from the ground up. Either approach maintains content in a database, which makes migrating to new delivery technologies like DHTML or XML fairly painless.

On the other hand, these database-web systems typically require a higher level of technical expertise to plan and develop than HTML only sites. Adding new features to these systems usually requires a programmer, instead of a web designer. And when a bug appears in a templated page, it typically is repeated again and again throughout a whole site. The overall system becomes more complex, with more opportunities for technical problems. We'll look at how each of these factors plays out in choosing or creating your own system.

Developing a Media Management System

The process of choosing and designing your own resource management system involves these steps:

1. Needs analysis - Clearly define the current and projected production and delivery issues.
2. Review available tools - Given your needs analysis, review options. Narrow the field to three or four that best match your needs.
3. Test drive - Get trial copies of the "final four" products identified in step two and build a typical application. Develop a formal evaluation checklist to compare the outcomes of your test drive.
4. Review outcomes - Your evaluation may have unexpected results. Does adopting a new technology change your operations plan?
5. Develop Budget and Implementation Plan – Project your costs and get approval, if necessary.
   Develop a stepped implementation plan with target dates for each part of the transition.
6. Evaluate the outcomes – Did you accomplish what you expected?

Let’s next look at each one of these steps in detail and examine what can be involved in each.

**Needs Analysis**
Each institution will have different needs, but a common one is the ability to reuse resources such as images, sound clips, chunks of text, teaching cases, and movies, in different ways on different projects. We found ourselves with thousands of images that had the potential of being used across many disciplines—if anybody could find what they needed. As a result, our top priority became a sharable image/sound/movie database. We also had thousands of practice quiz questions, which were difficult to update in HTML. So our second priority was a question database with easy access by faculty for editing. You may have similar needs, or ones that are completely different.

**Review Available Tools**
There are hundreds of tools currently on the market, from simple image databases to turnkey management systems from the likes of Oracle and IBM, to specialized course management systems. Some of these systems can be learned in a day, while others require programmers earning $80K a year. With your needs analysis in hand, choose the 8-10 more promising tools for your project. Read everything you can find in print and on the web and talk to people using those products. Monitor the support newsgroups for the tools. Create a checklist of your desired features and narrow the field to the best matched three or four.

**Test Drive**
With trial copies, build the same application in your “final four”, one that you would actually use. We built an image database and an evaluation system using multiple choice questions. Can it handle the required security? Can it handle the number of users you project? Is setting up a new project a breeze or a nightmare? Are there good support options available? Is there a clear migration path to more powerful system as your needs increase? Use these and your own questions to formally compare each of the products. Identify the best choice(s).

**Review Outcomes**
So you think you have chosen the best tool for your situation. Now you should take some time to mull over the possible outcomes. Will existing staff be able to meet the new challenges? What training will be necessary? How will your clients react? Is it worth the investment given the projected outcomes? Take time to talk again to people using the product and find out their likes and gripes. In short, perform a reality check before moving ahead.

**Budget and Implementation**
Draw up a formal budget that includes not only software tool cost, but also staff, training, support, and hardware. Develop a-step-by step plan on how you will migrate to the new system. What components will be required first, second and third? Include adequate time for testing of the new system by staff and clients before rollout of each phase. Take you initial time estimates and double them.

**Evaluate Outcomes**
Take time to review your accomplishments after six months and a year. Has the process evolved as you expected? Have you met the goals identified in your initial needs analysis? Is your team happy? Are your clients happy?

After this stage the next step is.... do it all over again! With the pace of technological change you may actually be faced with a whole new set of problems and opportunities that require going through this process again. But using the systematic approach described above, good planning, and a little bit of luck, you will have chosen a system that will grow with you into the future.
Encouraging New Conversations In Software Design.

Glenda Jacobs
School of Communication
UNITEC Institute of Technology, Auckland NZ
gjacobs@unitec.ac.nz

Duncan Meyer
Long Bay College, Auckland NZ
duncan@chalksoft.com

Abstract  This paper describes and critiques current user-designer feedback channels, and suggests why and how these could be augmented, particularly in educational settings. It is argued that current feedback mechanisms exclude the majority of users. Although academics remain sceptical, increasing numbers of software designers in New Zealand are recognising lost opportunities for client support as well as customization and improvement of services, and are pursuing new paradigms for designer-user communication.

Introduction

Mechanistic ‘sender-receiver’ models of the communication process provide a superficially convincing representation of the interaction between computer users and their PCs, with the computer application seeming to show communicative behaviour similar to that of a human partner.

While acknowledging this seemingly ‘social’ interaction with the technology, however, it is easy to undervalue the real (if asynchronous) communication relationship that exists between software designers and their users. The design process involves, in effect, the construction of a delayed ‘conversation’ between designer and user, where the users’ needs are anticipated and predicted, and appropriate responses are provided to meet them. However, in this relationship, only the designer/sender is actively aware that communication (albeit indirect) is taking place, while the user/reciever participates in the process without having to recognize it as communication at all.

The result is communication that is one-sided. Despite ‘Know thy user’ being accepted as axiomatic by modern developers, occasions for actually getting feedback from users are limited. For many developers, the only such occasions would occur during usability testing, ending shortly after system implementation (Pausch, Conway & DeLine 1992, Petersen C, 1996; Saltzman & Rosenthal 1994).

Adequacy of Existing Feedback Channels

One needs to distinguish, at this point, between Product Support Desks that exist for users who simply need help operating a piece of software, and channels that allow for queries about, commentary on and criticism of various features of a software product. One is tempted to assume that, for users who want to engage in the latter, emailing or telephoning the developers would be the obvious option. Consequently, a survey to assess the usefulness of existing user-designer feedback channels was conducted at UNITEC Institute of Technology, four Auckland secondary schools, and at the Chalksoft educational website. A summary of the results follows (Detailed results can be found at www.chalksoft.com/questionnaireresults).

Overall, 88% of respondents had never contacted the developers of the software they used. Reasons for not contacting developers were given as follows (respondents were allowed to choose more than one reason): It never occurred to me (72%); It would be too much trouble to try to get hold of the developers (52%); I have nothing I would like to tell the developers of the software I use (51%); Software developers don’t have time for
users like me (26%); It would be too much hassle to try to explain myself (9%). In addition, fifty-eight percent of the respondents who had never contacted software developers did not know how to go about doing so.

These results suggest that, at least in the limited educational context of this survey, the majority of users are unlikely to take advantage of (or in some cases even know about) the channels currently available to them for communicating with the designers of the software they use, the main reasons being that the possibility of, (and to a lesser extent the need for), such a 'conversation' does not occur to them, and that finding appropriate channels would be simply too much trouble.

Current Channels for User Feedback

Recent demonstrations of interest in ongoing user feedback by major companies include dialogue boxes which appear when the application detects an error condition (eg Netscape, Muzak) and the provision, within the application, of a link to a company web page or a trouble-shooting discussion forum (eg Blackboard). However, the weakness of the former lies in that the user has no control over when feedback is possible. In addition, there is the nigh-impossibility of users being able to identify and then describe accurately in retrospect their exact sequence of acts preceding an error message.

A weakness of the discussion forum option lies in the assumption that users have the confidence and the vocabulary to make their difficulties or suggestions public. This is particularly untrue of many teachers, whose use of computers is intermittent (but not unimportant) and who do not regard themselves as part of the computing inner circle (Dawes, 1999, Pate, 1999). It also does not address the problem of non-expert (but not necessarily unintelligent) users having to explain in writing what they mean or want, while not knowing what is relevant to achieving their goals (Sellen and Nichol 1990, Pausch, Conway & DeLine 1992).

Design Solution

The authors of this paper have designed a feedback feature that addresses these obstacles. Although useful in any organisational context, it has been designed for inclusion in the authors’ educational software, and is as a result aimed at educators in particular.

The feature provides the user with the opportunity at any time when using an application (not only when the application encounters an error condition) to click on an ‘AUTHOR’ button permanently on the screen. This calls up a feedback form, addressed to the software developers, with space for the user to write down any comments about the programme’s performance. What makes this feedback form unique, however, is that it automatically adds to the user’s message a complete history of the user’s choices since the session was started. This does away with the need for the user to explain what he/she was doing at the time a given problem arose.

The advantage to the user is access to software developers in the midst of the routines, breakthroughs and breakdowns that define typical use. With increased demands being made on faculty to manage their own instructional technology, this not only provides increased support, it also recognises the user as a ‘dialogue partner’ (Anderson 1999) rather than merely a consumer. The advantage to the developer, on the other hand, is “backtalk”: that is, feedback not only from what users say, but from what they actually do (Brown & Duguid, 1992). Developers can also easily check and reproduce phenomena reported by their users. When the application is installed, moreover, the user has the opportunity to add individuals or groups (eg IT support) to the mailing list, so that they too can keep a tally of the sort of problems or issues users are encountering.

Consequences of Implementation

Since the software feature described in this paper is itself still in the beta-testing phase, it remains to be seen whether users find the possibility of immediate feedback practical, and whether developers find the ensuing response worth the effort. It would further be interesting to observe whether such a feature adds to or detracts from users’ ‘social/dialogue’ mental model of their interaction with their technology.

Meanwhile, what this paper advocates is an exploration of the wider communication opportunities, the new ‘conversations’ (Winograd, 1986) that are becoming possible during routine software use. To this end, this paper argues that software applications can, in addition to their primary functions, become feedback channels that allow shared responsibility for the success of user-developer communication.

International Group Work: New Roles for Interaction?

Diane P. Janes
Distance Education and Technology
University of British Columbia
Vancouver, British Columbia, Canada
diane.janes@ubc.ca

Abstract: In 1997 a partnership was created between the Monterrey Institute of Technology (ITESM)'s Virtual University and the University of British Columbia (UBC). This partnership resulted in the development of a Certificate in Technology-based Distributed Learning, a series of five graduate courses launched internationally in the fall of 1997. This paper and presentation will explore the international project work and online collaborative experiences of a group of international students registered in a web-based, graduate-level distance education course offered by UBC and its partner, ITESM.

Background

On June 21, 1997 the Virtual University of ITESM and Distance Education and Technology signed an agreement for the development and delivery of five courses in technology-based distributed learning (Bates, 1999). This became the post-graduate Certificate in Technology-based Distributed Learning (http://itesm.cstudies.ubc.ca/info/).

Consisting of five graduate-level courses, the Certificate was launched in September with the first course, Designing, Developing and Delivering Technology-based Distributed Learning, opening in September 1997. This was followed by Selecting and Using Technology for Distributed Learning (winter, 1998), Planning and Managing Technology-based Distributed Learning (fall, 1998), Social Issues in Technology-based Distributed Learning (winter, 1999), and Research and Evaluation Issues in Technology-based Distributed Learning (September 1999).

Designed using international collaboration, team meetings were held and decisions were made, via videoconferencing and email. The course technologies included: print – textbook and selected readings delivered to students in their package; a Web Site – comprised of study guide, original teaching materials, online discussion groups (in both English and Spanish), online resources (online articles, journals, access to the extension library), a bookmark database (dynamic due to student input), student and instructor biographies; e-mail; and on one course (Selecting & Using TBDL) a specially-designed CD-ROM (Bates, 1999)

In addition to discussions and an international café, the program also invited international guest visitors, often the authors of the texts or readings, to conduct weeklong discussions with the students.

Social Issues in Technology-based Distributed Learning

Social Issues in Technology-based Distributed Learning was offered to students for the first time in 1999. Team-taught, the course had an enrolment of 38 students from 10<sup>1</sup> countries while its partner University (with its own Spanish-speaking instructors) had a concurrent enrollment of 100+ students from Mexico, Chile and Venezuela. Over the 13 weeks of the course, the students engaged in a number of online and interactive activities designed to increase their contact with each other. Three short papers discussed the social issues and technology-based learning issues raised by the course readings and analyzed using several frameworks. The online 'Brainstorm', which

---

<sup>1</sup> The 10 countries represented were Australia, Botswana, Canada, China (Hong Kong), Finland, France, Germany, Mexico, the United States, Yugoslavia.
followed the short papers, had the students identifying the issues they felt needed to be discussed in the course. Immediately after the brainstorming period, students were divided randomly into groups. Each group (consisting of 3 international students) was assigned the task of deciding on what issue, or part of an issue, raised by the brainstorm and set out by the framework, they wanted to research and present to the larger, full class. The final assignment was a formal paper, which analyzed and reflected on an issue raised by the course.

Collaboration and Leadership in International Groups

The observation of this course and its students with respect to collaboration and leadership within international groups was quite valuable for the instructors and the student/participants. Interestingly, many of the issues that seemed to be prevalent could be considered issues in f2f collaboration (Janes, 1999). Areas that required consideration included

- ‘disappearance’ and ‘silence’ of team members for long periods of time when decisions were necessary within the group;
- the encouragement of some of the more ‘quiet’ group members by some of the more ‘vocal’;
- the recognition that ‘lurking’ does not mean lack of engagement with the ideas or the learning
- the need to respect the ‘time’ it takes to collaborate online, to achieve consensus without having met the person or persons you are working with; and
- to respect, at all times, the points of view of the group and to create a ‘safe’ environment for discussion, disagreement and compromise

I learned a lot about the collaborative learning process...This certainly has been important for me and dramatically extended my understanding of the complexity of TDBL [technology-based distributed learning] in the real world. Article posted by Student T

...Groups. Again, a completely different experience than other ones! It’s amazing the juggling that goes on. In a way, I rather liked that we were assigned to groups because it’s more true to life. It’s very time-consuming to organize groups virtually. Personalities came through which humanized the process for me. Two things were difficult for me. (i) some members didn’t make contact for ages, so I even wondered if they were still there; (ii) Sometimes feedback was needed asap and some group members seemed to vanish just then. We resorted to a lot of communication via email as some of us had difficulty with web and interaction was critical... Article posted by Student K

Conclusion

This course was the first offering of an online course that was complex in design. While the course designers and instructors anticipated many of the outcomes (Bullen & Janes, 1998), this course was a testament of the dedication and interest of its participants. From all corners of the world and from many and varied backgrounds came a group willing to tackle some of the most current and interesting topics with respect to teaching, learning, technology and society. Many of the techniques and strategies for international group work come from those who have experienced this phenomena and who come to the challenge from a common sense perspective, a healthy respect for those involved and a willingness to try a new way of interacting.

University of Missouri-Columbia
Columbia, MO 65211

Abstract: This presents the findings of a study of the use of a hypermedia program, Perspectives on Emotional and Behavioral Disorders, with undergraduate students in introductory courses in special education (SE). Upon completion of the chapter on BD we examined 1) patterns of usage created by audit paths, 2) perceptions of program quality, and 3) perceptions of feasibility of use between non-special education (NSE) majors and SE majors.

Instructional programs using interactive hypermedia case studies have been created and demonstrated to be an effective tool in preservice training of individuals preparing to work with children and adolescents with emotional and behavioral disorders (Fitzgerald & Semrau, 1996). The instructional approach used in this interactive hypermedia material strives to develop cognitive flexibility for problem solving within an ill-structured knowledge domain. There was some concern that learners who may have little background information or interest in the area of special education are at a disadvantage. Therefore, we were concerned that the use of a hypermedia program on a topic in special education by NSE majors may place students at a great disadvantage and result in negative opinions of the program and consequently reduced usage of the program.

Research Questions

Do major and nonmajor preservice teachers: 1) utilize the hypermedia training program differently with regard to engagement time; 2) have different perceptions of the quality of the hypermedia training program, and 3) have different perceptions with regards to the feasibility of using the hypermedia training program?

Participants

Non-special education major students (n=34) enrolled in the undergraduate class, The Exceptional Student in the Regular Education Classroom, and special education majors (n=19) enrolled in their initial special education program course, Introduction to Exceptional Children, participated in this study. All participants were trained in using the interactive program on CD. None of the students had prior special education course experience. The hypermedia program used in this study was Perspectives on Emotional and Behavioral Disorders - Zach (Fitzgerald & Semrau 1999).

Measures and Results

Total Elapsed Program Engagement Time

Using audit trail data provided by the AStudent® disk, the researchers computed a total number of minutes in which each student used the training program. The mean elapsed time for NSE majors was 110 minutes, while the total elapsed time for SE majors was 134 minutes. The difference between the two groups was not significant. The total engagement time was substantially less than the mean of 420 minutes reported by undergraduate students who had completed foundational courses in special education, behavior management, assessment procedures, and instructional strategies as reported by Fitzgerald and Semrau (1996).
Perceptions of the Value of Using the Multimedia Training Program

Five items from the Multimedia Training Program Survey (MTPS), created by the authors of the program, were used to investigate the students' perceptions of the usefulness of the multimedia program for teacher training in emotional and behavior disorders: (e.g. I feel this program was a productive use of my time because it added to my knowledge). For each item the student responded on a scale of 1-5 with 1=strongly disagree to 5=strongly agree. Responses for each of the above were summed and divided by the number of items to form a score for Perceptions of the Value of Use which was used in the data analysis. Special education majors had significantly more positive (p --- .02) perceptions of the training program (mean = 4.06) than the NSE major students (mean =3.72). Both groups thought the program offered a positive learning opportunity and was effective in accomplishing its instructional objective. In exploring the data for relationships beyond those stated in the purpose, we found a weak positive relationship between a student's program engagement time and perception of program value (r = .234).

Perceptions of the Feasibility of Using Multimedia Programs for Teacher Training

Three items from the Multimedia Training Program Survey (MTPS) were used to investigate the students' perceptions of the feasibility of using the multimedia program for teacher training with SE and non-SE majors in emotional and behavior disorders: (e.g. 14. I became confused while using the multimedia training program). Using the same scale as described above and correcting for the negative wording of the items, a mean was determined and subtracted from 5 to form a score for Perceptions of the Feasibility of Use which was used in the data analysis. There was no significant difference between the SE majors’ (mean = 2.70) perceptions of the feasibility of using the program and NSE majors’ (mean = 2.71) (p = .970). Both groups viewed the program as somewhat difficult to use and mildly frustrating for use in teacher training. A weak negative relationship was found between a student's program engagement time and perceptions of feasibility (r = -.082). A moderately positive relationship between a student's perception of program value and perception of feasibility (r = .371).

Discussion

With multimedia programs becoming more readily available for use in teacher education, instructors must carefully select programs which meet the content and skill needs of students, present information in a manner which is perceived as useful, and be feasible to use by the student outside of the formal structure of the classroom. We know that case-based hypermedia programs are well received by students with background knowledge of the content being taught by the program Fitzgerald & Semrau, (1996); therefore this study was designed to explore how learners responded to a hypermedia learning environment in content in which they were novices. While there was a significant difference between the ratings, both groups of students perceived the training program to be a valuable learning experience. Also, both groups of novice learners rated the program as Adon't know@ when asked to rate the program on the feasibility of using the CD-based program for instruction. Based on the students’ perceptions of feasibility, it is imperative to support student use of hypermedia programs with in-class instructor or peer-led guided activities.

References

Abstract: Developing and using active learning exercises in classroom settings works well to engage the learners, but the instructor's challenge is to take those same exercises and make them meaningful in a distance education model. This paper describes several techniques used by the author in a creative problem solving course redesign.

Creative Problem Solving Course Redesign

Teaching creative problem solving requires some creativity on the part of the instructor. Rote lectures have never been optimal learning experiences, nor are they conducive to teaching creativity. In the design of the course, the first challenge was to get the students to loosen up and understand paradigm boundaries that are often self imposed. During the semester, the exercises were chosen to demonstrate specific uses and points of creativity techniques for problem definition, alternative identification, evaluation of alternatives, planning/implementation, change management, and monitoring.

Problem Definition

The exercise to demonstrate self imposed paradigms requires 25 inflated balloons and at least 8-10 people. In the classroom the students are formed into two circles, and not allowed to say anything to each other or ask any questions. Two students are designated as observers and balloon helpers. The students are given the instructions to not let the balloons hit the floor. Then five or six balloons are tossed inside the circle. After they toss them back and forth for a minute, the rest of the balloons are tossed into the circle. Some of the students figure out they can hold the balloons, pop them, push them into the other circle, or rub them on their heads to generate enough static electricity to stick the balloons onto the walls. At this point, some students start declaring that these tactics aren't fair. The instructor stops the exercise, and asks them to observe what happened and why. The observers describe the tactics used, and the means of non-verbal communication employed. They eventually come to the realization that the 'rules' were self imposed and the instructor had set no limits on actions to keep the balloons off the floor. The instructor then asks them to relate the strategies for balloon management to the behaviors at work. Tossing the balloons to the next circle is similar to passing off bad work or problems to another department.

When this exercise was given to the distance ed learners, they were asked to gather a group of family or friends to do the exercise, and act as the instructor/observer. Then each student posted his/her observations to the interactive area of the WWW based class management software. The groups included family members from 2 to 80, a cub scout pack, a coffee group from work, and a group of friends in a bar. The results were consistent, and the comments among the students lively.

Problem Solving Strategy

This assignment was about designing a new monetary system for a small, island country in the South Pacific. First the students had to identify all the paradigms associated with currency as used in the US (shape, color, denomination, media, uses, ownership proof, durability, portability, and drawbacks). This provided students with experience with other monetary systems to bring in samples and provide descriptions. Many students did WWW
research on money/currency prior to the class and brought in the printouts. The consistent response was that no-one
had ever considered that all currency wasn't just like the US system worldwide. Then the students were divided into
groups of 4 or 5, given paper and crayons, and sent off to design a new monetary system that could be used by the
islanders and the tourists visiting the island. Although the exercise write up named the island Freedonia, only one
student out of 250 over 5 years was a Marx Brothers fan and recognized the name. The usual solutions are for chip
embedded plastic cards that draw down on an account established with an island bank, with a hole in the card for a
plastic chain to wear around tourists necks or pin to bathing suits (and a solar powered energy source on the island
so the card readers would keep working).

Translating this exercise for the distance ed format was relatively easy. Each student did his/her own WWW
research and personal research for other currencies, then submitted a list of paradigms for US currency. The class
was then divided into groups, and they collaborated via e-mail and fax for designing a solution. The group posted
their solution on the interactive area of the WWW class management tool. Some students even drew solutions and
scanned them into the site for other students to view.

Process Mapping

This exercise is based on a common student experience of getting advisor approval, registering and paying tuition
for a class, and getting books. The students first list all the steps they go through, and all the departments of the
university that are part of the process. The students are given pads of sticky-paper notes on which they list each
process step individually. They post the steps on a white board or large piece of paper by department, and draw in
lag times to determine elapsed cycle times for each step. Then the students are asked to redesign the process using
on-line WWW registration, fee payment and book ordering and recalculate cycle times and the effects on each
department involved. The costs and benefits are estimated for the current and proposed processes. The students also
have to identify opportunities for fraud and where security was needed. This exercise usually stimulates questioning
as to why the university doesn't do all this right now, which leads to a good discussion on impediments to achieving
perfection in the real world.

Converting this exercise to distance ed teams was more challenging because the WWW tool did not have a site
amenable to using sticky paper notes for posting. The teams used faxes with each other, and assigned process
streams to each member. The results were posted on the interactive site in words, unless a team member had a
scanner available. The results were similar though, because the students had experience with both traditional in-
person classes and distance ed classes. The distance ed students were more ingenious in devising ways to break into
the system to subvert it, as well as identifying security risks.
Tips and Tricks for the Development, Delivery and Management of Online Courses

Jonathan Kadis
Utah State University
Multimedia and Distance Learning Services
3075 Old Main Hill
Logan, Utah 84322-3075
jonkad@mdls.usu.edu

Abstract: Distance education programs throughout the world continue to grow in size and scope. As online courses escalate in size and numbers, educational leaders say content and customization is the key to successful learning and not the numbers of students served. Understanding best practices in distance education via tips and tricks for development, delivery and management of online courses will be central to the future of this industry.

Innovative Online Course Ideas- Tips and Tricks

Background
USU currently offers over 70 fully online courses and two masters degree programs. In the past year we've developed nearly 100 courses with web supplements. We've delivered over 100 courses via digital satellite to over 90 sites across the intermountain west. We have had over 3000 students registered for courses this past semester and expect nearly 6000 this coming semester. Multimedia and Distance Learning Services and the Faculty Assistance Center for Teaching provide workshops, instructional design, video production, web development, engineering, electronic classroom support, etc.

Online Course Questions
What are some of the issues, strategies and best practices in developing online courses?
What are some of the innovative uses of emerging technologies?

Problem Identification:
Is your organization fragmented? Are faculty moving in multiple directions? Are you struggling with rapid technological changes? Is there a lack of focus? How do you cope with the myriad of software applications?

How We Began...
We started by doing our own programming, looking at and using many software applications such as Web Course in a Box, Learning Space, WBT, Blackboard, Syllabase, etc. We eventually settled on WebCT as our core program.

What We Did...
We pulled together the various organizations involved in online course development across campus. We then looked at and narrowed the hardware and software technology we were using. Our third step involved offering appropriate training to faculty and staff. We completed our initial efforts with a focus on student learning assessments.

Tip 1 Instructional Design Steps

Tip 2 Conversion Process
Design appropriate templates/architecture. Specify content/media needs. Author/customize interactions. Develop a content outline. Convert multimedia assets. Test and maintain applications. Create a pilot project.
**Tip 3 E-Learning** (Elliot Masie- Techlearn)
Incorporate the following in your online courses; Engagement, Curiosity, Simulation and Practice, Remediation, Coaching, Peer Learning, Social Dimensions, Action Learning, Performance Support, Intensity, Assessment and feedback, Teaching Culture.

**What Should You Do?**
Take baby steps, engage your students and unify your efforts- work with others- don’t give up

**Tricks**
**EMAIL Overload**- Online courses can generate lots of emails. Technical issues, assignment clarification, content issues, turning in assignments, etc.
Use bulletin board instead of Email. Then you only have to answer the question once. Tell your students to read them first before asking a question. Compile and use this for future sections. (FAQ)

**Getting Started Section**- Use tutorials (how to use tools, WebCT, etc), downloading and installing plug-ins, getting latest browsers, could be part of the first lesson.

**Frequently Asked Questions** – You know most of the questions you get asked, keep track and compile them after the first class, put them online and consider using a discussion group.

**Clear Assignments and Objectives**- Clearly state objectives, clearly state what is expected to complete the current lesson, keep pages consistent and don’t hide them deep in the course pages.
- **Example of good objectives**-
  - Read chapter 2 in your textbook (pages 19-32)
  - Carefully study the important concepts
  - Watch the videos on vibrating systems
  - Be able to determine the frequency of vibration for simple harmonic motion of different systems.
  - Be able to describe the motion of complex vibrating systems as harmonic or non-harmonic.
  - Take the self-test by clicking on the “self-test” icon at the top of the page.

**Printable Documents**-
Create online learning, not online reading, use Adobe Acrobat, format clean printable HTML pages, stay away from dark backgrounds with light text, they don’t print well.

**Student Loneliness**-
Have them introduce themselves to you and the class in a discussion group, do collaborative projects in small groups, provide a chat room and provide a list of students in the class. (Email)

**Quizzing**-
Provide a sample quiz online so students can gain some experience using the testing interface and technology.

**Summary**
"The society that will be successful in the future will not be the nation-state or community that can accommodate a steady stream of students, but that nation that can lift the level of learning among all its students rapidly and repeatedly,...higher education ought to be focused on content, not hardware." Gov. Michael O. Leavitt

VISUALIZATION OF SYMBOLIC INFORMATION: EMPOWERING STUDENT INTROSPECTION

Paul Juell
Department of Computer Science
North Dakota State University
Fargo, ND 58105
juell@plains.nodak.edu http://www.cs.ndsu.nodak.edu/~juell

Abstract
We are developing 3D visualizations for use in AI classes. This paper presents the process of developing visualization for symbolic information for classroom use. The basic process is to: determine the questions the user should be able to ask, determine what information will help in answering the questions, find a representation to present the information, prototype the visualization in VRML and build tools to allow students to build the visualization. The emphasis is on how to visualize symbolic information rather than numeric data. The visualizations are to aid in presenting and understanding complex symbolic based material. We are using them to present the internal processes of the AI techniques. The visualizations are presented as interactive 3D worlds. The worlds are written in VRML and accessed by the Web. This combination allows easy distribution of models for the students to inspect and control. The students use the tools to build visualizations of their own programs. The response to visualizations and the visualization building tools has been positive. The author feels they have significantly improved the student understanding of concepts.

Introduction
Visualizations can help in the process of understanding classroom material, techniques and processes. This paper presents suggestions to aid in developing visualizations for a class. The focus of this work is on symbolic information rather than quantitative information. Traditionally visualizations have been used with quantitative information [Tufte 83]. The Visual Program project http://www.ndsu.nodak.edu/instruct/juell/vp [Juell August 1999] [Juell March 1999] is working on improving the tools that can be used in an Artificial Intelligence class. This project has been developing visualizations to aid in the understanding of various AI techniques. This paper presents the analysis and recommendations that produced our best products. The process includes the following stages:

- Determine the question(s) you want the viewer to be able to answer.
  Each visualization allows someone to see some patterns and hides other. For the visualization to be useful and valuable, you need to address the particular questions that are useful in the situation being studied.
- Determine the information you want to show.
  Limit the information to that which is salient to the questions you want answer. Ignore bookkeeping and internally used information. This will result in simpler and clearer visualization and make the rest of the process simpler.
- Design and prototype the visualization.
  Once you have a goal of answering a question and the information you are going to use, build a prototype of the visualization.

- 2D Diagrams
  We start our projects with a 2D design. Symbolic information can be specified by character strings positioned in 2 dimension space on paper. We then consider replacing the strings with graphics. We are interest in showing the operations of a process, so one dimension is normally time. For several problems, we have then used a mapping of the state space for the other dimension.
- 3D Diagrams
  We then consider how to use 3D to better show data and information. 3D diagrams can be more attractive than the 2D images. In addition, we found the extra dimension important because of the high number of dimensions in our original problems. Visualizations work by allow the eye to
see patterns. For symbolic information, using a tall box for each symbol can allow the eye to see repeated patterns in spatial location. If the data is presented so that the eye identifies important patterns, this presentation can allow the user to convert the data into information.

- **Interactive Diagrams**
  We use interactive diagrams to aid active learning. Most of our work uses 3D worlds created in VRML [Hartman and Wemecke 1996]. The VRML allows the presentation of movies and allows the viewer to control flying through the images. In addition, motion can be supported directly in VRML or by adding JAVA applets.

- **Layering of Information (hot links, layered displays)**
  Traditional visualization techniques can add additional dimensions of information to the picture. You can map information into false colors, sizes and other information overlayed on the icons in the images. In addition, you can link the items to other images and pages.

- **Instrument the program/process at the symbolic level.**
  We want the students to build visualizations of their own programs. To do this, we need to provide tools which will create the visualizations for them. They run their program. Its output is then processed to build the visualization. To make this work, the program is instrumented to capture data to be converted into the visualization. The instrumentation code needs to capture the state information of the state space search. It is very hard to reconstitute this state information later. The code may have to make explicit state information which is implicit in the program.

**Example - State Space Navigation**
A small example may clarify some of the points. A typical example of a state space search is the river crossing problem. We built a visualization for this, with a goal of addressing "where does the time do in a blind backtracking search?" For one dimension we used spatial information about the boat and the people. We used three positions: the side the people start at, a position in the middle of the river and the river side the people want to reach. At each of these locations, we placed objects representing the people and the boat. The father, the two sons and the boat were each represented by a different sized block. We tried to stay with very simple objects because we felt a small amount of detail, would allow the viewer to more easily see patterns. For the other dimension (for the 2D example) we used time. One image then showed all of the steps of the search. In the process of developing our visualizations, these images underwent a number of changes to improve the overall usability of the image. One problem we repeatedly had, was that improving the esthetics of the images often, in the author's opinion, made it less likely that that the useful patterns would be visible in the final image. Once acceptable prototype of the visualization was developed, an instrumented program was prepared and a tool was developed to produce the visualization. This combination was then used by the students for their programming assignment.

**Summary**
We have presented the process we are using to develop abstract visualizations. These visualization are intended to be used in class to aid in understanding complex concepts. These guidelines have helped us to produce a variety of visualizations. We have used these in the classroom and as parts of homework projects. The students were very positive in their response to the visualizations. The author has noticed that questions asked by students changed following the use of the visualizations. The questions now represent a higher level of thinking. The questions before were mainly "what does this line of code do?" and now they are frequently "how does this effect the visualization we are creating?" We feel the above notes give a good start in developing visualizations for symbolic information. We also believe these visualization are important in allowing students to explore and understand a wider scope of information about the material presented in the class.

Abstract: This paper will review the progress of work being done by a consortium of higher education institutions, working with a public broadcasting television station and commercial courseware developer to create and deliver courses in the converging environments of the Internet and broadcast digital television. The experience of moving traditional broadcast telecourses to an online courseware package will be presented, along with the opportunities and challenges faced as digital television broadcasting technology evolves.

Introduction

WHYY, the Public Broadcasting Service affiliate in Philadelphia, Pennsylvania, established and hosts the Delaware Valley Distance Learning Consortium to address the common distance learning needs of the region's higher education institutions. Under the leadership of Delaware County Community College, Camden County College and Community College of Philadelphia, the WHYY Home College Service broadcasts over five hours of telecourse programming daily, during overnight hours. Students enrolled at DVDLC institutions videotape the programs for convenient viewing, complete assignments and receive college credit for their work.

With the growth of the Internet, and recognizing the pedagogical opportunities online courses present, WHYY and the DVDLC began a cooperative venture to deliver courses on the World Wide Web. In addition, all United States television broadcasters are under mandate from the Federal Communications Commission to transition to digital television broadcasting. Along with the larger convergence of media types and delivery methods, this presents an opportunity to develop next-generation courses that repurpose current content using converging technologies.
WHYY is the central technology provider, licensing the courseware and integrating the courseware servers into the WHYY Technology Center. WebStudy, Inc., a Philadelphia region company, supplies the courseware, WebStudy. WHYY provides technology support and faculty training. WebStudy supports the courseware and the faculty and student help-desk. Consortium institutions offer their courses, enroll students, and are responsible for the quality of the courses and establishing content ownership. Beta testing of the courseware began with fall semester in 1998.

**Early Experience**

In fall 1999, Delaware County Community College began building “hybrid courses,” using the curriculum already developed for telecourse-based courses. Hybrid courses include media streams of broadcast telecourses, traditional reading and writing assignments, and interactive asynchronous forums. In January 2000, three courses, English Composition I, English Composition II and Geology, were offered to DCCC students in the Philadelphia region, either as traditional telecourses or as hybrid courses. Students in the hybrid courses have the choice of viewing lower quality streaming media or higher quality broadcasts. An additional test group of students from outside the Philadelphia region was enrolled in the courses, but not able to receive the telecourse broadcasts. Other DVDLC members are offering courses using WebStudy with content unrelated to the broadcast telecourses.

**The Future**

Digital television is a work in progress. The technology promises high bandwidth distribution combining the advantages of broadcasting with the interactive and data features of online learning. Digital television is a broadcast signal with an effective datarate of approximately 19 megabits per second. Like today’s analog television, the datastream can be received by anyone in the broadcast area. Many types of data, including high definition television, multiple channels of standard definition television, packages of data delivered like a CD-ROM, datastreams that accompany broadcasts or stand alone, Web pages, pre-delivered content - essentially anything that can be delivered in digital form, can be in the datastream. While the technology is still in its early stages of development, digital television receiver cards are available that can be installed in home PCs. Manufacturers are designing "set top boxes" that include an operating system and the necessary hardware and software to decode, store and display digital broadcast data, either in real time or acting as home servers. A relatively low bandwidth Internet connection will allow data to be returned to central servers, either in real time or on a scheduled basis. Each device will have its own unique identifier, similar to an IP address, allowing content to be directed to a subset of users.

We are investigating many ways to use the datastream. Hybrid courses now streamed on the Web could download to the student’s “digital television device,” an advanced set top box with capabilities of a computer, so the student could work off line, CD-ROM style, with updated content delivered when necessary. Content, including "television quality" video, could be pre-delivered to the student when bandwidth is available, using the device as a local cache. Using the low bandwidth Internet connection, real time interaction can occur, and work can be submitted to the instructor in the background. The "digital television device" will be standards based, with a common interface, significantly reducing support issues. The experience will be like "turning on the television," though not like television as we know it today.

Abstract: This paper shows how concept maps, a tool utilized rather widely these days, can be advanced to new horizons using computer-based approach. The author discusses general structure of concept maps, their use as dynamic instructional tools, and then presents a model for implementation of computer-based concept maps in college-level business courses. Most advanced concept maps are generated using multimedia authoring software and can be either qualitative or quantitative in nature. Such computer-based concept maps, located either on a computer in a classroom or on the Internet, are a very powerful and unique tool contributing to other learning techniques and assessment methods.

Concept Maps: An Introduction

A concept map is defined as a graphical knowledge representation that hierarchically links concepts. Novak (1984), a leading authority on concept mapping in education, proposed that different learners structure their new current and new knowledge in a variety of ways, therefore validating use of concept maps in teaching and learning. If the instructor's role is to guide the learner in creating new meanings and deeper levels of conceptual understanding, then concept mapping can be an effective instructional and assessment tool to use in undergraduate lower division business courses. Knowledge is accumulated in a continuous fashion, and developing connections between prior and new knowledge is critical to the learning process.

In a traditional concept map design, the most general or most important concept is placed at the top of map, and concepts on lower levels are subsequently more detailed. Key concepts are connected by links that have descriptive words on them explaining the relationship between concepts. Concepts maps, by their visual presentation, have traditionally been used as very effective vehicles for organization of concepts within the domain. Traditional concept maps were of "paper and pencil" type, and were used mainly to organize qualitative or conceptual knowledge. Thus, in rethinking course curriculum at the undergraduate level, the number, organization and plan for the systematic development of concepts are worthy considerations in terms of curriculum restructuring necessary for improved student performance.

As concept maps evolve, there are variations in their development, discussed by Shavelson et al (1994), including free-form versus hierarchical, concepts' position on the map, collaborative effort by a group of students. These variations provide for greater instructional flexibility as well as for more diverse learning experience. In the last decade, a noted increase in interest in and use of concept maps has resulted in the identification of many valuable instructional purposes for mapping.

A Model for Implementation of Computer-based Concept Maps in College Business Courses

An advent of computers, word processing and flow-chart software, as well as later developments in multimedia authoring software enables instructors to push the limits of usefulness of traditional concept maps far beyond "pencil and paper" representation. It is worth noting that in this respect the following stages of software development can be identified:
1) Non-dedicated word-processing or flow-chart software allowed for passive creation and use of computer-based concept maps

2) Software dedicated to generating concept maps results in production of more responsive and interactive computer tool

3) Multimedia authoring software for fully interactive knowledge building and assessment using computer-based/multimedia concept maps.

This article presents initial approach undertaken in implementation of concept maps in college-level business courses, and creates a model suitable for implementation in any business courses for computer-based knowledge building and alternative assessment using concept maps. Since this represents significant evolution of concept maps, we will refer to them as (c)omputer-(b)ased qualitative and quantitative (k)nowledge (m)aps (CBKM).

Software

For the purpose of this model, software from above mentioned stages 2) and 3) is used. Software dedicated to generating concept maps such as Inspiration® (or comparable) is used by students almost exclusively. Instructors use Inspiration® for knowledge maps presented or developed during classes. These presentations are very effective and lead to interesting interactions when presented on a large projector screen. The set of standard knowledge maps as well as the ones developed during classes is uploaded on the Internet under the course’s Web page.

Multimedia authoring software such as Authorware® by Macromedia (or comparable) is used by instructors to prepare highly interactive software used by students in- and/or out-of-classroom to build new knowledge, form linkages, and to build critical thinking and analytical skills. Multimedia authoring software enables instructors to provide students with an interactive study tool that provides them with an instant feedback, where each one of superordinate or subordinate concepts, linkages and propositions is a hyperlink providing immediate response or guidance. In addition to having such developed and customized software place on computers in business computer labs or individualized study labs, this software can be made available on the Internet.

Conclusions and implications.

Computer-based, qualitative and quantitative knowledge mapping is a tool that can be used by both instructors as well as students to meet the challenge of planning, organizing, teaching and learning. Computer-based knowledge mapping assists students in fulfilling quality outcomes in learning business. Used traditionally, concept maps provide concrete visual help to organize information to be learned. Business instructors for lower division courses at colleges who have been exposed to this tool are finding that they provide a logical basis for deciding which main ideas to include in a course. Computer-based knowledge maps can be as large as the entire course, one or more unit, or even a single class period.

It has been shown before that traditional concept maps are valid vehicles for documenting and exploring conceptual change (Wallace & Mintzes, 1990). This proposed model of computer-based qualitative and quantitative knowledge maps that is currently used as a pilot in a limited number of chemistry classes, in conjunction with authors experience in practical using concept maps, have provided convincing evidence that many instructors would be able to present more continuous learning experience for their students, who in turn would benefit from CBKMs as described above. Computer-based knowledge maps can be a powerful tool, that contributes to the other learning techniques and assessment methods, and addresses both knowledge and its organization.

Research on field dependence/independence in the learner reveals a number of interesting factors about preferred learning modalities. The field independent learner is most typically intrinsically motivated, for example, while highly field dependent people, who are more socially oriented, are motivated by external rewards. Additionally, and more important for the design of on-line instruction, field dependent learners require and prefer more structure, direction, and support from authority figures and colleagues than field independent learners.

Field independent learners are able to discriminate key concepts in the material to be learned or analyzed to construct a "big picture" of the material with little auxiliary assistance. Field dependent learners, on the other hand, prefer to proceed step by step and are most likely to benefit from outlines and advance organizers to have the context constructed for them.

Fortunately, measuring field independence/dependence is uncomplicated. The Group Embedded Figures Test (GEFT) measures the cognitive style dimension of field independence and field dependence. The GEFT consists of 18 complex figures. Individuals must find a simple embedded geometric figure that is hidden in a complex one (Donlon, 1977; Thompson & Meloncon, 1987; Willard, 1985 and Witkin, Oltman, Raskin & Karp, 1971). The figures are easily picked out by field independent learners; field dependent learners have more trouble isolating the figure from its background. The GEFT can be administered in under one-half hour and can help instructors identify students' tendencies towards field dependence or independence.

In the summer of 1999, we taught a graduate level class that was conducted entirely on line. That is, we had no face-to-face meetings with students and conducted all communication through e-mail, chat rooms, bulletin boards, and web sites. This was the first Web-based course conducted in the department, and therefore we knew this experience would be the first of its kind for all of our students. We found that 12 of the 16 students enrolled in the class were field independent.

Our approach to design of the site, course requirements, course activities, and communication came from a constructivist perspective (Duffy & Cunningham, 1996; McManus, 1996). The site was divided into twelve primary sections; Welcome, Navigating this Site, Course Overview, Calendar of Events, Syllabus, Grading, Outcomes and Criteria, Class Project Topics, Participant menu, Bulletin Board-Chat-Surveys, and Resources. Being aware of the literature concerning field dependence/independence, we purposefully designed the site to provide for the needs of both types of learners, giving detailed instructions, examples, and templates in more than one context to provide maximum support for all field dependent individuals. For example, we provided two locations that specifically detailed all course requirements in locations that were identified by traditional names, Syllabus and Outcomes and Criteria. Likewise, due dates for class assignments were identified in multiple locations; Calendar of Events and under each Outcome section. We included a resources area, giving detailed instructions on obtaining email accounts, designing a web site, and accomplishing a web search.

One of the course requirements was that students prepare a web page that summarized findings of an extensive search for information on a topic they selected from a provided list. Since this was not a class in designing a Web site, students were given the opportunity to attempt development of the site by themselves, seek out the assistance of an individual they knew with experience in Web site creation, or send all graphics and text files from Word files and we would place the materials on the course Web site for them.

The record of students' interactions with the instructors reveals interesting interaction patterns. While all students were a bit apprehensive at the start of class, Field independent learners tended to proceed with comfort and
confidence very quickly. Field dependent learners’ questions and messages increased significantly in number over those from field independent learners and tended to express discomfort or fear about navigation, competence, and about the formal structure of their own web page, even though the template was available at all times. Research also reveals differences between field dependent and field independent learners’ satisfaction with collaborative learning. A study conducted by Whyte, Knirk, Casey, and Willard (1991) investigated satisfaction and achievement factors among students paired for a learning experience. Pairs included two field independent learners, two field dependent learners, and mixed pairs. The results indicate that mixed pairs achieved the highest results, followed by pairs of field independent learners and then pairs of field dependent learners. Field dependent learners, who have a higher likelihood of preferring social interaction, were most satisfied with collaboration. Field independent pairs showed dissatisfaction with pairing for collaboration.

Inclusion of collaborative projects and on-line chats in WBI is often incorporated into class design. During the WBI class we taught, we placed four to five students in working groups for the purpose of sharing their summaries, discussing common problems in project completion and resources, sharing common experiences on specific questions revealed in the summaries, and conducting on-line chats to discuss the issues. This group work was accomplished through both synchronous and asynchronous means. The learner experiences in a group setting, indicated that field dependent individuals relied on feedback from their peers significantly more frequently than did field independent individuals. The statistics from these observations will be shared in the presentation.

We propose to present the results of these two studies, participant experiences, guidelines for improving the Web-Based Instructional learning experience from a perspective of page design, determination of graded events, and communication issues for both types of learners.

Abstract We live and learn in a world filled with information. To prepare students and employees for the competition and globalization of tomorrow's world, universities and enterprises are faced with an increasing need of up-to-date information and learning material at reasonable costs. Because of the fast changing requirements of professionals, lifelong learning is required in practically all areas, especially those related to information technologies. The objective of the project OR-World is to respond to today's increased education need and develop a World Wide Web based framework for sharing high-quality learning material between universities, educational institutes, self-learners, and interested companies, in various countries.

Project Description

Although the World Wide Web has experienced an unprecedented growth during the last five years, its potentials are by far not used optimally yet. In the world-wide digital network, teachers and learners do not have to be physically present at same place and time in order to be in contact and interact. The availability of electronic communication and network-structured, hypermedia content opens up completely new ways of higher education in universities and education centers. The project OR-World has been proposed in the European 5th Framework Programme and will be funded by the European Community (EC). The goal of the project OR-World is to achieve innovations in areas such as hierarchic structuring of content modules and flexible thematic combination (metastructure) of content modules, use of case studies within a learning network, and distributed self assessment and grading. The project consortium consists of seven partners, four universities and three companies.

A central goal of the project is the development of a user-friendly, World Wide Web based framework to generate hypermedia content for distributed, collaborative learning. The framework can be used to create learning environments that enable education and training centers to share reusable learning objects and maintain integrated learning services. With the term "learning objects" we refer to any digital or non-digital entity, which can be used, re-used or referenced during any learning activity, according to IEEE-Standards (IEEE 1999). An important issue when dealing with learning objects is granularity. In the project, we will work on several granularity levels. This means that the general framework will support the following building blocks to be used in constructing flexible, reusable learning environments:

- a media element, refers to text, animation, simulation, video or audio sequence,
- a learning element comprises one or more media elements,
- a content module consists of one or more learning objects, and is understood as a node in the hypermedia network,
- a thematic metastructure defines guidelines how to use content modules to build thematic structures relevant for a specific study goal; such a structure can be put together in individual ways, thus adapting to different combinations and profiles.

Thus, a teacher can set up his or her own content modules and offer them to others via the Internet. We suggest to build a consortium of trusted members, who want to work together, thus extending their own learning materials offering in a meaningful way. Above these content modules, various thematic networks can be built, which represent larger learning units, like a course or guided tour. The reusability will make it possible to create
a "web of networks" using the same building blocks but setting different viewpoints and preferences. The objects at each hierarchy level are tagged with metadata to facilitate their flexible use in different contexts. The framework will be usable in a multilingual environment. It will support networked communication between tutors and learners outside the classroom. The framework will provide a general structured environment to input any (structured or semi-structured) contents. A certain level of structuring of the learning material is a prerequisite for applying the framework. Teachers will be able to use the framework in creating their own specific learning environments where they can combine their own learning objects with those generated by others. Thus, there will be a metastructure above the hyperspace of learning objects allowing multiple views on a certain subject area.

Project Objectives

Within the project, use of the framework will be demonstrated with contents of the subject area Operations Research/Management Science (OR/MS). However, the framework itself will be content-independent and usable to teach most content areas. It will be suited for using by a consortium of teachers (or learning institutes) who are willing to share material and are convinced about the quality of all partners, thus allowing a flexible extension scheme by each member without bureaucracy. Furthermore, if several universities and companies adopt the framework and methodology, they will be able to share a learning environment and strengthen their cooperation, thus providing high-quality teaching and learning materials. The project OR-World itself gives an example of sharing a learning environment, it involves four universities from three different countries, all offering courses in joint central subject areas.

Case studies are a well-known interactive teaching and learning method, not only in business and management, but also in various other fields, like engineering, law, agriculture, etc. (Erskine 98). OR-World will offer a concept and toolset to facilitate the use of cases in a virtual, distributed learning and teaching environment. Over one hundred years, the case method has proven to be successful; we aim to bring the method over to the environment of computer-supported distance learning. However, we do not believe that cases can be used totally without personal communication between learners and instructors. Thus, a goal of the project is to develop new guidelines and tools in order to achieve an optimal organizational form for the use of case study teaching within the virtual network.

Another objective of the project is to carry out a large-scale experiment to promote European integration and to develop a European identity for the subject. Thus the participating four universities and three companies will work closely together, each providing specific individual strengths either in the area of emerging digital technologies or content production and structuring. The learning objects will allow new schemes for virtual collaborative learning to be tested in cooperative joint university-industry education frameworks.

Because the initial standard Web markup language HTML does not support efficient structuring, retrieval, and linking among very large amounts of documents, more general technologies, such as the extensible markup language XML and XSL, are emerging. XML responds to a strong need to separate content of a document (text, graphics, video etc.) from its logical structure (content table) and representation (formatting on the screen or printer). The project OR-World will use XML on each granularity level to describe the elements and hierarchic structure of the learning hyperspace. The IEEE Working Group P1484.12: Learning Objects Metadata Working Group, is currently working on standards for describing learning objects in terms of metadata. According to the working group, “This standard will specify the syntax and semantics of Learning Object Metadata, defined as the attributes required to fully/adequately describe a Learning Object. Learning Objects are defined here as any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning. Examples of technology supported learning include computer-based training systems, interactive learning environments, intelligent computer-aided instruction. The proposed metadata scheme will be used in the OR-World project to facilitate the re-use of existing material.

To demonstrate and test the power of the OR-World concept, we will implement some contents from the interdisciplinary area Operations Research/Management Science. The exemplary implementation will comprise the whole functional spectrum including multilingual content components, distributed learning, self assessment, and grading.

Transforming Traditional Curricula: Enhancing Medical Education through Multimedia and Web-based Resources

Abstract: This paper describes the transformation of a traditional medical curricula into a problem-based learning technology-enhanced educational setting. The use of Information Technology (IT) is an important feature of the new curriculum. Case-based medical problems are delivered to students in a tutorial setting via TopClass over the Web. Additional learning resources such as Web sites, image banks, practical experimental simulations, self-assessment tests, Shockwave learning modules and multimedia modules are also accessed via the computer. This paper outlines the critical attributes of this educational context, and then discusses the web-based and computer facilitated learning (CFL) based aspects of the curriculum.

Educational Context

Traditionally, the medical course at The University of Melbourne has been taught using a discipline-based approach. In the early years of the course, students undertook discrete subject blocks from the pre-clinical departments of Anatomy and Cell Biology, Biochemistry and Molecular Biology, Microbiology and Immunology, Pathology, Pharmacology and Physiology. Exposure to clinical scenarios in situ came later in the course (predominantly in years 4-6), after students had gained an understanding of the basic sciences relevant to medicine. Internal review mechanisms and student feedback in recent years highlighted a number of deficiencies in the traditional course. These included insufficient integration between basic and clinical science, insufficient attention to communication skills, problem solving skills and social aspects of health, an overload of biomedical detail and unnecessary duplication of content. In an effort to incorporate current theories of medical education a new medical curriculum was introduced in 1999. The pedagogical model for the new medical curriculum incorporates elements of Problem-Based Learning (PBL) and Self-Directed Learning (SDL) (Koschman, Kelson, Feltovich & Barrows, 1996). The primary focus of learning in Semesters 2-5 will be medical problems (referred to as 'Problems of the Week') which are presented to students in small group tutorial settings. Key features of the new curriculum are the horizontal integration across disciplines and the vertical integration of clinical situations with basic scientific material (Keppell, Elliott, & Harris, 1998).

The use of Information Technology (IT) is an important feature of the new curriculum. IT is utilised to deliver medical content in three ways. These include the use of a Learning Framework (TopClass); the web-based problem of the week embedded in TopClass and multimedia stand-alone modules. The TopClass Learning Framework provides a central access point for students to enter the on-line course work, complete self-assessment tests, view class announcements, participate in discussion groups and send and receive messages from teachers or peers. The problems of the week are delivered to student tutorials over the web via TopClass. At the completion of the first year of the medical course 18 problems of the week have been designed, developed and implemented. Approximately 160 problems of the week are required throughout the entire medical curriculum. Self-directed learning resources, in the form of multimedia teaching and learning modules, are also required to support the core content of the problems. Approximately 40 modules are currently under development and it is envisaged that 80 modules will be required to support the curriculum (see http://www.medfac.unimelb.edu.au/bmu/projects/survey.asp). This paper will describe and demonstrate the features of one Problem of the Week and one computer facilitated learning (CFL) module. Through this...
demonstration, the way in which IT, interactive multimedia and web based resources are being used to support the new integrated curriculum will be shown.

**Computer-based Problems of the Week**

The problem of the week begins with the "trigger". The aim of this photograph or video sequence is to set-the-stage for the student by providing a visual of the hypothetical patient and the circumstances surrounding the case/problem. In development we attempt to match the appropriate media type (video, Shockwave movie, photograph) to the nature of the medical condition or context which needs to be displayed. For example medical triggers which need to portray a medical condition such as myasthenia gravis need to show the progressive nature of the fatigue that occurs in skeletal muscle. Consequently video is the most appropriate media type for illustrating this progressive nature. Other medical triggers which need to demonstrate distinctive changes in a sequence can be portrayed through a series of photographs using a Shockwave movie. In other medical triggers a single photograph is sufficient for conveying the context and the necessary information required for beginning the problem-based learning approach. Following the trigger, students are instructed to list information about the patient, identify the presenting problems, list possible causes of each problem (hypotheses), provide a rationale for each hypothesis, prioritise the list of hypotheses and then determine what other additional information (physical examinations, laboratory tests, etc) is required to differentiate between the hypotheses. During this process students are given supporting information in the form of a history, past medical history, physical examination, progress, investigation results. An example of a problem of the week for the medical curriculum is shown at:  

**Multimedia Modules**

An important aspect of our approach is the emphasis on interactive CFL modules. These multimedia teaching modules are used extensively in the new course as learning resources in areas that students have traditionally had difficulty understanding or in areas where the use of media, such as video, audio or animation is particularly appropriate to demonstrate a concept or principle. The emphasis of these teaching modules is on complementing the learning objectives of the problem of the week.

For example, we have designed and developed a multimedia module which examines the communication process between doctors and patients and focusses on integrating biological, psychological and social factors in clinical diagnosis. When investigating a patient's complaint (such as chronic tiredness) the body language and emotional response of a patient is often as important as his or her verbal response. Video is an ideal medium to capture both verbal and nonverbal responses and to portray these for students. The module we have developed allows medical students to listen to a doctor's questioning method and to see how question tone and wording affect a patient's reactions and demeanour. Students are able to view a patient's response and answer questions about their perceptions and understanding of the clinical interview. The introduction of this module into first year medicine should begin to sensitise students to the complexities of the communication process between doctor and patient. It is hoped that this will enhance their own clinical interactions in the long term. The presentation associated with this paper will demonstrate this module as an example of the types of interactive multimedia that are being used to support the new curriculum.

A Conceptual Framework for Web-Based Authoring System

Badrul Khan, The George Washington University, USA

After reflecting on the various factors critical to open and flexible learning environments, Khan (1997) developed a Framework for Web-based learning. Various WBL factors are clustered into the following eight dimensions: pedagogical, technological, interface design, evaluation, management, resource support, ethical and institutional. AuthorWeb - a comprehensive authoring system is rooted in the WBL framework. The inception of AuthorWeb's development began with a vision of providing a tool that would assist educators, trainers and course developers to create meaningful online courses without prior skills or knowledge in instructional design, computer programming and issues critical to distance learning environments. AuthorWeb's development process benefits from the input of various substantiated perspectives, including instructional design, cognitive and educational psychology, curriculum development, distance education, innovation and change, telecommunication, database, artificial intelligence, software engineering, and media production.
Function Design of Adventure Game for Education Considering Developmental Psychological Feature of Elementary School Students

Hyeong-Joo Koh

Abstract: These days, a variety of educational methods using computer games have been studied to increase interests regarding the study using adventure game for educational purpose. If a part of learning contents of elementary school students is developed in courseware of adventure game way rather than conventional CAI way to apply it to the class of the students, learning effect is likely to improve greatly. From the viewpoint of developmental psychological features, elementary school students are much interested in courseware of game way. As a result, the study suggests function design of adventure game for educational use considering developmental psychological features of elementary school students.

Adventure game

Definition of concepts
Adventure game may be classified with contents and methods in respect of software. The one, who enjoys the game, takes proper action of accidents or problems depending upon the game's story to resolve them and reach final destination. The game shall include contents of adventure or rare events. Furthermore, there exists only one kind of order and solution, which should be followed to solve the event.

General features of adventure game
General features of adventure game may be analyzed as follows:
1) There exists only one solution based on preset scenario.
2) Most of time background occupies unknown world.
3) A hero shall never die.
4) There exists a sequence of scenario to solve an event.
5) Graphic, music and other multimedia effects are used.

Essence of computer game
Roger Gaiyo, a French sociology scholar, has classified a play as four kinds(See Fig.1) Horizontal axis means "Does intention of a player?", while vertical axis does "Is there a rule?".

The game is said to be a summary of four kinds of the plays that Roger Gaiyo has defined. In other words, the elementary school students concentrate on the game because it includes a variety of competitions to allow them to enjoy imitation, luck and dizziness at the same time while playing the game. Such a fact can be understood as follows: When each scene of the game, which can draw attention of elementary school students, is analyzed, it mostly includes four kinds of play factors evenly. Nonetheless, elaborate arrangement of competition, imitation, luck and dizziness does not always stimulate interests of the students to become an educational game.

Fig 1. Four kinds of plays
They are continuously so mad on good games for educational purpose without boring feeling thanks to following reasons: 1) continuous supply of stimulus enough to create motivation, 2) the stimulus considering educational accomplishment that includes qualitative change. In other words, to design a good game, quantity of the stimulus shall be effectively supplied, and furthermore quality of the stimulus shall properly change.

Function design of adventure game for educational purpose

Factors of adventure game for educational purpose
The computer game may be used in various ways depending upon purposes and contents of learning, while adventure game for educational purpose can be used more effectively in the learning contents requiring empirical situation. The learning contents may be presented to students naturally through empirical situation to let them learn effectively through their experience.

Factors of adventure game for educational purpose shall be understood as the ways of not only developmental psychological features but also computer game to improve their study efficiency and make use of the game as an effective media. Major factors of the game are:

1) The game shall be easy to make use of it through easy and convenient visual design, and shall be equipped with various kinds of events to let students be interested in it. Furthermore, it shall include various kinds of educational strategies and study methods.

2) They shall be allowed to learn different game stage depending upon individual difference. The game's process shall include curriculum and training procedure.

3) Outcome of education shall be shown in accordance with development of the game by stages.

4) Conditional and unconditional divergence function shall allow each user to play game depending upon his or her feature.

5) Flexible extent of permission of exactness is to be given against a user's response.

6) Progress of the game shall be recorded, managed and maintained.

7) If possible, cooperative game through network shall be done.

8) They have to learn "social nature" while playing a game for multiple players.

9) The game shall maintain its activities continuously, and furthermore shall be rewarded or punished depending upon outcome of their actions.

10) Students shall be allowed to repeat to play a part of the game that they want to do.

11) Elementary school students are easy to give up or express strong rejection when they are unable to play game smoothly or do not understand it enough. As a result, they have to be given Help or Tip menu to help them solve problems.

Functions for adventure game for educational purpose

1) Mouse

- Movement
  - Rotation mode: 360°rotation, adjacent area, up/down and left hand/right hand.
  - Movement mode: Walking and running each one step forward.
  - Jumping mode: Jump over obstacles forward.

- Selection
  - Move mouse to change its shape and select or pick up an object.
  - Select a variety of options.

2) Keyboard

- Enter user's information.
- Supply an abbreviated command key.

3) Help mode

They may select "Be quiet", "Common" and "Talkative" of the game environment to let Help mode to give a suitable tip while playing game.

4) Zoom-in and zoom-out mode: The mode enables a player to watch surrounding area, environment or objects carefully.

5) Chatting with other characters.

6) Interactive mechanism mode: The mode enables a player to pick up, collect or make use of an object.

7) Time and space movement: A player is allowed to move under a variety of time and space zones.

8) Bonus and penalty: When a character faces a certain situation, he or she is given bonus or penalty to carry out job in easy or difficult way.
Completing Design Concepts for Lifelong Learning

Huberta Kritzenberger, Michael Herczeg
University of Luebeck, Institute for Multimedia and Interactive Systems
Seelandstr. 1a

{Kritzenberger, herczeg}@imis.mu-luebeck.de

Abstract: Lifelong learning denotes learning as a process, which continues after leaving school. This perspective has a far-reaching influence on conceptual design models of educational software. It regards learning as one aspect of work and opens the way to including concepts from industrial psychology into software design. This paper will discuss factors influencing the learning process, such as burden, demand level or motivation, and the resulting consequences for the development of educational software.

Lifelong Learning

Lifelong learning denotes that learning does not end after finishing school or university. More and more people have to attend courses in further and continuing education to keep their knowledge level and market value or to gain knowledge for another kind of professional work. Situations demanding for learning will be pervasive in people's life and in consequence the division between education, work life and leisure time will fade.

Learning is one aspect of work

Understanding lifelong learning as a permanent process also involves the perspective on learning as one aspect of work. This view allows us to integrate concepts from industrial psychology into conceptual models shaping the design of educational software. Industrial psychology has a holistic view on human nature. Humans are supposed to search for self-realization and autonomy, which should be supported by changes in work places and organizational structures in order to enlarge the individual’s area of responsibility. It involves personality development, formed in the individual’s tackling with challenges provided by solving the tasks at work.

Industrial psychology deals with aspects of qualification. Learning tasks are viewed as a sort of chain, where burden and demands alter with effects on the change of mental states. In order to initiate successful and effective learning processes it is most important to find an adequate demand level, which causes positive mental states like happiness, motivation, increase in performance and, in the long distance, even qualification and positive development of personality. On the other side, inadequate demand levels cause negative and undesirable mental states, e.g. a feeling of tiredness, drop in performance, frustration, and even psychosomatic illness.

Lifelong Learners

It is a challenge to develop educational software, which is adaptable to burden and demand level. Software designers have to find concepts and techniques to make software as flexible and interactive (Fischer 1996) as to adapt to altering demand levels. One step into this direction is to orient teaching strategies to the characteristics of groups of learners, which may be deduced by taking into consideration the context of learning and the purpose. One can distinguish different learner groups. For example, learner group 1 wants to do basic studies in the domain in order to pass exams and earn diploma. The learners want to study all modules relevant to the curriculum, need guided tours to differ relevant from irrelevant knowledge with respect to passing exams. Learner group 2 does not want to go through all the knowledge modules offered in the database, but wants to study only some modules for task-oriented knowledge acquisition. Often a current problem or a knowledge gap is the starting point for learning. Learner group 3 is characterized by exploring the knowledge domain according to personal interests. The behavior of learners in this group is comparable to browsing libraries, reading books and magazines.
Conceptual Modeling

The important role of the conceptual model for the development of educational software has been strengthened by didactics as well as by software-ergonomics (Herczeg 1994). With this background in mind, we want to ask what kind of conceptual models do developers of educational software have in mind.

Theories of Learning and Teaching

Theories of learning and teaching, which are mainly derived from psychology, normally shape the conceptual models of educational software developers. Examples are behaviorism, cognitive information processing, theories on constructive and situated learning. In the early phase of computer-based training, dominated by behaviorism, reinforcement, serial ordering, small chunking were seen as the basic mechanism enabling learning processes. Information processing approaches focused on cognitive aspects of knowledge representation like conceptualization or schemata. Other theories strengthen the vital role of experience for the learner’s perception and activities in knowledge construction, which change cognitive structures (Bonner 1998), stressing the importance of communication and social negotiation as inevitable for learning processes to occur.

Task Analysis

Learning theories focus on either behavioral or on cognitive aspects of the learning process. However, software-ergonomics claims that conceptual modeling should also take into consideration the domain, the user’s skills and experiences, certain cognitive aspects (like memory capacity, laws of perception etc.), and also the task and the context of completing the task. Especially task and task contexts have been neglected by current psychological theories. Task analysis intends to reveal relevant characteristics of the learner and her or his task (Herczeg 1999). Some aspects of the learner’s task have been discussed in the section on lifelong learners. The three groups mentioned above may further differ according to aspects like previous knowledge, learning style and motivation. For example, not the aspect of being motivated is important, but the reasons that cause motivation. That is, the distinction between intrinsic and extrinsic motivation, as intrinsic motivated learners will hardly ever need external stimuli, whereas others do.

Summary

Regarding lifelong learning as one aspect of work enriches developer’s conceptual models with concepts from industrial psychology. An important aspect is task analysis in order to shape the task according to demand levels. Task orientation means that interests and engagement are caused by characteristics of the task itself. The conditions are to give a person as much control as possible over the subtask and over the devices for task completion. Furthermore, the task has to be structured in a way that the level of burden and demands is adequate. Too simple or less structured tasks will result in monotony or disappointment. More research on this subject is needed in order to develop educational software with a more holistic model of the learner, and by the way improving job and learning conditions, and last but not least preventing illness.

Letting Adjunct Migrant Faculty in from the Cold: Assisting Adjunct Faculty with Technology

Karen Krupar and Clark Germann
Metropolitan State College of Denver

krupark@mscd.edu
germannr@mscd.edu

Abstract: This presentation addresses the debate between quality of instruction issues of adjunct versus full time faculty. With an almost 40% increase in the numbers of contract and adjunct faculty in all institutions in the past decade (Hancock, 1998), very real questions need to be raised about the technology development of this cohort of faculty and their abilities to transmit critical technology skills and information to university/college students.

Introduction

While considerable efforts are being made to provide professional development opportunities with the full time faculty (Jacobsen, 1998; Nance & Strohmaler, 1998) very little is being done to provide information, skill training, and experiences with technology for adjunct faculty development. As J. Digranes reports (1995), "Adjuncts frequently receive less institutional support including e-mail accounts, computers, technology training...than their full time colleagues"(p. 162). The impact of this lack of training in technology is felt by students who "are dumped in a lab almost as though it were a 'babysitter' with the inexperienced and ill trained adjunct trying to maintain order" according to Steve Leone (1997, p. 8).

Purpose. This paper/presentation examines the documented level of competencies in technology of a large group of adjunct faculty at an urban college and describes a professional development program in technology training that enhances these faculty's ability to use technology in their classrooms to improve student learning.

Review of the Literature

Limited research documenting the adjunct faculty's knowledge and competency in applying technology to the classroom exists in the literature. This is largely because institutions as well as researchers have refused to acknowledge the growing role of this group of faculty and their subsequent influence on teaching and student learning. Like their full-time counterparts, adjuncts exhibit varying degrees of knowledge about technology. To test the specific knowledge (cognitive and application) of adjunct faculty at the institution, a survey was constructed and delivered to a sample of the adjunct faculty (10%), full time temporary faculty (10%) and full time faculty (10%). The following data reflects the significant differences between the faculty responses to survey:

- Despite a significant difference in the degree of importance placed on knowledge of the Windows 95 Operating system for all three levels of faculty only 6 (adjuncts) claimed to have no knowledge of this basic operating system. The adjuncts were more inclined to not see the importance of Excel software.
- A majority of all three types of faculty said that MSWord was extremely important, a program that they used constantly. However, of the 8 people who said is wasn't important, 7 were adjuncts.
- There is a general proficiency in MSWord for adjunct instructors. MSPowerPoint like MSExcel was split between those who liked and used the program and those who didn't. Its perceived importance matched the existing skill level among adjuncts surveyed.
- Ability to use Web browsers is generally viewed as important, although a nine adjunct said they never used them.
- Conducting searches for research was considered extremely important by adjuncts. 50% in them claimed to have excellent to mid-range abilities. Of those who didn't have excellent to mid-range skill, majority-adjuncts(38%).
Half of the adjuncts felt creating Web Pages was important. 50% said it wasn't important. 80% of the adjuncts said they had little to no experience with this competency.

Over 70% of the adjuncts had no experience with Web applications at all.

The use of currently available classroom systems was viewed as important by the majority of adjuncts. Those who said it was unimportant were predominately adjuncts (80%). Eighty-eight percent of all adjunct faculty claimed no experience with this application.

Using multimedia applications was also viewed as important by adjuncts. Approximately 80% of the adjunct faculty had no experience with this application.

Of the three groups surveyed in this study, adjuncts demonstrated the fewest competencies in technology. In many cases, they had little opportunity to develop those competencies through their attendance at professional development workshops, seminars, classes that emphasized these technology skills. There are fewer rewards for these faculty to make extra assignments that involve technology applications in their courses.

The Plan for Addressing this Need

To address the lack of technology professional development of adjunct faculty, our institution applied for and received $508,000 U.S. Department of Education Title III grant. It provides technology training (among four other areas) for the 650 adjunct faculty at the institution.

Population and Research Model is a simple pre-test, intervention, post test design research model provides the organizing function for this grant. Each year approximately 10% of the adjunct faculty enroll in the program of workshops, technology fellowship program and other grant supported activities. For the first year, sixty adjunct faculty participated. All adjunct faculty provided two forms of baseline data, student evaluations for two semesters (from 1998 to 1999) and one peer observation data from the same time period.

Technology Competencies is used to determine what technology education for adjunct faculty was needed, the grant staff developed a survey on technology skills. The survey paralleled that instrument used by the college's Technology Task Force and its Academic Technology unit for full time faculty at the institution. For the technology facilitator requires knowledge of types of software, hardware and applications of technology to curricular, classroom management of instruction and technology infusion.

Based on this survey, six technology workshops were built for the second year of the grant. In September a workshop plan and training schedule was developed. Instructors were secured from among the full time faculty and technology staff. Since many adjunct faculty find it difficult to attend workshops even when these kinds of professional development aid their knowledge base and make them more valuable instructors at the institution, migrant adjunct faculty have difficulty attending training (Geppa, 1993). Multiple sections of each workshop had to be arranged to accommodate the adjunct faculty's schedules. Since some of this faculty cohort are already experts (early adopters) in technology, effort was made to use these faculty to assist other adjunct faculty in the development of advanced training in technology. Seven adjunct faculty were selected from those participating who had recommended technology expertise. These adjuncts were given an additional contract to work 40 hours during the academic year in small group training sessions with adjunct faculty needing technology assistance.

Each adjunct Technology Fellow had to develop a Technology Assistance Plan covering goals, goal management and measurable outcomes that was negotiated with the dean of the school in which the adjunct's discipline was housed. Each adjunct produced 40 hours of documented technology work for which the adjunct was paid $1000. Several of the adjuncts included goals addressing the finalizing of courses on-line. Other adjuncts specified training for their adjunct colleagues on a variety of topics including Web Authoring, Researching on the Internet and Multimedia presentations. Other (2) adjuncts set up one-on-one sessions with other adjuncts in their academic divisions (sciences and humanities). It is evident that adjunct faculty need more assistance in both learning specific technology programs and in applying the technology into their coursework. The technology fellowship program using the "Train-the-Trainer" model is yielding some remarkable results including increased numbers of faculty invested in using the technology in the classroom in research, assignments on the web, and the development of five additional on-line courses including ones in biology, speech communication and sociology.

In conclusion, adjunct faculty who increasingly instruct large numbers of undergraduate students need to invest in faculty development activities, in particular technology training. Usually interested in their own development, institutions need to make such training readily available (multiple sections) to adjuncts and encourage (reward) them for building competencies in it to improve their students' learning.
Cognitive Issues for Learning and Performance from Multimedia Interfaces: Implications for Design

Maria Lorna A. Kunnath
Ed.D. Candidate
University of Central Florida
Orlando, Florida
mak05307@pegasus.cc.ucf.edu

Abstract: The paper discusses factors that affect users' learning and performance when they interact with a computer interface. Research in Instructional Systems, Cognitive Science, Human Computer Interaction and Design and Human Factors show an overlap of findings. All disciplines contribute to understanding how the human and the machine relate to one another and offer some very useful insights in our quest to producing better designs for multimedia learning systems.

Cognition

Perception

Research in interface development has shifted from perceptual and motor issues to cognitive issues such as perception (Aspillaga, 1996; Winn, 1993), attention (Taylor, 1992), selective encoding (Taylor, 1992; Paivio; 1991; Hodes, 1994), contiguity effect (Mayer, R. & Sims, 1994), and concurrency of information (Paivio, 1991) with implications to learning and performance (Blatter, 1994). These factors influence a person's ability to process the visual and verbal information on a computer screen. Research has shown that a well-designed presentation of information with consideration to a person's cognitive resource positively correlates with improved learning, retention and performance. During ‘perception’ vision is not yet ruled by attention because the viewer is confronted with processes occurring rapidly and simultaneously. The eye therefore, merely retains what it visualizes. For designers it is important to know what these perceptual processes are because any change in the instructional message can lead the user to unconsciously misinterpret the message. One of these early perceptual process is stimulation change, i.e. change in vision from light to dark and vice versa. Another perceptual process is the figure-ground which explains why users tend to create figures against a background. During the design, the designer should make clear distinctions between the figure and the ground by making the boundaries of an area very clear, coloring or filling the bounded area and judging the completeness of the figure.

Objects are perceived as complete shapes on the basis of their arrangement and the way their geometric boundaries follow simple alignment. Similarly, objects that line up, in a straight line or on a curve are grouped together (Winn, 1993) A viewer is attracted to the simplest organization of the parts of the display explained by the concept of emergent property. In conformance with the Gestalt principle of close proximity or spatial proximity i.e., parts of a message that are perceived as being close together will be processed as one. Various views have proliferated on where the eyes tend to focus in a group of images. Winn (1993) cited the work of Kinchla and Wolfe (1979) espoused a middle out approach. Others hold that people choose to view an image which is more dense and detailed. There are others who believe that perceptual organization naturally orients towards the horizontal-vertical overriding the perceptual factors of focusing attention, interpretation and behavior. Visual elements such as shape, space, size, color and location are processed according to their properties. Perceptual Grouping or Similarity Grouping, categorizes similar and different. Aspillaga cited Kawabata's work to emphasize that the density and orientation of elements affect their perceptual grouping. This research proves that perceptual grouping and layout uniqueness account for higher recollection (Aspillaga, 1991; Bundesen, 1990 & Gropper, 1991 as cited in Aspillaga 1991). Defined as the size of the image relative to the visual angle, a person's unique visual perception will ultimately determine where he focuses and gives attention to group/s of images (Winn, 1993).

Attention

A key component in learning and communication, attention has limited capacity for performing several processes at one time since it requires the use of cognitive resources of apprehension, temporary storage, elaboration of information and the use of short term memory. Short-term memory and processing speed are limited resource since it is serial, slower and draws heavily on long-term memory. Being selective, both resources do not need irrelevant information. For a multimedia interface designer it is important to determine which parts of the message should be emphasized because the cognitive mechanisms guiding attention determines where the user focuses attention. Parts of the message that stand out due to contrasting qualities are brightness in color, size, shape, typestyle and motion. Color in black and white is effective. Similarly, red will stand out because of its single unique feature (Nakayama, & Joseph, 1998) in a field of green distractors. Speed of presenting information affects depth of processing. Researchers conflict in their advice on the best rate of presenting information so that a user has enough time to decode, interpret and acquire the message. Some (Bellard, Taylor, Canelos, Dwyer & Baker 1985 as cited in Winn, 1993) recommend seven seconds of processing time. But researchers such as Hannafin recommend learner control which is contradicted by others who recommend that learners must be advised on how to proceed with the lesson. Providing the appropriate sequence of attending to information through the use of graphic devices such as arrows and lines will assist in guiding the eyes.
towards this information because the eyes tend to follow lines and contours. Being a medium for attention getting, multimedia can be used creatively by designers to gain, hold, control, and direct learner's attention (Taylor, 1992). After attention is given to the instructional message, the learner tends to focus on information that is perceived to be important. Through a process called selective encoding (Hodes, 1994), this information processing is strengthened. Through the use of elaboration strategies e.g., image generation, the user is able to meaningfully process and learn the instructional material. Hodes emphasized the significance of presenting clear, well-planned, and organized visual information to facilitate selective encoding and elaborative processing.

Schemata and Mental Models
Schemata is a person's organized network of prior knowledge. It is often said that the more sophisticated a person's schemata, the better one is able to assimilate, arrange, construct, and reconstruct prior information with new information. In the same light, one who has acquired an elaborate and diverse schemata possesses better metacognitive skills i.e., one is able to regulate his/her cognitive processing and monitor information needs. Anderson, R. & Spiro, R. (1978) conducted a study on schemata as scaffolding for representing information in connected discourse and found that food from categories determined to be part of people's restaurant schemata were better recalled by students who read the relevant narrative. When faced with new information, a person matches that information with slots in his schema and if it matches, it is learned and remembered. If not, it is considered insignificant. Mental models are based on schemata but possess both the figurative representational attributes of schemata and the dynamic properties of representation systems

Concurrence of Information
Dual Code Theory DCT holds that verbal and non-verbal systems are processed independently yet interconnectedly (Paivio, 1991). An extension of the dual code theory, contiguity effect holds that learners build referential connections faster when verbal and visual materials are presented contiguously than when they are presented separately (Mayer & Sims, 1994). In a verbal/visual presentation, the learner constructs a mental representation in his/her working memory of the verbally presented material and a mental representation of the visually presented material. The process of going from an external to an internal representation is called building representational connection or, verbal encoding and visual encoding as the case may be. As a result of all three viz., verbal encoding, visual encoding and referential connections, the user responds favorably to tests of retention and transfer which results in better problem-solving transfer and performance.

Seoul, Korea
Inlee@sejong.ac.kr

Abstract: A learning-oriented web environment is a place of highly demanding learner control. The current research appraises learners' perception of and learning styles and strategies in a web-based learning environment. A few laggards' pains buried under the majority who well adjusts oneself should be recognized and resolved. There is a strong need for instructional efforts to maintain the proper levels of learning and instructional demands. In contrast, deliberate efforts are demanded in order to induce active discussions and interactions among learners. In addition, this research shows significant gender differences in the categories of expression strategy and information processing strategy, in which males showed stronger abilities and positive attitudes without exception. The findings are not entirely surprising, since they replicate many of the existing findings from the areas of communication, linguistics, and sociology and more.

Introduction

A learning-oriented web environment is a place of highly demanding learner control. In this environment, learner issues are the core element for success (Bonk & Dennen, 1999). The web environment has been expanding to educational communities worldwide; however, it is not clear whether all and every learner will benefit equivalently from this new learning technology. So far, insufficient attention could be found in the literature concerning learning strategies in the web. In addressing this question, the current research (a) appraises learners' perception of and learning styles in a web-based learning environment, and (b) determine whether online learning strategies varied by gender.

The learner-oriented environment requires learners to make decisions by themselves during this process and, therefore, requires a high level of self-regulation and metacognitive abilities in the learning. Substantial numbers of literature inform the important roles of learning strategies for learning performance and some researchers worked on the learning strategies in the cyber context. Burge (1992) and Eastmond (1992) found the fact that learners transfer many of learning-to-learn approaches from other traditional learning context to cyber setting. At the same time, however, they also identified cyber environment request learners idiosyncratic ways of learning strategies of dealing the nature of cyber environment. Lyman (1998) stressed that cyber learners need to develop learning strategies called, 'information literacy' in order to take benefit especially in a resource-based learning environment through the Internet.

The Research

Subjects were 156 undergraduate students – 35 males and 121 females- from a medium size university in Seoul, Korea. They were from three different educational technology courses. The web system in this research was utilized mainly to facilitate discussion among learners, to submit assignments, to provide feedback from instructors, and to provide additional learning materials. Especially, the web used for the purpose of discussion was operated with asynchronous, open, text-based, task-oriented, and gender-mixed features.

Two different surveys with 42-items questionnaire were implemented and the survey data were computed by mean scores, chi-square and t tests. At the first week of the semester, 14 items survey was conducted in order to
find out subjects' information literacy level. A 28 items survey questionnaire was conducted during the last week of the semester to determine learning styles and strategies.

Findings and Conclusions

The findings of this study, taken together, suggest various ideas regarding instructional strategies for better online instruction. A few laggards' pains buried under the majority who well adjusts oneself should be recognized and resolved. It could be a starting point to find out some answers about what common characteristics those learners share, how to identify them, and how to support them, and so on. We also need to consider feedback systems that will satisfy learners' high expectation and concurrently avoid instructors' working overload. There is a strong need for instructional efforts to maintain the proper levels of learning and instructional demanding. Most practitioners agree that an online environment intrinsically has a high potential of producing learning and instructional overload. Nonetheless, there is a rare perception that this quality may exhaust learners and instructors and, as a result, seriously hinder learning performance. It is desirable and yet easy to demand learners to share with others information and learning outcomes. In contrast, deliberate efforts are demanded in order to induce active discussions and interactions among learners.

It seems clear that males tended to use computers more at least in their daily life and to have stronger experiences with the Internet than females. This research shows significant gender differences in the categories of expression strategy and information processing strategy, in which males showed stronger abilities and positive attitudes without exception. The findings are not entirely surprising, since they replicate many of the existing findings from the areas of communication, linguistics, and sociology and more (Ebben, 1994; Hatton, 1995; Herring, 1993; Herring, 1994; Herring, Johnson, & Dibenedetto, 1992; Kramarae & Taylor, 1991; McDowell & Schuelke, 1998; Selfe & Meyer, 1991; Spender, 1995; Tannen, 1991). The current research also confirms that awareness of gender differences in learning strategies is critical to know its potential effects on learning process and outcomes. Currently dominating modes of cyber courses demonstrate structures and functions in favor of males. However, it should not be taken for granted but we have to move toward a gender-equal cyber learning environment. This can be achieved by including instructional design and implementation which might more respond to learning strategies in favor of females. Of greatest potential that leads to gender inequality in a cyber learning environment is its text-based, public, and information overload natures.

Integration of Varied Cognitive Activities in a Multimedia Environment.
The PHYLOGENE Example.

Dominique Lenne, Monique Dupuis, Jean-François Rodes, Naoum Salamé
Institut National de Recherche Pédagogique
France
dominique.lenne@inrp.fr, monique.dupuis@ac-versailles.fr, JFRodes@wanadoo.fr, naoum.salam@inrp.fr

Abstract: This paper describes PHYLOGENE, a multimedia open environment we designed for evolutionary biology teaching and learning. The progressive approach of evolution it implements, relies on a set of biologic, anatomic, morphologic and molecular data and allows different articulated activities from observation to evolutionary trees construction, including comparison, selection and classing of animal species and characters. All these activities provide the students with multiple entries at different teaching level.
The main feature of PHYLOGENE is that it combines on one hand an hypermedia environment enabling navigation among documents describing species and their characters, and on the other hand, analysis tools enabling to select, class and organize the hypermedia explored data. It provides thus as well knowledge exposition as learning activities that encourage an active involvement of the learner. We argue for the interest of such multimedia open environments in science learning.

A lot of software tools can be of great interest in learning about life evolution, but most of them only offer a particular approach. We describe in this paper PHYLOGENE a multimedia open environment that integrates varied cognitive activities to allow a global approach of evolution.

Learning the Concept of Evolution

Evolution of life is a fundamental concept in the understanding of a great number of biological phenomenon. This concept relies on various kind of knowledge relative to Earth history, biochemical process at the origin of life, living organisms development conditions and stages, species apparition and extinction (biological crisis and crossing off), species relationships. Therefore evolution is central in the biology curriculum organization at all school levels.
At these different levels, varied cognitive abilities are required from the students. At the beginning, they are centered on a global recognition of macroscopic characters. Then they have to analyze (in a qualitative or quantitative way) details or data able to constitute arguments to reconstruct evolution and to integrate selected information in a global representation such as an evolutionary tree. Finally, they are led to integrate new knowledge in the framework of evolution theory, taking into account the current debates.
Though some software tools can be useful in the learning of evolution related concepts (Jones et al. 1997), none of them provides an integrated approach. That led us to design a multimedia open environment called PHYLOGENE, allowing such an integrated approach by giving access to the different kind of knowledge implicated in the study of evolution and by enabling different cognitive activities (Dupuis et al. 1997).

Description of PHYLOGENE

In order to support a global approach of life evolution, PHYLOGENE has the main following features:
- It allows to combine different abstraction levels through different kind of activities,
- Different entry points are possible, taking into account the nature of the question to study and the students school level (middle school, high school, university),
- Students can choose freely the species and characters they want to study.
One of the major goals is to let the student be active by solving problems, while following a naturalist approach (morphologic and biologic data). Unlike other tools, the tree structure is not pre-established and the species characters are not all evolutionary characters.

PHYLOGENE is thus organized in different activities exploiting a database of species:

- Observation activity allows to study the animal morphology, to discover some of its biologic characters (habitat, diet, fertilization, social structure) and anatomic characters (breathing organ, locomotor organ, skull, extra embryonic membrane) characters.
- Comparison activity (Fig. 1) allows to display simultaneously up to four species images or characters sketches. New species and new characters can be easily taken into account.
- Grouping and classing from a range of species gives the possibility to choose a subset of species and characters, to fill a table with the observed characters states and then to build a hierarchical classification on the basis of these states.
- Trees constructing (Fig. 1) can be realized on the basis of a table or a classification. Trees can be constructed step by step in a MacClade like way (Madison), by choosing the positions and grouping together of the branches.

The main feature of PHYLOGENE is that it combines on one hand an hypermedia environment enabling a navigation among species and their characters and on the other hand analysis tools enabling to select, class and organize the data explored in the hypermedia. It provides as well knowledge exposition as learning activities that encourage an active involvement of the learner, allowing discovery learning (Van Joolingen 1999). We think that such hybrid tools are well adapted in experimental science learning.

PHYLOGENE has been experimented with success in a few middle school classrooms. It will be distributed in the course of the year 2000. A scientific and pedagogical documentation will go with it and additional data will be found on our web site (http://www.inrp.fr/Access/Biogeo/accueil.htm).

How does one evaluate the effectiveness of electronic learning in a South African context?

Context

Significant aspects of the context include the following. The University of the Western (http://www.uwc.ac.za/) has adopted the mission to—“Assist educationally disadvantaged students gain access to higher education and succeed in their studies”. Consequently, the university has provided access to students from previously disadvantaged communities. As a consequence our classes are ethnically and culturally diverse. Moreover, the quality of the educational experiences of these students also vary widely. From such a heterogeneous student population, one infers that a rich learning environment, that accommodates individualisation, flexibility and self-paced learning, would be ideal. Over the last few decades computer assisted learning has been suggested as a resource to meet such needs. The technological infrastructure at the institution is still underdeveloped, but it is improving rapidly. Despite the enormous inequalities of the past, the recently established democracy brings the promise of rapid progress. Such a context requires rigorous evaluation of the impact of the new technologies on education in order to ensure that our society reaps the maximum benefits and avoids possible pitfalls (Reeves, 1998).

Rationale for evaluation

What is evaluation and how is it related to research? Evaluation is defined here as: the systematic acquisition and assessment of information to provide useful feedback about some object (Trochim, 1999). The object in this case is technologically enhanced learning. The generic goal of evaluation is to provide useful feedback to various stakeholders that influences decision making at various levels. Evaluation, the same as research, is concerned with the collection and analysis of valid and reliable empirical data. The two may, therefore, utilise many of the same methodologies. However, because evaluation takes place within an organisational and political context, it requires sensitivity to multiple stakeholders as well as managerial and political factors (Trochim, 1999). In addition, in practice the relationship between evaluation and the actual decisions taken is not a simple one. Thus, the question arises is evaluation necessary?

Reeves (1997) argues that there are at least four reasons for the lack of useful evaluation of CBE. Firstly, consumers of technological innovations for education uncritically accept the advertised claims of the producers of the technology. Secondly, evaluation of CBE has often been reduced to a numbers game. Thirdly, evaluations that have been previously conducted lacked utility and impact. Fourthly, the inappropriate reliance on traditional empirical evaluation methods that compare an instructional innovation with another approach, frequently led to disappointing results. He, therefore, proposes fourteen pedagogical criteria for evaluating various forms of CBE in order to obtain more valid and useful evaluations.

Quality learning

The key outcome of this project should be an improvement in the quality of learning by our students and teaching by our academics. The Multimedia Computer together with its sophisticated software is merely a means to this end. Laurillard (1993) argues that a mix of teaching and learning methods will always be the most efficient way to support student learning, because only then is it possible to embrace all the activities of discussion, interaction, adaptation, and reflection that are essential for quality learning. Entwistle (1996) stresses the importance of research into student learning for improving tertiary teaching.

Methodologies

Nightingale and O’Neill (1994) recommend Action Research as an approach to enhancing the quality of learning in higher education. It is adopted as a broad approach because of its focus on improving practice rather than merely proving theories. It is seen as a self-reflective spiral that involves planning, acting,
observing and reflecting with further iterations of the same cycle. Trochim (1999) discusses, four strategic approaches to evaluation: scientific-experimental models, management-oriented systems models, qualitative/anthropological models and participant-oriented models. He also points out that, although vigorous debates may rage among the proponents of these schools, one should borrow from each as the need arises.

Action research defines the broad approach within which more specific research techniques will be employed. For many reasons a pure experimental design is unlikely to be fruitful. Ethical, practical and technical considerations, all render controlled experimentation inappropriate (Entwistle 1996). Both qualitative and quantitative techniques will be employed as deemed appropriate. Specific techniques used, include: surveys and questionnaires, interviews, student achievement under different regimes. In brief, careful observation of students involved in CAL; supported by surveys and questionnaires as well as detailed interviews will be employed to provide the raw data.

Case studies

Case studies of efforts to introduce computer supported education and its effects on student learning will be presented. Some questions to be explored are -
- How do students interact with CD-ROM delivered material?
- What factors promote or hinder their learning when using this medium?
- How should CD-ROM be used without compromising quality of learning outcomes?
- Does technologically delivered learning materials live up to its promise?

Using Technology to Teach Linear Algebra

Lawrence E. Levine
Department of Mathematical Sciences
Stevens Institute of Technology
Hoboken, NJ 07030
llevine@stevens-tech.edu

Abstract: An introductory mathematics course in linear algebra was taught using laptops and Scientific Notebook. Computer technology was utilized as an integral part of presentation as well as learning and testing to the extent that the instructor did not write one thing on the board the entire semester. This approach has implications for other disciplines besides mathematics.

Introduction

Stevens Institute of Technology has required its students to purchase a PC since 1984. This requirement has now been replaced with a requirement that all students purchase a laptop. To prepare for the switch from PCs to laptops, last year Stevens set up a laptop classroom so that faculty could experiment with teaching in a new environment. The author used this classroom to teach an introductory one-semester course in linear algebra.

Scientific Notebook

The author has used Scientific Notebook (SNB) for several years in the second year mathematics sequence taught at Stevens. SNB is a word processing package that incorporates a Maple kernel. This Maple kernel allows one to perform a wide variety of mathematical operations. A particularly nice feature of SNB is that one can use the Maple kernel without typing any code. One simply types the mathematical expression and then clicks on the appropriate operation to be performed. SNB then performs the operation.

Structure of the linear algebra course

SNB was used to prepare a complete set of lecture notes. The notes incorporated in-class exercises to be worked on during the lectures. Thus each class meeting was a combination of lecture and hands-on doing. When the instructor was lecturing, laptops were required to be closed, whereas when the students were working on the exercises, the laptops were open. The class moved seamlessly between the two environments of a “standard” classroom and a computer laboratory. Homework had to be done using SNB. No written work was accepted.

Use of the Web

Notes for each class were posted on the Web. A feature of SNB is that one can put a tex file on the Web, and then download by simply clicking on it. Thus each lecture began with the instructor downloading the lecture from the Web to his laptop and then projecting it for the class to see.

All homework assignments were also posted on the Web. In addition, solutions to homework problems and exams were put on the Web site. A good portion of the quizzes and exams were also given over the Web. The Web served as a crucial resource for the course. To see what was actually done go to http://attila.stevens-tech/edu/~llevine/.

Exams and Quizzes

Many of the short quizzes and portions of all exams were designed so that the students had to use SNB to solve the problems. These had to be downloaded by the students, worked on, and then uploaded to a site. The exams and the final were in two parts: one part to be done with paper and pencil, and the other part requiring use the Maple kernel in SNB to solve the problems. Having a networked laptop classroom made this approach possible.
Engaging the student in the teaching/learning experience

One of the goals of a good educational experience is to engage students in the teaching/learning experience. Active learning is certainly more desirable than passive learning for a wide range of reasons. However, within the classical lecture format it is often difficult to get students actively involved in what is going on in class. Given the approach taken in this linear algebra course active student involvement became the rule rather than the exception.

Advantages of this approach

Integrating the use of computer technology into this one semester linear algebra course in the manner described above had the following advantages:

- Students learned to use sophisticated mathematical software as a tool in mastering mathematics.
- Mastery of linear algebra entails being able to perform many arithmetic operations. Students often make mistakes while performing these operations. Using software judiciously avoids this problem and allows the student to concentrate on the underlying concepts.
- A laptop classroom is actually two classrooms in one: with the covers of the laptops up it is a computer laboratory, whereas with the laptop covers down one has a "standard" classroom.
- The active learning described above is certainly a major advantage of this approach.

Problems encountered

- The time investment required preparing for and teaching such a course is considerable.
- Preparation of exams that incorporated the meaningful use of SNB required considerably more thought and time than preparation of "standard" exams.
- Some students found it difficult to deal with a mathematics course in which writing was not a key component.
- There were a number of technical difficulties encountered vis a vis the hardware.
- Many of the short quizzes and all of the exams had a computer component. This component was downloaded from a server, worked on by the students and then uploaded to the server upon conclusion. Thus security was very much an issue.

Applicability to other courses

The approach taken with this linear algebra course can certainly be used to teach other mathematics courses as well as courses in other disciplines. Indeed it is this author's opinion that using such an approach would enhance the learning experience for many students.

However, this approach does have limitations. The linear algebra course had 28 students in it. There was also a teaching assistant present during all classes. Thus two people were necessary to handle a class or 28. The class size could have been increased to perhaps 40 without foreseeable problems. However, this is probably the upper limit for such a course. The point is that this approach will not work with a lecture class of say eighty or a hundred.

Conclusions

Students were asked to complete surveys on the web a couple of times during the semester. The vast majority of students liked the course, but there were a few who were very unhappy with the approach. Approximately 90% of the students indicated that they would be willing to take another course that was given in this format. Perhaps the overall conclusion to be drawn is that while some students will always be unhappy with a course that employs the extensive use of technology, the vast majority will benefit greatly from courses that judiciously employ technology as part of the teaching/learning experience. The challenge is for faculty to find meaningful ways to incorporate this technology into their courses. This is far from a trivial challenge.
Towards an Intelligent Authoring Shell on Reuse

Kam Wing Li
School of Computer and Information Science
University of South Australia
Australia
li@cs.unisa.edu.au

Warren James
School of Computer and Information Science
University of South Australia
Australia
warren@cs.unisa.edu.au

Abstract: An authoring shell that supports the reuse of teaching material should not only allow the author to search for the existence of the material and retrieve it. When there are too many "matched" items, an authoring tool should be able to identify those that are relevant and create a suggestion list to the author. When there are "no matched" item, an authoring shell should be able to suggest a list of materials that are closely related. This article describes how an Intelligent Authoring Shell (IAS) can provide suggestions to a teacher at authoring.

Introduction

To enable reuse, IAS has employed database repository method (Sarti and Marcke 1995) to store useful information of each piece of teaching materials, activities and lessons. Along with database repository method, IAS also uses learning objective as the key to reuse teaching materials (Kam Wing and Warren 1998). Learning objective has two main components: an object and a keyword, the letter drawn from a learning objective. An object is a concept, or skill, or entity that is described in a learning objective. Keyword is the verb being using in the learning objective. With object, we can search for the existence of a related teaching material/activity/lesson. With keyword, we can know the purpose and usage of each piece teaching material/activity/lesson. Therefore, learning objective is the backbone for IAS to enable reuse.

IAS has three main modules: keyword module, strategy design module and course design module. Keyword module and strategy design module are bases to provide intelligence in IAS. Reuse of teaching materials and providing intelligent suggestions to a teacher on reusing teaching materials take place in course design module.

Keyword module

It facilitates the input of learning objective taxonomy (keyword) into IAS database. IAS uses the structure of Bloom's taxonomy (Bloom, Englehart et al. 1964) as reference. Bloom has classified learning objective taxonomies into three different domains: cognitive domain, affective domain and psychomotor skill domain. Under each domain, taxonomies are further classified into different levels forming a class hierarchy. In IAS, we have used this module to enter Bloom's taxonomy on cognitive domain. Users can use this module to enter other taxonomies or even create their own set of taxonomy and define the use for each keyword.

Strategy design module

It allows teachers to design their own teaching strategy. In IAS, a teaching strategy is composed of a set of activities with different activity type. Each activity type may consist of sub-activity type. For example, a lesson using concept attainment (Joyce and Weil 1986) as its teaching strategy will contain introduction,
example(s), counter-example(s), analysis and conclusion. Example is composed of sub-activities such as description, question, answer and explanation. In designing a teaching strategy, the author will construct the teaching strategy structure by arranging activity types in order. The author will also indicate which domain and taxonomy class are likely/unlikely to be suitable for the teaching strategy. With this information available, IAS can use the keyword from learning objective to provide suggestion list of appropriate teaching strategies to a teacher at authoring.

Course design module

It helps a teacher on designing curriculum of a course, lesson and learning activities within a lesson by providing suggestions on reusable materials to a teacher at authoring.

In designing the curriculum, a teacher will construct a hierarchy of learning objectives for the course. On inputting a learning objective, IAS will check the keyword with previously entered learning objectives' keyword by using the class hierarchy. This is useful to detect any illogical sequence of learning objective. According to constructivism learning theory, any illogical order of learning objective hierarchy will increase student's difficulty in learning. Therefore, such a checking feature can help to improve quality of a course. At the same time a teacher is building learning objective hierarchy, an object hierarchy is also built using the objects from each learning objective. With this object hierarchy, we can identify the relation between each object. This relation will be useful in deciding which teaching materials may be appropriate for reuse and also in searching and retrieving closely related materials for the object.

In creating a lesson, a teacher will select a teaching strategy from the appropriate teaching strategy list. This list is suggested according to the class of domain keywords being used in the learning objective and the information from the strategy design module.

After teaching strategy of a lesson is selected, the author will follow the structure of the teaching strategy to design learning activities and sub-activities. URLs of multimedia files for each activity and sub-activity will be recorded into IAS database. In designing learning activities, IAS will suggest reusable activities and teaching materials for the author to select. The suggestion criteria available are based on activity type, learning objective, keyword and object. Suggestion criteria based on activity type will use activity type as filtering element. For example, if the activity at authoring is an example, then IAS will only list those activities that are examples only. Suggestion criteria based on keyword and object will list related activities/material according to the keyword class hierarchy and object hierarchy. This will reduce author's time in searching for reusable teaching materials, particularly when the database has hundreds of teaching materials available.

Conclusion

Using database repository method, normal authoring shell is able to provide simple reuse of teaching materials. Using learning objective with database repository method, a normal authoring shell will become more intelligent. It can provide some suggestions to teacher and thus reducing a teacher's effort in creating on-line course. Even though our IAS can provide some suggestions to teacher at authoring, we are looking forward to optimising the suggestion criteria to improve the effectiveness of suggestions.

The Art of Technology The Technology of Art

Loy Lichtman
Victoria University
PO Box 14428 Melbourne City MC 8001
Victoria, Australia
Loy.Lichtman@vu.edu.au

Abstract: This paper explores what it means to be a visual artist in the age of information technology, and it explores how the degree in Computer Mediated Art at Victoria University attempts to answer this question. A number of Informing Principles are discussed which provide insight into the development and implementation of the program, a program which draws upon both traditional studio practice and digital studio practice. The paper concludes by examining how the technological shaping of (visual) culture produces an art of technology and a technology of art.

Art @ Technology.

Victoria University was initially configured as a university of technology intended to service the needs of its local industry based community in the economically disadvantaged western suburbs of Melbourne, Australia. In 1997 it was decided to change the low visual arts profile at the university into a high arts profile by introducing for the first time in the western suburbs, a fine arts degree. The degree however had two briefs: it could not be a conventional visual art degree as found in other universities around Australia; and it had to make digital technology central to it program.

Artists Adopting Technologies.

Artists have adopted technologies to their studio practice as soon as those technologies become available. These technologies have included the development of different types of paint such as oil, tempera, acrylics and gauche, the development and implementation of perspective and a variety of painting surfaces. In addition to these technologies, artists have also employed more mechanical innovations such as the camera obscura, photography and various printmaking methods such as off-set, silkscreen and etching. Electronic technologies such as video, photocopy and fax have been coopted into studio practice and more recently again, digital technologies through a variety of computer hardware and software applications.

Informing principle: If technology has always been a part of an artist’s studio practice, then the inclusion of digital technologies would simply be a continuation of that process and in this way, technology would be defined as a range of ideas and tools which are available to the artist in order to realize a particular set of intentions.

Technology and Art History.

Computers in general, and art software packages in particular, do not represent a significant discontinuity from previous technologies used in the artist’s studio. Software effects such as morphing were used by Escher in the early part of this century as were effects like interactivity found in Duchamp’s Readymade series. Zooming and magnifying techniques were used by Lichtenstein in the sixties while Oldenburg played with changes in scale at the same time. As for hardware, the monitor, which physically resembles the landscape shape/format of a traditional canvas, is inherently perspectival.

Informing principle: Computer mediated art is primarily art made using the brain rather than the hand and it is this difference that turns the computer into more than an ordinary tool studio tool because it disturbs the ‘taken for grantedness’ of art praxis. Is the computer a tool like a paintbrush or pencil? Of course the answer will depend upon how ‘tool’ is defined, but what makes the computer interesting in the creative process is its potential to take on a role that traditional tools cannot by for example, generating automated creative processes through the use of scripts.
Used this way, the computer becomes a decision making tool which acts to amplify intelligence rather than replace it.

**Atoms and Bits.**

Central to this new artistic environment -the artist in the age of information technology- is an emphasis upon both atom based art and bit based art. Digital art consists of a series of electronic charges on a monitor rather than the physical presence of an analogue painting. Inherent in bit based art is computer memory and its ability to store, retrieve and manipulate image, sound and text in ways not previously possible in analogue art. In this way the distinction between master and copy typically found in the artmaking process is no longer viable. Each subsequent copy is now a perfect master.

**Informing principle:** Students will develop computer mediated art work which is either static two dimensional images in much the same way as atom based art work on the wall is static two dimensional as well as time based art which may or may not be interactive. As well, they may produce work which is three dimensional that can move fluidly without constraint, conveying us through various modes of discourse. Students will complete the degree with both a folio of analogue work and a folio of digital work on a CD-ROM/Web/DVD.

**Aesthetics and Technology.**

Computer mediated art provides no panacea for aesthetic problem solving nor for resolving the issue that while computers are being used to generate images, meaningful art still needs to be created irrespective of the technology. Artists need to consider what the end result might be and what part a computer might play in this being achieved. What can be done with traditional tools does not necessarily become more interesting because it has been generated on a computer: what is interesting is what was not conceivable before computers. The art software packages not only allow artists to work in substantially different ways to analogue art by allowing the combination of what would normally be considered mutually exclusive techniques -for example oil paint and watercolor- they also undermine one of the central goals of analogue art- the goal of fixed perfection. The Undo command allows artists to undo at will any mark or fill deemed inappropriate which may result in an art which lacks commitment or be too timid.

**Informing principle:** Alongside both analogue and digital art students will participate in a program which examines aesthetic issues in relation to technology as well as an art history which does not focus only on dead, European, white males. Aesthetic issues based on Asian art as well as issues of gender, particularly in relation to the art software packages being used, will be examined.

**Virtual Studios.**

A virtual studio will be established between students enrolled in the Bachelor of Arts-Computer Mediated Art and students enrolled in the visual arts stream of a Bachelor of Education at Deakin University in order to investigate the use of that virtual studio as a collaborative learning forum for creating computer mediated art. It will also examine the way artists are grappling with new digital technologies in their studio practice. The software which will be used for this virtual studio will be *Painter* 5.5 because it has tools which are familiar and recognizable to artists. To achieve this, *Painter* relies on analogies with traditional artistic techniques such as virtual pens, virtual pencils and virtual canvas. *Painter* is also being used because it has a facility which allows it to be used via a TCP/IP connection. Essentially, there are two frames on the monitor-one for the artwork which is asynchronous and one for a chatline which is synchronous. Students at Deakin will be able to watch digital art being made at Victoria University and when that work in finished it can be sent down to the other student as a file, and vice versa. *Painter* also has the ability to record every stroke and combination of strokes in the creation of the visual image which can then be replayed at later stages to investigate issues of participation, patterns of use and the application of virtual technologies to the art making process.

**Conclusion.**

The Bachelor of Arts-Computer Mediated Art is not a multi media program, although possibilities exist for its use. Rather, it is a course aimed at fine artists who wish to use traditional paint brushes as well as paintbrushes which are plugged in to the computer in their studio practice, and to understand the implications and consequences of so doing.
The Status of Online Professional Development Available to Support Higher Education Staff.

Andrew Litchfield and Peta Spear
Centre for Professional Development
Macquarie University, Australia
andrew.litchfield@mq.edu.au

Abstract: The authors have conducted a survey to identify online learning resources specifically designed to support the professional development of higher education staff. This short paper outlines the survey and principle findings, and presents an overview of the pdonline website with links to the identified 'best-of' online resources. The authors offer the pdonline website for use with professional development activities to support higher education staff.

Introduction

The rhetoric, rationale and emerging practices of 'online learning', 'flexible delivery', 'just-in-time', 'anytime anywhere' education for learning and teaching programs is just as relevant for staff development. Online communication, activities and resources can enable more flexible ways of supporting diverse individual staff learning needs. Online media can be used to improve the support for mentored and facilitated 'just-in-time' professional development services.

When considering the design issues of online individualised staff development the authors considered a necessary first step was to survey and identify relevant online resources. This survey informed the content of a website of links to what we considered were the best of the identified online resources. We offer the pdonline website for use by higher education centres of staff development to assist their activities. The website is located at <WWW. cpd. mq. edu. au/pdonline>.

Survey Description

The survey aimed to identify the quality and scope of accessible, online resources specifically designed to support the development of English language university staff. The research was conducted from September 1998 to February 1999. All Australian, New Zealand, and United Kingdom universities, all Canadian and American universities with online teaching centres, and all known virtual campuses were investigated via the web. A total of 385 university websites were surveyed in detail.

The survey was designed to investigate and scan the web for accessible online university staff development programs and resources in learning and teaching, leadership and management, research, administrative and specialist support, and community service. The study's secondary focus incorporated other university centres such as flexible and distance learning centres, materials developed by faculty such as tips on teaching, web resource links recommended by staff development centres, and general web and database searching such as for corporate training websites.

The authors acknowledge that not all relevant websites were able to be examined within the funding and time constraints of this survey. Websites are constantly changing and without doubt there are now new useful resources online. Nevertheless we believe the study is extensive enough for useful observations to be made.

Survey Findings

The survey identified a vast amount of online activity generated by universities. Some had comprehensive online programs, resources and links in an impressive range of areas. However only a relatively small amount of activity was found to be specific to our staff development focus. Every university in this survey provided some form of in-house tuition for its staff and students in using the internet and substantial resources are dedicated to the
development of software and web skills. Staff development was offered almost exclusively via in-house workshops in all universities. Where online modules were offered, content invariably focused upon opportunities offered by the web as a communication, authoring and publishing tool.

Although North American universities due to their number and size dominate the survey, Australian universities made a proportionately good showing in providing online staff development resources. Australian universities have approximately a 1:4 ratio of providing some useful online resources, with North American universities the ratio was approximately 1:6, while in the United Kingdom the ratio was 1:17. The ratio for North America is due to the high use of online resources which originate from Teaching Assistant handbooks.

The online resources found are predominantly in learning and teaching with a strong emphasis on teaching tools and the use of information technology. There are very limited online staff development resources in university leadership and management. Minimal activity was identified in research development, administration and specialist support, with no activity in the area of community service.

Apart from skill training in how to use the internet, the survey found nothing by way of a single, cohesive package of online staff development specifically designed for both faculty and general university staff. The closest to a comprehensive online program in university professional development was found in online courses of professional accreditation.

The *pdonline* Website at <www.cpd.mq.edu.au/pdonline>

Despite the overall bulk of material the quality of resources varied widely necessitating careful assessment of the materials chosen for inclusion on the *pdonline* website. Of the 385 universities surveyed in detail only 65 universities were assessed as having produced suitable online resources. All sources of chosen links were contacted for their approval before the website went online and are acknowledged on the website. When maintaining the website in late 1999 13 links were no longer active and were removed.

Selection criteria included a judgement of the quality of theoretical rigour and written expression, and the usefulness of the resource in staff development as a self-learning aid, an adjunct to workshops, and as a support for future online development activities.

*Learning and teaching development* was the best represented of all the areas investigated. Four main categories were devised; (1) teaching advice including general teaching tips, planning, lecturing, teaching large classes, group learning, diversity, assessment, (2) theories of teaching practice, (3) teaching portfolios, and (4) teaching using the internet. Resources originating from secondary sources were incorporated into each category as useful resources.

Online resources in *leadership and management development* were scarce. Only two links originated from within universities and other links are to private management training corporations and to websites of individuals.

The site includes links to three accredited online professional development courses in higher education.

Conclusion

Our survey clearly indicates universities everywhere are actively encouraging the use of online media in learning and teaching. Ample resources are available in how the technology works however staff are under-represented as learners and consumers in these new processes. There was no evidence of a comprehensive program of online professional development specifically designed for higher education staff.

We located and produced a unique bibliography of links to the 'best of' resources identified in the survey. The authors offer the *pdonline* website to support individualised learning plans and to provide supplementary resources for workshop-based programs. Hopefully this work can prevent at least some 'reinvention of the wheel' when staff development centers produce their own online resources.

Interesting opportunities exist in using online resources in the professional development of higher education staff. Online communication, activities and resources can enable and support 'just-in-time', flexibly delivered and individualised learning plans and this is the direction of the authors applied research. The *pdonline* website is a key resource to support this work.
Supporting the millennium teacher: faculty development in the use of information and communications technologies

Allison Littlejohn
University of Strathclyde
Graham Hills Bdg., 50 George St.
Glasgow, Scotland
allison.littlejohn@strath.ac.uk

Abstract: The UK government has established an Institute for Learning and Teaching (ILT) and will soon require that all professional teaching staff in Higher education (HE) achieve membership through either a portfolio or upon the successful completion of accredited courses. This development is driving a rapid expansion of coherent staff development programmes offering full recognition of the professional development staff undertake. The aim of this paper is to examine ongoing research which will inform future developments in faculty development in the use of Communications and Information Technologies (C&IT) in teaching and learning. An analysis of responses to an accredited staff development programme is presented within the context of the shifting role of the university teacher. This study will be of interest to staff developers who wish to offer this form of support to faculty within their own institution.

The shifting role of the university teacher

Traditionally staff development in HE has been through workshops offered on a need-to-know basis. However, there is no clear evidence to suggest that these have made a major impact in changing the nature of teaching and learning in universities within the UK. In 1997 the Scottish Higher Education Funding Council (SHEFC) commissioned a nationwide survey of staff development needs aiming “to investigate the training requirements for staff in HEIs to enable them to use the MANs (Metropolitan Area Networks) effectively and efficiently in teaching, learning and research” (Higginson & Tombs, 1998). The results of this analysis do not reflect an adherence to current educational theories advocating the development of students' adaptive and transformative attributes. For example most academics advocate using the WWW for delivery of information and teacher-initiated communication, corresponding to the conventional role of the teacher as the provider of knowledge and information. Likewise student-centred methods were allocated low priority by respondents.

These findings highlight the limited conception amongst HE teaching staff of how to use the World Wide Web (WWW) effectively for teaching and learning, echoed in other studies (for example Thomas et al, 1998). Littlejohn and Stefani (1999) reported that academics often view the WWW as another means by which they can ‘deliver lecture notes’, ignoring the importance of student dialogue. This was due mainly to the misconception that the use of new technologies involves transferring traditional teaching methods into an electronic format, with no regard for the underlying pedagogical implications. It seems clear that knowledge of web authoring skills without pedagogical design skills will not lead to effective online teaching. Despite this notion, a recent survey conducted by the Scottish Higher Education Funding Council examining the present state of ICT staff development in Scotland reported a significant gap between coherent courses which are pedagogically driven and a plethora of short, technology-driven workshops (Alexander, 1999). There is a need to bridge this gap by providing a faculty development programme which models current thinking in online teaching and places faculty in the role of an online learner.

In 1998 the University of Strathclyde piloted an innovative, accredited programme of this nature. Entitled ‘Advanced Academic Studies’, the Postgraduate Certificate/Diploma course offers modules spanning various aspects of academic practice including Web Based Teaching and Internet Communication for Teaching and Research. The Web Based Teaching module takes place over a three month period with full day face-to-face sessions. In the first session Getting Started participants critically evaluate examples of web based teaching. The next stage is Planning your Educational Website in which participants storyboard an online learning activity. Following this Incorporating Interactivity focuses on introducing online discussion and assessments. Finally Creating your Educational Website is when participants create the necessary webpages and present their online learning activity as their final assessment. A major feature of this module is that it places faculty in the role of an online learner enabling experimentation and evaluation of new technologies at first hand.
This gives faculty the opportunity to foresee learning and technological problems which their students may experience (Ryan, 1998).

Analysis of faculty responses to this staff development programme

Group interviews followed by an online evaluation study took place upon completion of the Web Based Teaching module in May 1999. Nine of the ten course participants participated in the evaluation: four faculty members and five support staff including a librarian, a web developer, a learning support officer and audio visual staff. All the respondents thought the module increased their confidence in using the Web for teaching and learning. Perceived benefits included:

- The modeling of Web based teaching and learning placing faculty in the role of online learners.
- The use of learning activities building pedagogical and practical skills simultaneously.
- Online publication of assignments enabling participants to exchange and evolve ideas.
- Dialogue resulting from exchange of ideas online promoted the development of a community of scholars embracing the diversity of academic disciplines represented on the course.
- Publishing assignments on the Web made peer critiquing easy to facilitate compared with traditional methods.

Some drawbacks were also expressed including:

- Participants sometimes felt overwhelmed by the continuous learning activities. As a result some fell into the role of the ‘convergent’ student, for example by only completing activities which were to be assessed.
- Installing software on their own computers was occasionally problematic for participants
- ‘Drop in’ in web authoring sessions were requested

Most participants stated that the module enabled them to develop the required skills to improve an established class. However the final submissions of online courses indicated a continued adherence to teacher-centred teaching. Major barriers voiced against using the WWW for teaching focussed around three issues: negative attitudes of staff and students, lack of time to implement web based teaching and poor technical assistance. The most participants had access to an ‘IT literate’ person within their department who could offer immediate help with technical problems. The wide range of IT skills within the class may be alleviated in the future by linking with supplementary IT skills courses offered within the University. When the module was repeated in January - March 2000 there was stronger emphasis on the importance of strong educational design. A group interview with 15 participants offered evidence that participants' views had shifted slightly towards developing more student-centred courses. Participants requested that a further session could be offered in future enabling development and elaboration of their ideas in the form of storyboards.

The results of this study emphasise the requirement for full integration of current thinking in educational technology into teaching practice. The next step is to ensure that upon completion of the course faculty are encouraged to continually reflect upon and improve their teaching practice. Ongoing research aims to further improve this programme in an attempt to make a greater impact on changing teaching practice both within the University of Strathclyde and in the Scottish HE sector as a whole.

Alexander, W., (1999) TALiSMAN Review of Staff Development Courses and Materials for C&IT in Teaching, Learning and Assessment http://www.talisman.hw.ac.uk/CITreview/

Abstract: The dramatic growth of the Internet and subsequent use of the Internet for Electronic Commerce is fundamentally changing the business paradigm, at both a local and global level. The emergence of the global on-line economy is not only providing immense opportunity and threat for small, medium and large businesses at a micro-economic level, but is posing similar opportunities and threats at a macro-economic level, all at 'break-neck' speed! This requires training students and business operators at a rapid rate, which raises some critical issues for educators, such as course structure, delivery methods, collaborative ventures with industry and keeping up with technology and business issues.

Rationale

"The uptake of electronic commerce has the potential to transform the global economy more rapidly than the industrial revolution" (Department of Industry and Tourism, 1998). Projections like this have serious training ramifications. How can large numbers of business operators be quickly trained in on-line technology and business strategies in order to take advantage of this new revolution? The Australian Federal Government considers on-line and Ecommerce as being a priority area for future growth in Australia. The Department of Communications, Information Technology and Arts (1999) has identified the following priorities:

- maximising the efficiency dividend from Ecommerce for the economy at large;
- reducing barriers for the development of Ecommerce; and
- demonstrating a business case for the integration of Ecommerce into business

In order to meet these priorities in a timely manner, training of both the existing work force, and of new students entering the business environment is required. University courses spanning three years duration will not provide the body of knowledge or skills needed by Australian business to compete in this rapidly changing on-line marketplace. Graduating university students need short, bridging courses to account for rapid changes in technology and the impact that such change will have on business practice and process. These courses need to provide ongoing collaboration and mentoring with industry to ensure the knowledge acquired is current and relevant.

Case Study - Ecommerce Intensive Training Program

In September 1999, ninety-second year multimedia degree students from Edith Cowan University completed a 10-day intensive Ecommerce business planning course. They had no previous instruction in business planning or any understanding of Ecommerce issues. They were required to develop an Ecommerce business plan, which could be sustained economically by a business to sell products in an on-line environment, and possibly be implemented anywhere in the world, including third world countries. For example, Amazon.com in Pakistan?

The program was subsidised by the Office of Information and Communications (a State Government Department), and developed by Dow Digital (an E-commerce and on-line services consultancy and development company). The program was designed to educate students and business representatives on how to prepare an Ecommerce strategy and business plan. The pilot course covered six modules dealing with all aspects of creating an Ecommerce plan for small to medium sized enterprises. Presentations were made from Ecommerce experts and local businesses that had already established Ecommerce as part of their business model. The course culminated in the students presenting their plans to a panel of Ecommerce experts, members of local industry and their peers after the 10 days of intensive instruction.

The program was focussed on constructivist learning theory which emphasised social interaction, communication, exchange of views, collaboration and support for learners to take more responsibility for the learning process through learner-centred tasks (McLoughlin & Oliver, 1998; Collis, 1998). Students had to work collaboratively to create the Ecommerce plan and share the expertise of the group. Students were faced not only with new information and material, but also with a collaborative learning method promoted by the tutors, course
materials and student team leaders. The student team leaders were trained over two sessions to develop an emphasis on the required collaborative training process and to familiarise themselves with the materials. They were responsible for scheduling tasks, keeping the project on track, solving problems, encouraging collaboration, stimulating discussion, and ensuring that each student was contributing to the team effort. The students presented their Ecommerce plans on the final day of the program where they were assessed by a panel of industry experts.

The course ran for ten days and covered the following sessions: Ecommerce - paradigms and predictions; defining Ecommerce product; the Ecommerce transaction process; panel session of local businesses conducting Ecommerce; panel session of experts in Ecommerce technology; refining the Ecommerce plan; practising Ecommerce; feedback from tutors and experts on student plans; finalising the plan and presentation of Ecommerce plans. The overall objectives of the course were to:

- provide a ‘fast track’ program which trained students from any discipline in Ecommerce business planning
- provide an training model that promoted collaboration between industry, government and tertiary providers
- assess whether the course model could be applied to developing countries

Conclusions

From the experience of running this course and from feedback gained from the student questionnaires, the following recommendations are made with a view of improving the course delivery:

- a ten-day intensive program for this type of course is too short and a greater “lead time” was needed
- more time is required from tutors and advisers in the tutorial sessions to help student teams
- each business planning team should be working on a “real” industry product
- each team should consist of approximately 4 student members and one industry representative
- the course is more suited final year students who are ready for employment

Feedback from both students and the industry representatives strongly supported a greater implementation of this type of Ecommerce training course. Opinion was strongly in favour of promoting an understanding of Ecommerce strategic thinking, business planning, Ecommerce technology issues, on-line marketing and the generation of business ideas for the on-line environment. As indicated by the literature, business is rapidly moving to a global economy and judging from the student and industry attitudes gleaned from the evaluation sheets, there are still many new and fresh business ideas waiting to be exploited!

However, for a course such as this to be successful, it must be seen as valuable for all the “stakeholders”. Government must see tangible benefits to business and the community in order to be convinced to sponsor such a course. The business sector will want to be involved if productivity and profit margins can be potentially improved, and students will want to be involved if these skills provide a means of securing employment, or as an opportunity to start their own on-line business.

Ecommerce is now offering “level playing fields” to new business entrants who understand how to take advantage of this new business paradigm. Existing and new business merchants cannot afford to ignore this trend, which is continually being highlighted by government and other strategic research bodies. Ecommerce training courses are needed for business operators and graduating students in a timely, efficient and cost effective manner. These courses must be well structured and correctly marketed to attract and promote this new form of trading. The course implemented at Edith Cowan University provides an example of how students and business operators can be quickly skilled in this rapidly changing area.

Teaching Information Literacy to Undergraduates in the U.S.: Stand-alone Courses or Across the Curriculum?

Barbara G. Lyman
Southwest Texas State University
Department of Art and Design
San Marcos, Texas, U.S.
BL01@swt.edu

Abstract: This paper represents initial exploration of the relative merits of information literacy development for university undergraduates through stand-alone courses or an across-the-curriculum approach. Reasons for preferring stand-alone courses relate to the a) definition and scope of information literacy; b) rapidly evolving nature of the Web; and, c) various levels of prior exposure to Web-based learning represented among undergraduate students in the U.S.

A dilemma exists regarding the teaching and learning of information literacy among U.S. college and university students. With the increasing reliance on the Web as a source of information, both to augment and increasingly to supplant traditional course delivery, a pedagogical and policy issue is whether we need stand-alone courses, an across-the-curriculum approach, or some combination of both, in an effort to insure that students are armed with certain lowest common denominator skills and strategies for learning from the Web.

This paper represents an initial exploration of the relative merits of providing information literacy development for undergraduates through stand-alone courses or an across-the-curriculum approach. The stand-alone course approach provides assurance that the identified skills and strategies receive due and explicit attention. However, the stand-alone model begets the transfer of learning problem (Anderson, 1995), i.e., the frequent failure of learners to transfer skills and strategies to situational contexts which demand these abilities.

Nevertheless, there are three primary reasons for preferring stand-alone courses at the present time, relating to the a) definition and scope of information literacy; b) rapidly evolving nature of the Web; and, c) various levels of prior exposure to the Web among U.S. undergraduates.

Information Literacy

First, Marchionini (1999, p. 18) defines information literacy as "a continuum of skills, concepts, attitudes, and experiences related to information access, understanding, evaluation, communication, application, creation, and values." Similarly, Shapiro and Hughes (1996) say that information literacy consists of at least seven sub-literacies: 1) handling basic hardware/software (tool literacy), 2) mining/managing databases and archives (resource literacy), 3) recognizing social and institutional effects on information constructs (sociostructural literacy), 4) employing investigational tools/strategies (research literacy), 5) communicating findings (publishing literacy), 6) maintaining currency with advancements in information age tools (emerging technology literacy), and 7) evaluating the worth of information and information technologies (critical literacy). How do we know that due attention is being given to this intricate array of skills and strategies without offering dedicated stand-alone information literacy courses?

The Protean Web
Secondly, even a cursory look at the medium of the Web itself reveals a size and complexity which beg for a grasp of the whole as well as of its parts. By one estimate over 800 million Web pages have been created (Rabinovitch, 1999). The search engines designed to assist users with selection and access seem increasingly inefficient relative to this proliferation, although recent refinements promise improvements (Greenberg & Garber, 1999). The Web also changes constantly with sites appearing and evaporating in relatively short periods of time. Many sites remain in a limbo of partial construction. The validity of information on websites as well as the credibility of their creators often seem difficult to ascertain with any degree of confidence for one not already an expert in the domain of knowledge and opinion thereby represented. Once again, is it reasonable to expect that the multiple strategies and skills needed to tackle questions of authority, accuracy, and validity as students make their way through the Protean entity of the Web will be sufficiently taught without stand-alone courses devoted to this purpose?

Narrowing the Digital Divide

Finally, discussions of the digital divide (National Telecommunications and Information Administration [NTIA], 1999) and technological apartheid (Castells, as cited by Gerstner, 1999) strongly suggest and the data show (NTIA, 1999) that there are wide gaps in the information literacy of various groups of students entering higher education in the U.S. Should not courses therefore be provided which are designed to level the technological playing field? Stand-alone courses in information literacy have the potential to help insure that the digital divide is diminished rather than reinforced within institutions of higher education. Of course, stand-alone study and learning skills courses, to refer to one example from current practice, because they are often seen as remedial in nature may have a corresponding stigma associated with them. However, offering stand-alone courses does not necessitate buying into remedial models of intervention. Such implementation mistakes are to be avoided in providing information literacy courses.

A Dual Approach for the Foreseeable Future?

While an initial discussion of the relative merits of stand-alone and embedded or across-the-curriculum models for teaching undergraduate information literacy may raise more questions than it answers, the level of dialogue surrounding the issue should increase. More of us should be debating the question: Should teaching information literacy to undergraduates be accomplished via stand-alone courses or an approach of developing information literacy across the curriculum, or both? The already crowded curricula of undergraduate programs lessen the likelihood of offering dedicated stand-alone courses. However, unless existing courses throughout the curriculum are evaluated for the extent to which they incorporate information literacy, there are no assurances of systematic teaching of critical thinking for Web-based learning. A reasonable approach may be to advocate for both: stand-alone courses to narrow the digital divide and across-the-curriculum efforts to teach information literacy in context.

USING VIRTUAL REALITY IN TEACHING SECONDARY SCHOOL PHYSICS

Bruce Ma, Division of Language Studies, City University of Hong Kong, Hong Kong, bruce.ma@cityu.edu.hk

Peter Mak, STFA Tam Pak Yu College, Hong Kong, ptermak@hkstar.com

Abstract

The use of Virtual Reality (VR) in education has been depicted as an interesting and promising area where constructivist learning theory can be put into practice. This paper describes a work-in-progress project attempting to take advantage of the current VR technology for constructivist learning practices in the teaching of secondary school Physics.

The project involves the creation of 3D VR environments for use on the World Wide Web where learners are exposed to virtual physical environments. These environments incorporate rich and meaningful physical phenomena and relationships so that learners can navigate and explore freely, view from different perspectives and visualize the various physical concepts and relationships which otherwise can be difficult to visualize using traditional teaching material in the form of texts and graphics.

This paper also discusses the initial reactions from learners as well as colleagues teaching on the subject.

Introduction

The central tenet of Constructivism is that knowledge of the world is constructed by the learner (Boyle 1997). Constructivism proposes that courseware should be designed in such a way to provide an environment conducive to the construction of knowledge by the individual, rather than supplying knowledge directly. Constructivism also emphasizes collaborative learning and personal introspection into one's learning process (Brooks & Brooks 1993, 1996). It has been viewed by many (e.g., Moore 1995; Osberg 1997) that virtual reality (VR) offers promising grounds for creating and developing learning environments that promotes constructivist learning.

VR refers to computer-generated 3-D interactive environments in which the learner is an active participant (Bricken 1991; Bricken & Byrne 1992). The learners interact with and act directly upon the virtual environment and influences the variables in the environment (Moore 1995). Although some comment that the VR technology is still in a relatively rudimentary stage of development, it is our opinion that what is currently available can already be applied in teaching.

In secondary school Physics where many topics to be studied, for example, those in Mechanics, involve cognitive visualization of distance, direction, inclination and speed and intricate relationships between these elements, it is our belief that VR can play an effective role in creating 3-dimensional virtual environments that promotes learning.

Rationale

The traditional Physics class is predominantly filled with experiments with which students observe physical phenomena, record data, analyse data and the relationships they exhibit in order to verify established or current theories. While doing experiments promotes the principles of the Scientific Method, the drawback of conventional classroom experiments is that it is difficult to allow learners to design their own learning curve. In fact, under the constraints of the physical settings of a school laboratory and the apparent authority of teacher instructions, learners typically pursue in their experimental work outcomes that are expected of the experiment, either by the teacher or by the textbook. The individual differences in learners are rarely addressed and individuals rarely have the opportunity to develop unique ways of experimentation.

Moreover, the typical secondary school physics laboratory is simply not sophisticated enough to meet many learning needs. Observation and visualisation of complicated physical phenomena is a virtual impossibility. The collision of gas particles in the micro world, the circular motions of celestial bodies in the macro world, perfectly elastic collisions, frictionless environments are some typical examples.

To teach concepts and theories related to these physical phenomena, teachers often depend on 2-dimensional chalk and board or textbook-based descriptions and explanations. To learn them, students have to rely on their own creative imagination to construct in their mind a 3-dimensional space. Blackboard descriptions, and by the same token textbook descriptions, only allow the learner to view phenomena from a single rather than multiple perspectives. The use of static images to teach ideas involving motion is an understandably difficult task. What learners have constructed in their imaginary 3-dimensional world can differ tremendously from one another, and
can deviate phenomenally from what the teacher is attempting to describe. This typical scenario presents great barriers in learning and makes in-depth classroom discussion and further exploration very difficult.

This project attempts to break through this barrier by constructing an interactive web-based VR environment in the secondary school Physics teaching classroom. This environment is created with a PC-based 3D virtual reality technology. In the initial stage of this project, the following areas targeted at Form 4 secondary school students have been selected:
1. Relative Motion: Ships in the Sea; Sun Rise; Rotation of Planets
2. Pressure and Collision of Particles
3. Gas Pressure against Gravity
4. Periodic Motion: Simple Pendulum; Pendulum of 2; Pendulum of 5

Building and using the VR
To build the interactive environment, which we call 3D Physics World, the following software has been used:

- Superscape 3D Webmaster (Evaluation version)
- Microsoft Frontpage

3D Webmaster allows users to create virtual reality environments called Worlds. In its Drag and Drop Warehouse, different 3D models including buildings, cars, plants and animals are available. Users can create their own models or modify from ones available. Most of the models used in this project were created by modifying the primitive objects in the Drag and Drop Warehouse using the Shape Editor provided. By assigning these objects in different initial positions and setting different initial velocities for them, a VR simulation was thus created.

Learners when working in this virtual world can observe the physical phenomena from any perspective and any frame of reference. The navigational controls provided by 3D Webmaster are intuitive enough for secondary school learners to grasp with ease in a couple of minutes. Once feeling comfortable with the navigational tools, the learner can view the physical phenomena from a perspective of his own choice. He can then initiate movements of objects by dragging and dropping and observe the motion created in different settings. He can also pause all motions to observe more closely for as long as he likes, or return to the initial settings at his discretion to start all over again. This kind of experience is not what traditional 2-dimensional texts and graphics alone can produce.

Initial Observation and Feedback
The material developed in this project was used with a group of Form 4 students in the 1998-1999 academic year. Students seemed to be greatly impressed with the possibility of being able to control and explore with objects in a VR environment. There was an obvious surge in interest in the subject and in the motivation to learn. Many were excited by the hands-on experience and expressed the opinion that it was fun to learn compared with a situation where only the textbook and blackboard would be used. Peer discussion and share of experience among learners was also seen to increase as excitement about the different observations mounted.

Colleagues teaching on the subject also expressed positive comments after trying to use 3D Physics World in class. They felt that the lesson was conducted with less teacher talk and resulted in better understanding of the subject being taught. Some commented on the need to design follow-up activities to go with the Web material in order to maximise learning.

Conclusion
It is believed that this project represents initial attempts by front-line secondary school teachers taking advantage of the available VR technology in teaching. It is hoped that the project could be further developed in the following lines:
- Extension to other topics
- Post-VR activities

More structured research can be carried out to study learner reaction, and learning outcomes as compared with the more traditional chalk and board approach. It is our hope that teachers teaching on the same topics will attempt to use 3D Physics World posted on the World Wide Web (http://i.am/3dphysicsworld/) and give us their comments and suggestions for improvement.

A Game-play Intranet-based Multimedia Teaching Support System for Information Systems Training

Hing-Yin Mak  
Hong Kong Baptist University, Hong Kong, jhymak@comp.hkbu.edu.hk

Andrew P. Mallard  
Brunel University, United Kingdom

Introduction

The analysis and design of information systems is not only based upon the understanding of an organisation's objectives, structure, and processes, but also on the knowledge of how to exploit information for advantage.

Whilst traditional teaching techniques can prepare our students with the required methodologies and techniques that they need to design and develop information systems, it is extremely difficult within the confines of a lecture room, to convey any 'real' sense of the business environments in which they will have to apply these theories. Our challenge therefore is to find an effective method of conveying to our students, with little or no business experience, the analytical techniques and interpersonal skills required to quickly understand the relevant structure, processes and dynamics of a business - in order for them to practice their problem solving skills and conduct a thorough systems analysis.

This paper describes current work-in-progress on a project to design and develop a game-play Intranet-based Multimedia Teaching Support System (IMTSS) for our information systems students. We will first describe the background of the project. Then briefly discuss the methodology used, including game-play and the active learning approach. Finally we will give an overview of the system and highlight our conclusions to date.

Background

The aim of the proposed system is to assist and enhance the 'Systems Analysis and Design' and 'Group Project' course modules, which are both core subjects of the second year Computing Studies Information Systems (CSIS) Degree course in the Department of Computer Science at the Hong Kong Baptist University.

In the past the CSIS degree course was structured as a two-phase five year course, consisting of two years full time and three years part-time study, the latter including three years part-time industrial experience. However as a result of the re-structuring of our CSIS course in 1995 to a three year full-time study program, many of our students no longer have any direct IS related work experience. This problem has been further compounded by the scarcity of summer jobs resulting from the Asian financial crisis.

Over the last few years, our department has conducted a series of feedback exercises such as informal surveys, teaching evaluations and student-staff consultation meetings. These have revealed that whilst our students believe that the IS concepts and methodologies taught are very useful, they have found many of the ideas rather abstract. They have therefore requested more relevant examples to explain these concepts. However as most text books originate from North America or Europe, the case studies used are often not very relevant to Hong Kong. In addition our teaching staff have indicated that our final year project students not only need to improve their analytical interviewing techniques, but somehow also need to build their confidence at interacting with business users.

Therefore the objective of our IMTSS project has been to:

- provide a framework based on a game play approach, to help students develop analytical and problem solving skills through active learning
- make use of multimedia and internet technology to help provide students with a virtual organisational environment in which they can conduct their systems analysis
- incorporate the above into the design and development of an on-line bilingual multimedia teaching support system

1440
Methodology

With these objectives in mind, we chose to adopt a combined active learning and game-play approach in the hope that students could develop analytical and problem solving skills through active learning, whilst stimulating and increasing their interests in the subject through the game-play approach.

This is based upon much historical research showing that playing games can be highly motivational and enhance learning through visualisation, experimentation, and creativity of play (Thomas and Macredie 1994, Betz 1995-96, Amory et al. 1998). Other research has shown that students learn more when they are actively engaged in their own learning, which leads to an increased ability to think critically and to solve problems. Furthermore this active learning approach helps students to learn content and process at the same time (Booth 1980, Page 1990, Marlowe and Page 1998).

Our justification for utilising multimedia technology in the form of streamed video, is that research has also demonstrated that users playing simulation games performed significantly better with highly graphical feedback, than when the simulation provided only textual feedback (Rieber 1996).

The IMTSS System

For this project, we have initially chosen a number of distinct case studies from various Hong Kong business sectors. For each of these cases our research team have conducted a series of interviews, in order to collate relevant material from the chosen end-users. This material has then been analysed, in order to create the business case structure and scripts for the multimedia teaching support system. These have then been translated into corresponding English and Cantonese scripts.

Each case study is comprised of a series of interactive multimedia elements, most of which are video clips. These video clips were either taken of business people on their own premises, or conducted by student actors at the University. These elements include explanations of the organisations background, current work environment, business processes, and interviews with relevant staff. Once the system content has been acquired and edited, it is stored into a client-server database. The overall system framework makes use of an intranet web server to control the interaction between the user and the multimedia elements held in the content database. We have conducted much research into the investigation of optimal video delivery methods, including clip duration, file size and effective delivery rates.

For each case study, the student is provided with an introductory video describing the relevant business environment, followed by an introductory interview from the case study sponsor. This introduces them to the various staff that are available for interviewing. They are then presented with a variety of options to navigate their way through the whole series of interviews. For each interview a series of questions may be asked, and each of these are tagged as good, neutral or bad. If the student chooses a good question then they are rewarded with a complimentary video clip and given some useful information. However should they choose a bad question then they may be confronted with a bored, sarcastic or annoyed response. In this way the students are able to navigate their way through the various interviews, collecting various pieces of useful information, and identifying the users requirements. If they run into problems they are able to return to the sponsor to get some additional hints, although this will decrease their overall score. The progress of each student is monitored throughout by the web server.

The proposed framework allows for the number of interviews per case study, and their relevant importance to be weighted individually. It is also designed to be both flexible and scalable, in order to allow additional business cases or alternative languages i.e. Mandarin Chinese, to be added over time. Furthermore this flexibility also allows for existing multimedia elements, that have been identified as causing confusion for students, to be easily updated or replaced.

Conclusions and Discussion

Although research is still ongoing, results so far from our prototype version of IMTSS have been extremely encouraging, and have clearly indicated that the system can provide our IS students with a stimulating and valuable means of bridging the gap between the theory learnt in the classroom, and practice in the business environment. Furthermore, the use of IMTSS also appears to help our students gain confidence to interact with end-users, which in turn should improve their final year honours projects, as well as better prepare them for their careers.

In addition we hope to demonstrate the potential benefits of this type of flexible framework to complement traditional teaching methods. Where students can study at their own pace, and in the language of their choice, free
from the normal time and geographic constraints of lectures. Also we are currently investigating ways in which the system can be further improved to better monitor the students progress and absorption of study material, as well as highlight problem study areas.

Finally, we believe that the framework and methodology used in this system could also be adopted by other faculties such as Business, Management, Accounting etc. whose students also need to develop analytical skills for certain sections of their courses.

Multimedia Performance Based Language Assessment: The Computerized Oral Proficiency Instrument (COPI)

Valerie Malabonga

Center for Applied Linguistics, Washington, DC, USA
valerie@cal.org

Dorry M. Kenyon
Foreign Language Education and Testing Division
Center for Applied Linguistics, Washington, DC, USA
dorry@cal.org

Introduction

The Computerized Oral Proficiency Instrument (COPI), is a multi-media, computer-administered oral proficiency test that is an adaptation of the tape-mediated Simulated Oral Proficiency Interview (SOPI) (Stansfield & Kenyon, 1992). The COPI uses simulated real life tasks to elicit speech samples and is rated according to the Speaking Proficiency Guidelines of the American Council on the Teaching of Foreign Languages (ACTFL) (ACTFL, 1999). The COPI has two parts: a self-administration program for examinees and a rating program for human raters.

Self-Administration Program

Steps in Taking the COPI

After being welcomed and introduced to the program, examinees perform the following: enter and check personal information, complete a self-assessment of their proficiency level, listen to an adequate response to a sample task, practice with the same sample task, respond to performance tasks (the actual test), and receive feedback about the levels of their tasks. While taking the test, examinees hear test directions with accompanying text and pictures in English and/or in the target language (depending on the proficiency level of the task) and record their responses. Depending on the choices that examinees make, they respond to 7-11 test items and take anywhere from 30-50 minutes to complete the test.

Examinee Control

The main goal of the COPI's self-administration program is to use the advantages of computer technology to provide examinees more control over the testing situation. Our assumption is that more test control will lead to anxiety reduction and ultimately improve test performance. Examinee control is achieved by giving them choices in the following: amount of preparation and response time, speaking function, topic, level of difficulty, and language of directions. The large pool of tasks (over 100 per language) is also very important in ensuring that examinees can make these choices.

Examinee Choice

The COPI provides more preparation and response time for higher- than lower- level tasks, but examinees still have the choice to use up all the time allotted or take less time. Also, after completing a task, they are
given a choice of three new tasks, and an algorithm ensures that they get each speaking function and topic only once. Likewise, the examinees' self-assessment scores and the choices of levels during the practice task determine the level of difficulty for the first task. However, after the first task, the program alternates between giving examinees a choice of difficulty level or not. During the times that examinees are not given a choice, the algorithm pushes them to higher level tasks to ensure that they are given an opportunity to reach their performance ceilings. Lastly, lower-level speakers are provided with both English and target language directions whereas higher-level speakers are given a choice of getting the directions in English or just the target language.

Rating Program

The main goal of the rating program is to increase raters' efficiency, i.e., help them rate as quickly but as accurately as possible. The rating program does this by allowing raters to quickly access the examinees' audio, navigate quickly from one task to another, and listen to the tasks in any order. Also, as raters assess each task, elements of the task, such as its proficiency level, the picture accompanying the task, directions, and the native speaker prompt appear on the screen. These elements give raters background information about the task and facilitate the rating process. The program likewise allows raters to write notes to examinees so that, aside from providing a global rating, raters can give task-specific and overall feedback to the examinees. In addition, the raters can write notes to themselves about the examinees' responses and can go back to these notes when determining the task rating. Lastly, an algorithm calculates the global rating for each examinee.

Technical and Programming Requirements and Specifications

The COPI program works well with computers that have a Windows 95 operating system or higher, a Pentium processor and 64 MB of RAM and a soundcard. The examinees' responses can be recorded on internal or external zip drives, or the hard drive. We do not recommend the use of Windows NT or laptop computers because the small memory space in these computers makes recording difficult. The program was developed using Authorware 4.0. The directions in Arabic script were gif files inserted in the text box.

Future Directions

We just completed a study comparing student and rater performance and affect on the COPI versus the face-to-face interview or Oral Proficiency Interview (OPI), and the COPI versus the tape-mediated or Simulated Oral Proficiency Interview (SOPI). The results of this study will show us if the COPI is a viable option to the Oral Proficiency Interview (OPI), which can be too expensive or inconvenient; and if the COPI is a significant improvement over other technology-based oral proficiency tests such as the SOPI.

DIVIDED ATTENTION IN MULTIMEDIA LEARNING

Bruce Mann
Memorial University Of Newfoundland, Canada
and
Paul Newhouse, Jeremy Pagram & Alistair Campbell
Edith Cowan University, Western Australia

The subjects in this research were Year Seven (12 year old) students (n= 42) from two primary schools in Western Australia. Our prediction was that temporal speech cueing would better enable school-age students to focus their attention than those in the temporal text cueing group. Small sample sizes are not uncommon in experimental multimedia research (Austin, 1994; Bridgman, 1990; Carroll & Mack, 1987; Shell, 1990). Year seven students were chosen for the study because this is the final year of primary school and thus the results from the study were more likely to be relevant for both primary and secondary students. In addition, primary school students were more suitable because the primary school curriculum is more thematic and flexible readily allowing the addition of content and a variety of teaching situations.

Materials

The "Engines" computer program was developed as a sequential hypermedia learning environment to provide learners with a linear path through a set of related nodes, as suggested in previous studies (Mann, 1993; 1995a; 1997a). Mann's (1996) procedure for adding sound prompts to hypermedia learning environments was used for the "Engines" program. "Temporal speech cueing" was operationalized as information about future or past events digitized in enthusiastic female speech prompts. Also, future or past event speech or text was implemented to elicit student writing in the Workbook. Further, the Engines program utilized Mayer's (1992) "description of phenomena" instructional approach, wherein a scientific explanation exists when a scientist observes events and describes them. In this study, the student-scientists read or listened to information, observed animated graphics and movies, and described their observations in a workbook. Both versions of the software, test, workbook and questionnaire were trialled with Year Seven students. The software, test, workbook and questionnaire were modified based on their comments. Two versions of a simple tutorial program introducing "Insects" was developed to be used as practice for the "Engines" treatment.

Design of the Study

This study employed a repeated measures quasi-experimental design with two treatment conditions, temporal speech cueing and temporal text cueing. Students were randomly assigned to one of the two treatment conditions based on their gender, reading ability as determined by their teachers' long-term observations, perceived modality preference on the auditory-visual-tactile/kinesthetic learning style inventory (Murphy-Judy, 1998), and students' attitudes toward using computers as determined by the Computer Attitudes Scale (Loyd and Gressard, 1994).
Procedure

The procedure in this study followed those suggested in previous studies of this kind (Knussen, Tanner, & Kibby, 1991; Mann, 1997a). A number of activities were done simultaneously and the final schedule was established at the mutual convenience of the participants and the investigator. First, the consent of teacher, principal, and parents were acquired. Next, over the course of a week of classtime, a reading test, computer attitude survey, modality inventory were administered. Later that week the computers were installed and checked (19/5/99). A week later the pre-test (26/5/99) was administered by teacher. The two treatment groups were created by the researchers based on students perceived modality preference, gender, reading ability, and attitude toward using computers.

Three weeks after the pretest was administered, the treatment and posttest were given. Each class was done separately as was each treatment group. The main intervention was conducted by two of the researchers using the 13 computers in the room set-up between the two classrooms. The entire process lasted just under 40 minutes and comprised the following steps. On the day of the treatment, subjects received information, training and practice on the "Insects" program. The main intervention involved the students in using the "Engines" program. Subjects were instructed to proceed through the program while following the instructions and writing their answers in their Workbooks. The post-test was then completed after they had quit the "Engines" program. Finally some free time to use the KidPix graphics package. No instruction or feedback was presented by the investigators at this time. Notes of the proceedings were maintained.

Results and Discussion

A repeated measures ANCOVA calculated on the data using the pretest as a covariate. Results of the analyses showed that statistical differences between auditory and visual groups were not significant. A correlation matrix showed low positive correlations throughout all the scales, with none significant. The dribble files showing efficiency with the program were also not significant. The consensus among the investigators however, was that the auditory group appeared to be more focused on the critical information presented in the computer program than the visual group. During temporal speech cueing, the room fell to silence with all eyes focused on their screens. We speculated that the students in this group were more involved, because they were listening to the instructions and directions coming through their headphones. During temporal text cueing however, the students were restless in their chairs, frequently looking around the room; the investigators having to remind them not to talk to their neighbour and to keep their eyes on their own computers and workbooks.

Conclusion

We think that the significance of this study resides in our discovery that temporal speech cueing in educational multimedia is only necessary, and therefore need only be employed on difficult, divided-attention tasks. Unlike previous research, our results appear to have been a consequence of tasks that were too easy or too familiar for these students. You'll recall that on easy tasks with familiar items, people use automatic processing which
occurs in parallel; that is, we can process two or more different inputs simultaneously. Apparently, students in the present study implemented pre-attentive processing to work on easy tasks or highly familiar items presented in the "Engines" program. We think that our conclusion is a significant finding in itself, providing a new proviso into educational media research, which previously reported that the presence of speech could improve multimedia learning. A follow-up study has been planned at a different campus of the same school. Based on the findings of the present study, the Engines multimedia program will be revised to require serial processing from this same population of students.

PHASE THEORY: A TELEOLOGICAL TAXONOMY OF WEB COURSE MANAGEMENT FOR DISTANCE EDUCATION

Bruce Mann
Memorial University of Newfoundland, Canada

Theories are meant to explain something or to help us understand the way things are within a certain domain (Wilson, 1997). Phase theory is intended to help educators understand the way things are for using Web course management systems. A Web course management system is a set of software tools, customarily grouped together under a course name and protected by a password, and considered a system; a Web course management system (WCMS). Some examples of popular WCMS's include LearningSpace (Lotus Corporation, 1998), Virtual-U (Harasim & Calvert, 1997), TopClass (WBT Systems, 1997), and WebCT (Goldberg, 1997), to name a few. Central to phase theory is the view that instructors learn to adapt their instruction to a Web course management system in phases, namely: Lesson Enhancement, followed by Resource-Based Teaching and Learning, then Online Learning Environments.

Lesson Enhancement

Lesson enhancement is the initial phase of Web course management and is often introduced to students as an extracurricular activity. Usually with help from the resident technologist, the educator will decide to introduce the Internet or Web-supported material as extra-curricular activities to enhance the curriculum. Three types of lesson enhancement are classified for this phase, as follows: 1) immersive collaborative environment; 2) online self-expression; 3) online lesson assessment.

Resource-Based Teaching

Resource-based teaching is the second phase of Web course management. "Resources" can be of any form, namely: text, pictures, video clips; and of any knowledge-type-declarative, procedural and/or strategic knowledge for subsequent retrieval by students. The mindset for resource-based teaching is similar to that of storing and retrieving materials in a media repository or school library. I have counted as many as fifteen types of RBTL using a Web course management system and operated directly by instructors themselves, namely: 1) to provide content (i.e., online notes, online reader, or an online resource pack); 2) to support a learning activity (i.e., online manual, online lab guide, a seminar guide, a fieldwork guide; online projects facts guide, or an online work placement guide); 3) to support a learning process (i.e., online skills guide, skills profile, or an online student log); or, 4) to build on other resources (i.e., online textbook study guide, online readings guide, or an online lesson outline). These types are reminiscent of the conventional resource-based learning categories described in Parsons and Gibbs' (1994) "Developing Teaching" series published by Oxford Brookes University Press. Resource-based teaching may require a re-definition of pedagogical goals, restructuring of curricular offerings, provision for educator training and support material, and
sufficient online tools for the collection of student data. Terms like "stockpiling", "massing", "stacking", "accessing", "accumulating" might well define the linguistic framework of the resource-based teaching phase.

**Online Learning Environment**

An “online learning environment” is the third phase of Web course management that demonstrates the application of cognitive psychology to education. A learning environment is a place where learners work together and support one another as they use a variety of tools and information resources in their pursuit of learning goals and problem solving activities (Wilson, 1997). The focus is on meaningful learning that is active and involves the students in learning by discovery. Five components comprise the learning environment, adapted from Perkins (1991), namely: 1) information banks; 2) symbols pads; 3) construction kits; 4) phenomenaria; 5) online microworlds, and; 6) virtual environments.

**Conclusion**

Phase theory can assist practitioners in the determination of their own inventions with Web tools based on their intuition, personal preferences and prior educational experiences with Web course tools (Mann, 1998b). And as a descriptive taxonomy (Reigeluth, 1997), phase theory may be applied as a descriptive theory of professional development in Web course management. One future direction would be to implement phase theory as an instructional strategy to train a different sample from the same population of novice Web managers. See Mann (2000; 1999a; 1999b; 1999c; 1998b; 1998e) for further discussion on the first principles and underlying assumptions of phase theory.

Reconfiguring the Academic Library for the New World of Learning

James W. Marcum, Library, College of Staten Island, CUNY
Marcum@postbox.csi.cuny.edu

Abstract: Knowledge modeling, knowledge-based systems, and other technology-based learning support systems utilized in business training can help the academic library meet the challenges of refocusing attention from instruction to learning.

While today's academic library is undergoing major changes in structure and purpose, it remains fixed within a model of education that steadily becomes less relevant, the model of instruction and information processing and transfer. As attention shifts to what the student actually learns (Katz, 1999), we must rethink and reconfigure the library in order to preserve and enhance its role in higher education.

The new learning is influenced by the ideas of multiple intelligences, learning styles, and the psychology of individual differences. A generation of work in the cognitive sciences has demonstrated that the mind actively engages in the creation of an individual's "reality" (Ackerman, 1999). Yet many in academe are not yet cognizant of how individual learning profiles, group versus individual learning preferences, personality and trait factors, self-monitored learning, better understanding of informal learning, and the conscious development of learning strategies require new behaviors and new policies. We must rethink and reconfigure the library to support the emerging culture of learning. One option is to create a new environment where learning-support teams (including subject specialists, information specialists, technical support, and instruction designers collaborating with expertise in personality and intelligence testing) maximize the possibilities of the new learning.

Useful models for emulation are available from business and management training, including knowledge modeling, knowledge-based systems, and other "learning strategies." For instance, "knowledge modeling" stresses the role of the "transactional mind," the central role (generally left to chance) of other influences upon the learner including peer interaction, self-directed inquiry, and the context the learner carries with them. Much more is going on in academia beyond the instructor-guided model that relies on lectures and defined readings (Greene, 1993, pp. 513-553). There are other approaches to the knowledge-modeling concept, running at very different levels of complexity, from the arcane world of artificial intelligence to a basic level, where knowledge modeling can be utilized to construct clear, manageable, and measurable knowledge structures detailing:

- the critical role of prior knowledge and context
- the differences between definitions, descriptions, and comparisons
- the nature of steady states
- cognition, classification, and categorization
- the role of time in the organizing of simple events
- steps, classes, and conditions of processes
- knowledge acquisition through accumulation, tuning, and restructuring

Other approaches include knowledge-based systems. These systems can assist human operators, support decision-making, generate, critique, and evaluate knowledge structures, and monitor implementation. Such systems can address many of the problems we face today, including the need for individualized instructional methods to deliver material and dynamically model student comprehension (Hayes-Roth and Jacobstein, 1994). Indeed, we must ask whether the learning process-focused world of business training enjoys significant strategic advantage over the professor-centered world of academe.

All of these methodologies amount to the early development of "learning support systems," an approach that stresses the process of learning, not the mastery of traditional, discipline-bound information content. Utilized in business training, learning-support systems rely on mentors and facilitators to help
learners understand their personal learning styles, consider performance standards, and test against competency measures (Davis and Davis, 1998). A case study drawn from a software learning project indicates that a variety of "lesson" formats, the provision for experimentation and encouragement of mentoring are means of bolstering and supporting the learning process (Harp, 1997). Clearly, comprehensive strategies for setting criteria, measuring prior knowledge, identifying learning traits, and tracking the accretion of knowledge and the impact of learning can be realistically pursued, particularly considering the software available today.

The potential of learning-support systems contains exhilarating implications for academic libraries. Learning is not something that is limited to the classroom; that's just where information and rules are transferred and learning challenges issued. Emergent learning occurs in groups, in study rooms, in laboratories, in individual study, and in dialogue (both face-to-face and electronic). To date, academic librarians have given little thought to the learning process. Traditional library evaluation focuses on materials, access, and the usage of materials and services. Only recently has concern about the impact of instruction and consultation become matters for measurement and evaluation. One prescription for this work calls for cultivation of "active learning," that is, crystallizing our goals, studying the impact of information technology on learning, and studying how students actually learn. The key is providing context, and problem solving is one good approach to that end. Academic librarians can and should adopt the goal of becoming the locus and advocate of technology-based learning and teaching on the campus. (Wilkinson, pp. 181-196).

What does all this demand of the library? First of all it requires thinking beyond the "digital library" to embrace a range of patron behaviors -- such a group learning and team development -- as well as more comprehensive utilization of continuous media. New organizational structures are needed to utilize the more varied professional skills demanded by this complex learning environment. Other requirements include greater learner access to the Internet (via ubiquitous data outlets), more powerful networked servers for video storage and on-demand delivery, experimentation with thin-client and wireless configurations, and widespread use of "output" devices (such as CD-ROM/DVD printers), together with a variety of group study spaces, computer labs, and support for group inquiry by means of "collaborative portal" technologies. All this places enormous new expectations on an already overburdened institution. The challenge and the opportunity are there if we will but seize them.

Background

In 1996 the University of Virginia developed a system called "The Faculty Instructional Toolkit." The Faculty Instructional Toolkit ( Toolkit) is a Web-based (http://toolkit.virginia.edu) application that allows instructors at the University of Virginia to easily create and manage class home pages -- selectively use electronic features such as class e-mail lists, class rolls, anonymous course feedback, student homework submission, and final grade submission.

While the Instructional Toolkit system does enable University of Virginia faculty to quickly and easily create course web sites, faculty have an inability to modify the appearance of course web sites. Basic Toolkit navigation is included on all the class sites the system creates. The Toolkit's name and icon identify the system to students.

The interface of the University of Virginia's Instructional Toolkit had changed little since 1996. Toolkit support staff, through interaction with faculty and students over various issues regarding the increase in user options, had come to the conclusion that navigational issues could be addressed with an interface update. In the spring of 1999, Toolkit management expressed interest in developing a more "modern-looking" Instructional Toolkit, in addition to several usability enhancements.

The Study

The original Toolkit interface contained an image of the Rotunda, the flagship building of the University of Virginia. In an attempt to better utilize the "toolkit" metaphor, an interface highlighting a laborer's toolbox and a "folksy" color scheme was developed. In addition, the toolkit metaphor was extended to the navigational choices. The use of different tools, plans used in building, supporting documentation all easily map to functions of the Toolkit system.

A prototype showcasing the interface changes was developed. Several ITC staff were polled informally and their response was favorable. In July of 1999, a portion of University of Virginia faculty with previous Toolkit experience were polled concerning their reaction to the new interface design.

Later, a second interface was developed which maintained the same basic layout as the first redesign, yet replaced the toolbox and related icons with images of the Rotunda. The Rotunda images spanned the life of the building - its conception, construction and current state. The original survey participants were then again polled.
Findings

The response concerning the initial redesign’s laborer’s toolbox were mixed. Only a little more than the majority of the survey participants agreed with the statement, “The new colors and icons reinforce the ‘Toolkit’ metaphor.” In response to the question, “Which best describes your feeling regarding the new Toolkit colors and icons?” just as many participants selected “Very satisfied,” as selected “Not quite satisfied.”

The census of open-ended responses was that the interface, specifically the colors and icons, “doesn’t seem as professional.” Distress concerning the replacement of the image of the Rotunda, “that old favorite,” as it was referred to by one individual, was expressed. Even though “University of Virginia,” was clearly stated it was evident that some users felt that the laborer’s toolbox did not sufficiently tie itself to the University. The icons made the “toolkit part] bigger than the UVA part,” according to one survey participant. One survey participant was very clear that the system now “looks ‘canned’” and asked it if the system could be changed so that course web sites do not appear as if they’ve been made with “cookie cutters.”

Individuals contributing to the second survey were much more comfortable with the second design. The overwhelming majority expressed satisfaction with the colors and images of the Rotunda. The design “looks classier and more like UVa,” according to one individual. The images representing the life of the Rotunda reinforced the toolkit metaphor, according to some individuals, while others concluded that “toolkit” is a poor metaphor for the application and would prefer the ability to drop the label.

Conclusions

Pinpointing the source of faculty dissatisfaction with the toolkit interface designs is difficult. One conclusion is that branding inadvertently occurred when the toolkit metaphor was extended into the application’s interface and navigation. According to WebMonkey, a web development resource, the goal of a brand is “to encourage consumers to feel a certain way about [a] product.” A brand encourages association, but has little to do with usability.

Prior to the redesign, the Toolkit system utilized an image of the Rotunda, an icon that gave context to the application. An attempt to give the Instructional Toolkit its own identity caused faculty members to focus on their association with the system. Paula Petrik, a professor in the Department of History at the University of Maine, expressed discontentment with “courseware in a box” products,” finding them “unacceptable in terms of aesthetic design.” Teaching is a personal activity and she wants her class sites to “reflect my sense of myself as teacher and scholar.” Uva faculty members using the Toolkit have are unable to disassociate themselves with the Toolkit’s icon, as it appears on every course web sites the system creates. An association with an application that fails to emphasize the context of its use, the University of Virginia, or the personality of the course web site’s owner was one that most survey participants were not eager to make.

Maintaining the University of Virginia iconography allows users of the Instructional Toolkit to associate their work with the institution. However, the ability to personalize course sites, by choosing a color palette or incorporating their own icons into their course, would allow faculty to leverage their own identity with the identity of the application. Faculty would then be able to associate with the Instructional Toolkit because the application associates individuals with their own course web site.

The distance educator's tool box: An overview of technologies for on-line learning

Thomas Fox McManus, Ph.D.
Saginaw Valley State University
7400 Bay Rd.
University Center, MI 48710
Mcmanus@svsu.edu

Abstract: Every day new tools become available to creators of distance education. Keeping up with them is almost impossible. This article gives a very short overview of several of the new technologies that have become available to distance educators in recent years, and touches on their instructional implications. Tools mentioned include DHTML, XML, Flash, Coursewrap, NetMeeting, ColdFusion, ASP, and Generator.

Introduction

Increasingly educational institutions and organizations are looking to the Internet as a primary means of delivering instruction to learners. Up until a few years ago, instructional designers and course creators have been limited to HTML and CGI or PERL scripts to create their online instructional environments. Then content creation and delivery tools like MacroMedia Director Shockwave and RealVideo came on the scene, and allowed designers to improve their instructional environments by adding a bit of rich media and interactivity. But the bandwidth demands of these tools still made it difficult to have environments which went far beyond the clickable book stage.

Today, distance educators need to harness the power of a new generation of tools to meet the growing demand of the learners who have become accustomed to business and entertainment sites that are interactive, personalized, and easy to navigate. Some of these tools have been in use in e-commerce and business for a few years, while others have been developed solely for the distance education field. These new tools affect all aspects of distance education, from course creation and communication to interaction and record keeping. Each tool, or class of tools, has instructional implications of which designers need to be aware.

Page Creation Tools

Cascading Style Sheets (CSS) are design templates that are used to provide augmented control over presentation and layout of HTML elements, thus separating the way you design information from the actual HTML content. DHTML is any combination of Style Sheets, JavaScript, Layering, Positioning, and Page Division used to create movement on-screen or user interactivity. This means that you are able to create complex interactive animations that do not require that learners have a particular plug-in installed. The disadvantages include that DHTML does require the user to have one of the newer versions of their browser, 4.0 or later, limiting the usefulness in some educational environments with legacy systems.

XML lets you create your own tags that describe the content of your document rather than its presentation. For example, whereas the <H1> tag in HTML specifies text to be presented in a certain typeface and weight, an XML tag would explicitly identify the kind of information: <TESTITEM> tags might identify evaluation questions, <CORRECTANSWER> tags could describe feedback for correct answers. One example of XML use with instructional implications is the Mathematical Markup Language (MathML) which is used to display mathematical and scientific notation effectively.
**MacroMedia Flash** is used to create highly interactive animations with file sizes equivalent to the current image maps used on many sites. This tool allows the designer to finally break out of the clickable book design metaphor and present instruction in the most contextually appropriate fashion. The disadvantage is that it requires the learner to install the appropriate plug-in before they can access the instruction. Flash can also be used to create small accent animations, like rollover buttons with audio feedback, for use in more traditional web pages.

**Communication & Collaboration**

Coursewrap has become the generic term for software packages that help the distance educator put their instruction online, foster communication and collaboration, and to track student progress through the environment. Examples of this include WebCT, Blackboard.com, and PathWare. Each package has different strengths and weaknesses, far too many to go into in a short article. But anyone heavily involved in delivering instruction online is likely to use one.

Network Conferencing software, like **Microsoft NetMeeting**, is another communication and collaboration tool that has great instructional potential. NetMeeting allows for multiple learners to work together in a shared virtual space. Tools include chat, whiteboard, file sharing, and voice/video communication. This allows for everything you can do in a classroom except touch. The disadvantage is that bandwidth constraints can negatively impact sound and picture quality and can cause lag in the shared resources.

**Dynamic Web Pages and Databases**

To get truly interactive web pages, ones that will get information from your learner and return an appropriate page, custom created from information in your database, you need to use server side software. There are a few of which distance educators should be aware. **Allaire ColdFusion** is a database-to-Web software that has become a very popular tool for businesses that need to get lots of data onto the Web quickly. **Active Server Pages (ASP)** are server-generated pages which can call other programs to do things like access databases, serve different pages to different browsers, almost anything that can be coded. **MacroMedia Generator** accesses Internet optimized databases like Oracle 8I, which can organize any type of media file, to dynamically generate Flash animations and seamlessly return them to the learner's browser. These are complex and expensive tools, but by allowing an instructor to tie into the power and organization of large databases, they have tremendous potential in distance education. Some examples include randomly generated tests, with questions taken from a database of items, or instruction that is dynamically generated to meet an individual learner's needs. These needs might be determined by a customer preference tracking software like **MacroMedia LikeMinds**.

**Conclusion**

The potential of tools like these to enhance distance education learning environment is great. It is essential that educators do not fall behind in the effective use of new technologies. Not every new toy that comes along should be adopted. But if a tool can make a learner's experience better or an educator's job easier, it should be used, whether or not it was originally aimed for use in education.

Abstract: Effective staff development is the weaving together of many strands. We need to support staff in their current work, while providing them with ideas, incentives and resources to look for new ways to design learning environments which will enhance student learning. Staff development must be combined with specific projects where change is occurring. Ideas are not hard to find. Incentives and resources are another matter. The paper will outline some general principles for effective staff development. These principles will be applied in the description of the substantial investment RMIT has made in order to realise our Teaching and Learning Strategy. We have a model of ‘grass-roots’ faculty-based work funded by large-scale corporate ‘investment’. ‘Bottom-up’ meets ‘top-down’.

Introduction

Staff development can no longer be a pleasant ‘cottage industry’ on the fringes of academe or the enthusiastic enterprise of a few individuals supported by ‘soft’ money. Effective staff development is positioned at the centre of university functioning and yet needs to retain connections with the needs and perceptions of teaching staff. This is a demanding challenge. Staff development programs that are successful in meeting the needs of complex modern Australian universities need to be supported strategically (and financially) by their own universities.

McNaught et al. (1999) lists six key issues in staff development:

- The appropriate balance point between centrally provided and local staff development services needs to be determined in each university. Central services can be more clearly linked to university priorities; faculty or department services can be more in touch with local needs.
- As technology becomes more mainstream, support services need to be scaled up. This involves deciding on the level of support that can be afforded and the model of support which is most apposite. The educational design and evaluation, technical, and media production support services that universities currently have are under strain. It is unlikely that the existing examples of good practice at each university will be sufficient to ensure that new or revised subjects will be well designed and evaluated. By modelling good practice themselves, mentors can assist staff make optimal use of resources.
- A follow-on issue is determining the optimal relationship between staff development and production support services. Again, this needs to be decided in each university context.
- Even if an integrated model of professional development is adopted, there are still many professional development providers at most universities. Mapping the services of each provider and ensuring reasonable coordination is increasingly important as the need for support services scales up.
- Academic and general staff work load is a key issue. Careful work planning to ensure that staff have time to learn new skills and manage new processes is essential.

Learning Technology Mentors at RMIT University

RMIT University is an ‘old’ (in Australian terms; RMIT began in 1887) technological university. It is highly diverse - it is a cross-sectoral (includes vocational sector) university and has the largest number of international students of
any Australian university. There are seven strong faculties which often resist central directions (what's new?). The Information Technology Alignment Project (ITAP) report (1998) forms the basis for a $A50 million investment by RMIT over the four years, 1999-2002. The report comprises several elements:

- IT infrastructure aligned with the needs of education to deliver the systems and hardware necessary to provide students with an electronically connected learning environment and access to computer-based learning resources;
- a Distributed Learning System (DLS) compliant with the emerging Educom/CAUSE Instructional Management System (IMS);
- an Academic Management System (AMS), fully integrated with the DLS to provide enrolment and subject and course progress records electronically accessible to academics and students;
- an extensive review of all academic processes within the university in a Business Process Re-engineering (BPR) project; and
- extensive staff development.

We have to deliver on our promise that we can provide a flexible set of tools that will enable staff who are not technological whizz kids to develop pedagogically sound, interesting, and relevant online courses in an efficient and well administered way. Quite an ask. How have we designed our Distributed Learning System (DLS)? Here are some of our principles:

- a suite of tools, not just one;
- integrating educational principles into the description of the toolset;
- IMS compliance of all tools;
- a team approach to all online projects; and
- involvement of all seven Faculties in a benchmarking exercise to evaluate the toolset and the effectiveness of the learning environments we are building.

Learning Technology Mentors have been appointed in each department of the University. There are currently approximately 150 Learning Technology Mentors (LTMs) - two in most departments of the university and some in central areas such as the Library. These are mostly academic and teaching staff who have funded one day a week time release to develop online materials and support their colleagues in their departments to engage with online teaching and learning. Each LTM is funded for 26 days time release, and some for longer periods.

These LTMs undertake an extensive staff development program about a week long which covers training in the use of the DLS toolset, key principles in online educational design, and organisational learning within the context of RMIT. Additional staff development sessions are run each week. Topics include hands-on training sessions on all the DLS tools, quality improvement and evaluation of DLS tools, student induction methods, assessment strategies for online learning, evaluation strategies for online learning, the role of the Library in supporting online learning, managing digital resources using metadata, project management, graduate attributes and other curriculum matters, and planning for online development using the DLS support documents.

All LTMs develop a work contract with the first author; if individual staff wish this can be formalised into accreditation for a subject in a Graduate Certificate of Flexible Learning. While one day a week is not a great deal of time, it has been enough to give many staff a space in which to learn new skills and enact them. We are seeing that staff development and support for developing online learning materials and strategies must become distributed across the organisation. Therefore the role of the faculty-based Faculty Education Services Groups (FESGs) is pivotal. Growth needs to occur in these units rather than at the centre. We have been delighted by the enthusiasm of many Learning Technology Mentors. Have we reached critical mass yet, where the appropriate use of technology will roll out across the University? Probably not, but we feel we are on the right track.

Dynamic Databases as Knowledge Construction and Communication Tools in Online Courses

Sara G. McNeil
Department of Curriculum and Instruction, University of Houston, USA
smcneil@uh.edu

Bernard R. Robin
Department of Curriculum and Instruction, University of Houston, USA
brobin@uh.edu

Abstract: Database tools that dynamically generate Web pages have been in use by many commercial Internet sites for years. However, in the field of education, the use of database applications has mostly been used to support traditional classroom learning activities. The use of dynamic Web-based databases as research and communication tools in higher education is currently gaining popularity as development of online courses continues to grow. This paper describes a theoretical framework for using Web-based databases to support constructivist learning and provides an introduction to how these tools are being used to facilitate the construction of knowledge and support student and faculty communication in an online environment.

Faculty and Student Concerns about Online Courses

With the rapid growth and acceptance of the Web as an educational medium, universities are feeling pressure to produce online training and instructional materials. Faculty members at colleges and universities are being told almost daily that they need to change the way they teach, as the value of traditional lecture-based instruction is being reevaluated and the promise of online course delivery is being glorified. Although faculty members at many institutions of higher learning have already begun to create and deliver online courses, there are few standard procedures for doing so. At some schools, early adopters are leading the way, but the acceptance of emerging technologies by large numbers of faculty seems far away. One of many reasons may be that faculty who create online courses are uncertain about how best to proceed. For many, the development of Web-based materials is time consuming and requires learning new skills, and support systems are not yet in place that can accommodate large numbers of new technology-using educators. In addition to the need for technical support, faculty are also concerned about pedagogical issues that arise when distance education modalities are discussed. Designing a Web-based course requires a different set of instructional strategies and philosophical orientations, and while some faculty members see the Web as an opportunity for implementing instructional innovations (Khan, 1997; Owston, 1997), many are largely uninformed about the advantages and disadvantages of online teaching. In addition, many are unclear about the effectiveness of online courses compared with traditional, face-to-face courses (Reeves, 1997). Interactions between students and faculty, a critical component in any course, change dramatically in an online environment where such tools as e-mail, listservs, and chat replace the more familiar student and faculty discourse. Ongoing discourse among participants is the driving force behind successful online courses, but unfortunately, many online courses fail to take advantage of these interactions that can add richness and depth to the construction of knowledge.

Using Dynamic Databases as Teaching and Learning Tools

Many, if not most Web pages simply duplicate print-based materials in electronic form. In education, converting existing course information to a Web-based format is not enough to effectively produce meaningful online courses. Attention must be given to the needs of the students, including facilitating social and instructional interactions, creating a sense of a learning community, and delivering the most timely and useful information. The use of dynamic databases allows users to dynamically generate Web pages that present the
exact information that is being sought. This is important because it increases interaction between students and
the course content and empowers students with control of the course environment. Additionally, the body of
knowledge in the course does not remain static but continues to change and grow without requiring extra work
on the part of the instructor.

Examples of Dynamic Databases

Students in our online classes use a variety of communication technologies, including a Web-based discussion
list. To enhance the feeling of an electronic learning community, students' pictures are taken at orientation and
uploaded to the database. Then, when a student posts a message to the listserv through a Web form, the message
is displayed dynamically with their picture displayed. Students may also submit a variety of assignments
through a Web form. The forms may contain text fields, pull-down menus, and radio buttons to submit different
types of information. In addition, attachments may be uploaded and are entered in the database. Students may
then use the query form to search the database by content area, audience, or author. After students submit their
assignments, the instructor may use a faculty review form to provide feedback for the assignments that have
been posted. Since all of the student postings are available in the database, this allows the instructor to review
all of a particular student's assignments or all of the postings on a specific assignment, utilizing the common
sorting functions of a database application. If desired, the database program may also be configured to
automatically send the feedback to a student's e-mail address, a feature that helps students feel a greater
connection to the course, the content, and the instructor.

Conclusion

Our use of dynamic database tools has helped us improve our online courses as they give students greater
control over the information covered in the courses. However, some limitations to the use of this technology do
exist. First, instructors who would like to incorporate dynamic database tools into their courses face a steeper
learning curve than is required to create traditional web pages. A greater understanding of information design
and information management is required and those educators who choose to learn these skills must commit
more time and effort to this endeavor than originally anticipated. Additionally, students may require some
instruction in the use of these database tools before they become completely comfortable submitting
assignments and checking the progress of their coursework.

The Third Time is the Charm: the Evolving Nature of Web Design

Martha Meacham, Ph.D.
Instructional Technology
St. Edward's University, Austin, Texas US
martham@admin.stedwards.edu

Abstract: The iterative process of an instructional designer working with faculty members to develop a web-based module for an interdisciplinary freshman studies course is described in this paper. During the process, as it was necessary to change pedagogy to benefit from the use of the technology, teachers and students redefined their roles. The process has occurred over 3 years. The majority of planning, design and development occurred in the summer when faculty could collaborate with instructional technology staff and students who helped create the web pages.

What was Done

Since 1996, St. Edward's University has offered faculty members the opportunity to develop web-based, multimedia instructional materials for their classes during a 60 hour, 3-week Summer Technology Institute. Faculty members submit proposals and receive stipends to develop projects that range from the comprehensive redesign of courses to stand-alone tutorials to supplement instruction. The Instructional Technology department collaborates with the Center for Teaching Excellence to offer these intensive, individualized, hands-on classes. Faculty consult with the Instructional Computing Coordinator who acts as instructional designer and project manager.

In this particular case, a faculty member in the School of Humanities, who did not use his computer for much more than email, was recruited to attend the summer institute. The proposal addressed the need to develop instructional strategies to improve student mastery in a freshman course. The course was an interdisciplinary one (Humanities and Rhetoric and Composition) that had been revised many times to create consistency among the many writing teachers affiliated with the course. Traditionally, lectures were delivered twice a week and the other times students attended Rhetoric and Composition classes. The module this professor taught was a 3 hour lecture for a course that was a general curriculum requirement for freshmen. He would lecture in an auditorium of about 150 students twice a week.

During the first summer as course material was moved to the web for delivery of instruction, the professor learned the rudiments of designing web pages, including how to use an HTML editor, use graphics and how to manage online, asynchronous group discussions. With the support of student interns, a great deal of information about Japan was put on a web page that was created to support the class. Using streaming video and audio, freshmen students could hear Japanese spoken, they could see a slide show of images and listen to Japanese music with a narration introducing the culture.

The Process

Amidst the learning and practicing of the technical skills involved with web page production the first year, the faculty member and I consulted to focus the course content by specifying the learning objectives for students. We talked about changing the manner of assessment that had been in place for so many years, but we didn't get around to that. We consulted with the many faculty involved in teaching sections of the course to get their input. At the end of that first summer we had a dazzling web page that had lovely graphics, lots of links to supplemental information, audio and slide shows. That fall we implemented the site and requested student and faculty feedback in the form of surveys. Writing teachers and students used the web page as a resource to master the course content. The faculty member used his lecture time to introduce additional course information.

When all was said and done, the feedback was far from complimentary. Students and faculty alike complained that there was too much information and not enough clarity of learning outcomes. No one could figure out "what was going to be on the test". We had succeeded in demonstrating the lesson that we had added...
technology, but not "added value"! We had not changed pedagogy. We now had a glorified online lecture which had the Internet as it's boundary. Links led to links which led students to still other links around the globe.

The second year, in an effort to provide a structure or framework for learning the information, we designed a "WebQuest". This particular format, which is essentially the process of a systematic approach to instructional design, was developed at San Diego State University in early 1995 by Bernie Dodge with Tom March. The idea is that students take an active approach to their learning. Learning activities give students real world scenarios with which to work and experience collaboration.

The development of the WebQuest included faculty other than just the person who had delivered the lecture. The reading specialists contributed as well as other writing faculty. That fall the web-based module was implemented with much more success. Students and faculty felt that a framework had been provided. Surveys using the Flashlight Network toolkit were used to evaluate the use of the web this time. Additionally, the professor changed his assessment of student learning to reflect the change in pedagogy. Still a multiple choice exam, it now measured higher order thinking skills rather than simply literal or factual knowledge. Students need to reason and draw conclusions using the facts to answer test questions.

The plans are to still revise the web page yet again for a third time. We want to provide an interface that uses real-world metaphors and intuitive navigation. For example, the opening splash screen may be a student's room, desk, computer and maps on the wall. Students will interact by choosing objects to give them specific information. For example, by selecting the map of Japan, the student will get information on the geography of Japan.

The scenario will be changed again to reflect an activity with an even more meaningful context for the student. Students will seek information to answer questions related to living abroad for a semester. The framework for learning will focus on what the student needs to know to live in Japan for a semester such as what to expect socially and culturally. The authentic assessment will include a travel brochure on Japan compiled by teams of students.

Why it is Important

The process of creating instructional web pages is an iterative and collaborative process. The collaboration is among faculty and instructional designers and students. It stands to reason that many faculty are intimidated by learning new technology skills and then having to change their instructional strategies. Suggestions made by professional instructional technologists can not be forced on faculty. Faculty need multiple experiences and guidance to understand that it's not about the technology, it's about how you apply the technology to teaching. It takes surveying the students who use the web page to understand their perceptions of how the technology is being used to instruct. It takes analysis of the students' achievements and learning outcomes to see if objectives are being reached.

Not only should revisions be made in the instructional design using the formative feedback of the primary users of web pages, but designers should be constantly aware of ways to provide real-world applications for students through the use of technology. The web is changing the nature of learning, but we need to quickly move beyond "the syllabus and Powerpoint lecture online" use that is so prevalent. In a 3 year period we have been able to move toward a new paradigm of learning in a course that was traditionally lecture-bound. As this process occurred, both the roles of the students in the course and faculty member changed.

The lecturer realized how profoundly the students' roles changed by remarking how the students were active and engaged in their learning and took on responsibility. He no longer felt his role was to be the "sage on the stage". Although he did still use his lecture time to tell stories and provide bridges to the content that was on the web page, he enjoyed his new role as facilitator of knowledge and found that he could lead students to higher achievement with his new manner of teaching.

This process of collaboration and solicitation of student feedback ultimately seems to have evolved into a successful experience. It takes time for evolution. Change is slow. It takes team work. Hopefully this paper can encourage faculty, who may feel unsuccessful in their first attempts to add value and technology to their course, to "try again".
UNLOCKING THE GATES OF THE KINGDOM: 
DESIGNING WEB SITES FOR ACCESSIBILITY

Steven C. Mills, Ph.D.  
University of Kansas  
2601 Gabriel  
Parsons, KS 67357  
Stevem@ukans.edu

Abstract: Most web page authors are completely unaware of accessibility issues and have little or no experience in making their web pages usable by persons who cannot see the screen or use a mouse the same way they do. The World Wide Web Consortium (W3C) has recognized a disparity in web accessibility and has developed a set of web page design standards to address the issue of web accessibility.

Introduction

Overall use and availability of information resources through the Internet have continued to skyrocket; however, cyberspace predominantly has been the domain of persons without physical or mental disabilities. While sighted people hold the keys to the virtual kingdom, for all practical purposes the kingdom gates have been closed and locked for persons who are visually impaired or have other disabilities. According to Tim Berners-Lee, World Wide Web Consortium Director and inventor of the World Wide Web, “The power of the Web is in its universality. Access by everyone regardless of disability is an essential aspect.” Most web authors develop web pages to convey content visually and do not allow for the eventuality that some web surfers may not see, hear, move, or process some types of information, may have difficulty reading or comprehending text, or may not have, or be able to use, a mouse or keyboard. The World Wide Web Consortium (W3C) has recognized a disparity in accessibility to the Web between persons with and without disabilities and has responded by developing a set of web design standards and strategies that specifically address the issue of web accessibility.

Problem Statement

Web accessibility is an issue that must be confronted by site developers and page authors. In a recent opinion from the U.S. Department of Justice (see http://www.internetlawyer.com/ada.htm), the Americans with Disabilities Act also applies to cyberspace. According to this opinion, entities covered by the ADA that use the Internet for communications regarding programs, goods, or services, must be prepared to provide these communications through accessible means as well. Additionally, Section 508 of the U.S. Rehabilitation Act requires federal departments and agencies to evaluate the extent to which their electronic and information technology is accessible to and usable by individuals with disabilities (see http://www.508.org).

In April, 1997, the W3C created the Web Accessibility Initiative (WAI) as an official activity under the Technology and Society domain of the W3C. The WAI is funded separately from other W3C member activities and is supported by representatives of web development industries, disability organizations, research organizations, and government. Some of the WAI sponsors include the National Science Foundation (NSF), National Institute on Disability and Rehabilitation Research (NIDRR), Microsoft, IBM, Lotus Development, and NCR.

To facilitate the efforts for promoting Web accessibility, the WAI joined forces with the W3C HTML Working Group in the design of HTML 4.0 and in December, 1997, HTML 4.0 became a W3C recommendation (see http://www.w3.org/TR/REC-html40/). Additionally, in May, 1998, an official W3C recommendation for Cascading Style Sheets, Level 2, (CSS2) was issued (see http://www.w3.org/TR/REC-CSS2/). In May, 1999, the WAI issued the Web Content Accessibility Guidelines 1.0 (see http://www.w3.org/TR/WAI-WEBCONTENT/). These guidelines incorporated the recommendations of HTML 4.0 and CSS2 and were intended for use by all web content developers including page authors, site designers, and developers of authoring tools.

Developing Accessible Web Pages

Web accessibility is based on design principles that provide for the development of web pages that accommodate the needs of a broad range of users, computers, and telecommunications systems without regard to age or disability. When a web site is accessible, anyone browsing the site should be able to gain a complete
understanding of the information presented on the site as well as have an undiminished ability to interact with the site. Since many educators are commonly authoring on-line courses or publishing research findings in web pages, they need to implement and apply the design strategies of the Web Content Accessibility Guidelines to the development of web pages that facilitate accessibility for web surfers with disabilities. The Web Content Accessibility Guidelines (WCAG) consist of 14 guidelines that are formulated around two general web page design strategies: (1) ensuring graceful transformation, and (2) making content understandable and navigable.

Ensuring Graceful Transformation
Web surfers may operate in contexts very different from the one in which a web page is developed. The WCAG support and promote the development of pages that transform gracefully. A page transforms gracefully when it remains accessible despite any constraints that may include (though not be limited to) physical, sensory, and cognitive disabilities, work constraints, and technological barriers. For example, a web surfer may not be able to see, hear, move, or use a keyboard or mouse, or may have difficulty reading or comprehending text. The surfer may have a small screen, a slow Internet connection, an early version of a browser, a different browser, a voice browser, or a different operating system. Web pages transform gracefully when text or text equivalents are provided because text can be rendered in ways that are available to almost all browsing devices and accessible to almost all users. Web pages should not rely on one type of hardware and should be usable by people without a mouse, with small screens, low resolution screens, black and white screens, no screens, or with only voice or text output. The theme of graceful transformation is addressed primarily by Guidelines 1 to 11.

Making Content Understandable and Navigable
Web page authors should make page content understandable and navigable. The language of a web page should be clear and simple, but also provide understandable mechanisms for navigating within and between pages. Providing navigation tools and orientation information in web pages maximizes accessibility and usability. Not all surfers can make use of visual clues such as image maps, proportional scroll bars, side-by-side frames, or graphics that guide sighted users with graphical desktop browsers. Web surfers may also lose contextual information when they can only view a portion of a page, either because they are accessing the page one word at a time as with a speech synthesizer or a Braille display, or one section at a time as with a small or magnified display. Without orientation information, users may not be able to understand very large tables, lists, or menus. The theme of making content understandable and navigable is addressed primarily in Guidelines 12 to 14.

Principles of Accessible Web Design
The WAI has produced an extensive set of guidelines for authoring accessible web pages. The HTML Writers Guild (see http://www.hwg.org) has proposed six principles of accessible web design upon which the WCAG were written:
1. Create pages that conform to accepted standards. Use the W3C recommendations for WCAG, HTML 4.0, and CSS2 for designing web pages.
2. Know the difference between structural and presentation elements. Use HTML structural elements to convey page content and style sheets to convey page presentation and formatting.
3. Use HTML 4.0 features to provide information about the purpose and function of elements.
4. Ensure that pages can be navigated by keyboard.
5. Provide alternative or text-based methods to access non-textual content that includes images, scripts, multimedia, tables, forms, and frames for user agents that do not display them.
6. Be careful of common programming techniques that can reduce the accessibility of your site such as ASCII art, blinking text, or adjacent links that are separated by non-printable characters.

Conclusion
As the use of the Web is perceived to be an effective tool for dissemination of research findings or for the provision of asynchronous instruction, the issue of accessibility of web page information will become more relevant. The World Wide Web Consortium has embraced the issue of accessibility through its Web Accessibility Initiative and essentially thrown open the gates to the virtual kingdom for persons with disabilities. The implications of accessibility features for sound web page design are a benefit that offsets the additional time and labor required to author accessible web pages. Because of the commitment of the W3C to web accessibility, the statutory requirements that ensure equal opportunity and access for persons with disabilities, and the preponderance of resources available for web authors to use in the development of accessible web pages, new and experienced web authors have a compelling mandate for including accessibility features in web pages.
USING SCENARIOS TO CREATE A CAL DESIGN METHOD

Michelle Montgomery Masters
Dept. of Computing Science
University of Glasgow, Glasgow G12 8QQ
+44 141 339 8855 ext. 8330
michelle@dcs.gla.ac.uk

Abstract: There have been recent advances in educational theory at Higher Education level, reflected in Laurillard's conversational framework [3]. Current Instructional Design methods and their underlying educational model, are not compatible with current views of the Higher Education teaching and learning process. Therefore there is a need for a practical instructional design method which is inspired by the Laurillardian view of the teaching and learning process. The rest of this paper discusses the way in which design methods developed for highly interactive computer systems have been employed to solve this CAL design problem.

CAL DESIGN

In the United Kingdom a government white paper in 1991 detailed the government’s plan for a cost effective expansion of the Higher Education system, this included the use of CAL to combat increasing student numbers. Following the white paper’s publication the government set up a number of initiatives to develop CAL for Higher Education, Computing in Teaching Initiative (CTI) and the Teaching and Learning Technology Programme (TLTP.) These initiatives resulted in large quantities of CAL being produced across disciplines. Investigations conducted on a sample of these resulting CAL packages, indicated that very little formal design was carried out on Higher Education CAL [5]. The only formal design method in evidence, followed an Instructional Systems Design (ISD) approach to design.

THE CONVERSATIONAL FRAMEWORK

ISD's underlying model of the teaching and learning process is very teacher centred - however a student centred approach is currently a much more popular idea in the education community. Laurillard's "conversational framework" [3] falls somewhere in the middle ground. The framework promotes equal roles and dialogue between the teacher and learner in the complete teaching and learning process. The framework identifies twelve activities that Laurillard believes must happen [3]—by traditional methods or by computer—in a given learning situation for learning to take place.

CREATING A DESIGN METHOD WITH AID OF SCENARIOS

At a British HCI group workshop in 1997 on “Usability and Educational Software Design,” it was stated that educational design is a craft not an engineering process. Schneiderman [7] says that “Design is inherently creative and unpredictable.” CAL design can be made less dependent on the particular skills and talents of a few artisans by applying some science to the design process, embodied in an explicit design process. As Schneiderman goes on to say "in every creative domain, there can also be discipline, refined techniques, wrong and right methods, and measures of success." In order to impose such a discipline, it was necessary to find some
way to use Laurillard’s conversational framework in an instructional design setting. The discipline comes from the imposition of the conversational framework on to a CAL design by the instructional designer. To make this a reality, it was necessary to work out when and how to use the conversational framework.

Traditional methods for solving this type of task have relied on the use of observational techniques such as video recording or interviewing, to capture knowledge on the way activities are performed [6]. Scenarios have in the past been used in place of observational studies. A Scenario is “a narrative,” “it is a description of context, which contains information about users, tasks and environments.” [2]

Jack Carroll [1] says that scenarios can help to ensure that computer systems are “easy to learn/easy to use,” that they

1) Supporting the generation of design ideas.
2) Evaluating a proposed design.
This work adds a new use for scenarios, an enhanced version of role 1) -
3) Supporting development of new design methods.

Maclean & McKerlie call type 1) scenarios envisioner scenarios. The fundamental idea behind the use of envisioner scenarios being that they “drive...and contribute to the evolving design.” [4]. Although scenarios have been used in the past to envision interactions with an implemented system, these statements seem also to apply to the creation of a design method.

THE DESIGN METHOD

From observation of existing design methods and the way people generally approach CAL design, identifying aims and objectives of the package was the place to start. Although this is the same starting place as the traditional instructional design methods that were earlier criticized, the follow on is radically different. The scenarios acted as a prompter - what way now? By constantly returning to the scenario, requirements for the design method were elicited.
e.g. Having identified the aims and objectives, what do I do now? How can the framework help me to proceed? It was clear there was a gap. It identified the need for explicit instruction to take each objective and work round the conversational framework. But before this it was clear decisions had to be made with respect to how each activity in the conversational framework would be implemented - was it a human to human activity or human/computer or by some other means. These decisions resulted in formulation of a table indicating the possible implementations.
Use of an enhanced envisioner scenario allowed the design problem to be made more realistic and concrete. The scenario provided a setting to explore requirements for a new design method and to discover what instructional designers would require from such a design method. It does however remain true the method was generated through a creative process, not the mechanical application of a systematic method. The use of a scenario contrasted with actual immersion in a real design problem saved considerable time and effort. In principle, the technique could also be used to test the method with problems and in contexts, which would be difficult or impossible to use for real.

Representing Oral Traditions through Interactive Multimedia - an example from Hindustani Classical Music

John Myers
Simons Rock College of Bard
84 Alford Road
Great Barrington, MA, 01230 USA
johnm@simons-rock.edu

Abstract: This project utilized object-oriented programming in Lingo and the Director authoring environment to bring together video, audio, text, and graphics in an instructional CD-ROM program presenting the classical tabla traditions of South Asia. Working in a highly collaborative framework in which the subjects were partners as well as informants, the developers were able to use interactive media to reflect the pedagogic structure, mnemonic techniques, historical development, and performance practices of the oral traditions being represented.

One of the greatest challenges faced in the fields of ethnomusicology, anthropology, folklore and related disciplines is the issue of using the written word as a mode of communication when describing traditions that utilize non-verbal modes of expression. Even in cultures with their own written languages and elaborate taxonomies, we find that the simultaneous presence of gesture, pitch inflections, iconography, color symbolism, and other forms of communication serves to intensify and expand an experience that is not just verbal, but truly multi-sensory in nature.

Interactive multimedia, particularly when delivered in high-bandwidth contexts such as CD-ROM presentations, offers the possibility of transcending the limitations of writing, but without sacrificing writing's potential for conveying and promoting analysis and reflection. In particular, the branching structures of interactive presentations allow the designer to present a body of material in an organized, analytic fashion, just as one can find in printed works, while the media elements themselves offer a more profound experience of the actual subject matter.

In the world of music, the experience of learning an instrument is almost always associated with oral transmission. Even in cultures that make extensive use of music notation, there are many subtleties of interpretation, many nuances of pitch, rhythm, and tone color that are learned only through careful listening, observation, and imitation. Often this body of knowledge is passed on through generations of musicians, and represents a kind of living cultural treasure. While nothing can replace the human relationships on which this transmission is based, the three-fold process of listening, observation, and imitation mentioned above can also take place when the traditions are conveyed through computer-based media. If the material being presented has the required quality and integrity, the sonic aspects of a music genre can be accompanied with the appropriate amounts of visual and textual information, and the level of learning can more closely approximate the presence of a teacher, a qualified "carrier" of that tradition. This project attempts to utilize an interactive presentation, delivered on CD-ROM, to represent and introduce the major oral traditions of tabla, the premier percussion instrument of Hindustani classical music. The single word tabla is used to refer to a paired set of drums that are generally played by finger strokes rather than by hand strokes or sticks.

The intended audience for the program is quite broad, and includes learners with a background in music and/or Asian studies as well as those with a more general or casual interest. Because we have chosen to focus on one instrument, a comprehensive view of its diverse musical genres can be gained, and a practical sense of how to play the instrument can also be acquired, without exceeding the stringent storage limitations of the CD-ROM format. In the classical music of North India, oral transmission of musical knowledge was originally achieved through the system of gharanas, families of elite musicians. These families served in the courts of the emperors, nawabs, and rajahs of the Hindustani cultural region, which extended from Pakistan in West, Afghanistan in the North, throughout North India, and Bangladesh in the East. This entire region was once dominated by the Mughal Empire,
which dominated South Asia from the 15th century until the rise of British colonial power in the 18th century. Because the musical families often continued to serve the same courts for several generations, a certain amount of regional variation developed in terms of instrumental technique and musical structure. During the 20th century, with the acceleration of communication and travel, the geographic isolation of the gharanas began to break down, and the context of the music changed. It was no longer heard exclusively by the elite, and became more accessible through emerging media such as records, tapes, audio CDs, and broadcast media. Among professional Hindustani classical musicians, it has become more common to learn repertoire from outside one’s own gharana, and the collective body of musical material, in spite of its massive size, is now being viewed as a group of bundled, closely-related traditions.

Therefore it is important for the program to include representative selections from each of the major gharanas, even though the basic strokes are held in common. Working with tabla virtuoso Enayet Hossain and his colleagues, we used a DV camera to videotape several selections from each tradition, and edited the clips in Quicktime format for inclusion within the interactive presentation. Along with solo repertoire, we recorded tabla duets, tabla trios, and tabla in its more common role as an instrument that provides accompaniment for melodic soloists. Through Mr. Hossain, we also acquired additional material from sources in India, and brought it into the program. These performances, however, include many rapid passages that would be far too challenging for most beginning learners.

In order to accommodate beginners, we have been able to draw upon the traditional South Asian system of teaching and transmitting musical patterns. This system evolved in India over hundreds of years, and is learned by dancers, vocalists, and melodic instrumentalists as well as percussionists. In a lesson with a live teacher, these rudiments constitute the first material to be learned. The system is a kind of drum "language" in that every possible sound made on the tabla has a corresponding verbal syllable. Although it is quite sophisticated, it is not a language such as the drum languages of West Africa, because the system is completely non-lexical, and is used only for musical or artistic purposes, even though many of its syllables are shared as phonemes in Hindi and other South Asian languages.

We found that the media capabilities of CD-ROM make it an ideal vehicle to convey the actual sound and display the required technique. Therefore a section was included which focuses on the basic drum syllables, or "bols." Each spoken syllable corresponds to a discrete sound made on the drums. Working with professional tabla players to make sure that the lexicon was complete, we represented each stroke with a high-resolution audio clip of each spoken drum syllable, a small video clip showing how each stroke is produced, and phonetic transcription in text. This section serves both as a reference for advanced musicians and as a primer for beginners.

To communicate with the widest possible audience, we chose to create a cross-platform CD-ROM that can be played on both Macintosh and Windows systems. As an authoring tool, Macromedia Director enabled us to create the application rapidly, so that we could build a logical navigation structure and present the layers of textual information without losing the multi-sensory dimension that is so crucial to the learning process. The video clips were presented in Quicktime format, because Quicktime is also cross-platform and can be easily controlled with Lingo, Director's scripting language. Most of the programming involved navigation control. Aside from simple branching commands and navigation cues, I using Lingo's object-oriented features to create a "watcher object" that would keep track of the places visited by the user in any given section. The places are stored as a two-dimensional array in RAM, and the object increments the array with each program location visited, allowing the user to backtrack through the program. Other programming allows the user to play the Quicktime videos in single frame slow-motion, so that the music students can observe details of the strokes.

Although the main function of this CD-ROM is pedagogical, there are also documentary and historical aspects that would be of interest to more general students, and to scholars in ethnomusicology and Asian studies. Maps are provided to show the original geographic locations of the various gharanas, full artists' profiles are included, and a historical section is provides background on each of the various gharanas, as well as on the general development of tabla as an instrument. The CD-ROM will also serve as a kind of digital archive, preserving the work of several representative artists from living oral traditions at the turn of the millennium.

As a means of conveying oral traditions, well-designed interactive multimedia programs are able to combine the most useful aspects of both print media and linear media to provide learners with a more comprehensive experience. But in order to reflect the subject matter accurately, the designers must themselves be knowledgeable of the material being represented, and must try as much as possible to incorporate traditional pedagogy as part of that experience.
Scaffolding Student Learning in Information-Dense Technology-Enhanced Teaching and Learning Environments

Abstract: This paper is fundamentally about supporting learning in technology-enhanced educational settings where students are often confronted with very large amounts of information, and where they are also required to exercise a great deal of independence as part of their learning activity. First, it outlines very briefly, the critical attributes of such educational settings, the challenges to learning that they pose, and some ways of supporting students in their learning as they are confronted with these challenges. The paper also discusses the pedagogical foundations for building these types of cognitive supports and discusses some preliminary work that is being carried out on these lines at The University of Melbourne in Australia.

Technology-Enhanced Learning Environments

For the purposes of this paper, technology-enhanced learning environments refer to those educational settings where some element of instructional technology (such as CD-ROMS or the Web) is used to support the interaction between the teacher, the learner and the educational content. Students in these educational settings are often confronted with very large amounts of information by way of databases and other resources (making them information-dense) which they are required to use to pursue self-directed and open-ended inquiries. Interest in building these educational environments, where students are immersed in learning by doing and where the meaning of knowledge and skills are realistically embedded in authentic problem situations, has been growing in the last decade (see Brown, Collins, & Duguid, 1989). These environments are designed not so much to "instruct" as to provide contexts wherein understanding and insight can be uniquely cultivated. Papert's concept of "microworlds as incubators for knowledge" reflects the philosophical bias of these technology-enhanced, student-centered learning environments (Papert, 1993, p. 120). They are called student-centered because the focus in these learning environments is more on learning, and less on the delivery of the content. Examples of these student-centered learning designs are goal-based scenarios (Schank, 1997), and problem-based learning (Koschmann, Kelson, Feltovich & Barrows, 1996).

Challenges and Problems of these Learning Environments

Technology-enhanced student-centered learning environments do not, in themselves, lead to learning efficiency or effectiveness. Indeed for some learners, the use of technology and the student-centered nature of these learning environments can be quite daunting, and pose a real threat to their success and motivation to learn. While creating opportunities for student-centered learning, these environments also create demands for new skills in managing complex information and higher order cognitive processes. Being successful in such learning environments requires the ability to organize, evaluate, and monitor the progress of one's learning. Not all learners have the skills to function efficiently and effectively in such educational settings. Students need help with acquiring learning strategies to enable them to organize and reflect on information they have encountered. They have to be taught the learning skills and self-monitoring (i.e, metacognitive) strategies which would in turn enable them to take advantage of rich databases, and open-ended inquiries (see Weinstein & Mayer, 1986; Jonassen, 1988). While a considerable amount of work has been done in supporting students' learning with various types of learning strategies in such educational settings (see for example, Bernard & Naidu, 1992; Edelson, Gordin, & Pea, 1999), work on supporting student learning with software-based cognitive tools is still lagging.
What does this Work Involve?

Weinstein and Mayer (1986) suggest that the development of learning strategies (i.e., in learning how to learn) can influence learner characteristics. They argue that employing these strategies and methods can help with the encoding process, which in turn affects learning outcomes. These authors have identified several categories of learning strategies, namely rehearsal, elaboration, organizational, self-monitoring and motivational strategies. These strategies provide a pedagogically sound framework for supporting "learning how to learn", and they can also be used to guide work on scaffolding and supporting student learning in information dense, technology enhanced learning environments. They have guided the research and development work that is reported in this paper.

As part of our work on the design and development of technology-enhanced learning environments, we have been exploring both, the pedagogical designs and the technical architecture of a variety of these types of learning supports. Some examples of these are comparison frames to view content elements in relation to each other, clusters for organizing data by themes, modeling and simulations for exploring dynamic processes, and chronological traces for providing students with representations of their own actions.

Comparison frames (an instance of an elaboration strategy) are particularly useful in areas such as medical and the biological sciences where students are often observing cells and images of anatomical parts to determine unique characteristics and/or abnormalities. Clustering (an instance of an organizational strategy) is useful for organizing data or information to draw out and represent meaningful relationships among them. Interactive modeling and simulation (instances of elaboration and self-monitoring strategies) are useful approaches to support tutorials in applied domains such as in mathematics as well as in the natural sciences. As part of this, concrete dynamic models with which the student can interact and experiment are used to represent abstract concepts. Chronological traces (an instance of organizational and self-monitoring strategies) allow students to observe their own actions and problem-solving behavior after they have reached a solution, and compare it with other solutions.

The presentation of this paper will focus on "The Skin Atlas" which is an instance of an elaboration strategy. The "Skin Atlas" is a multimedia module that contains images of the histology and pathology of human skin and associated disorders, which allows students to study specific images in detail and to select and compare images.

Conclusion

We believe that the kind of work that is described in this paper has the potential to significantly expand our knowledge about scaffolding student learning in information dense, technology enhanced learning environments. By improving the scaffolding of student learning in these environments, we hope to assist the efficiency of student learning. Furthermore, a record of students' actions at a number of levels (e.g., gathering, comparing, clustering, and organizing data, as well as self-monitoring), has the potential to provide a richer picture of their learning activities. These can be reflected upon by students themselves for revision and group discussions, by the teachers for assessment purposes, and by researchers to understand and improve student's learning experience in terms of content gathered, and the types of reflective learning activity in which they have been engaging.

Increasing Interaction through Computer-Mediated Communication in Distance Education

Kwok-chi NG
School of Education and Languages
The Open University of Hong Kong
Hong Kong, SAR, China
kcng@ouhk.edu.hk

Abstract: This paper reports on the first phase of a research project which aims to support student learning through computer-mediated communication among a group of about 20 students enrolled in an educational management course in the Open University of Hong Kong. It describes the results of a questionnaire designed to collect information on how ready the students are to access a Web-based course. Their interaction patterns in the Discussion Board during the first few months of the implementation are analysed. Some challenges for managing the online communication activities in the institutional context are discussed and the next action steps are then suggested.

Introduction

The Open University of Hong Kong (OUHK) is the only distance learning institution in Hong Kong. For the April 1999 presentation, the OUHK launched a pilot project to promote an online course delivery system: the Online Learning Environment (OLE). A Web course development tool – WebCT – was selected as a unified platform for delivery. It is intended that the Interactive Tools in the WebCT – Email, Discussion Board and Chat Room – will create an interactive learning environment for communication among students, tutors and the Course Coordinator.

Course E805 Effective Leadership and Management in Education was chosen for the pilot. E805 is a postgraduate level course in the Master of Education, which aims to improve participants’ professional capability in educational management through developing knowledge of theory and critical reflection on practice. An invitation letter describing the nature of the online mode of learning was sent to all E805 students before the commencement of the course. There were 70 students on the course in total, and eventually 20 students chose the online mode. A videotape on setting up the OLE system and a User’s Guide to the OLE were provided to these students.

In the literature, computer-mediated communication (CMC) has been discussed largely in terms of providing an additional medium to assist students’ learning (Burgstahler and Swift 1996). Claims have been made that it can provide an environment through which learners can interact and engage themselves in social activities such as discussion and debate. As the Course Coordinator (CC) of the course, the researcher is concerned about how the CMC tools in the OLE system can support student learning by providing more opportunities for them to share their understanding of theories and their reflections on management practice with their tutor and other students.

The Study

This study is the first phase of the project, which aims to gain insight into how students had adjusted to the E805 OLE during the first five months of implementation. Students’ views of CMC in learning and how ready they are to use the CMC tools in studying the course were collected through a questionnaire survey. The electronic communication messages over this period were reviewed as a source of information for understanding whether any interaction exists and how it relates to learning.

Questionnaire Data

The questionnaire was sent to all 20 online group students. Seven students responded, a response rate of 35%. The questionnaire comprised 26 questions which probed the following 3 issues:

Internet access. All of the respondents had their own PCs, and were able to access the Internet at home or at the workplace. When asked how many hours per week they used the Internet, students most often responded 1-5 hours, and two students indicated usage of more than 10 hours. Web browsing and Email were the most common functions used, and the activities included communication (33%), online study (33%) and entertainment (20%).

Skills in using the Internet. Responses were given on a 4-point Likert Scale (1 = strongly disagree and 4 = strongly agree) to indicate their skills in using the Internet. In general, the participants showed competence in using Email and Web-browsing (mean 13.0), but were less competent in using the Chat and electronic conferencing system (mean = 2.5) in the Internet.

Use of the E805 OLE. At the time the survey was conducted, all the respondents had accessed the OLE for E805. Most of the respondents (86%) spent less than one hour per week on the OLE, and accessed the OLE system at home (71%) most of the time. This survey paid special attention to students’ use of the Interactive Tools in the OLE. Respondents were asked about the usefulness of each of these features up to that point in their studies. Email was
rated as at least ‘somewhat useful’ by more than 50%, but the Discussion Board and Chat features were not rated as highly. Some students had not used the latter features at the time the survey was conducted. Of those who had, more than half the respondents thought they were not very helpful.

Online Discussion Content

There were 41 messages in the Discussion Board over the above period. The items are arranged according to chronological order. In the column on student postings, the alphabetic letters indicate individual students.

Table 1: Summary of the electronic messages in the Discussion Board

Reflections and further actions

Based on the survey outcomes, students' training needs were further identified. Despite the fact that this was a self-selected group with a reasonable level of computer competence, they needed more guidance on using the Discussion Board and Chat features. To help students become more familiar with these features, the researcher will summarize the procedures and highlight some of their useful functions. Briefing sessions will also be arranged.

The electronic messages showed the interaction patterns of the online group. Among the 13 items, only four of them showed student-student interaction and, in general, students were not involved as active partners. Only six students posted messages, but only three of them were more active members. To motivate students to become more involved in online discussion activities, Chat room sessions will be organized. This is to allow students to have a real-time interaction to discuss their assignments or the suggested topics. The tutor will be invited to join the Chat room sessions, and the transcript of the Chat discussion will be posted on the Discussion Board for further examination with students' permission. Hopefully, in such ways, students will be encouraged to play a more active role in utilizing the interactive features in the OLE.

It should be noted that most of the discussion topics were related to course content or assignments. Based on the item titles, it is difficult to tell whether online communication can promote improved learning. These messages need to be further reviewed through content analysis (Mason 1992) to understand whether any interaction exists and how it relates to learning. Last, statistics on users' login records and the time spent on each component in the Interactive Tools will be collected. This will help identify individuals who read the messages posted but do not participate in discussion (so-called 'lurkers').

A Framework for Generating Non-trivial Interactive Mathematical Exercises in the Web: Dynamic Exercises

Ossi Nykänen
Digital Media Institute / Hypermedia Laboratory
Tampere University of Technology
Finland
ossi.nykainen@cc.tut.fi

Introduction

Successful tutoring is largely a matter of well-timed and focused feedback. A computer program can hardly replace a good, motivated teacher, but it can certainly do better than a non-existing one. Computer-verified interactive mathematical exercises are useful cognitive tools supporting the development of personal mathematical skills and knowledge in the absence of human tutoring. Our goal is to find out and propose specific means supporting computer-aided solving of computer-generated mathematical exercises. We aim to achieve this goal by introducing a concrete system called Dynamic Exercises (DE) for doing non-trivial exercises interactively in the Web.

Exercises created with DE are said to be in the Web, since they are accessed via Internet and processed by using basic WWW services. Exercises are said to be interactive, because the process of solving exercises is carried out in incremental steps, in an interaction with a computer program being capable of interpreting and manipulating user input and providing feedback. Finally and most importantly, exercises are claimed to be non-trivial since exercises are designed and interpreted as multiple code modules using DE extended Maple programming language. Solving exercises does not require understanding Maple language since input can be elaborately processed using arbitrary text filters.

This study continues our previous line of work of designing and implementing Internet-based learning environments, especially from the viewpoint of teaching and learning university-level mathematics (see, e.g., (Pohjolainen et al, 1999) and (Nykanen & Ala-Rantanla, 1998)). Motivation of constructing computer-generated interactive exercises originates largely from a recent survey conducted with our A&O learning environment (see (Pohjolainen et al, 2000)). DE aims to develop things further.

Design Framework

The design and implementation process of creating interactive exercises consists of three phases: designing a dynamic exercise, implementing it as a set of form template files, and publishing it under a DE server, which finally runs the exercises when requested. Each dynamic exercise consists of one or more forms. Forms are logical sub-tasks of the exercise, compiled from form template files on demand. Forms introduce mathematical tasks, formulae, textual descriptions, variables, and graphics for the user, and accept input from the user.

User input is interpreted automatically by form's input evaluation programs. Feedback is presented by means of textual or graphical output including comments, variable values, and formulae. In addition, input evaluators may branch the execution flow to other forms, thereby providing entire forms as an output. This kind of branching of the form execution makes it possible to effectively implement exercises with non-linear structure. For instance, branching enables recognising and accepting various kinds of different solution strategies instead of a single one.

Programs generating exercises and providing input-sensitive feedback are written using the DE extended Maple programming language and are embedded in the form template files. Program blocks essentially set up task variables, produce graphical plots, and evaluate user input when present. Publishing an exercise means putting the exercise form template files in some appropriate DE author directory. In addition, classes of exercises can be compiled into libraries, the use of which can be optionally controlled and monitored using some additional WWW mechanisms.

Syntax for form template files is kept as straightforward as possible. Each form template file is a text file consisting of a logical combination of the following DE elements: INITIALCODEBLOCK, TEXTFIELD, OUTPUTFIELD, INPUTFIELD, IMAGELINK, LOADFORMBUTTON, and RESETBUTTON. These elements (with proper attribute values) initialise form's mathematical task, provide static text descriptions (optionally including other media elements), and print dynamic DE variable values for the user. In addition, elements accept, parse, and evaluate user input, insert hypertext links pointing to generated images, add buttons for manually launching other forms, and finally, provide a button for
resetting the exercise and generating a new one. DE also enables generating demonstration-orientated exercises instead of problem-based ones. Figure 1 presents an example of a simple exercise in action.

![Figure 1: Solving a simple exercise: interacting with a form via Web browser.](image)

DE elements INITIALCODEBLOCK and INPUTFIELD introduce Maple programs needed for initialising the form's mathematical problem and evaluating user input. From non-technical point of view, the interaction scheme is quite straightforward: first a set of problem variables is generated, which are presented to the user along with some static descriptive text fields. When user types in an answer it is parsed and processed by the program defined in the selected INPUTFIELD. Answer evaluator produces elaborate feedback to the user or jumps to another form that is compiled and presented to the user. After one interaction step is complete, DE server is ready to receive the next input from the user and the process continues. DE monitors the interaction process and maintains a simple symbol table of DE variables recording essential state information. To get a better idea how forms are designed and written in practice, please see the DE home page at <http://matrisis.ee.tut.fi/~onykane/deserver/>.

**Implementation**

DE is based on a well-known CGI-based client-server architecture. Server software effectively exploits Mathedge development library providing full Maple V Release 3 Kernel functionality (Waterloo, 1995). Performance requirements for clients are minimal since DE server carries out all computations. Technical implementation of Dynamic Exercises follows guidelines found in (Nykänen & Pohjolainen, 1998). MathEdge is a relatively expensive product, available for HP9000 and Sun platforms, and the large-scale use of the software is limited inside our university with effective licensing policy. Maple is a well-known (commercial) general-purpose computer algebra system by the Waterloo Maple Software and the University of Waterloo. Maple includes a nice mathematical programming language and a rich set of mathematical packages and plotting facilities (see, e.g., (Heck, 1993)).

Abstract: During the last four years, the Hellenic Pedagogical Institute (HPI) has had a consistent presence in the WWW virtual space, providing various educational services to the Greek schools' community (http://www.pi-schools.gr). With the implementation of the project "Added Value Services on the Greek Web for Schools", the HPI aims to create an integrated learning environment over the WWW, which is going to complement and extend the already existing infrastructure. This paper addresses the objectives, the design principles and the functions of the project.

Project's philosophy and design

During the last three years, the Greek Ministry of Education has been attempting to introduce and utilize Internet technology in the educational process. Through various projects, secondary schools around the country are supplied with advanced computer and networking equipment as well as Internet access. None the less, the use of sophisticated equipment and Internet connection does not necessarily mean utilization of Internet technology to the educational process. Having access to the information does not necessarily mean an advance of knowledge (Laurillard, 1993, p. 123). The critical point for the effective incorporation of Internet services in the educational process is related firstly with a convenient access to high-quality content and secondly with teachers' capability to use the provided information and services as structural materials and components for the design of educational activities.

The HPI with the design and implementation of the project "Added-Value Services on the Greek Web for Schools" is aiming to create an integrated environment for the distribution of educational material and services through the Internet, for Greek secondary schools. The HPI's objective is not to enforce a centralized educational model on the Web, but to establish a number of services and design principles for the creation, expansion and maintenance of the Greek Educational Web. These services are classified along two main axes:

1. Implementing a distance learning center (in a pilot mode) over the Internet for the increasing training needs of Greek secondary school teachers.
2. Providing the schools with the ability to promote their projects and activities through the WWW.

The project creates an integrated learning environment, which is going to cover the functionality and activities for both axes. The users of the environment will have different access levels to the information and services provided according to their roles and needs. The services and activities are described as virtual "spaces" following the standard Internet terminology.

The first axis aims to create a flexible Internet based educational platform for the design, implementation and delivery of teacher training services at a distance. The adopted training model is based mainly on the principles of Supported Self-Learning model. In this model, the trainee has the ability both to use educational material and manipulate its flow and structure according to his/her learning goals. In addition, in order to avoid feelings of isolation and inactivity which are common during tele-training programs, dynamic communication channels (one to one, one to many, many to many) will be established (Nipper, 1989). In the framework of the adopted model, the distance-training center includes the following virtual spaces:

"Space" of training material, which is structured over two levels (level of resource-based training and level of structured training). The resource-based training level will function as a reference "place" for the teachers as well as a rich source of educational material for the enhancement of their work. The level of structured training aims to support the implementation and delivery of structured training programs for specific topics, making use of flexible tools appropriate for the demands and features of the Web-based learning environment (Dabbagh, 1999).
Promotion "Space" for the teachers' work. The structure and the function of this space will follow that provided by online journals, which are very common over the Web. Teachers' "Meeting point", providing the community of teachers with both synchronous and asynchronous communication channels.

The design and implementation of the second axis aims to offer to the members of the educational community the opportunity to contribute their own work and activities on the Greek Web for Schools. Additionally, already existing digital educational material can be gathered and structured under thematic categories in order to facilitate the search process (Luebke et al., 1999; Collis, 1995, p. 6-9). The second axis includes the following virtual spaces:

Space of educational material. The material will be annotated according to the developing international standards for educational metadata. The users will be able to submit remarks and comments on the provided material along with their own work.

Kiosk for school projects. In this virtual place, school projects and activities will be accommodated under specific thematic structures.

Exhibition of educational software. In this virtual space, informative material will appear concerning evaluated titles of educational software.

Schools' "meeting point", providing the members of the educational community (students, parents, teachers, managers) with both synchronous and asynchronous communication channels.

Operating specifications of the project

Online database of training and learning material. The database will cover the needs of the educational material and software along with those related to the level of resource-based training. Also, through the database application, both the needs of the Promotion "Space" for the teachers' work and the Kiosk for school projects will be facilitated.

Applications for the access to the Learning/Training material over the Internet. Through this application, the members of the educational community are going to dynamically interact with the material through their favorite browser over the Internet.

Online courses' authoring and delivery tools. These tools will facilitate instructors to create dynamic web-based courses and make them accessible over the Web.

Applications for text-based synchronous and asynchronous communication. These applications are going to serve the needs for the "meeting" points of both axes.

On-line help desk and search engine. The application will serve all spaces described.

Future plans for the project involve the creation of intelligent help agents and searching machines which will be included in the learning environment. Furthermore, the potential and the abilities of the collaborative virtual spaces (MOO) for educational purposes will be investigated. In addition, peripheral content servers will be created in order to accommodate issues of local interest. Finally, a lot of effort will be put on the enrichment of the environment with educational content. Towards this direction, all related authorities and organizations have been invited to participate.

A Multi-Method Strategy for The Assessment of Adult Literacy Software

Graham J. Passmore, Wayne Lewchuk, Geoffrey Rockwell, and Sandy Shaw
McMaster University
Canada

Abstract: This paper investigates the introduction of software into an adult literacy program. Pre and posttests, questionnaires, focus group interviews and iterative observation are combined to form a multi-method assessment strategy. The method is used to assess the satisfaction that users derive from computerised instruction. It is also used to assess the culture of learning that develops in the classroom. Six components of user satisfaction are identified: learning, teacher role, tedium, real-world applications, software and gender differences. An approachable, friendly and interactive teacher is found to be the key component of a successful learning environment.

Introduction

This project sought to identify best practices for introducing technology into the classroom. It was determined that this matter would best be investigated by answering the following questions: what is the nature of the satisfaction that users derive from a computerised adult literacy course, and what is the nature of the culture of learning that develops in such a course. Current thinking has it that multiple methods are needed to capture the variety of outcomes that students derive from an educational experience. A multi-method assessment strategy is described below as are the results obtained from its application.

The study

Five software modules were developed. They were designed to teach the following literacy skills.
Module 1: Reading words and phrases
Module 2: Filling out forms
Module 3: Writing for various purposes
Module 4: Following instructions
Module 5: Reading to find information

Savenye (1992) considers suitable methods for answering common research questions. Her suggestions lead to the selection of the following methods for this study: participant observation and focus group interviews to assess user satisfaction and the culture of learning. Paper and pencil tests to assess learning outcomes (the quantity of learning) and questionnaires to assess attitude and socio-demographic background. Arrangements were made to access two basic computer literacy classes that were run in the Toronto Offices of the United Food and Commercial Workers Union. Each class contained 13 students. The methods were applied in each class over five consecutive weeks in the following manner. Prior to the first class the attitude and socio-demographic questionnaires were administered. Pre and posttests were administered before and after the students studied each module. Students were observed as they worked with each module and a focus group interview was run at the end of each class. Data from the first set of observations was collated into groups. The name of each group was said to represent a component of user satisfaction. Confirmation of the accuracy of the first set of observations was sought during the first focus group interview. Data from the interview was used to update the components of satisfaction as necessary. The interview process was repeated for each module and the descriptions of user satisfaction and learning culture were refined at each iteration. The attitude questionnaire was rerun at the end of the study.

Results.

The attitude questionnaire consisted of six questions that were measured on a Likert scale of strongly agree to strongly disagree. At pre-test, the participants answer the questions were that they: enjoy using computers to learn, think that it is important to learn how to use computers, look forward to using computers to learn, think it is easier to learn using computers, think that computer use makes for faster learning and that computers provide a better way to learn. Cochrane's test was used to detect attitude shifts from pre to posttest. Significant changes were detected for questions 1 (p = 0.004), 4 (p = 0.025), and 5 (p = 0.001). The change for question 1 was positive; the changes for questions 4 and 5 were negative. Despite these changes alone the Likert scale's participants' overall attitude (as described by the above responses) did not change over the course of the study.

Three sets of t-tests were run on the remaining data. Set one compared the mean responses of the socio-demographic groupings at pre-test. It indicated that females thought that learning to use the computer was more important than males (X1 = 1.26, X2 = 1.11, p = 0.02). No significant differences were detected between the remaining socio-demographic indices. In set two, pre-test scores were subtracted from post-test scores to determine which modules successfully taught what they were designed to teach. Modules 1, 3 and 4 produced significantly different pre- and post-test scores (module 1 (X1 = 20.02, X2 = 65.14, p = 0.00), module 3 (X1 = 20.02, X2 = 27.31, p = 0.00), and module 4 (X1 = 32.00, X2 = 39.56, p = 0.01)). It is not known if modules 2 and 5 were inappropriate designed or whether the material they covered is unsuitable to computerised instruction. The third set of t-tests examined the influence that socio-demographics have on learning outcomes. No significant differences were detected for the socio-demographic groups.

The iterative observation process identified six components of user satisfaction: learning, teacher role, tedium, real-world applications, software, and gender differences. In regard to learning, the students reported that the computerised instruction simulated one-on-one student-teacher interactions. That is they felt that the feedback provided by the software enabled (to some extent) self-paced learning. Teacher role was seen as a pivotal component of a successful computer course. A teacher who is interactive and approachable is needed to alleviate the students' initial anxiety toward computerised instruction and to provide continuing support when problems arise. The above qualities develop a spirit of collaboration in the classroom. Although the students reported that they enjoyed using the software they also felt that it would be tedious to take an entire course on a computer. The fourth component, "real-world application" is an inherent plus for computerised instruction. Computer skills were seen as a ticket to a better job and a better life. The software component indicated that the skills of the learner have to be accounted for during the design of the software. At the start of the study students with very little computer experience required help from the teacher. Had the disparities between their skills and the software's operational demands been much greater they might have proven a barrier to learning. More experience computer users reported that they would have liked a more interactive multimedia format. Designers can avoid these problems by matching software to the skills of the learner. In regard to gender differences, a few of the male participants expressed an interest in a home-based computer course. Females indicated that there were too many distractions at home for them to learn effectively there.
A friendly, interactive teacher who encourages camaraderie and a fast pace of learning was deemed essential to the development of a positive culture of learning. Such a teacher promotes a sense of “we are all in this together.” The small class size (13 computers) with students sitting close together was also thought to influence the creation of a collaborative atmosphere. The observer postulated that a positive class culture engenders faster learning as strong participants can provide timely assistance to the weak. When students interacted, they interacted in small groups of two or three. Operational problems of the software and the computer were discussed. By week three participants had become familiar with the software and their interactions dropped off considerably. From this time on data was primarily obtained from the focus group interviews.

Conclusions
Iterative observation affords repeated runs at a question so that it can be explored in considerable detail. Multiple assessments mean that inaccurate conclusions drawn from initial observations may be removed. Iterative observation also affords the reallocation of resources to accommodate factors that are only discovered part-way through a series of observations. Evaluators wishing to use this technique should expect that changes will have to be made to their initial evaluation strategy. The ability to embrace these changes will determine the success of the investigation. The participants change in attitude toward computer learning may be a result of the hyperbole associated with the computer industry. If participants entered the study thinking that computers make for effortless, extremely rapid learning they would have been disappointed. Computerised instruction is not without problems, it works best when used in conjunction with a friendly interactive teacher who instills a spirit of collaboration in the classroom.

Abstract: This paper provides the experiences of two faculty members learning technology and how to integrate it. Both members have received grants to revise curriculum to integrate technology. Based on their experiences and the awarding of a technology challenge grant, faculty members are learning to choose their tools wisely.

Introduction

Given the current climate of technology integration in education, our institution has begun to encourage faculty to use technology within their classrooms. The mandate is clear from the governor on down to the college levels that technology will be used. Thus, there has been an increase in the number of faculty trying to use technology in their teaching. The real issue, however, is not using technology, but rather using it wisely.

The experience of a lifetime

Both authors have been recipients of summer grants awarded within the state’s higher education system. Because of these awards both authors revised existing courses with the goal of increasing the technological aspects of the courses. These courses were requirements in the undergraduate teacher education program. The purpose of the awards was to increase technology skills and knowledge by both education faculty and students. The grant covered salary and provided each instructor with $5,000 to spend for equipment and training during the summer.

In each case the authors begin the process by investigating equipment they could purchase. This was welcomed because the existing technology had not been recently updated and therefore many of the project goals were not possible. One of the barriers encountered was the system for ordering equipment and software. The process was a complex process in which faculty took weeks of their project time to obtain bids and order the equipment they need to accomplish their goals.

Another issue that arose was support in terms of training on equipment use and programs. Faculty receiving the grants had to actively seek campus resources to order equipment, gain training in computer skills including WebPage design, course software and presentation media. Some training was offered through the Instructional Technology Center on campus, however, not all participants attended. Once discovered, the support persons were available to the awardees and provided guidance.

During this process the authors found that the grant was wonderful for receiving new equipment and learning skills. However, the actual course design and integration was an evolving process. In fact, the authors have found the longer they worked on their grant projects, the more they realized that technology integration is an ongoing process. Even though the spirit of the grant proposal was accomplished, some of the faculty found that more time, resources, and thought were needed to go into their projects. Thus the authors are making significant revisions to their courses as they realize that using technology to facilitate...
instruction is a complex process. The time it takes to implement technology that is truly useful to our students' learning is, at the outset, tremendous.

Both authors decided to use web-based materials to support instruction for their grant projects. Besides the grant projects, the authors have infused technology into other courses they teach. The goal in using web-based materials was not to provide the lecture notes for their classes but rather to extend learning opportunities within their classroom. This meant increasing access and interactivity between instructor and student as well as to student to student collaboration.

In one project the author used WebPage templates designed by the university's instructional designer. The templates allowed the faculty member to put materials such as an online syllabus, course schedule, assignments and discussion on the web. As courseware became available during the following year the information was migrated to the new courseware application which provided password protection for the course materials and interactions. Another goal in this project was to increase the student's use of technology and was accomplished by specific training and required projects such as use of the digital camera, scanners, and PowerPoint.

In the other project, the author took existing materials developed for web publication and updated the materials as well as adding components such as discussion, online surveying and project development. Courseware provided by the campus was used at first to revise the existing course. This courseware was not sufficient for the project's purpose so the author used grant time to find other courseware options.

As the awardees learned skills and extended their ideas, they became aware of the barriers in integrating technology such as problems with infrastructure, the selection of the web-based courseware and the ability to locate resources to facilitate web-supported instruction. The other concern was that while increasing skills in technology, faculty members were not being trained as to how courses including technology should be redesigned. Technology integration requires that faculty rethink how the education process really happens.

As this realization hit, the college began participating in a technology grant. Through the five-year statewide technology challenge grant entitled Learning Organizations for Technology Integration (LOFTI), faculty members in the college have begun to receive both technical instruction and instructional design instruction. The authors feel that the focus should be on teaching our content using technology to enhance the learning process. Technology is a media decision, which should be dependent on the faculty's need to communicate with students, the content, and the educational environment.

In the first year of the LOFTI grant, planning was done by a group of higher education faculty, students and practicing K-12 teachers. This group's first activity was an intensive week of skills-building workshop for faculty members. This workshop was planned to concentrate on skills identified through a needs assessment and included e-mail, building internet activities, basic word processing, spreadsheets, databases, ethics and standards, and WebPages development. Faculty members chose the sessions they wanted to attend and were paid a stipend based on the number of workshops they participated in. Also in the first year, a request for proposals went out among faculty calling for summer projects that revised curriculum to include technology integration for undergraduate teacher education students. These projects were intense in nature and, while not providing the monetary value of the previous statewide grant program, allowed faculty members to concentrate on a specific course revision.

Currently in the second year of LOFTI, the planning group has determined that the focus of the grant should be staff development in technology integration, recognizing that skills training still need to be offered. One of the projects is conducting college seminars on using instructional design principles to integrate technology within existing courses. The seminars allow faculty an opportunity to discuss, brainstorm and educate themselves about the concept of using technology as a tool.

**Conclusion**

Through our experiences with the statewide grant and the opportunities presented by the LOFTI grant, we hope to encourage appropriate use of technology to facilitate learning. We have discovered that time and resources are vital to the success of technology integration, however, these are not the only variables at play. Good instructional design principles and support and encouragement by fellow faculty members are necessary factors in developing curriculum, which uses technology that enhances the learning process. Ultimately, learning to integrate technology that strengthens our undergraduate teacher education students experience will provide a model for them to take into their classrooms of the future.
Many young professionals in the field of Educational Technology view the process of getting published as one involving mystical wisdom. Some find the prospect of rejection intimidating and others just don’t know how to get started. While successful scholars in the field are sometimes characterized by an extraordinary intellect, most are primarily distinguished by a willingness to be systematic and persistent.

Why Publish?

Although the expression “publish or perish” has now become a cliché in academic circles, the importance of its message to faculty who desire to advance in higher education remains as strong as ever. For graduate students and recent graduates of educational technology programs desiring to obtain an academic position, publications can provide that extra edge that sets their credentials apart from those of other candidates. But even for those whose career success does not depend on publishing, there are considerable personal rewards of seeing one’s work appear in print.

Publication Outlets

There are many journals that publish articles on educational technology. In addition to the many journals that deal directly with the field, there are dozens of others that publish articles in which an application of educational technology in a particular content area is the major theme. Because we can’t review every educational journal, we have chosen to concentrate here on those journals that deal specifically with educational technology.

A review of Cabell’s Directory of Publishing Opportunities in Education, 5th edition, 1998 identified 37 journals that deal primarily with educational computing, Educational design, distance education, or other aspects of educational technology. Seventeen of these are listed in Table 1 showing circulation rate, acceptance rate, the time required for review of manuscripts, acceptable manuscript length, and the email address of the publisher. Information was not reported for the other 20 journals, so they have not been included. Readers should note that the information included here is self-reported and subject to change. This list is not meant as a comprehensive list but merely suggests the broad scope of possibilities for publication in educational technology.

Table 1: Educational Technology Journals

1482
It is worth noting that the same manuscript must not be submitted to more than 1 journal at the same time (American Psychological Association, 1994). However, it is generally accepted as ethical practice to present a paper at a conference and then submit the paper or a revision of the paper for journal publication.

**Final Thoughts**

In conclusion, learning to write for publication can be an exciting experience, help enhance your career, and earn you the respect of colleagues. Although at times publishing may be humbling, most aspiring authors become increasingly successful with experience.

**References**

Introduction

Web-based publishing presents editors and graphic designers with novel problems. Can a hypertext presentation deliver a coherent narrative? What written style suits screen presentation? How can professional standards of graphic and typographical design be rendered successfully in HTML? This paper suggests some answers to these questions using experience drawn from the presentation of a large-scale web course in the U.K.

The Course

In 1999 a web-based course entitled, T171: You, Your Computer and the Net was presented to 900 U.K. and European students (Weller, 1999). This was a pilot presentation, and now in 2000 the course is being studied by 12,000+ students in its first full-scale presentation.

Editorial Issues

Publishing via the web poses problems of narrative design and written style that arise from the disjointed nature of hypertext (Plowman, 1998) and the well-documented difficulties of reading from screen (Jones et al., 1998).

The problems of constructing coherent narrative in disjointed media are often described in terms of the search for nonlinear narrative, as if nonlinear narratives are a new phenomenon of the digital age. Umberto Eco has pointed out (Eco, 1993) that in almost all literary fiction nonlinear narratives are the norm.

Students of film studies are similarly familiar with the scope for nonlinear narrative in an otherwise linear medium (Chatman, 1989).

Eco makes an important distinction between narrative and exposition. In a book or film the exposition is linear, but the narrative need not be.

The issue with interactive digital media is not so much 'how can we develop nonlinear narratives?', but rather 'how can we present coherent narratives in a medium in which the exposition is both nonlinear and under the reader's and not the author's control?'

The answer lies in the scope web constructors have for shaping the exposition. In our course we exploited the advantages of the web for both guided and free exploration, while tying our students to a core linear flow of information.

This structure can be summarised as the 'bottlebrush' narrative model.

Reading from screen is neither as comfortable or as efficient as reading from paper (Jones et al., 1998). There is thus an advantage to writing in a concise style (Morkes and Neilsen, 1997,1998). In our course the web site provides 'wrap-around' materials to support two set books (Crigley, 1996; Hafner and Lyon, 1998). The books in themselves carried strong narratives, and provided detailed, discursive texts. So the web site could be presented in a more condensed style, without risking it being either too obscure or too light-weight.

Brevity leads to the second style question: where does one strike the balance between asking your reader to scroll through a long page, and asking them to jump to a new one? We suggest a rough rule-of-thumb: don't require your readers to scroll for more than about five screen depths, and design your pages to download in a reasonable time.
Visual Design

The graphic designers were given the brief to produce a stylish, restrained and simple design that would be stable when viewed with any one of the commonly available browsers.

The site was rendered and managed using UserLand’s Frontier. The graphic designers produced design templates in HTML using DreamWeaver, and the software support team wrote scripted macros that Frontier used to render tagged HTML files into finished designed pages. The generation of final pages was thus automated.

The first major design decision was whether to use frames or not. The arguments against frames included: the perceived difficulty of bookmarking framed pages, the relatively low browser specification that we had to accommodate, and the size and complexity of the site. The arguments for frames included: that the site would look more sophisticated (for example, menu lists would not scroll off the screen), and that navigation would be simpler in a frames environment. The final decision, however, was not to use frames.

We used tables to implement the design. Tables allow for quite sophisticated layouts, and it was not easy to decide how far to go in exploiting the potential of tables to deliver fine-tuned design. Compared to many commercial sites the T171 pages show a relatively simple design, but it should have been simpler. A balance had to be struck between the achievement of particular design effects, and the time expended to make them happen. For this balance to be struck both graphic and software specialists had to understand each other’s different perspectives.

Seigel (1997) recommends that an average web page should be around 30k in size. Sometimes this can rise to 70k, but should never exceed 100k. As modem speeds improve these figures may need to be revised upwards, but the T171 design took them as benchmarks. This led to difficult decisions about how far to reduce the visual quality of illustrations in order to meet the benchmark file sizes. A lot of the images that provided the basic design were used many times, and so we could rely on them being cached by the students’ browsers.

Conclusion

The web is a publishing medium, and web-based learning materials can benefit from support from publishing and design professionals. In supporting web-based educational publishing both editors and designers have to apply skills developed in the world of print publishing to a dynamic and potentially nonlinear medium.

In developing coherent narrative structures it is useful to recognise the distinction between narrative and exposition, and to employ narrative models that allow for exploration and discovery while maintaining an underlying narrative drive. The well-documented problems associated with reading from screen also demand conciseness.

Good visual design is important in enabling ease of use. Close teamworking between graphic designers and software support staff is essential, and both categories of staff need a good understanding of the nature of each other’s task, and the constraints under which each operates.

Design decisions should be informed by considerations of orientation, navigation, complexity versus practicality, and download times.

Evaluating Software for the New Millenium:  
An Example from Project Links

Jennifer C. Richardson, Karen Swan, and Dianna Newman  
University at Albany  
ED B-8, ED 114A  
Albany, NY 12222  
Jennrich1@hotmail.com, swan@cnsvax.albany.edu

Abstract: This paper reviews the design, implementation, and testing of Project Links’ WWW-based modules developed at Rensselaer Polytechnic Institute (RPI) to support the integration of mathematics, science and engineering concepts in undergraduate teaching and teaming. Using the Project Links experience as an example, the authors argue for particular foci, as opposed to generic approaches, and formative, as opposed to summative, testing in the evaluation of technology-based programs and the usability of particular software.

Perspectives

Project Links is part of the Mathematics and Its Application Across the Curriculum initiative funded by the NSF and aimed at reforming undergraduate mathematics, science, and engineering education by making clear the connections between mathematics and its applications in science and engineering. Project Links centers on the development of a library of WWW-based hypermedia modules that link important topics in mathematics with useful applications in engineering and science. Modules in the library cover the mathematical areas traditionally studied by undergraduate engineering and science majors, including calculus, differential equations, mechanics and linear systems, advanced mathematical methods, and probability and statistics.

In the Project Links modules, these ideas are both explored as mathematical concepts and contextualized within applied science and/or engineering situations. Each module consists of several sections that are designed to be completed in a single class session or in part of a single class session. An important feature of most modules is interactive simulations designed to help learners visualize the mathematical, engineering, and/or scientific concepts being illustrated. Although they are made so that they can be used in a variety of instructional settings, Project Links modules are designed to support an innovative model of undergraduate education pioneered at RPI known as studio teaching and learning (Wilson, 1994). In studio style teaching and learning, large lecture classes are replaced by many smaller, technology-supported studio classes that integrate lecture, discussion, and laboratory-type explorations, many of which are computer-based or computer-supported (Boyce & Ecker, 1994).

Methodology

The authors reviewed Project Links documents and worked with the Links Project Directors to isolate a set of defining factors that the latter believed best encapsulated what was most important in the project. These were: the explicit linking of concepts, support for studio-type teaching and learning, flexibility (the potential to be used in other sorts of teaching and learning situations), support for collaborative learning, discovery orientation, and multi-modality (the use of multiple kinds of representations for single concepts). These factors then became the basis for the formative evaluation of Project Links modules. This evaluation is ongoing and has taken multiple approaches.

Firstly, a software evaluation protocol was designed to explore whether or not the six factors deemed most important to Project Links were explicitly instantiated in individual modules. Evaluators were asked to answer a series of questions in a narrative format for each of these factors, as well as to rank the modules using a scale of one to seven. Two evaluators independently completed the software evaluations for each module, then came together to resolve any differences through consensus.
Secondly, we developed a version of think aloud protocols (Erickson & Simon, 1993; Pressley & Afferbach, 1995) to explore the ways in which students make sense of the modules. Representative students were asked to work on particular modules, "thinking aloud" as they worked. As they did so, both their faces and the computer screen in which they were working were captured on a single videotape using a video mixer and picture-in-picture technique. Users were also asked to tell what they remembered from the modules (retrospective report) and to answer specific questions concerning their behaviors while viewing sections of the tapes (stimulated recall). Tapes of all three were reviewed for evidence of sense making, reflection, and usability issues.

Finally, studio classes in which modules were used were observed to explore their actual use in such setting, and students within those classes were interviewed to gain more detailed information concerning the software.

Results:

The software evaluation review protocol proved to be invaluable in the revision process during the ongoing development of Project Links modules, especially regarding the formatting of information, the design of multimedia simulations, and the overall design of the modules. In fact, a template was created to ensure consistency of navigation and design as a result of the review process.

In addition, the think aloud protocols demonstrated that the Project Links modules could be used by four categories of students - content area novices and experts, and technology novices and experts. Usability testing is ongoing to try and determine students' cognitive processes while interacting with the modules. Classroom observations have indicated that there is still a need for professional development concerning classroom use of the Project Links software. In particular, cooperative use of the modules is rare. An initial professional development day was completed in the spring and more are planned for the 1999/2000 school year.

Educational Significance:

Project Links is an innovative program that is exploring new ways of teaching and learning math, science, and engineering through technology at the undergraduate level that integrate concepts across these disciplines and help learners visualize difficult underlying concepts. This study helps highlight the software features and teaching practices that make it successful.

Additionally, this study demonstrates the efficacy of contextualizing software evaluation according to the particular purposes for which software is created. Such an approach, we believe, is beneficial for two reasons. First, it only makes sense to evaluate educational software relative to pedagogical purposes because differing purposes are best served in vastly different ways. Programmed instruction, or objectives based programs, for example, is well suited to behaviorist and perhaps information processing pedagogical approaches, but ill-suited indeed for constructivist ones. Secondly, assessment always guides practice. Teachers teach to the tests just as students study for them. Similarly, software designers will write and revise based on assessment procedures. Evaluation protocols that focus on the issues important to a particular project or pedagogical need will help insure that those issues are held central.

How to Make the Most of Online Interaction

Introduction

The educational community is finding itself on the edge of a new era, online learning. Online learning has been shown to be more cost-effective and convenient than traditional educational environments as well as providing opportunity for more learners to continue their education. However, some critics claim that web-based or online learning experiences are not as effective as traditional classroom learning experiences (see Freeman and Capper, 1999; Noble, 1996; Perelman, 1992; Cuban, 1986). When queried as to the difference in the learning experiences across environmental format, many cite the lack of face-to-face interactions as being the foremost deficiency. However, when considering this challenge, researchers have to ask themselves if it is really the act of viewing, the instructor/students, that is an essential element of learning, and if not, then what element are these critics referring to? Perhaps it is the interactions that take place between the student and instructor, but interactions can take place in an online environment as well as in a traditional classroom. This being the case, we argue that the element that critics are referring to is that of “social presence.”

Social presence theory, a sub-area of communication theory, postulates that the critical factor in a communication medium is its “social presence,” which is defined as the “degree of salience of the other person in the interaction and the consequent salience of the interpersonal relationships” (Short, Williams, and Christie; 1976, p. 65). This is interpreted as the degree to which a person is perceived as a “real person” in mediated communication. Short, et al, further define social presence as a quality of the medium itself and hypothesized that communication media vary in their degree of social presence. Social presence is described as a construct that comprises a number of dimensions relating to the degree of interpersonal contact including the concepts of "intimacy" and "immediacy." Thus, it can be argued that social presence is both a factor of the medium as well as of the communicators and their presence in a sequence of interactions (Gunawardena and Zittle; 1997).

Review of the Literature

In the era of online and web-based learning and course offerings, there is an increasing need to understand social and political contexts of learning that are created by this type of learning environment. The significance can be demonstrated by the growth of available online courses. For example, The SUNY Learning Network (SLN), the most comprehensive online course network in the country, has increased the number of courses they offer from 4 in the 1995-1996 academic year, a growth of over 1,000 courses in the 1999-2000 academic year, a growth of over 1,000 courses in the 1999-2000 academic year, a growth of over 1,000 courses in the 1999-2000 academic year (Swan, Shea, Fredericksen, Pickett, Pez, and Maher, in press). Recent studies conducted by Jones (1998), Baym (1998), Agre (1998), Gunawardena (1997), Harasim (1993), Warschauer (1999), and Rheingold (1993) have emphasized the need for further research into the social context of web-based environments as it impacts learning and communication. To date there has not been much research done on Social Presence Theory and computer-mediated communications. A review of the literature produced only four articles pertaining to this area.

Although Hackman and Zane’s (1990) work examines a televised classroom environment, it examines issues in common with online learning and social presence. Their study investigated the effects of conveyance systems design and social presence, in the form of teacher immediacy behavior, on perceived student learning and satisfaction. The results indicate that system design and teacher immediacy behavior strongly impact student learning and satisfaction. In addition, system variables such as interactivity (e.g. students are able to comment during lectures) and clear audio and video transmission positively influence perceived learning and satisfaction. Moreover, it was found that instructors that engaged in immediate behaviors such as encouraging involvement, offering individual feedback, and promoting a relationship with off-campus students were viewed more favorably (p. 203).

Demonstrating the shift in social presence theory, Gunawardena (1995) conducted a two-part study examining whether social presence was an attribute of the communication medium or users’ perception of the medium. The studies were conducted in the Spring of 1992 and Fall of 1993 with students who participated in a GlobalEd computer conference course. GlobalEd “linked” graduate students in several universities to discuss issues related to distance education, engage in collaborative learning and research related to distance education, and experience distance education” by using technological medium conducive to the delivery of distance education (p. 149). The studies focused on students’ perceptions of seven point-five point bipolar scales related to the computer-mediated conference system. The GlobalEd conferences were conducted using a listserv, an electronic discussion list. The findings from both of her studies indicated that “although computer-mediated conferencing (CMC) is considered to be low in its ability to convey social presence, participants in this conference rated CMC highly as an interactive, active, and social medium” (p. 158). It is the researcher’s belief that these findings were due in part to the social cohesion of the conference and the individual input from each student that allowed them to create an online community. In other words, social presence wasn’t a quality of the medium, as Short, Christie and Williams (1972) initially proposed, but rather a quality of how the participants chose to interact with the medium. If the participants had not been committed to creating a cohesive online community then they could have felt victim to the medium. As Gunawardena explains, “the participants create social presence by projecting their identities and building online communities. In order to encourage interaction and collaborative learning, it is important that moderators of computer conferencing promote the creation of conducive learning environments. CMC participants can be trained to create social presence in a text-based medium and build a sense of community” (p. 163).

It is also Gunawardena’s belief that “in reviewing social presence research, it is important to examine whether the actual characteristics of the media are the causal determinants of communication differences or whether users’ perceptions of media alter their behavior. It was noted that social presence can be shared among teleconference participants, a position different from the view that social presence is largely an attribute of the communication medium” (p. 164). This study is especially significant because it demonstrates that Short, Williams and Christie work has become somewhat outdated in terms of defining social presence. Although to be fair, they could not have guessed the capabilities of today’s technological innovations.

In a later study by Gunawardena (1997), she examined the possibility of using social presence as a predictor of satisfaction within a computer-mediated conferencing environment. The participants were 50 graduate students from five universities enrolled in a “GlobalEd” conference course that provided a forum for graduate students in distance education to share and discuss research and experience distance education by using computer-mediated communication. The instrumentation consisted of a questionnaire developed to assess participants responses to CMC, the GlobalEd experience, and areas of theoretical interest identified in the literature as potential influences on CMC satisfaction; fifty-two five-point Likert-scale items were used as the measure (Gunawardena, 1997, p. 13). The results demonstrated that approximately 58% of the variance was contributed by social presence, suggesting that social presence is a strong predictor of satisfaction in a text-based computer conference. Moreover, it also “supports the view that the relational and social aspect of CMC is an important element that contributes to the overall satisfaction of task-oriented or academic computer conferences” (p. 19). In addition, students perceive instructors to have increased ability to express emotions by using emoticons (symbols that express emotions) to express emotions in written form. Overall, the findings imply the need for designing academic computer conferences where equal attention must be paid to designing techniques that enhance social presence and instructors will need to learn to adapt to the CMC medium by developing skills that create a sense of social presence (p. 19).

Finally, Boverie, Nagel, McGee, and Garcia (1996) conducted a study to examine elements of learning styles, emotional intelligence, and social presence as predictors of distance education student satisfaction needs. The participants were enrolled in two different class formats: a 16 week traditional format teleconference class and a weekend format teleconference class; e-mail was also used for group discussions and learner support. The results showed that of the three constructs, Social Presence was found to be a significant predictor of satisfaction. In other words, regardless of student location on-site or off-site, or status as a graduate or undergraduate student, participants who perceived higher social presence also perceived a higher level of satisfaction overall with the course. A secondary finding also indicated that those students who perceived a higher level of social presence
also tended to anticipate a higher outcome in terms of grades (e.g. A versus B). The researchers hypothesize that the higher confidence levels may also affect the students' perceived closeness with the instructor.

There is a need for further research in the area of socio-psychological perspective in computer-mediated communication as the measures and research methods to date have been few and have not been validated. In addition, the fact that studies conducted in traditional classrooms point toward teacher immediacy and/or social presence as a highly significant factor in improving instructional effectiveness, it is necessary for research to be continued in these areas in relation to online learning in order to build a better model of online education.

By beginning the examination of available research studies conducted on the construct of teacher immediacy, it is evident that this construct is essential to learning in terms of affective, cognitive, and student attitudinal effects. By reviewing the research, teacher immediacy has demonstrated that it not only affects outcomes but also student, and possibly instructor, satisfaction with a course (Moore, Masterson, Christophel, and Shea, 1996).

In addition, the construct of social presence appears to have subsumed that of teacher immediacy while also taking into consideration the fact that some medium (e.g. computer, satellite television, audio-tapes) is in some way altering the learning environment. Moreover, the research on social presence has demonstrated a shift in thinking for this construct. While social presence theory was initially considered a quality of the medium (Short, Williams, and Christie, 1976), it has been demonstrated by research studies that this may not in fact be the case. Instead, recent researchers in the area of online education and computer-mediated conferencing claim that social presence should be considered to be a quality of the users of a medium. Gunawardena claims that social presence can be created or "cultured" in computer-conferencing environments, just as it can be created in a traditional classroom. Although nonverbal immediacy behaviors, such as facial expressions and dress may not be transmitted via computers or other mediums, the possibility exists that users of a particular medium may not only compensate for their loss but also create a parallel set of behaviors (e.g. emoticons).

Moreover, these findings have serious implications for the development of online courses. As other areas of research have demonstrated, it is essential that courses are created in a way that demands interactivity among participants not only with the material, but also with each other and instructors (see Irani, 1998, Hiltz, 1994; Romiszowski and Cheng, 1992; Harasim, 1987). This area of research substantiates those claims by demonstrating that the amount of social presence and/or teacher immediacy behaviors play a strong role in the motivation and levels of satisfaction students derive from a course, as well as their learning outcomes in terms of cognitive and affective behaviors.

Finally, there is a significant need for further research into both teacher immediacy and social presence constructs. Not only because they have thus far proven to be essential to learning outcomes and student satisfaction, but also because there is a lack of research in these areas in both traditional learning environments and especially the online learning environment.

**Purpose**

XXX. More specifically, the purpose of this paper is to examine the course activities and the nature and frequency of instructor participation/interaction as they relate to students' perceptions of overall course satisfaction.

**Methodology**

Participants

In the fall of 1999, surveys were posted in a common "bulletin board" area and students enrolled in the online courses were asked to complete the surveys. XX of the XX students, only XX responded to the survey. The low student response rate is one limitation of this study.

**Instrumentation**

One focus of the posted survey was to gather students' perceptions regarding the social presence of the instructor, medium of delivery, and satisfaction with online course. Students were asked to give background information regarding their education (e.g. number of college credits, gender, age, etc.). Next, they were given 13 Likert-type questions with responses ranging from 1 to 5 (strongly agree to strongly disagree). Finally, they were asked to answer 6 open-ended questions to gather further detail regarding the Likert-type questions. All of the questions, both Likert and open-ended were then coded so that analyses could be run.

**Results**

Due to the low number of respondents, a nonparametric test of bivariate correlations (Spearman's rho) was run and analyzed. By looking at the bivariate correlations between overall course satisfaction and the Social Presence Scale (modified from Gunaward and Zittle, 1997) we found the following significant correlations:

- Online or web-based education is an excellent medium for social interaction.
- The instructor facilitated discussions in the course.
- The instructor created a feeling of an online community.
- The instructor facilitated discussions in the course (significant at the .05 level, significant at the .01 level)

**Discussion**

Thus, the significant correlations indicate that there is indeed a strong relationship between the social presence students' perceive in an online course and overall course satisfaction.

Subsequent studies are looking at these areas as they relate to students' perceived learning and to instructor reports of student learning. These studies are informing our instructor training process to emphasize effective use of "airtime" in designing course activities and in participation during course delivery.

**Implications for future research**

Future research implications include the need for further study into the area of social presence and online courses to determine the best possible course design as well as indicators for successful courses.
The Affordances and Constraints of Asynchronous Learning Networks:  
Looking at Interaction in an Online Environment

Jennifer C. Richardson, Craig Tunwall, and Carol Carnevale  
Center for Learning and Technology  
SUNY Empire State College  
Saratoga Springs, NY, USA  
JennRich1@hotmail.com

Introduction

As researchers in the relatively new dimension of online learning, we need to gain a better understanding of the different interactions that can and do occur in these developing learning environments, as well as their effect on students' levels of satisfaction. The positive relationship between students' satisfaction with instruction and their subsequent success in a course (Pascarella, et al., 1996) is further linked with the integral role that interaction plays in the level of learning attained by students (Vygotsky, 1986; Maxwell, Richter and McCain, 1995; Reeves and Reeves, 1996). More importantly, "few chances to interact with the instructor limits students' ability to clarify and negotiate instructional goals, explore alternative methods, or construct meaning within in a social context based on personal knowledge (Garrison, 1993)."

The importance of teacher-student interactions in successful teaching episodes is supported by a large body of research, much of which illustrates the belief that without interaction, knowledge, whether it be in the form of concepts, skills, or strategies, tends to be inert, and learner's lack the ability to apply the new knowledge effectively (see Laurillard, 1994; Bennett and Dunne, 1991; Webb, 1991; Clements and Nastassi, 1988; Vygotsky, 1978). To quote Oliver and McLoughlin (1997), "few dispute the advantages offered by interactive elements that support dialogue in teaching and learning. Communicative interactions can be used to engage learners, to cause them to reflect on and to articulate ideas. Interactions encourage and facilitate cognition and play an important part in promoting learners' intellectual operations and thinking processes (p. 37)." In addition, when high levels of interaction are present, students report that they experience more than in situations that involve low levels of instructor-student interactions (Richard, Gorham, and McCroskey, 1987; Gorham, 1988).

When dealing specifically with web courses or online courses, interaction and feedback have significant impact on the learning process since they add value that results in improving quality and success in those courses (Hazari and Schnorr, 1999). In addition, Comeaux (1995) has also found that interaction and involvement lessened the psychological distance for students at remote learning sites. Moreover, the findings of Moore and Kearsley (1996) and Cornell and Martin (1997) show that interaction and feedback from the instructor are factors that not only play a role in course satisfaction but also in course completion. Similarly, Barker, Frisbie, and Patrick (1989) argue that the effectiveness of distance learning is increased through enhanced instructor-student interaction. This line of research is further validated by studies on feedback within the distance education model and its relation to the attitudes of students (McCleary and Egan, 1989).

Purpose

The purpose of this paper is to determine if interaction in online courses has an effect on students' perceptions of that course. More specifically we would like to establish a better understanding of the possible relationships that exist between students' perceptions of interaction in online courses and overall course satisfaction.

Methodology

Participants
In the summer of 1999, surveys were sent out to students enrolled in online courses through the Center for Distance Learning at Empire State College for the Spring 1999 semester. Of the 127 possible participants, 37 responded, giving us a return rate of 29%.

Instrumentation
The focus of the distributed survey was to gain a better understanding of student’s perceptions of learning, learning styles, instructor interaction, and student-to-student interaction. Students were asked to give background information regarding their education as well as the number of courses taken in online format. They were given 13 Likert-type questions with responses ranging from 1 to 5 (strongly agree to strongly disagree) that dealt with interaction and course satisfaction variables. Finally, they were asked to answer 6 open-ended questions to gather further detail regarding the Likert-type questions. All of the questions, both Likert and open-ended were then coded so that analyses could be run.

Results
Correlations between three of the four interaction indicators examined were statistically significant at the p<.01 level. An examination of the analysis revealed the following: students’ perception of instructor interaction (in general) and overall course satisfaction had a strong positive correlation (.615); students’ perceptions of instructor feedback and overall course satisfaction had a strong positive correlation (.732); and students’ perceptions of interaction with other students for the purpose of offering support and/or differing perspectives and overall course satisfaction registered a moderate positive correlation (.474). However, students’ perceptions of interaction with other students (in general) and overall course satisfaction did not indicate a statistically significant correlation (.07).

Discussion and Implications for Future Research
The aforementioned findings indicate that there is indeed a strong positive relationship between students’ perceptions of interactions in online courses and their satisfaction level with those courses. Moreover, these findings indicate instructor feedback and course satisfaction are the strongest relationship, which tells us that students perceive the importance of scaffolding their knowledge with that of the instructor. Similarly, while students’ perceive interaction with other students to also be important, it is not perceived to be more important than interaction with the instructor.

Subsequent studies are in progress examining which course activities effect these relationships as well as how these areas relate to students' perceived learning and to instructor reports of student learning. Finally, these studies are informing the instructor training process to emphasize effective use of "airtime" in designing course activities and in participation during course delivery. These studies will also examine the demographic variables of the student population to look for potential effects.

Automating Online Course Evaluations Over the WWW

Guido Rößling, Bernd Freisleben

{roessling,freisleb}@informatik.uni-siegen.de

Abstract: Evaluations are regularly used in many universities. Manual evaluation is very time-consuming, and therefore a natural candidate for delegation to computers. To avoid duplicating code or evaluation forms, we have developed a collection of tools that can address all evaluation needs. Statistics can also be gathered on the fly by accessing the tools online.

Introduction

During the last year, we have implemented WebWorks, a tool suite for Web administration in teaching. In this paper, we describe the subcomponent for online evaluations of the WebWorks project. Several other components of the WebWorks tool suite have previously been described elsewhere (see references), and include support for administering online knowledge tests, text and animation generation, an animation tool, and automatic indexing.

Evaluations are regularly used in many universities for a variety of different courses. The basic evaluation process usually remains the same; sometimes, the only difference between two evaluations lies in some questions, date and title. Thus, it would be helpful to have a single tool that can handle an arbitrary number of evaluations and is easily customizable. For this purpose, we have developed a collection of Perl tools that support the whole evaluation process over the WWW. One tool is responsible for generating the evaluation forms and storing the entries, while another tool handles the generation of evaluation reports in a variety of formats.

In the following, we will briefly outline the tools and their functionality.

Generating Online Forms Using the feedback Tool

The tool feedback is responsible for generating a HTML form according to the settings for the current evaluation context and parsing user input. The basic structure of the feedback tool is shown on the left side of figure 1.

![Diagram](image-url)
All entries apart from date and title are components allowing for easy reuse and dynamic exchange. Thus, it is very easy to reuse a given set of questions and possible answers (called "catalogue") in a different context by simply replacing the author and course components. feedback currently supports standard text messages in both English and German, but can easily be extended to other languages. The formatter component can currently provide output in either ASCII, HTML and \LaTeX{}; we are also working on providing RTF output.

When a user accesses feedback with a given access key, the required components are determined and used to build a HTML form. The HTML elements radio button, selection menu, checkbox, text field and text area are supported. Upon submission of the form, feedback checks if all entries marked as mandatory are given, and if so, generates a new entry into the log file.

Each catalogue consists of a set of question entries. Each question entry contains a question text, type and a list of answers. Furthermore, the author can mark any question as mandatory, and select whether the evaluation of the entry should be available to all users, only the author, or remain completely hidden. Registering a new catalogue requires specifying the entries shown in figure 1 and entering a single line in the ASCII-based registry.

**Automatic Evaluation Report Generation Using backEval**

The backEval tool has the same basic architecture as feedback, as shown in figure 1. Any user may access the tool via the WWW to get up-to-date statistics on any given evaluation; however, as mentioned before, authors may restrict the availability of entries.

The generated page contains all questions visible to the current user including their evaluation. The evaluation lists the question, all possible answers and how often they were chosen by users. Text inputs resulting from text fields cannot be displayed in this way, as it is rather unlikely that two users have entered precisely the same text. Thus, text entries are shown in formatted lists.

Statistics are generated in either ASCII, HTML or \LaTeX{} format, with a RTF implementation under development. Except for ASCII format, colored bars are used to highlight the percentage of any given answer. It is thus easily possibly for any user to print the current evaluation directly from their preferred browser.

backEval has a number of options for modifying the display of the statistics. It can also show the submitted entries separately in the order they were given, making it applicable for tasks such as online registration. Due to privacy concerns, this evaluation can only be selected by the authenticated author of the given catalogue.

You CAN Get There From Here - Developing Assessments from Skill Standards

Peter Saflund, Bellevue Community College, USA
Lauren Hebert, The Chauncey Group International, Inc, USA

This paper describes effective ways that the nationally validated Information Technology Skill Standards developed by the NorthWest Center for Emerging Technologies have been used by the Chauncey Group, Division of Educational Testing Service to develop vendor-neutral certification exams in eight IT skill cluster areas. The paper will also describe preparation workshops and educator versions of the exams that allow faculty to demonstrate or certify their expertise in Information Technology, and how educators benefit from the program.
Collaborative Hybrid CD-ROM / Internet in a "Learning by Doing and Creating" environment

nsala @ arch.unisi.ch

Abstract: Constructivism is learning which takes place when learners actively construct their own reality and/or knowledge or least interpret it based upon their perceptions of experience. Constructivism, as theory of learning, is a subject which educators are beginning to discuss in connection with Distance Education and Computer - Mediated Communication. The use of multimedia technologies can help the constructivist theory because it is possible to build a "Learning by Doing" environment that combines multimedia technologies and the constructivist approach. In educational process the students generally build hypertexts and hypermedia on subjects which they know. Their teachers control and give them all information to include in hypertext. Using this approach the role of the students is passive, because they transfer, on digital documents, information furnished by the teachers. For this reason I have thought to control two different samples of students that have researched, selected information, and produced a hybrid CD-ROM/Internet on a subject which they didn't know before (Neural Networks). This paper describes this project which I have named "Learning by Doing and Creating" (LDC).

Scenario

Two different samples of students (aged 17-20) of a High School (specialization course in Information Technologies), during the school years 1997-98 (15 students) and 1998-99 (14 students), have researched, studied and built a hypermedia (on Neural Networks) using the new educational technologies and they will propose this CD-ROM to other students. This hypermedia has been developed in the Laboratory of System and Techniques of Transmission (3 hours in the week throughout the school year) in a technical institute in Italy. I have organized my educational project in three stages.

First stage of the project

In the first stage, school year 1997 - 98, I have worked with 15 students (aged 17 - 19). I have proposed them a simple multiple choices test (8 questions) to control the students' knowledge on the Neural Networks. The percentage of correct answers has been the 27,5% (33 on 120), deducing that my students didn't know the subject "Neural Networks" and they were a good sample to try my "Learning by Doing and Creating" (LDC) approach. After the test, the students have researched in the Internet: information on hypertexts and on hypermedia; (their history and their organisation), how to build a hypertext (using HTML) and hypermedia (with an introduction to Java Language and Java-Script). I have also explained them how to use some software and hardware tools to digitized the images, the movies, the sounds, and the correct calibration of the communication codes in educational hypermedia [Sala, 1999a; Sala, 1999b]. Inside this approach I have introduced some novelties. For example: a periodical "time out" which is a stop of all activities in the classroom. It is necessary to discuss the students' problem during the project (e.g., the coordination with the components of the group, the interaction between the groups, the organization of the hypertext, and so forth), and a journal of the classroom where the students resume all project' activities done in a day (like a "logbook"). The sample of the students has:

- researched in the Internet some information on Neural Networks,
- researched the main bibliography (using the public libraries),
- selected the information,
- built the storyboard of the hypertext (they have chosen a hierarchical hypertext),
- chosen other information to insert in the hypermedia (e.g., animations, movies, and so forth);
- realized and controlled the hyperlinks.

The hypermedia has been carried out using the Hypertext Mark Up Language (HTML) because it is easy to learn, it can be integrated with Java Applet and Java Script to introduce the multimedia codes (e.g., the animations, the movies), and
we can use a common browser without runtime module (e.g., Netscape Navigator™ or Internet Explorer™). First version of this hypermedia, finished in month of June 1998, comprises: 20 pages of hypertext, 20 animations using Java language and Java Script, 2 movies (one is an interview to an expert on Neural Networks, the other is on the authors). After the hypermedia production my students have studied, for six hours, the subject "Neural Networks" (NN) using their CD-ROM. During the learning phase the students have noted that it is difficult to study using only the monitor without a textbook. For this reason they have selected the text frames and, using "Copy and Paste", they have made notes. An other problem is the cognitive overhead, which is avoided only by the best students. I have also controlled their knowledge using multiple-choice tests (15 questions, the first 8 questions were the same of the first test). The worst case of this multiple-choice test corresponds to the question 15 ("To draw some model of Neural Networks") because this subject is difficult to understand for Secondary School students and it has been proposed in a long hypertextual page (using the scrolling). The results of these analyses have been encouraging, because the 65.3% (which corresponds to the 147 correct answers on 225) of my students have achieved the educational goals that I have established. The comparisons between the first test and eight same questions of the second have demonstrated that the students have learnt the subject Neural Networks (first test 27.5%, second test 72.5%). My contribution to the project has been well evaluated. I have used the negative data to modify my interaction with the classroom; this feedback has been important because all educational process was under control.

Second stage of the project

In the second stage, school year 1998-99, I have worked with another sample of 14 students (aged 18-20) of the same technical school. I have answered to the entry test on NN (the same of the last sample) and after they have analysed the hypermedia produced. They have evaluated, answering to the multiple choices test, the icons (e.g., the shape and the image should recall the linking function); the hot words, the text-frames, the visual interface, the navigation in the hypermedia. The results of this analysis have been used to modified the first version of the hypermedia. The second sample of the students have modified the contents of the hypermedia difficult to understand (e.g., some pages dedicated to the Hopfield's model), and they have added other pages (e.g., three pages dedicated to the Kohonen's model). New version of this hypermedia comprises a map which performs the "here we are function"; 90 pages of hypertext, 25 animations using Java language and Java script, 10 digitized videotaped segments (quick-time movies), 30 links to other Internet sites on Neural Networks. In the last part of this second stage, I have controlled the students' knowledge on Neural Networks using the same multiple choices test that I have proposed in the school year 1997/98. The correct answers have been 157 on 210 (74.8%). I have also made a comparison with the two samples of students using the histograms.

Conclusions

This educational project is a "work in progress". In the school year 1999/2000 I shall control a third sample of students that will study the Neural Networks using the traditional educational methods, and I shall compare the educational results with the other two samples. This LDC approach is an example of "Learning by Doing" environment where some students build an educational hypermedia and they learn while build it. I have added the term "Creating" because there was also the creativity during this hypermedia development (e.g., the creation of the animations, the choose of the graphics interface, and so forth). Some researchers, such as Spiro and Jehng (1990), have emphasized the active role learners must play in order to learn in hypertext-based learning environments. Therefore, the multimedia technologies can help the teachers to complete this evolution. I think that the "Learning by Doing and Creating" approach is in agreement with this old Chinese proverb: "If I listen, I forget; if I see, I remember; if I do, I understand".

A Study of Usability Evaluation for Interactive Computer Mediated Teletraining Systems

Françoise Sandoz-Guermond
sandoz@gprhp.insa-lyon.fr
ICTT - INSA de Lyon
Bat 401 -20 Av. Albert Einstein 69621 Villeurbanne - France

Gerard Beuchot
beuchot@if.insa-lyon.fr

Abstract: The objective of this study was to evaluate teletraining in an interactive computer mediated system through the communicative behavior, the specificity of each situation in order to better understand and to optimize the communication in group. In a first part, we propose a contextual evaluation method in order to evaluate performance reached by the trainees, actors and socio-technical system behavior, and satisfaction of actors. We have applied our methodology in the evaluation of CETTE (Communication Environment for teletraining in Engineering) (Gradinariu 1999). We present, then, some original results of this evaluation and their interpretation in lecture, practical works and cooperative project context.

Introduction

In a complex and new situation it is desirable to use several methods and different sources of information to evaluate the same objective on populations, which carry out the same task in the same environment and to increase gradually the complexity of the task by diversifying pedagogical strategies.

An other point which is seldom precise in studies about the experimental evaluation is how to analyze series of data and observations to which we attach different significance and which have not the same nature when the evaluation methodology is based on a multiplicity of methods.

Methodology of Evaluation

We propose a contextual evaluation method based on (see Sandoz-Guermond & Beuchot 2000):
- quantification of the training outcomes about cognitive activities: memorization, understanding and mastery
- analysis of communication types used during each activity to resolve the task. We suggest to conduct objectives observations made by human evaluators and measures on the level and the content of the communication, during each session of apprenticeship. The measures are collected by software sensors in order to evaluate the behavior of actors and the behavior of the socio-technical system during each training session.
- questionnaires on the perception and the usage of the different items of the environment (Rao 1994) that make easy the communication during the training session (interface quality, effectiveness of new technology, concentration, interaction, motivation) in order to evaluate the satisfaction of actors in the mediated environment.

Data Analysis and Results Interpretation

Experimental procedure

Experiments were conducted on two student populations with a lecture, practical works and cooperative project on numerical command language for mechanical tools: 19 students with the bachelor in manufacturing engineering which have a good background in the training subject and 6 undergraduate students with low knowledge in this subject. The same kind of session with the same contents of the training subject material was carried in a traditional environment with 8 students preparing their master in mechanical engineering.
Training outcomes

The question is to compare the training effectiveness in mediated environment with traditional situation. In an interpretative and comparative cognitive perspective both on the nature of the population (knowledge, capacities) and the technology (traditional, multimedia supported by the computer), we determine, for each of the three cognitive activities (memorization understanding and mastery) similarities, small differences, great differences, surprised on an ordinal scale and report. Statistical results indicates that trainees in the remote site achieved quite identical results than in the traditional environment. Training outcomes' standard deviation of the student in the mediated environment is very small compared to the student in the traditional environment, indicating that their grades were very homogeneous.

Satisfaction of the actors

In order to analyze the data from our study (Rao 1994), we firstly ran descriptive statistics on each of the items and their variables. The results (means and standard deviation) indicate that the different groups have appreciated the training progress, they are quite motivated to part in it. The students in the mediated teletraining system interacted more among themselves and with the professor than did those of the traditional environment. We observed a significant difference concerning the concentration: the remote students were also more concentrated than were those of the on-site location. The second step in the analysis of replies to the questionnaire is to understand which items indicate a difference of satisfaction in the population. The analysis of the variance of replies to questions allows thus to define the constructs of the usage quality with their variables (components) as below:
- Acceptability of the communication technology: perception of the teletraining environment, use of computer tools, remoteness
- Difficulty to achieve their task: quality of the interface, interaction, accessibility of the information
- Personal investment: motivation, participation, need to solicit the trainer, concentration
- Quality of feedback of the system: effectiveness of new technology.

Actors and system behavior

In a situation of physical isolation with possibilities limited of telepresence, the verbal behavior is the real reciprocal orientation tool in the cooperative work. In the cooperative project, generally two students (out of four) are speaking simultaneously. Three criteria allow to characterize the non-verbal behavior: the mutual orientation in the shared work, the behavior in critical situation and the research of the assistance. According to the trainer, due to the lack of feedback, it is very difficult to appreciate the level of comprehension of the trainees in a lecture context.

Conclusion

Our study, we retain a feasibility of the interactive teletraining with computer mediated systems. The usage of the new technologies seems as efficient as in traditional situation. There is no significant difference during their use. However, we note a greater students' concentration and tiredness during the teletraining session: the duration of the session must be reduced, the lecture re-designed and new pedagogical strategies introduced.

Abstract: Our experience in distance learning has shown us how important it is to have well structured materials which are designed from a pedagogical point of view, and keeping in mind what, how and when we want to teach or encourage learning. That is why we have created an authoring tool, which will meet the needs of our institution.

Introduction

The Methodological Resources Assistant (MRA) is a project being developed by the Universitat Oberta de Catalunya (UOC), which is a distance learning university based on the concept of the ‘Virtual Campus’ and the use of multimedia teaching materials.

We must place this project in the context of the task developed by the UOC and other institutions and companies created from the Foundation for the Universitat Oberta de Catalunya. In only few years the growth of services offered by our university and its associated institutions has created the need to contact a high number of collaborators, subject specialists, professors from other universities as well as professionals from the world of business, who could act as authors of our material or develop specific training tasks.

We have become aware of the need to train these authors (usually specialists in a field of science or other areas of study) in how to elaborate teaching material for distance learning. This implies a training task, centred not only in the understanding of the distance teaching-learning process, but also in the knowledge of resources and tools to make the elaboration of material easier. The MRA was created to answer the above-mentioned needs.

The Methodological Resources Assistant

Figure 1: ARM main interface
MRA main features

1. What is the MRA?

It is a system for the design and elaboration of methodological resources adapted to different objectives and training needs, in a virtual learning environment. Its aim is to provide a wide range of distance learning methodological resources as well as tools to facilitate material creation, for professors and authors.

2. What can be found there?

The MRA enables:
- Looking for resources
- Accessing to a concrete resource report by selecting its name.
- Acquiring / Offering ideas
- Consulting methodological aspects
- Creating activities: programs and templates
- Giving guidelines or advice of use

Every resource report provides information about the typology or category that the resource belongs to, the goals that can be reached with it or the activity given; the resource description – structure, stages, functioning, etc.; the application – guidelines or directions to improve the possibilities the resource offers; the work dynamics to follow; the view of concrete examples; the elaboration guidelines for the resource; the bibliography reference; and templates and programs to create resources easier.

3. Which is its structure?

The MRA is structured as a system composed of different elements:
- A communication space: a forum, a mailbox, FAQ's...
- Help or Guidance about methodological aspects
- The searching form (the tool that helps the professor or the author to know the best resource features for their material elaboration)
- The result of the searches' list
- The resource reports
- The examples
- The templates
- The data base that supports the system

Conclusions

- This space allows educators to gain access to up-to-date information concerning educational activities and the student body.
- The tools used in the evaluation process are also incorporated which allow educators to introduce and consult information concerning the progress and qualifications of students.
- The exchange of ideas and collaboration are encouraged between all of those people who participate in the teaching process by means of the environments that are reserved for telematic intercommunication.
- Another function of this integrated space is to grant direct access to the university's administration services and to help in solving educators' problems and doubts.
- Furthermore, educators are involved in an on-going process that is intended to improve the educational model through surveys and in this way detect strong and weak aspects.

Rethinking Education:  
How we Make our Learners Instructors

Prof. Dr. Mr. Ir. S.C. Santema, Ralph Genang  
Delft University of Technology  
s.c.santema@io.tudelft.nl  
genang@scgroup.nl  
Department Industrial Marketing, The Netherlands

Abstract  
This paper describes a pilot research-project that will be carried out during our courses  
at the Delft University of Technology in March and April 2000. After this pilot we plan  
to internationalize the project to interested foreign universities.

We believe the project “How we make our learners instructors” will make better  
learners, learners who learn to educate themselves and to educate each other, and  
learners who know how important knowledge sharing can be in obtaining better results.

We facilitate our learners to define their own learning paths through the knowledge and  
additional information in our learning environment. We focussed on the self-expression  
and judgement of the learner. This resulted in a dynamic knowledge interaction between  
the learners and the instructor, meanly led by the learners.

We would like to present the results of this project during our presentation at  
Edmedia2000

Introduction

As ICT practitioners for educational purposes, we feel that a new phase is coming up. The past years the learners  
learned to work with the tools and learned how to use them in the field, today our learners become more and  
more self-confident and self-instructing. For educational purposes this means that the discussion on ICT shifts  
from the techniques –how, to the content –what, and the instructors role (as compared to the learner’s role) –who.

In this article we focus on the role of the learner and the instructor.

In the first paragraph we describe how we educate our courses at the Delft University of Technology. In the  
second paragraph we will briefly describe what we have done in the past three years to understand more about the  
roles of the instructors and the learners. In the third paragraph we formulate the project in 2000. We will  
summarise the results of the project in the last paragraph.

Education at the Delft University of Technology, Business to Business marketing

In this paragraph we will briefly describe our thoughts about education and the social dimension of education.

Education:  
Education in our opinion is an instructor-learner relation where individuals challenge each other with new ideas.
As Francois Jacob (1991) has put it, human beings are programmed to learn, they are curious beings, a  
characteristic without they could not know. So education is learner orientated as well as instructor based. Our
main question at this point is: How can we challenge the learners, in order to make them so curious that they become their own (and each other’s) instructors?

Before the use of ICT we graded our learners on their problem solving capacities, their personal opinion, their theoretical founding and their knowledge on the subject itself. Our experience with this type of examination is that most students were used to reproducing content an instructor or book had told them, they were parrots. ICT changed students from parrots reproducing content into supporters of the knowledge. It gave us possibilities to improve the learner – instructor relationship. ICT offers solutions to warm up the knowledge flow between learners and instructors. We are mainly talking about the way knowledge is brought across.

In the next paragraph we will come back on our experiences with ICT based education.

Social dimension

According to Josef Schubert (1983) the activity specific to human beings is the cooperative use of “tools” in the production of “goods”. Our main question in our courses is:

How can we motivate the cooperative use of “content” in our classes to create “new knowledge” among the participants (learners and instructors)? Before the use of ICT we had no idea how the learners cooperated within their group to solve the assignments. In the next paragraph we will come back on how ICT enabled us to monitor the participation of the learners with the content and with the other learners in the course.

ICT based education at the Delft University of Technology (1996-1999)

The Delft University of Technology, Business to Business marketing development project on the use of ICT instruments started in 1996. The first instrument was the use of e-mail as a means of interactive communication between instructor and learners. The second instrument, videoconference (PictureTel), enabled us to interact real time with learners on a remote basis.

Streaming media: In 1998, the use of real-media resulted in the first online course (on the Internet) in the Netherlands. Next to the 80 regular students, 2500 individual people logged in on our course and followed the course Business to Business Marketing live on a remote basis.

Learning environment: During the last two years we developed a third instrument the learning environment based on WebCT. (http://webct.io.tudelft.nl:8900/public/B2B_online in Dutch). WebCT offered us an environment where we could easily upload our content in. It also contained all the tools we created ourselves for our first live online Internet course, like chat and a whiteboard. Besides these tools, WebCT made it possible to create student groups in which the learners could make their assignments. The most interesting tool of WebCT is the student tracking option. With this tool we can measure the earlier mentioned participation of the learners. We can monitor the learning path of each individual learner. How much time did he or she spend on the course site, how much questions did the learner ask and answer? Did the learners cooperate online? Of course we could not monitor the face-to-face discussions learners had about the course material or the time the learner spend on a document he or she printed but this monitoring tool actually made us change the way we taught our courses in 1999.

Bodies of knowledge: In December 1998 we divided the course material in 100 subjects. Each of the subjects represents a body of knowledge. We recorded a video clip for each subject where the instructor explains the subject in about two minutes, and we started building a database of related publications to the subjects. By the time our next course started in the spring of 1999, all the course content was available online in multimedia mode. The instructor did not teach in the classroom anymore. All we had to do is challenging the learners with
actualities and cases presented by the instructor or invited speakers or actualities the students themselves heard about in the news.

Dynamic content: According to their own learning habits, students who use our online learning environment are free to choose the medium that fits them best. The content has become dynamic. Their options are: textbook material on the subject, sheets (transparencies) with streaming media explanation by instructor, with bullets on the subjects, articles (papers) on the subjects, streaming media (realmedia), video of last years lectures, news forums, where students can discuss a subject, cases, other subjects (if any), e.g. links to companies working in the field or famous for their marketing efforts, or links to other universities.

In practice students choose their own paths through all this possibilities, media and content. The instructor coaches them, challenges them and tries to motivate them to learn more from the available material or each other.

As we now have over 80 learning paths of former students, we have clues how to digitalize the content of our course. We feel that in digital courses the non-linearity of the chosen learning path of learners and the possibility to monitor this path is very important. The dynamics are in the path, not in the content.

The multiple media approach has resulted in better grades for our students as compared to the traditional classes. The commitment, time spend and the grades did statistically significant change with previous years.

The ICT based education project at the Delft University of Technology in 2000

For educational purposes we use ICT as an open knowledge transfer tool, or perhaps better put: we facilitate the learners to define their own learning paths through the bodies of knowledge and additional information in our learning environment. The shift we created in these years' classes was a shift to dynamic interaction between the learners and the instructor.

So actually we want the learners to become instructors of each other.

The educational purposes of the 2000 project:

We have different levels of knowledge in our environment: commodity data, commodity knowledge and new knowledge. (Santema, Genang, 1999) Actually all the bodies of knowledge are just bodies filled with interesting data, or as we call it "commodity" data. As Karl Marx (1957) quoted, a commodity is a mysterious thing, a hieroglyphic - a picture thing, a "beautiful" system now taken to be difficult or impossible to decode. Last year we succeeded in motivating the learners to react on this "commodity" data in order to "learn" it, to deepen it and make their own knowledge of it. But this is not enough. The learner should be able to share his or her knowledge with other learners following the course. Can we motivate them to state what data they found (and where) and what they did to process it in order to make it knowledge for them. And what happens when they discuss it with other learners. Will they motivate their progress, will they change it, will they convince others and therefore deepen the knowledge they derived from the data? Can they add new knowledge?

In order to achieve this we have to reward the learners on information and knowledge sharing. We deliberately instruct groups of learners to look at a subject from different angles and using "knowledge" out of our learning environment or any available medium to substantiate their opinions. The focus of education shifts more to the self-expression and judgement of the learner. (Sakamoto, 1999). There will be no instructor-based lectures but student-based lectures. The lectures of the instructor are recorded and accessible through ICT. The time we save by not giving lectures anymore is now for learners. They can discuss face-to-face their learning moments, ideas with other learners or experts. Learners prepare their own subjects, they have to use their own hunger to learn to
motivate their fellow learners, they become their own instructors. This is how we motivate the cooperative use of "content" in our classes to create "new knowledge" among the participants. We summarise this set up in figure 2, model 2000.

Figure 2: model 2000, possibilities for ICT based classrooms, Santema Genang, Delft

Objectives of the 2000 project:
1. Monitor the interaction/exchange of commodity knowledge
2. Monitor the interaction/exchange of "www"-knowledge
3. Monitor the interaction/exchange via questions and discussions
4. Monitor the use of references stated by the learners

The interaction/exchange of commodity knowledge: We achieved that learners used the course content published in the learning environment to teach the other learners.

The interaction/exchange of "www" knowledge: The learners did look for information outside our WebCT-based environment. They had to find literature on the topics in our learning environment

The interaction/exchange of questions: Last year the 80 students created a huge database of questions on the 100 topics in our course. Each student had to post 10 questions and answer 10 other. We were surprised of the level of the questions. Actually the students really asked very difficult questions and the answers were also good to very good. They used examples out of multiple media resources to substantiate their answers. In the end each student could look up their posed questions and read the given answer. We would like to optimise this "self-examination" system more and we will create a database where students can look up last years questions and answers by topic. An interesting experience we have with questions posed by students is our Frequently Given Answer (FGA) list. Instead of making a Frequently given Answer list, which is actually not a personal way of communicating, we are able to personalize every answer we give to question of a student by copy-pasting the right answer from our FGA-list to his question in a personalized e-mail. The students like this way of communicating because they feel they get a personalised answer to their very important question.

Monitor the use of references stated by the learners: The more a learner shares his knowledge or uses one of the earlier described ways to offer "new knowledge" to his fellow learners, the more points he will get. In order to reward our students on their information and knowledge sharing, we have to monitor the use of references they stated in their new knowledge; this could be a reference to each other. So the graduation principle is based on
sharing knowledge instead of reproducing it. At this point we have no idea how we can monitor this and how much time an instructor has to spend in this process, but we think it is worth trying.

Summary of the expected results of the 2000 project

The project “How we make our learners instructors” will make better learners, learners who learn to educate themselves and to educate each other, and learners who know how important knowledge sharing can be in obtaining better results. Especially this last point is a very big issue in companies around the world: What to do with knowledge.

As the course will take place in March and April 2000, the results will readily be available at Ed-Media 2000.

Abstract: Due to the steadily growing interest in Austrian Literature, we had initiated an Open Distance Learning (ODL) course. For this purpose, we build a framework that allows to record the data required for publication in a highly generic form. The aim was to separate data from presentation, to prevent information loss and to gain flexibility for future use of the data in other (scientific) projects. We decided to store data in a database using a GUI for easy access. The database is then transformed into XML using Java and DOM/SAX libraries for flexible generation of different presentation formats like HTML and PDF. This guarantees usability in other contexts. With this approach, we anticipate the possible direct use of XML using XSL in the future.

Basic Ideas

Experiencing a steadily growing interest in Austrian Literature, Prof. Zelewitz, German language and literature scientist at the University Salzburg, initiated an Open Distance Learning (ODL) course in cooperation with a team of technicians in Vienna. A set of basic ideas were taken into consideration when starting the joint project:
Storage of generic information instead of direct publishing was required for having the option to reuse the data for future projects. So a highly generic representation of the data with a minimal loss of information was pursued. Furthermore, for the processing of the data, platform-independent tools were preferred (Java, XML, DOM, JDBC). Metadata initiatives like Dublin-Core and RDF should be considered for easy interoperability with other information systems (Lassila 1997, DublinCore 1997).

Besides this set of conditions further requirements for our co-operative work are: The two teams are located in two cities (Salzburg and Vienna) and therefore a good concept for information exchange and documentation is needed. Additionally colleagues from the Austrian Ministry of Science and from institutes of other European countries were interested in information exchange. Hence both results, discussions and also technical information and instruction into new software tools or database interfaces had to overcome a long distance.
Generic Concept

In our project it was our goal to avoid common problems of poor planning, i.e.: Loss of information, Low flexibility (reuse of data is not possible without a huge effort), Layout and content get mixed up (keeping a consistent layout in the whole website is a serious issue). We decided to use a generic data concept, where Information is structured and entered into a relational database management system (RDBMS); We try to collect and structure not only on the surface “hard” structured data, but even “soft” data like lecture texts. Following this approach we avoid the mentioned problems and it is again easier to add meta-information (metadata) like: keywords, subjects, abstracts, links, etc. and maintain the data (like URLs, image-links, and so on). The next step is the generation of XML files, which contain the information for publication and the meta-information. The XML data is then used to generate the files for publication (HTML and PDF).

Data Structures

Besides some “free” elements the data in our project could be divided into a set of main components, namely Biographical Articles, the “main” information for distant learning: Lectures, multimedia elements, original literature (Citations, Full Text) and an index.

Technical Details

We decided to use Microsoft Access 97 as database system. At the moment there is no need for a multi-user solution so Access is used as frontend as well as for data storage.

We recognized (beside others) the following advantages of XML for our project: XML is a text-format, hence platform and system independent (Bray 1996). This is an important factor to consider because we want to emphasize durability in the storage of information. XML offers the possibility to store all our data without a loss of information as well as handling flexibility which allows an easy publication of the XML data.

The optimal way of publication would be using XML directly! This seems possible as a part of the XML standardisation efforts is dealing with style-languages, particularly DSSSL and XSL. The conceived method is to keep the data without information loss in XML and publishing this data “through” a style “filter”. The problem is, that at the moment neither Netscape Navigator nor Internet Explorer are capable to perform this task in a stable way, but it should be possible with the next browser generation.

The conversion problem can be divided (at least) into two sub-problems: The building of the XML files out of the database and publishing the information as HTML and PDF. As Java has adopted XML as a kind of standard data format, lots of free XML parsers of high quality are available and also the database linking using JDBC (Java Database Connectivity) works reliable, we decided using Java as platform independent scripting language (Sun 1999, Leventhal 1998). So the XML file creation as well as the HTML/PDF publication were done using Java programs and conventional libraries like JDBC, LotusXSL, ProjectX and others.

Support Environment for Distributed Case Studies

Freimut Bodendorf & Manfred Schertler
Department of Information Systems
University of Erlangen-Nuremberg
Germany
bodendorf@wiso.uni-erlangen.de, schertler@wiso.uni-erlangen.de

Abstract: This paper outlines a multimedia based and telecommunication oriented approach to a case study concept. The scenario consists of different phases supported by online computer conferencing and offline groupware tools. It brings together technical and didactical concepts to overcome educational lacks of traditional learning scenarios and to achieve active learning processes. This research work is part of a project to develop teleteaching reference systems supported by the DFN-Verein (Association for Promoting a German Research Network).

Introduction

In higher education at universities the transfer of how to apply knowledge is not satisfying. The challenging combination of learning and practice is missing in many educational scenarios. Case studies are known as elements of a successful and efficient learning environment using special didactical strategies. In combination with new telecommunication technologies the case study concept leads to a modern educational arrangement, which we call "telecooperative case study".

Active Learning with Case Studies

As one of the major aims in pedagogy, active learning has its steady place in the learning process (Euler 1992). To create effective case studies, the contents have to be chosen from real situations. To match this requirement cooperation agreements with companies have to be formed. Companies provide up to date and real life problems which the students are supposed to solve working together in small teams (~ 5 to 8 students in each team). This kind of learning is active because the students need to collect information, find solutions and present their results. The didactical and pedagogical approaches of distributed case studies are based on principles of the curriculum theory, which determine the choice of contents within a case study. The principle of active learning closes the gap between the case study concept and other concepts of learning, e.g., learning by discovery or learning by doing. A combination of face-to-face and computer mediated communication is used to create synchronous and asynchronous communication scenarios. Groupware tools offer the possibility to control contents, time and sequence of the computer mediated communication.

Technical Approach

The technical concept of telecooperative case studies supports a wide range of different synchronous and asynchronous teleteaching scenarios. Flexibility and scalability are offered to all participants. On the one hand telecooperative case study environments have to meet high quality standards that are necessary to display all types of teaching media without loss of didactical effect. On the other hand, for reasons of cost effectiveness and flexibility in terms of location, it makes sense to use as much of the infrastructure as possible. At the University of Erlangen-Nuremberg a technical infrastructure has been set up for multiple kinds of access (Klein 1999). The infrastructure supports low end solutions based on the Internet protocol TCP/IP, medium quality solutions using one or several ISDN channels and high end solutions like transmissions over ATM (Asynchronous Transfer Mode) Codecs, which use the B-WiN network (Broadband Research Network of Germany) (Hoffmann 1996). The technical infrastructure of the telecooperative case study concept has to support the didactically coordinated phases of each case. A single case study consists of six phases (Kaiser 1983). In the first phase an overview of the case is
An external presenter explains the important aspects of the problem and provides the students with additional information. During the second phase the students use different information sources which they discover by themselves or by the help of tutors. In the following phase each student develops an individual solution. As the result of the resolution phase a team solution has to be selected by each group of students. The teams present their solutions during the disputation phase. Finally the students and the external presenter compare the team solutions with the real life solution closing up the case study. Each phase is supported by the telecommunication and telecooperation infrastructure. A more detailed explanation of the realized multimedia infrastructure at the University of Erlangen-Nuremberg is given in (Bodendorf et. al. 1996, Grebner 1997).

**Synchronous and Asynchronous Support Tools**

To support synchronous presentation and videoconferencing at the university as well as on the company side a multimedia managing terminal has been developed. With a special pen and a touch screen the teacher can write and draw as he/she usual does on paper. The editing on the screen is displayed by a local beamer and transmitted to remote access points via the network. The teacher can prepare computer-based presentations with animations, software demonstrations as well as hyperlinks to web pages. Annotations and other presentation material developed during a lesson can be saved and reused later. For distance education scenarios with a high degree of interaction the teleteaching terminal is equipped with feedback lamps beside the control monitors. If a remote participant has a question, he/she indicates this through the feedback lamp.

During the asynchronous phases of the case study the participants use information retrieval tools (e.g. Web-browsers) and Groupware tools to create the team solutions. To support asynchronous cooperation a multimedia repository is provided. The repository works on a database and integrates recorded lectures together with additional learning materials, e.g., presentation slides, graphics, animations, lecturer’s annotations or Web links.

**Conclusion**

The concept of telecooperative case studies offers various starting points to improve educational efforts. The students benefit from this form of teaching because they gain real problem solving abilities. The flexibility and success of this educational arrangement is strongly increased by adding telecommunication technology.

In the near future attention is being paid to new stages of network technology. The research on telecooperative case studies over broadband networks is part of a research project supported by the DFN-Verein called “Teleteaching/Telelearning Reference Systems and Service Center within the German Research Broadband Network”. Within the bounds of the project different technological aspects of distributed teaching and learning are integrated and reference systems are being developed. The service center supports and evaluates synchronous and asynchronous teleteaching scenarios, e.g. telecooperative case studies.

Creating an On-line MBA Program

Robert Schramm
Business Education and Office Systems, College of Business and Economics
schrammr@mail.uww.edu
L. Roger Yin
LEARN Center, Graduate Studies and Continuing Education
yinl@mail.uww.edu
University of Wisconsin-Whitewater
United States

Introduction

The Seminar in Business Communication course was piloted as the first On-Line MBA course offered at the University Of Wisconsin-Whitewater in the Fall of 1997. The College of Business & Economics has made a commitment to offer all courses necessary to complete the MBA degree on-line in a two-year period. The growth of the program coupled with the required availability of courses to enable students to earn their degree in two years has resulted in 12 courses scheduled to be offered on-line in the Spring of 2000. Nine more courses are scheduled in the Fall of 2000.

In addition to the On-Line MBA program, UW-Whitewater is partnering with the University of Wisconsin-Stout Hospitality and Tourism Department, Nottingham Business School, at Nottingham Trent University in the UK, the School of Hotel and Restaurant Management at Oxford Brookes University, Oxford, UK, and the University of Paderborn in Germany to form an international partnership to offer a new concentration in Global Hospitality Management for the Hospitality and Tourism Masters Degree which began in Fall, 1999.

We believe the On-Line MBA is quickly becoming recognized as an acceptable method of earning a quality education at an AACSB accredited school. The increased acceptance of on-line courses will continue to increase demand for our On-Line MBA program into the foreseeable future. The following case study outlines the process used at the University of Wisconsin-Whitewater to plan, develop, and implement the On-Line MBA program.

Defining the customer

The benefits of distance education are well documented. The most often cited benefits are the ability to break down the geographic and time barriers required in traditional classes. When defining your distance education customers, you must analyze their needs and combine those needs with your school’s ability to meet those needs. To excel in on-line courses, students must possess minimal technical skills or the ability to learn these skills quickly and become self-sufficient and self-motivated learners.

Recruitment

Recruitment techniques for on-line programs range from contacting current and past students to placing banner ads on the Internet. An adequate advertising budget is required for a successful on-line program. Tough decisions must be made on how best to use limited monies to recruit the most students possible who possess the capabilities to succeed in an on-line program.

Software

One strong force to push the on-line programs is the popularity and gradual maturity of the World Wide Web. To consolidate information sharing, scheduling, threaded discussion, e-mail, quizzes, gradebook, performance and participation tracking, and other teaching and learning activities, more and more integrated Web-based learning systems have become available. At this point in time, the major contenders in the academic market are WebCT, Web Course in a Box, CourseInfo, and Learning Space. Each of the solutions has strengths and weaknesses, and none is perfect for everybody to use. As the cyber
evolution continues, we advise that you evaluate them and weight the pros and cons for your situation, and select the system that best fits your program development needs, considering the scalability and technical support accessible to the local as well as the remote/on-line users.

**Hardware and Network Infrastructure**

It is essential that both faculty and students should have access to adequate computer systems to handle the demands of the software solutions. For those students and faculty who do not have access to the Internet via local area networks, a 56K modem is the minimum requirement to get on-line.

Uninterrupted network connections and communication channels are the key to maintain continuous interactions among faculty and students. The site where the servers reside should have at least a T1 (1.5Mbit date throughput rate) line to go to the outside world. If more and more streaming video and audio are requested to distribute course content and relevant materials, then multiple T1 lines or even faster communication lines (e.g., T3) should be considered. Carefully planned switching Ethernet may be implemented to relieve the bandwidth requirement for the on-campus network traffic. Faster and more robust application and Web servers also add importance to a reliable and speedy communication line.

**Teacher acceptance/resistance to change**

Resistance to change is an extremely powerful force in any organization. Many people fear change for personal and political reasons. The faculty must adopt on-line programs as their own if the program is to be successful. Training sessions, workshops, individual faculty support, and peer support network are required to gain acceptance of the program. Most successful on-line programs have started with a small core of enthusiastic faculty who were willing to overcome the start-up obstacles present when launching any on-line programs. Once this core of faculty is able to demonstrate successful teaching/learning, other faculty will gradually follow to form the critical mass.

**Technology Training**

Student and faculty training are critical. One of the most common student complaints is the frustration with using distance education tools. Student and faculty training may take the form of a video presentation, on-line presentation, small group training workshops, or individual training via the phone or Internet.

**Student Learning**

Effective distance learning depends on the presence of self-directed learning abilities of the students which can be considered both a component and result of distance education classes. While virtual classes require independent thinking and exploration, community interaction is equally important. A question related to the level of student interaction is that of asynchronous and synchronous instruction. One major drawback of virtual classes is the isolation of students. Synchronous communication can help overcome isolation and allow students immediate feedback from faculty and other students.

A third question pertains to the level of open-ended learning vs. directed learning in distance education courses. Faculty dependence on one-way communication in distance education systems, tends to promote transactional distance between students and faculty creating little more than a correspondence course. Faculty must learn to be the facilitators of learning, providing students with small modules of directed instruction to be followed by open-ended learning opportunities for students.

Finally, when students are first exposed to the non-linear, individual-mediated learning environments created using distance education tools, they are often confused concerning how to interact with the technology. Many students also require training on how to develop independent learning skills.
The NURAXI Web-Based Learning Environment Architecture

Introduction

The fast evolution of today world impels corporations to provide their employees just-in-time training, adapted training and more generally continuous education. To be able to satisfy this demand, authors need means to specify once didactic material and then to reuse, select, adapt and distribute it to different users in different contexts.

Since September 1998, Mediatech is developing the NURAXI multimedia research platform aimed at the design, generation, deployment, management and use of intelligent distance learning environments. NURAXI interacts with the user on the basis of the competency assessment (initial, on-going progress and final), the individual learning style and collaborative learning. Our solution is departing from a document type based organization of courses and training material towards a functionality and competency based model. We consider models and structures for information, knowledge and competencies more appropriate to the new on-line delivery environment than the document-based old one (html-based or not). From a technological point of view, this was made possible by the recent arrival of XML technology, coupled with Java and Web application technology.

Services, Actors, and Core Structures in NURAXI

NURAXI is a flexible platform, built in such a way that the borderline, which separates tasks done by humans from tasks done by machines, is a moving one depending on the context and on the people needs. We use the notion of service to model this moving frontier. You can see services in NURAXI as points where humans can take the control over the system in order to inject more sophisticated information. At the same time, these services release authors and learners from complex tasks. For instance, an author can decide to select solely the competencies he/she wants to teach, letting NURAXI decide the pedagogical activities. Alternatively, the author can decide the competencies and precisely specify a path through pedagogical activities.

NURAXI supplies many services including: effective individualized courses based on competency models, ontologies for documents, learning styles, teaching strategies, adaptive interfaces, and dynamic computation according to previous actions; dialogue and communication support in groups; and didactic material creation using DTD as templates coupled with XML and XSL.

Different actors interact with the platform: the author of the didactic material, the student, the guest, the administrator, the librarian, and the tutor. The two main actors considered hereafter are the author and the student.

The NURAXI platform architecture is composed of various modules corresponding to actors and functionalities involved in the learning process. Every action and interaction in this process occurs around the same core elements that form both the basic structures of the teaching material and the basic infrastructures for the learning process. The author and the student use these common structures in a different way. The main structures introduced in NURAXI include: competence, knowledge, course, pedagogical activities, contents and student model.

A competence is the ability to do something well or effectively. In particular, in our pedagogical context, competence is an abstract concept which can be reified through attributes or properties that qualify and quantify the ability. Within NURAXI competencies are classified according to the domain area (e.g. Computer Science, Languages, Mathematics) and to Bloom's learning outcomes (Knowledge, Comprehension, Application, Analysis, Synthesis and Evaluation) [WestEd 1999]. A competence is connected to other structures, including the knowledge, and activities. When actuating a competence to perform a task an individual makes consciously or unconsciously use of a certain amount of information and knowledge.

A course is defined by an author as a list of learning objectives which aim to a particular pedagogical goal. The learning objectives are the same for all the students attending the same course; therefore they may represent a
predefined shareable set of learning objectives. Thanks to this nature, a course can be certified, assuring in this way the individual ability in the specific field. The course structure contains information such as the list of competencies that must be the training target for the student; the audience to whom the course is addressed; a description of the certification that is obtained; the authors of the material, and the creation and last updating dates.

**Pedagogical activities** are associated with each learning objective that they aim to reach. At the highest level, activities have been classified into two broad categories: individual, e.g. answering, problem solving, and collaborative activities, e.g. brainstorming, debates, etc. A number of properties are associated with each activity in order to specify learning outcomes, learning styles, competence objectives, complexity, and contents.

The **contents** represent the didactic material and constitute the basic bricks of the NURAXI platform. The contents are used to generate the activities presented to the student, and may be used in different ways in several activities. Contents can be created by authors or imported from external sources and integrated into the system by means of meta data. The innovative idea is to re-use the same contents, appropriately filtered, in many activities. This could be easily achievable if the content is formalised in XML.

The **student model** is made of a static and a dynamic part. The static part contains information such as personal data. The dynamic part contains information about the initial learning objectives, the learning style, the learning status of the student, and the competence level.

**Processes**

The author is responsible for creating a course. The steps involved in the **authoring process** can be summarized as follows: the author will select a list of competencies for a course; he/she will select or create a number of pedagogical activities that the student may undertake to get that competence, and create or integrate the associated didactic contents. The authoring process is supported by services that the NURAXI platform provides in the form of visual tools, such as competence, activity, and content editors.

The student uses the platform with the purpose to reach some learning objectives, i.e. to acquire new competencies (learning process). These learning objectives can be associated to a course (in this case a certification can be obtained) or be selected independently from a course by the student. The most interesting aspect of the environment is that the training path can be dynamically created. The training path is a trail through pedagogical activities that are created on the fly by combining various contents. The path is determined on the basis of the student learning objectives, competence level, and learning style.

**Conclusions and Developments**

The NURAXI learning environment is designed to provide content re-usability, adaptability, modularity, and interoperability, thanks to the integration of technologies such as the XML, DOM, XSL, servleis, software agents, distributed databases, UML modeling technique, JSP and JAVA programming. Some of these technologies have been already tested in various demonstrators ([Moulin 1999], [Cenati and Sommaruga 1999]) implemented to show particular functionalities or potential features of the NURAXI platform.

Web-Based Courses Improve English-Language Skills of Foreign University Science Students

Yvonne Stapp
University of Tsukuba
1-1-1 Tennodai
Tsukuba, Ibaraki 305, Japan
stapp@sakura.cc.tsukuba.ac.jp

Abstract: Three English courses for first-year Japanese science majors were designed to accelerate reading skills and acquisition of science concepts by using Web-based materials. The Web materials were selected especially for high quality illustrations (graphics, pictures, simulations) that clarified unfamiliar scientific concepts. To evaluate the effect of such materials on students’ reading comprehension in English, an experiment compared students’ comprehension results from three types of texts: (a) paper text, no illustration (b) paper text with an illustration; and (c) text on Web with more elaborate illustrations. The best comprehension scores were associated with Web materials. The positive effects of the Web materials were especially significant for the most abstract concepts.

Science concepts in a foreign language

For today’s science and technology students in foreign universities, English proficiency and Internet skills are now almost as important as quality training in the students’ respective majors. Web-based English-language reading courses can develop language and Internet skills, and simultaneously provide students everywhere with the most current and authentic learning materials in their subject areas. However, because of curriculum structure, these students may encounter unfamiliar science concepts as freshman in their English courses before they study them in their departmental programs. Since many science concepts are complex and abstract, reading about them first in English instead of the native language may be difficult. The potential obstacles to comprehension, however, may be offset by the quality and array of illustrations available for almost any science or technology topic. Well designed graphics (including pictures, diagrams, photographs, animations, simulations, videos) often accompany or link from science articles on the Web. With a little experience, an English instructor can assemble a set of illustrative resources for any given topic in a modest amount of time. Nevertheless, many instructors are reluctant to shift to Web resources, and many feel that there is very little difference in comprehension effect between standard paper texts and readings on the Web. Although this perspective may be valid for some types of reading, it may not be true for science and other types of technical material (Simpson, 1994).

What, exactly, is the effect of illustrative material on comprehension, especially where unfamiliar science concepts are introduced? Most science texts include illustrations of various types, clearly with the objective of reinforcing difficult ideas. If illustration does matter, the difference between standard texts and the offerings on the Web is staggering.

Mental concepts: Naïve learners vs. experts
There is usually a substantial difference between the naïve learner's mental representation of a concept and that of the expert. This differential has been studied extensively (e.g., Kumar, Helgeson & White, 1994; Larkin, 1983; McClosky, 1983) with a specific interest in bringing the learner's understanding into alignment with the expert's understanding. Where concepts are particularly complex and abstract, this is not an easy task. Perhaps as a kind of recognition of this problem, scientists often create metaphoric labels that conjure up images: the big bang, black holes, string theory—to name a few of the familiar ones. But what these metaphors represent to experts is quite distinct from what they represent to naïve learners. So to further clarify ideas experts also include diagrams and other graphics in instructional material. If graphic elaboration of abstract concepts facilitates learning substantially, then the offerings on the Web easily justify the use of Web-based materials.

**Testing the effect of Web materials on comprehension**

To test the effects of illustration on comprehension, freshmen majors in science fields in a Japanese university were presented with three types of English texts in rotation: (a) text only; (b) text with picture; (c) Web-based text with selected and varied illustrations (e.g., simulations, graphics, photos). For each timed reading (e.g., Black Holes) one group read (a)-type, another group read (b)-type, and a third group read (c)-type. The group that read (a)-type for the first topic rotated to (b)-type for the second topic, and (c)-type for the third reading. In this way, all groups read three separate topics in three separate formats. Students indicated by 1-5 rankings on their test sheets the level of difficulty, whether the topic was new or familiar, and whether the topic was interesting. Comprehension for each reading was tested by multiple choice questions which targeted the respective concepts.

The results were most interesting where readers were most naïve and topics were most abstract. For the real novices, comprehension was substantially better for the Web-based material than for either of the standard written materials, that is, (a)-type or (b)-type. Where readers were more familiar with the target concept the differential was not so great. This initial investigation suggests that the Web materials were most helpful in presenting challenging concepts to naïve readers. Further refinements of the experiment are underway, which include a larger set of readings at two levels. This will help to clarify the potential of Web-based materials for accelerating comprehension at different reading levels; that is, for both the novice and for students who already have some familiarity with a given concept.

j.a.steel@shu.ac.uk

Abstract: The focus of this paper is on the preliminary findings of research into the perceptions and experiences of educational technologies of teaching staff and students at Sheffield Hallam University in the UK. These findings explore the relationship between educational technologies and pedagogic processes as well as wider social and cultural aspects. Initially this research stresses the importance of an ongoing dialogue between teaching staff, students and university management concerning the appropriate, context specific use of educational technologies, as unconsidered approaches on the part of practitioners can impact negatively on the quality of the student learning experience.

Introduction

As a result of research commissioned by the Learning and Teaching Institute at Sheffield Hallam University (SHU), this paper will present the initial findings arising from research into perceptions and experiences of staff and students using educational technology as part of their learning and teaching at SHU. The primary objective of the research is to gain a qualitative insight into the ‘real lived’ learning and teaching experiences of students and teaching staff using educational technologies as part of their educational life at Sheffield Hallam University. Fundamental to this task is an investigation into social and cultural factors that shape their perceptions of educational technology and the pedagogic processes of teaching and learning within the framework of specific learning contexts.

Methods

The first key stage of the research was based around interviews of members of teaching staff and centred upon uncovering and exploring learning and teaching within given contexts. These interviews were structured so as to allow the participant to describe in an open ended manner their experiences and perceptions of educational technology. The themes on which the participants were encouraged to talk included notions of value of educational technology in learning and teaching; perceptions of changing roles and relationships with students; views on changes within higher education and finally, perceived negative aspects of educational technology use. The findings of this section of the research point to a multiplicity of perceptions of educational technology. However, the overwhelming theme that emerged, was that considered and appropriate use of learning technologies should be encouraged as the quality of student learning can be enhanced and enriched. It was considered that the view that educational technologies as a ‘quick fix’ solution to the problem of student numbers should be challenged as this can only demean the potential of educational technologies within the learning and teaching process.

The second stage of the research is primarily, but not exclusively, focussed on the learning experiences and perceptions of students at SHU, with reference to the use of educational technologies. Five separate
case studies or 'contexts', which seek to investigate different elements of the teaching and learning from the perspective of the student have been developed. These research contexts are being formulated in order to investigate particular aspects of the teaching and learning experience of the student body. These contexts are centred around the following areas:

♦ Web Based Material, 'Enriching' the Student Learning Experience.

♦ Tackling the Issue of Student Motivation with Educational Technology: An Action Research Model.

♦ Student Expectations

♦ Reflections on Computer Conferencing from Lecturers as Students.

Conclusion

The material from the interviews, coupled with the four research contexts, provide a detailed introduction to a number of issues that face students and lecturers when engaging with educational technology in a learning and teaching context. The data that will be produced from this research will provide an insight into how students and lecturers deal with educational technology, in terms of their experiences and perceptions of educational technology's roles and functions; as well as how it is incorporated into pedagogic processes. Finally, an understanding of the staff and student perspective of educational technology in relation to wider culture is generated from this research.

A Web-based instruction model for open learning - A theoretical and practical framework

Dr Armand St-Pierre
Professor at Royal Military College, Kingston, Canada

Abstract: As computers becomes more prevalent in the field of education, educators are obligated to plan and provide for classroom of computer technology. The combination of media and technology offer the possibility of developing a computerized virtual learning model. This paper describes a framework to develop Web-based instruction models (WBI) to help the teacher to deliver course materials on site and at remote. This WBI prototype will help the learners grasp a rich learning content and provide opportunities to do some collaborative work.

Introduction

Web-based instruction could be defined as the application of a repertoire of cognitively oriented instructional strategies implemented with a constructivist and collaborative learning environment using the attributes and resources of the World Wide Web (Lebow, 1993; Perkins, 1991). The teacher becomes a facilitator for finding, assessing and making meanings form the information discovered from a variety of media (Relan, Gillani, 1997). The Web can become a resource center for the teacher and the learner.

The objective of this paper is to present a theoretical and practical framework for creating an WBI model.

Context

The Canadian Royal Military College, located in Kingston, Ontario, is an academic institution which provides education to young Canadians who want to become Officers and at the same time obtain a University degree. Various academic programs in Engineering, Science and Arts are offered. These programs, given on site in Kingston, are delivered through traditional means and methods.

Cadet enrollment for the 1997-1998 academic year in the undergraduate programs is approximately 1000 students, from the age of 17 to 25. Graduate programs are offered to a small population of 400 students. The college is planning to add certificate degrees to help people in the rank get a University degree.

Military Men and Officers are located in different military units and participate in military missions overseas. They must be retrained every five years to perform with a high degree of proficiency in their jobs. The Military College will have to use distance education and other forms of delivery to be able to educate its work force. A challenging and rewarding avenue for this institution to look into.

The vision of the Military College is to enhance learning through collaborative educational technological tools in the year 2000. Every student must be able to learn at remote and use interactive computer tools for a more enriched learning environment. This vision requires this institution to define a new mission. The Military College, the only high level military training in the Canadian Armed Forces, will be dedicated to the creation of knowledge and the advancement of learning in the Armed Forces.

The mission of the Canadian Royal Military College will be:

- To produce well trained personnel capable of using computer tools and skills in their working setup.
- To train professors in education technology and distance education in order to deliver rich training content at remote.
Identified Need

We are entering into the age of communication rather than information. Databases are easily accessible at a very minimum cost for our students. Computerized real-time teaching is possible due to a fast network infrastructure, but we need the players: the teachers and the learners who could use these educational tools efficiently and effectively.

One of the challenges we are forced to face as educators is that we have to upgrade our teaching skills using technology. Enhancing learning through technology requires more than just access to computers, software and networks, it also demands new ways of teaching, new roles for educators, new teaching and learning goals, and a strong educational support system for the teachers and students. Householder (1993) produced a vision statement which includes four goals to guide our work:

- Position technology as a basic area for academic teaching and learning.
- Provide leadership in developing curriculum using technology.
- Support teachers in implementing their programs using new teaching methods.
- Enhance participation of students in experimenting new educational learning media.

One of the primary goals in the year 2000 will be to support the mission of the Military academic institution through successful integration of technology into the educational process. The Military College has to maintain educational leadership in its environment in order to receive the proper funding from the National Defense Headquarters to achieve their mission.

For the purpose of this course, new medias will be introduced through Internet, which will facilitate, on one hand, the delivery of the contents by the professor and, on the other hand, the learning of the concepts of the course and the successful completion of the Marketing fundamentals course enrolled by students.
CONSTRUCTIVIST ENVIRONMENTS VERSUS BEHAVIOURIST DEMANDS

Abstract: Constructivist approaches (Duffy & Jonassen, 1992, Boyle, 1997) advocate the provision of learning experiences which facilitate the students' learning acquisition, rather than the more behaviourist approach (Skinner, 1974) of deriving objectives and learning outcomes for the instructional material. However, there is both external pressure, from QAA audits and internal pressure, from students, to identify and assess learning outcomes and adopt a more behaviourist practice. This paper looks at a solution which seeks to accommodate both ideals.

Background
Constructivist approaches (Duffy & Jonassen, 1992, Boyle, 1997) advocate the provision of learning experiences which facilitate the students' learning acquisition, rather than the more behaviourist approach (Skinner, 1974) of deriving objectives and learning outcomes for the instructional material. The constructivist approach is admirable and aims to transfer the emphasis away from lecturer driven teaching, a central tenet of behaviourism, towards more student driven learning. The conflict in the adoption of this approach is derived from the lecturer's wish to facilitate learning and the student's wish to be taught. Students admit to being motivated by assessment and, to this end, they perceive a key factor in their learning as the provision of criteria to underpin the assessment process.

Within the modules undertaken in an undergraduate or post-graduate course, the criteria are derived as learning outcomes which are used to assess levels of student performance. In an effort to provide an environment where more constructivist approaches are encouraged, a web interface has been developed which attempts to bridge the two ideals. One of the aims of this approach is to provide a gentle "nudge" for students who exhibit a high degree of dependence on lecturer centred teaching towards a more independent student-centred learning experience.

Using existing legacy material coupled to WWW facilities, amalgamating and delivering them as resources for an individual module, the lecturer and the student progress at a pace which allows both to feel secure with the innovative approach. Several elements from the conventional teaching approach, such as lecture notes and slide presentations, can be combined with WWW facilities, such as web pages via links and email communication, to provide a comprehensive learning experience.

Approach
The module chosen to pilot this approach was a level 3 (final year) undergraduate module entitled Computer Based learning (CBL). Existing resources include: Assignments (Word Documents); Lecture Notes (PowerPoint slides); Additional notes (Word Documents). To these were added WWW resources which include: access to the home pages of staff teaching on the modules (HTML); external Links (URL’s); on-line tutorial systems for Authorware (internal and external links); sample CBL material (developed in Authorware, then "shocked" to allow its delivery via the WWW). Email facilities for students provide asynchronous communication between students and between staff and students. The module interface to the material is delivered via the WWW, is frame based and ensures that students may access the resources whilst remaining within the module framework. This allows exploration of the resources without the fear of getting “lost in hyperspace” (Conklin, 1987).

CBL Module Interface
Figure 1 http://www.comp.glam.ac.uk/pages/staff/gstubbs/tutorial.gif
Figure 2 http://www.comp.glam.ac.uk/pages/staff/gstubbs/staff.gif
The contents links frame provides selective access to resources, the links form a typical hierarchical structure as illustrated by the indented points below:

- Staff on the module;
This structure is sufficiently flexible to be tailored to individual module and lecturer needs but is simple enough not to confuse students. The environment offers the student access to the assignments and hence the learning outcomes but also provides additional learning opportunities such as on-line tutorials or links to external resources. Thus, providing constructivist opportunities for students to develop deeper learning and providing an extension to the conventional “chalk face” teaching and learning activities.

Staff Issues
The implementation of this interface raised some interesting issues from several members of staff who viewed and evaluated the facility. The two major issues raised were:

(i) “I don’t want my notes to be an open access resource but I don’t mind the other resources being open access”

This concern can be easily addressed, solutions include, provision of resources via local servers so that only local students may access them; protected tutorial groups where students have a login name and password; or a combination of these together with the open access resources.

(ii) “I haven’t got time to convert my material to HTML”.

This was not a problem as no legacy material was altered. Staff were impressed that materials were accessible in their original format and this engendered a more favourable attitude to use of the facility.

External Demands
An additional factor influencing the transition from traditional to more innovative delivery mechanisms for module resources comes from the external audit body the “Quality Assurance Agency” (QAA) whose primary function is “to review the performance of universities and colleges of higher education”. To fulfil this role the QAA visits Higher Education institutions to “assess their quality and standards of teaching and learning”. Institutions are rated as excellent, satisfactory or unsatisfactory, these are based on several factors but the QAA report of 1994 stated that “subject providers judged to be excellent, and some others, were able to utilise high-quality resources to provide innovative and effective teaching and extensive opportunities for independent learning by students”, (QO, 1995) this area is, thus, seen as an important factor in gaining an “excellent” QAA rating.

Conclusions
Within UK Higher Education institutions, there is a move to attract higher numbers of students and “to widen access”. Attracting students is a complex process depending on location, courses and entry requirements but the additional advantage of advertising a School as “excellent” certainly confers a benefit over those rated as “satisfactory”. Students are also more familiar with technology in the form of the WWW, email etc. and their expectations on a Computer Studies course extend to the use of these technologies within the courses, however, in a learning environment they often request the more behaviourist approach of providing learning outcomes. In the UK over the last two years the issue of the abolition of student grants and the introduction of student loans has initiated a “consumer approach” to education, the onus is being placed on staff to teach rather than students to learn. If this is continued, it will provide an impoverished learning experience for students in general. In order to accommodate the facilitation of learning whilst at the same time fulfilling the student demand for both technological innovation and provision of behaviourist principles, care must be taken to progress at a pace that supports both students and staff. The integration of legacy material within a constructivist environment seeks to achieve a satisfactory outcome for the two viewpoints.

Abstract: When undergraduate wet lab experiments are converted to multimedia simulations, opportunities become available for addressing old problems. The simulation described in this paper provides many of the same advantages that other lab simulations have in the past. However, "Frog Heart Physiology Lab" goes further. Lab activities were redesigned to achieve learning outcomes that were previously elusive. The distinguishing features of the simulation are described, along with examples of how the lab is used. When using the simulation, students are encouraged to generate and apply various methods of administering treatments, and to make better use of the resulting data.

Introduction

This paper discusses a set of biology laboratory experiments that are simulated using multimedia. The simulation is being used to replace a wet lab for a third year undergraduate physiology course. The “Frog Heart Physiology Lab” simulation shares advantages with other simulations of wet labs. It avoids the cost, effort and ethical issues of acquiring live animals for testing. The redesigned simulation gives students a look at the work involved in dissecting a frog and setting up the experiment, but avoids the technical problems which often occur when working with live animals. Simulations also provide opportunities for students to take chances in a safe environment. In addition, it allows students greater flexibility to move between activities, and allows them to stop working on the lab when they want, and to return to the lab as often as they want. Previously, they had to do all of their work in one lab session with one animal. There would be many advantages if the simulation simply replaced the wet lab. However, we wanted to go further.

We redesigned the lab in an attempt to achieve specific learning outcomes that were difficult to achieve in the wet lab. The addition of “matching” tasks enables students to relate mechanical and electrical tracings to the movements of a beating heart. In the simulated lab, students are encouraged to think critically, by drawing tracings to predict treatment effects, and deciding what is likely to change, and by how much (McCormick, 1998). In addition, students are asked to justify their predictions, thereby defining what they believe are the treatment mechanisms. They are asked to do this in an attempt to dispel naive patterns of misunderstanding which might otherwise persist. (Perkins & Simmons, 1988). The flexibility provided by the simulated lab allows these activities to be started a week or more before the chemical and electrical investigations are conducted. This gives students more time to think about and research their predictions and justifications. One desired result of these activities is that students’ misconceptions are drawn out and confronted. Students are asked to compare the variations they observe with the data set they constructed, that is, their drawings. This in turn encourages students to explore alternative activities, and entertain alternative ideas. Another desired result is that students must make use of evidence to find relationships and support their arguments. That means that they are given responsibility for discovering “new” treatment effects. This approach, of asking students to make inferences based on their observations, rather than telling them what to look for, has been used successfully in the redesign of other undergraduate biology labs (Udovic, 1996). In general, we wanted to encourage a higher percentage of students to adopt a problem solving approach and to be more “playful.”
Tales of two labs: students then and now.

In the wet laboratory, somewhere in the middle of the lab period...

“Tracey and Ed read in their manual that they are to investigate the effects of calcium chloride on heart function. Unlike their last investigation with epinephrine, they are not sure what they are looking for. Ed applies one and a half droppers full of calcium chloride directly on the heart muscle. After less than a minute, there is a noticeable difference in the movement of the heart, and the mechanical tracing. Tracey and Ed examine the tracings produced by the application of CaCl2. In their lab report, they note that calcium chloride reduced the height of the tracing, and there was an initial increase in heart rate, before heart rate slowed. They go to the literature, and find an explanation of the mechanisms of CaCl2, which they paraphrase and add to their findings.”

In the computer simulated laboratory...

“Bill had written on one of the lab ‘prediction’ worksheets, ‘the roof part of each cycle depends on the extracellular calcium concentration. The more extracellular calcium there is, the more Ca2+ will flow into the cells and so the longer the tracing in this part.’ Bill had traced over the baseline wave on the worksheet, making the peaks of his new waves higher, and the valleys between cycles narrower. He and Marie are now surprised again to find that the data generated by the simulation don’t match their predictions. Heart rate has slowed, and amplitude is reduced, not increased. They begin to examine the data more closely, and discuss the discrepancy. Marie makes an observation, ‘if calcium chloride slows down the heart and shortens the height of the waves, then it must be pumping out less blood. So less blood comes back to the heart. And so the atria move less, and that part of the tracing is smaller, because it’s not working as hard.’

Students who used the simulated lab usually made mistakes when they first attempted the trace matching tasks. However these students stated that “(The tasks) did help in determining the contraction state for the chemical additions”, and that “the exercise helped me realize the actual orientation of the heart during the procedure.” Students also stated that they “particularly liked matching the video images with the tracings”, and that “one of the most important things learned from the simulation was what parts of the... tracings corresponded with which contractions in the heart.”

In addition to mistakes made during the trace matching tasks, students stated that “my predictions were also quite wrong. However, I think it was good to have done them, as it required learning about the potential effects... before actually performing the investigations”, and that “discussing the tracings with other students with whom I worked was a good way to stimulate new questions about what was occurring in the investigations.” Other students stated that “Predicting before performing the investigation really made me think. I put much more effort into this lab because of these instructions”, and that they “found making the predictions very worthwhile because it made you sit and think about what was going on...”

It appears that the simulation created an environment where students enjoyed learning from their mistakes.

Support for this work was provided by the Centre for Learning and Teaching Through Technology and the University of Waterloo's Learning Technology Innovation Fund. Special thanks to Tom Carey for input on this work.
Abstract: In this paper, we describe situated learning connoting the importance of context to meaningful learning. In particular, based on the writings of authors such as Brown, Collins, and Duguid (1998), we draw implications to instructional design and attempts to recommend practical situating environments as part of a holistic learning through the advent of technology.

The Situating Environment

John Seely Brown, Allan Collins and Paul Duguid in their paper "Situated Cognition and the Culture of Learning" (1998) said that learning must involve activity, concept and culture as they are interdependent. The model of situated cognition is based upon the notion that knowledge is contextually situated and is fundamentally influenced by the activity, context, and culture in which it is used. Moreover, such activity contexts are mediated by tools. Looi (1998/9) suggests the supportive roles of technology for the inquiry process (within the activity context) - as instructive tools, constructive tools, communicative tools and as situating tools. The instructive environment that holds the content, remains the central part of the learning environment. It would start from the didactic approach of posting the domain knowledge to the learner. As the learner picks up the knowledge, construct his own knowledge from it, he returns the newly-constructed knowledge back to the system, adding up to the knowledge base. Collins and Ferguson (1993) proposed epistemic tools as the basic building blocks for knowledge construction to help learners to recognize, judge and organise patterns of information, engaging learners in constructive inquiry. In addition, the communicative dimension of tools and environments provides the hub for community exchange, providing support to the learner, to the learning process.

In fostering meaningful learning within activity context, Figure 1 below shows the processes. There is a deliberate effort on the part of the Instructional Designer to provide opportunities for the learner to engage, not only in the content, but also in his life: activities and situations of his life. A situating environment is thus an essential part of a total learning environment for the learner. The application of meta-cognitive skills will raise the learner to a level that he will be able to exercise cognitive dexterity in transferring the knowledge acquired to many situations in his life.

In the following sections, we describe what needs to be situated, ways of situating, and we discuss implications to the instructional design process.

On what to situate?

Context, Culture, Activity are three components as recommended by Brown, Collins and Duguid (1989) to be essential in learning as they are interdependent on each other. To situate the learner to the "hardware" and "software" of the situation, the lesson should provide not only the hard facts in the content, but also the peripheral knowledge. By "hardware", the author refers to the tool, which the learner is supposed to
learn to use. This could be an equipment, a machine, a word processing tool or the control panel in a cockpit. By "software", we mean the surrounding environment, in the form of climate, smell, heat, water, room, people, etc. This places the learner in the context and culture of the ultimate application of the lesson. We attempt to provide not only the cognitive situationing, but also (if possible) the physical, emotional and mental situationing.

Ways to situate

Various ways have been recommended to situate a learner. The "Adventures of Jasper Woodbury" (Pellegrino, et. al, 1990) is a well-designed videodisc program to exemplify situated learning. It requires the learners to consider real-life needs. Opportunities are embedded for the learners to explore, discuss, articulate possible problems and solutions, ultimately to "transfer" his classroom knowledge to a near real-life situation in the program.

To bring students to a deeper immersion to the culture, context and activity, tertiary education for most students (in Singapore) have included industrial attachment as part of their curriculum. The civil engineering students are sent to work for 6 months in the construction site. Secondary schools send teenagers to experience the rigour of work in the real world outside school. Simulators are developed to bridge the gap between textbooks/manuals and the real environment. In computer-based training, situating the learner takes place by presenting multiple scenarios (including the use of immersive and non-immersive Virtual Reality) that trainee would be likely to encounter. Variables in the scenario are identified and changed for the various scenarios to vary complexity and to increase diversity. Interactive hardware is now attached to desktop computers so that the trainee can be brought to a step closer to the real situation by touching the actual equipment.

Implications for Instructional Design

To bring the discussion to a practical level for a hypermedia Instructional Designer, how then can we design for situated learning? The authors suggest the following considerations appropriated from notions of cognitive apprenticeship.

1. Past and present situations and predict areas of future application

Presenting past, present and future nodes for linking to the current point of learning is a strategy for situating to enculturate the learner. Presenting a meaningful relevant past node provides the association from a new and unknown area to be taught on a known area. The present node would be one that the learner is experiencing and would require the new knowledge to have immediate application. This should bring about an 'uh huh' effect in the student. A future node must be one that is foreseeable by the learner. Taking the learner on an untouchable trip, to an unreachable destination will result in the student, learning for learning sake, for the sake of satisfying the teachers' demand and for passing examinations only.

2. Complexity and diversity and multiple practice for each situation

Increasing complexity can be done by gradually increasing the variables in the simulation. In the use of equipment, where knowledge is structured, multiple practice under different conditions should be provided, so that the students become competent in the job. However, one must be careful not to over-situate. (Over-situating is a condition when the learner is provided intensively with only some very specific situations, where he becomes very conversant under this condition. The extreme result of over-situating is that the learner is not able to perform the same activity given a changed condition.) To prevent over-situating, diversity in the situations is created through various different situations, through the varying of each dependent parameter for both the "hardware" and the "software". In the teaching of wave characteristics, the sequence starts with the simple wave equation of \( C = \frac{\lambda}{F} \). A picture to represent the equation is shown. Simulation is shown of the effect of a change in the \( \lambda \), keeping \( C \) constant, causing a change in the \( F \) value. The student is allowed to suggest any value of the parameters to view the effects on the other parameters. This allows the student to quickly grasp the implications of the variation. Then, the complexity is increased by introducing another wave of the same frequency, followed by the intervention of another wave at different frequency. The learner would see the change in the overall effect. To further increase the complexity, as in a real-life situation, we would show the attenuation of the wave due to interference caused by obstacle such as a tall building or the occurrence of rain.

3. Opportunity for learners to situate themselves

Having the student to reflect on his own past experience and associating with the new knowledge that he has just picked up are applications of the knowledge learnt or related to the knowledge learnt. This deliberate effort involves the student's active participation in relating his own experience to that learnt. He may even be
able to construct his very own knowledge based on his unique culture and context. In the study of Pythagorus theorem, the student may consider a route that his father normally takes to drive from school to home. He can calculate the amount of petrol saved if his father uses the "hypotenuse" road rather than the 2 adjacent roads. Real life problem of having to go through more numbers of traffic lights, become the deciding factor that the father did not use the "hypotenuse route" - a peripheral knowledge. Allowing the students to explore into the various possible real-life situations also help to elicit erroneous concept of the knowledge, which the expert-teacher can then correct.

4. **Situations in opening and closing and within main content of the lesson**

   Situating the learner at the opening of a lesson provides him with an end in mind as he begins the lesson. Providing multiple situations within the main content brings his focus to the culture, context and activities of his required performance, so that the content will not be "dead" knowledge, but truly knowledge alive, used by the experts and practitioners. At closure, there is a need to highlight as divergently as possible, the many situations of application. Transfer of the skills and knowledge from the simulated situation to real-life situation must be emphasised.

5. **Environment for learners to learn from the experts and practitioners**

   In situating the learner in an expert's environment, the learner is exposed to the multiple perspectives from various experts in the same area, providing him with a rich context. With the advent of technology, we throw open an environment for the learner to have access to the interested experts and practitioners. In the learning process, an environment where the students can hold discussion with other experts and practitioners should be provided. This would help build a virtual community for the students. Principals and teachers in schools who are interested in this area of constructive learning, situated cognition, cognitive apprenticeship, should also access to this site to collaborate to provide synergy in joint projects.

**Conclusion**

Situated learning is beneficial for the learner in providing the **culture, context and activities** that are inseparable from the domain knowledge, for meaningful learning. Diversity in all the three elements provides richness in the learning environment. To ensure cognitive apprenticeship, there needs to be expert to provide the modelling, coaching, scaffolding. Activities for collaboration must be designed. Opportunities for learner to articulate their learning and experience must be provided, through writing their own stories or observations that he has made. Reflections on their learning, on other expert's work must be encouraged and facilitated. The advent of technology has compelled us to consider the best use of it for the overall benefit of learning effectiveness and efficiency. To be able to implement all that are described would mean that the teacher/instructor must be an expert in her areas of teaching, have experienced the richness of life in the subject matter, have many years of experience in authentic activities and be involved in current works in the industry. It is thus recommended that the teacher must have rich experience in the community, in the industry. Schools should be encouraged to employ people from the industry and these candidates should be remunerated more than those who have no experience at all.

Preliminary Investigation of IMM Evaluation Instrument

Jennifer D.E. Thomas, Ph.D.
Associate Professor, Pace University
1 Pace Plaza, N.Y., N.Y. 10038
Email: jthomas@pace.edu

Introduction

The suggestion has previously been made that an instructional multimedia (IMM) application will support learning to the extent that it offers support to user performance speed, memory, effort, comfort, content and course management. (Thomas, 1998). An instrument based on this model was then proposed (Thomas, 1999). A preliminary study using the qualitative measures of the model is presented in this paper. Subjects evaluated an interactive multimedia application to teach children how to draw. The results indicate that users were quite consistent in their evaluation of the application and that these opinions did not change a week later, after discussions of good design principles. The only exception was a change in the perception of the support of memory provided by sound.

Model and Instrument

In applying the proposed dimensions to evaluating instructional multimedia (IMM), speed is considered a function of how fast one can learn the material or search for answers. Support for memory would be indicated by the ease with which encoding of information can occur as a consequence of the integration of multimedia. The extent to which images, sound and text contribute to conveying ideas or concepts to be taught will determine, in part, the efficacy of the application design. The amount of effort which must be expended in learning can be gauged by the structure and the levels which must be navigated, that is, the hypermedia components. The comfort dimension measures the aesthetic appeal of the images, sound and text included in an application. These will be a function of the number and quality of various features, for example, resolution, clarity, font style and size, layout, navigational tools, help aids, etc.

The instrument, based on the model, suggests that the dimensions can be assessed objectively as well as subjectively. (Scriven, 1990; Teng and Jamison, 1990; Roberts and Moran, 1983; Holcomb and Tharp, 1991; Davis, 1989; Schneier and Mehal, 1984; Murphy, 1992; Khalifa, 1990; Polson and Kieras, 1985; Preece and Keller, 1990). In this paper, the focus is on the subjective or qualitative assessments and asks users to assess Speed, the time needed to complete or learn the application, as fast, moderate or slow. Support of memory, as a consequence of integrating text, images and sound into the application, may be assessed as high, moderate or low. The structure of an application will dictate the effort required in navigating it. The more links and branches there are, the more complex the application and the more effort required in finding answers and in making associations among the various concepts. Users are likely to view this effort as extreme, moderate or minimal. The aesthetic appeal of an application, its comfort level, will be a function of the quality of good package features included in it, and can be rated as excellent, good, or poor. The quality of the content of the application can be assessed in terms of completeness as complete, adequate or superficial and, in terms of relevance as relevant, peripheral or inappropriate.

The Study

The instrument was tested with information systems students in a graduate introductory multimedia course who used the instrument to evaluate the qualitative aspects of an application to teach children how to draw. The instrument was administered during the first lecture prior to the presentation of any material, and then a week later, after discussions of good design principles. In this preliminary study, the research questions investigated were:
1. Are users' evaluations consistent using the instrument?
2. Do these evaluations change after exposure to good design principles?

Results

The sample was mostly males in the 20-29 age group. In total, there were twenty-three users filling in evaluations in the first lecture and twenty-one a week later after discussions of good design principles. Most had extensive computer experience, moderate computer assisted instruction experience and minimal multimedia design experience.

Users rated the application as “Average” on most of the dimensions initially. Their opinions did not change after discussions of good design principles, except with respect to support offered by sound to memory which went from high to moderate. This is puzzling. Perhaps users have more experience with the use of text and images for learning, while the purpose of sound may be less evident without instruction as to its use and merit.

Conclusion

The instrument would seem to be stable in eliciting qualitative assessments of interactive multimedia by end users. This would need to be validated with a larger sample size and across different applications. The results, however, are encouraging and suggest continued research along these lines.

The Emergence of ‘School’ as a Factor Influencing Patterns of Navigational Choices in Hypermedia

Abstract: This paper focuses on the qualitative results of a study that examined the effects of learner characteristics and the learning environment on students’ acceptance of control opportunities while using hypermedia software. A covariance structure analysis revealed substantial effects of the school which students attended on their navigational choices within the software. Analysis of data from student interviews and audit-trail data collected during use of the hypermedia software suggest that three possible factors may have contributed to the strength of the variable of school. Specifically, they may have been the genders of the students, students’ epistemological beliefs and different the learning environments created by the cultures of the two schools the students attended.

Introduction

A related paper entitled ‘The Effects of Activity Structure and Learner Characteristics on Acceptance of Control Opportunities in Hypermedia Environments: A Report of Quantitative Findings’, in this proceedings, introduces a study which explored the effects of activity structure and individual characteristics on student acceptance of control in an hypermedia environment. The quantitative analysis identified that the school which students attend was a factor influential in navigational choices made by students. This paper focuses on the qualitative findings of the same study, identifying possible reasons for the strong influence of the school variable.

Analysis of the qualitative data and examination of relevant literature identified three possible factors that may have influenced the strength of the school factor. Specifically, these were the gender differences of students at the two schools, the epistemological beliefs of students and the different cultures and learning environments that existed at the two schools.

Qualitative Findings

In an attempt to determine the reasons for students’ navigational choices and their adoption of particular navigational strategies during software use, interviews were conducted with eighteen students directly following computer-based lessons. During the interviews students were asked to explain their reasons for particular navigational choices when required to demonstrate how they would locate particular information in the software. In addition to the interviews a detailed analysis of the audit-trail data of software interactions for those students interviewed helped to identify patterns of choices that represented particular navigational strategies.

Gender: Gender differences between the two school populations is the most obvious interpretation of the large influence of the school variable. Analysis of audit-trail data showed the boys more likely to engage in focused information seeking and girls more likely to explore. Interview data also revealed gender-related patterns of
responses, with most girls expressing the opinion that they enjoyed the autonomy offered in the computer-based lessons. In contrast, most boys indicated that the computer-based lessons were ‘better’ than normal lessons. Also consistent with the responses regarding autonomy, most girls interviewed also expressed the opinion that they would like the opportunity to explore the software in addition to completing worksheets, while the boys mostly considered the worksheets of prime importance.

Epistemological Beliefs: Comments made by students in interviews and the information seeking behaviours they exhibited when using the software suggest that the majority of students may have possessed naive epistemological beliefs, beliefs that knowledge is absolute, is simple, is handed down by authority and is acquired quickly or not-at-all. Those exceptions were girls who were more likely to make larger numbers of choices and engage in exploration of the software, suggesting that they sought more detailed information, and possibly alternative, supportive data for answers to questions (either their own, or questions set in the tasks).

The Cultures of the Schools: A third potential area that may offer explanations for the differences in the information-seeking is the distinctive differences in the learning environments of the two schools. While both schools adopt a holistic approach to the development of the person, the girls’ school aims to create an environment in which co-operation and group work are valued and promoted. The boys’ school however, aims to create a different learning environment in which individual academic performance is valued, and one in which students are encouraged to observe the discipline standards in willing co-operation rather than from a fear of breaching them. These different environments may have contributed to students’ different approaches.

Discussion

An important outcome of the study is that the findings of the research have identified some implications relevant to classroom practice. Awareness of the three identified factors will help educators to consider the possible effects of learning environments they create and the tasks they set students on usage of complex computer-based software and learning outcomes. Future research could also productively investigate the effects of gender, epistemological beliefs and school cultures on learner acceptance of control opportunity.

Cultural and gender differences in computing among secondary school children

Johan van Braak
Department of Education

Pleinlaan 2
1050 Brussels Belgium
Johan.van.Braak@vub.ac.be

Abstract: In this study, some figures are presented on the presence of a home computer, frequency of computer use and computer tasks among a large group of secondary school children in Belgium. In particular, relationships have been sought between the variables mentioned above and two demographic variables: gender and cultural background. In correspondence to previous studies, differences between boys and girls in the field of computing remained visible. Figures on cultural background differences in computing were less pronounced than gender differences, but still apparent.

Background

In the last two decades, a great amount of literature has been produced on gender issues in the field of computing. Many researchers have pointed at differences between males and females, with males generally showing more favorable attitudes towards computers, having greater access to computers and spending more time using them. Gender inequality is discussed in many reviews of the literature and meta-analyses (Sutton, 1991; Whitley, 1997; Kirkpatrick and Cuban, 1998; Liao, 1999). Although research conclusions are not always similar, overall, males seem to have more favorable attitudes towards computers than females (Martin, 1991; Okebukola, 1993; Shashaani, 1997). For example, Okebukola (1993) demonstrated that boys in high school show less computer anxiety and have more interest in computers than girls. Shashaani (1997) confirmed that male students show more computer interest. In contrast to the interest in gender issues in computing research, less attention is paid to the impact of social background on computer access and use at home. In a review of computer research in the eighties, Sutton (1991) stated that besides female students, socially disadvantaged and minority students had less access to computers both at home and at school.

Methodology

The purpose of this study was to examine the existence of inequalities between adolescent boys and girls and the effect of cultural background on the accessibility of computers and computer use at home. A brief questionnaire was administered to 1500 children (age 12-20). Information on demographic variables was collected (age, gender, cultural background). Furthermore, respondents were asked to indicate their computer experience, frequency of use and computer use for school and/or leisure activities. After removing missing data from the sample, descriptive statistics and tests of significance were performed on data from 1305 children.

Results

The average age was about 15 years. Of the sample, 51.6 % were male and 48.4 % were female. To indicate the cultural background of the respondents, the nationality of the parents was measured. For 215 respondents at least one of the parents were not of Belgian nationality (16.5 %).
In total, 81.1 % of the respondents owned a computer at home. The group of children of 16 years had the highest percentage of computer ownership (87.5%). A linear increase of computer ownership by age might be expected, but could not be confirmed. Computer experience of secondary school children in this study was 33 months on average. Children of 16, 17 or 18 years old had more or less the same amount of computer experience (40-41 months). Of the
subgroup of children with a home computer, 20.1 % never or rarely used a computer, 15.3 % used the computer about once a month, 37.9 % on a weekly basis, and 26.6 % daily. The older the respondent, the higher the frequency of daily use ($X^2 = 13.9$, $p < .05$).

Chi$^2$ testing revealed significant differences between gender and computer presence at home ($X^2 = 14.1$, $p < .001$). Of the males, 85.0 % had a home computer, as compared to only 76.9 % of the females. Although more boys owned a home computer in all age groups, the gender gap was only statistically significant for 12-, 16- and 17-year olds. So the assumption that gender disparities are increasing with age could not be confirmed. Overall, girls had significantly less computer experience (29.3 months) than boys (37.1 months) ($F = 23.2$, $p < .001$). When controlled for computer presence at home, this association remained significant ($F = 10.8$, $p < .01$). In addition, males (32.2 %) were found to make more use of a computer on a daily basis than girls (12.0 %) ($X^2 = 78.8$, $p < .001$).

Results indicate that gender disparities depend on the nature of tasks being performed with computers. The use of computers for leisure activities is clearly reported as being a masculine activity. Significantly more boys (73.7 %) reported to use a computer for leisure activities than girls (58.6 %). This gap remained significant when children without a home computer were excluded from the sample: 86.3 % of the boys versus 75.5 % of the girls ($X^2 = 20.2$, $p < .001$). The situation appears to be different when considering computer use for school activities. Similar proportions of girls (58.5 %) and boys (58.1 %) use a computer at home for school activities, but if respondents without home computer were not taken into account, significantly more girls (75.3 %) reported to use computers than boys (67.9 %) ($X^2 = 7.17$, $p < .01$).

The presence of a home computer was significantly lower among children of non-Belgian origin: 73.9 % versus 82.5 % ($X^2 = 8.0$, $p < .01$). The association was only apparent for the oldest among the respondents (17 years or older). Overall, Belgian respondents reported to have six months longer experience with computers ($F = 6.8$, $p < .01$). However, when the effect of computer ownership was imported as a covariate in the test, no significance was found between the two groups ($F = 1.4$, $p = .23$). Moreover, no differences between groups could be demonstrated for frequency of computer use variable. Respondents of Belgian origin did not report to use the computer more often on a daily basis than non-Belgian respondents. This finding is confirmed for both males and females. Comparing Belgian and non-Belgian respondents, in general Belgian students accounted for a wider use of computers: 8 % more made use of a computer for school activities ($X^2 = 8.8$, $p < .05$) and 12 % more for leisure activities ($X^2 = 12.3$, $p < .01$). The presence of a computer at home seemed responsible for the difference in use for school tasks. In other words, if respondents without a home computer were removed from the sample, no significance was found. This finding could not be confirmed for leisure use: non-Belgian respondents made significantly less computer use for free time activities, even when controlled for computer presence at home ($X^2 = 4.1$, $p < .05$).

**Discussion and conclusion**

The present findings confirm other studies which clearly have demonstrated gender differences in computing. Besides, this study suggests the existence of cultural differences in computing. Although there are many social and psychological factors responsible for gender and cultural inequalities, the absence of a home computer seems to accentuate the differences between groups.

Evaluation of IT Course Material in the Context of an Acoustic Design Project

Pieter Vandaele, Dick Botteldooren, INTEC, Ghent University, Belgium
Els Van Zele, Josephina Lenaerts, Center for research in physics education, Ghent University, Belgium
Raoul Meuldermans, KaHo Sint Lieven, Belgium
Marc Van Overmeire, WERK, Vrije Universiteit Brussel, Belgium
Gerrit Vermeir, Laboratory for Building Physics, K.U.Leuven, Belgium

Abstract: To evaluate the use of newly developed IT course material in the domain of acoustics, (http://educinno.rug.ac.be/wetenschapsmuseum), the students had to perform an open design project. The way engineering students at Ghent University tackled the problem and used the available tools to do so, is evaluated through their results and their opinion expressed in a survey. At the same time, their global ideas about the usefulness of information technology in education are explored.

Introduction

To evaluate the learning environments from the project "Distributed Development of a Virtual Science Museum with Guide Applied to education in Acoustics" [1] and test their effectiveness in improving students' insight in complex formulas and concepts, a suitable student project had to be built. A design project seemed the ideal option considering the numerous alternatives and various possible ways to achieve an acceptable result and the different learning paths and styles to be used. The specifications of the project corresponded to what an engineer can expect in real life situations. Students were instructed to design Helmholtz resonator: basic acoustics were known in advance, but the students had to explore more specific information on the Helmholtz resonator themselves. The IT project provided them with learning objects containing illustration of concepts, mathematics, models, model limitation, simulation tools, etc.

To solve the problem the students could follow five different problem solving paths. The path of...
1. the rote experimenter: look briefly at the general operation principle and use the virtual experiment to accidentally come up with a reasonably good solution.
2. more intelligent trial and error: derive a mathematical relation between a few design parameters from the general operation principle and investigate only valuable combinations experimentally.
3. a meaningful experimenter: start with some trial and error, realize there must be a reason why some parameters do not seem to have any influence, turn to the theory to find out if there is a theoretical background for this and eventually return to experiments to determine the last degree of freedom.
4. a theorist (pure mathematics): combine the available mathematics to come to a result possibly using some numerical solvers.
5. an expert: use the formula to relate some parameters, investigate more detailed theory to find some physical and technical restrictions, solve the last degree of freedom using mathematics and their own software or the applet, finally turning to the derivation to find out if their design is well within the limits of applicability of the theory.

Survey and exam results

The students reported their ideas about the importance of the several factors for solving the problem: the virtual experiment, derivation of equations, limits of the theory, other Internet pages, communication with peers, literature, and their perception of the insight they gained in some acoustic concepts. Despite a small statistical population of 27 students, some interesting conclusions can be drawn:
• Part of the goal of the design project was to urge students to learn the theoretical background by exploration of additional resources. About 66% of the students state that they gained insight into the theoretical background. We consider this a reasonable success.
Students focusing on experiments affirmed they gained insight in the problem at hand but they did not learn about the theoretical background. They probably followed paths 1 or 2 mentioned above.

The more students perceive the equations and underlying derivations as important (solution paths 3, 4 and 5), the more they get the impression they understand related theoretical topics. However the correlation with their impression of understanding how a Helmholtz resonator really works gets lower and even becomes negative, although this tendency is not reflected in the students’ exam result of questions related to the topic. Perhaps students only realize the complexity of the matter when they study the topic thoroughly.

There is a negative correlation between the student’s global result and his perception of insight gained. This can mean several things: the material is not good enough and better students are left somewhat unsatisfied, or better students do not easily state understand something completely, or the students who perform well in the current educational system are not inclined to put much effort in an alternative project. One thing is sure: it is a question of perception since there is no negative correlation with their examination score on the question related to the subject.

This project forced students into using IT. After this (for some students ‘first’) IT-experience for educational purposes some general questions about the appreciation of IT were asked. The following trends reflect their ideas:

- there is a strong negative correlation between the wish to get more interactive multimedia material (as was presented to them) and the student’s performance in the current system.
- the students almost unanimously approve the usefulness of self-assessment tools to evaluate the level of understanding they have reached.
- applets allowing students to explore the influence of parameters in a mathematical theory are highly appreciated, as are additional self-assessment tools.
- the possibilities of hypertext to hide unessential information or to cross-link different topics is not estimated very high by the average Flemish engineering student.

**Conclusions**

In general students appreciate the collaboration and the exploration type of approach of a design problem on a subject they had no prior knowledge of. The exploration stopped at an earlier stage than hoped for. This could be due to the way the problem and the tools were presented, but “the study culture” of Flemish engineering students probably explains a lot. It is not a habit of these students to consult literature, search the web, etc. When using IT in education one has to be considering the study culture of the students, which is hard to change.

There was an unexpected negative correlation between the general performance of students in the traditional educational model and their appreciation of the project and IT in education in general. Since one of the initial goals of this project was to make sure “better” students had the opportunity to learn more than in the traditional educational approach, some tuning seems appropriate, in order not to loose those students.

As we expected, there is some fear of loosing track and of doing things that are not really essential in order to be able to pass the exam. In the first semester of 1999-2000 we try to respond to this by structuring the software agent we called “the guide” in such a way that a clear path through the material is outlined and that the structure becomes more evident. Hyperlinks are applied in a more structured way by the use of icons indicating which type of hyperlink can be expected: example, practical application, additional explanation, more background, etc.

Malaysian Smart School – Vision Vs. Reality

Vijaya Kumaran K.K. Nair
Multimedia University
Cyberjaya, 63000 Selangor, Malaysia
vij@hypermedia.com.my

Abstract: The Smart School Project is one of the flagships of the Multimedia Super Corridor. The Malaysian government has established partnerships with the private sector through the Concept Request for Proposals (CRFP) process. This paper will critically analyze the concept of Smart School in the Malaysian environment and look into the issues relating to implementation of this concept as per the vision of the Ministry of Education Malaysia. The paper will go further to provide empirical proof with regards to the mind set and the response to the Teaching-Learning component of the Smart School Concept, from the view point of in service teachers.

Introduction

In July 1997 the Prime Minister launched the Flagship Application documents to invite proposals for solutions from the private sector within and from outside the country. The Education Ministry based on critical and creative teaching-learning approach planned the Smart School concept. Technology as an enabler became an important component of this flagship. The exercise is to help the Malaysian student community to cope with the Information Age.

The main components in the Malaysian Smart School are:

1. Teaching - Learning Process - here self-accessed and self-directed learning will be encouraged
2. Management and Administration - the school Management and Administration will be technology driven for efficient and effective management of resources and to support the teaching-learning process in 1 above.
3. Human Resources, Skills and Responsibilities - active role play by Parents, Community and the private sector as Stakeholders
4. Processes - review of input and output
5. Technology - to be used as an enabler i.e. as a means to the end and not as an end to the problem
6. Policies - changes in existing policies and regulations over and above new policies and regulations

Objectives

The objectives of the Smart School Project are:
1. To produce a thinking and technology-literate workforce
2. To democratize education
3. To increase participation of stakeholders
4. To provide all-round development of the individual
5. To provide opportunities to enhance individual strengths and abilities

Implementation

The Ministry of Education has planned for a three-year Smart School Pilot Project through the CRFP process. Ninety (90) pilot schools have been picked for the pilot stage which will involve three levels of technology, i.e. level A, B+, and B.
### Level | Total Number of Computers | Description
--- | --- | ---
A | Primary – 406  
Secondary – 479 | Schools in this level will be equipped with state-of-the-art technology. Each school will have two computer labs and each classroom and science lab will be equipped with computers.
B+ | 86 | This level is based on classroom model. This model is based on group-based activities and project work. Computers are available whenever needed for information access, writing reports, developing presentations, e-mailing etc.
B | 42 | The majority of schools will implement technology supported learning by use of a computer lab. Students will use the facility to access information, use software application for various purposes and work on available courseware in the four subjects.

The Government intends to play a role as an architect and driver for the Smart School Project. The Ministry of Education will prepare guidelines and provide the basic amenities to schools according to their individual needs. The Ministry is also actively encouraging schools to become Smart Schools on their own initiative by using their own financial resources and expertise. The Pilot Project period is three (3) years from 28th July 1999 to 22nd July 2002. It is projected that all schools in Malaysia will be Smart Schools by the year 2010.

### Reality

The Malaysian government is spending over RM. 300 million for only 90 schools to be wired, of which RM. 183,573,737 for Capital Expenditure and RM. 116,426,263 for Operating Expenditure. As per the time line set, from 13th March – 22nd March 2000, the installation of Release 1 software (Teaching-Learning Materials and the Smart School management System) is to take place.

However on 20th February 2000, The Star (National Daily) reported the Director – General of Education saying that the “smart school” project in 90 schools nationwide will be further delayed because of hitches in the software development for the lessons. He had said that the “slight delay” was due to the fact that it took time to develop the courseware. The pilot project was suppose to take off on Jan 1st 1999, but was delayed for several reasons including lack of funds and courseware. The infrastructure for the implementation is ready in ’80 of the 90 schools for the full implementation. The Education Deputy Director General stated that the software for the 4 subjects took time to write, and to evaluate them. He went on to say that it will take about 4 years to fully develop and implement the program.

Among the reasons for the delay were:
- lack of fully developed smart school curriculum
- lessons being rejected several times
- difficulty in contacting evaluators (Ministry of Education)
- lack of communications
- rejection after many rounds of evaluation
- evaluators not exposed to technological limitations

Should the consortium entrusted with the development of the courseware implement software engineering principles in developing the courseware? If the basic software engineering principles had been incorporated, couldn’t most of the above reasons for rejection be done away with?

Evaluation throughout the Life Cycle of a Multimedia Tutoring System

Maria Virvou, Victoria Tsiriga
Department of Informatics,
University of Piraeus,
Piraeus 18534, Greece
E-mail: {mvirvou | vtsir}@unipi.gr

Introduction

One of the primary aims of educational software is to be used in real school classrooms. However, a lot of educational software has been criticized that has not been designed to meet the needs of real school settings. The above criticisms show that there is a need to introduce research results of educational technology into the environment of real classrooms. A solution to this problem may be the involvement of school teachers in the development of an ITS (Virvou & Tsiriga 1999a) and the application of evaluation methods on every stage of the tutoring system's life cycle. In this way we can ensure usability and learning effects.

For the purpose of this research, a multimedia tutoring system was developed. The system is called Easy Math and incorporates intelligence. EasyMath's model of life cycle has been based on Object Unified Process (Kruchten 1999), an object oriented process that suggests multiple iterations of the software development phases. In this way, we have ensured multiple iterations of evaluation of the design and executable releases of Easy Math.

Evaluation of the Design

Evaluation of the design of Easy Math was considered very important in order to ensure that the expertise incorporated in the error diagnosis component would be acceptable by the majority of school teachers. EasyMath's error diagnosis and student modelling have been based on reconstructive approaches which have been used in many ITSs such as (Brown & Burton 1978). These systems reconstruct the problem solving process and generate mal-rules from hypothesized faulty solution paths which are used for the modelling of students' misconceptions or procedural bugs.

At this stage we aimed at evaluating the error diagnosis component in terms of its cognitive principles and completeness. Therefore, ten school teachers were given a computer based questionnaire with questions that had been answered erroneously. The faulty answers were produced using the library of the most common misconceptions that were encoded in Easy Math. The questions covered the whole range of exercises included in Easy Math. The questionnaire consisted of ten questions. In each one of the questions, each teacher had to provide a justification of what s/he thought the underlying misconception was. One problem in this stage of the evaluation process was that many teachers did not provide any explanation and just gave the correct answer to the question.

Evaluation of a Primary Executable Release

In an early stage of the development, a prototype of the tutor was ready to be used by its end users. This prototype was used in order to perform a primary evaluation of the system. In the phase of the primary release evaluation, two school teachers along with ten students were involved. The evaluation methods employed comprised qualitative techniques, such as direct observation and questionnaires.

The main focus of this phase was on the evaluation of the user interface and the several types of the exercises provided by the system. Teachers and students were asked to comment on the working environment of Easy Math. Furthermore, they had to express their opinion about whether the amount of different exercises encoded as well as the form of these exercises were adequate.

The teachers and the students involved in this phase were introduced to Easy Math and were then asked to use it for about an hour. During their interaction with the system, an evaluator was present, trying to note down the difficulties that the users had encountered while performing predefined tasks. After the interaction with Easy Math, both the teacher and the students were given a questionnaire to answer. The questionnaire...
was designed taking into account a set of “usability heuristics” presented in (Nielsen 1994). The questionnaire included questions such as:

1. Were instructions for use of the system visible or easily retrievable whenever appropriate?
2. Were the symbols and the words used in the different components of EasyMath consistent?

The first question corresponds to the need for recognition rather than recall, while the second question is related to the need for consistency and standards. The comments made during this stage of EasyMath's development were used as the basis for the refinement of the requirements of the system and the construction of the final product.

**Formative Evaluation Using a Set of “Learning with Software” Heuristics**

The involvement of school teachers in the phase of the evaluation of an ITS was considered crucial. In addition, it is also important to track students' use of resource based packages very closely to uncover the problems and successes. For the above reasons, in the phase of the formative evaluation of EasyMath, 10 school teachers as well as 240 students were involved. Both students and teachers were asked to evaluate EasyMath in terms of the purpose of education. In addition, teachers were asked to evaluate the overall performance of the system and express their opinion about the usability of such an ITS in a real classroom.

In the stage of the students' evaluation of EasyMath, the students were separated in two portions. The first 120 students were introduced to EasyMath and were asked to use it for an hour. Then, they were given a questionnaire to complete. For a more detailed description of the results of the questionnaire, the reader is referred to (Virvou & Tsiriga 1999b). As for the rest 120 students, they were taught half of the syllabus in algebraic powers without the use of EasyMath and they were given a written test. Then they used EasyMath while being taught the rest of the syllabus. In the end they were given another written test and the grades of their first and second test were compared. The results showed that 46% of the students obtained a better grade in the second test, 43% obtained the same grade and only 11% obtained a lower grade in the second test.

The evaluation questionnaires used in this phase were constructed based on a set of "learning with software" heuristics, introduced by (Squires & Preece 1999). These heuristics are an adaptation of "usability heuristics" (Nielsen 1994), so as to relate to socio-constructivist criteria for learning. "Learning with software" heuristics have been suggested by their inventors as a method for performing predictive evaluation. However, we have used them to construct a formative evaluation questionnaire, that would give us insight about the integration of both usability and learning issues.

In the phase of the overall evaluation of EasyMath, the teachers who participated in the evaluation were asked to role play an average student interacting with EasyMath. Next, they were given a questionnaire to fill in. The questionnaire was carefully designed so as to ensure that questions are related to as many of the "learning with software" heuristics as possible.

**Conclusions**

To produce efficient educational software, there is a need to ensure the correctness of the domain knowledge as well as to evaluate the usability of the product. One way to achieve the above goals may be the application of evaluation methods on every stage of the tutoring system's life cycle. In addition, evaluation should involve both human teachers and students in order to maximise usability in real classroom settings.

Neuromance, Or Is The Old Flame Still Best?

Simon Walker
School of Post Compulsory Education and Training
The University of Greenwich
UK
S.H.Walker@gre.ac.uk

Abstract. This work in progress paper reports on whether hybrid CD-ROM technology used to train or supplement the training of mentors of beginning teachers in Vocational Education and Training is an improvement upon traditional face to face and print-based delivery. It argues that the shifting ground in pedagogical models can confuse educational software developers but an understanding of a theoretically driven level of explanation of learning may assist decisions about learning approaches and choice of technology.

Introduction.

Faced with a climate of change, educational institutions are under increasing pressure to explore new ways of learning. Emerging trends in Information and Communication Technologies (ICTs), combined with national government initiatives to use ICT and widen participation in lifelong learning (in the case of the UK, the influential Dearing, Higginson and Kennedy reports), have created a framework for supporting an increasing community of participants in education and training.

The development and introduction of ICTs into the further and higher education and training sectors has stirred debate about pedagogical performance versus educational efficiency. In training, the debate has focused on issues of Return on Investment (Hawkins, et al 1997). Factors of cost and value for money versus amount of learning and quality of learning characterise educational and training evaluations A lack of separation of these factors has created a cloud of confusion, and decisions about allocations of scarce resources are not always made in a manner that maximises the collective benefit of the community.

Many would contend that ICTs are not only cost efficient (Boulet & Sene,1997; Greenwood & Recker, 1996) but they also promote more effective learning (Resnick, 1987; Fjuk & Dirckinck-Holmfeld 1999). Others call for more caution to be exercised about such claims. In the UK, the push towards the integration of computer-based education within education and training has been made at the highest levels with funding to match. The premise is that ICT can deliver more effective learning than traditional media.

There is no single recognised right way of thinking about learning; theories constantly change and tend to reflect the attitudes and technologies of their time. The literature points to shifting ground in pedagogical models.(Reiguluth 1999; Herrington & Standen, 1999). Currently the debate is influenced by ICT.

It is of some concern therefore, that educational software developers have an understanding of a theoretically-driven level of explanation that identifies the kinds of cognitive activities (such as learning, memory tasks and problem-solving) that could take place through the physical activities provided by an interface. To produce successful tools for learning, it is necessary to understand the nature of the learning process and the impact of context within which learning operates.

Background

There is a particular need at the University of Greenwich each year to train up to 250 new and existing workplace mentors who support trainee teachers on the Post Graduate Certificate of Education (PGCE) in Post 16 Vocational Education and Training (VET) during their teaching practice.

The learning demands and needs of these mentors are relatively different to the more conventional learner and it may be argued that the instructional approach is different. Firstly, it concerns the training of trainers. Secondly, there is no set curriculum to follow, or assessments to be made; thirdly, there are no prerequisites other than being a teacher/trainer within the selected institution and lastly, whilst the institution is paid for the efforts of their staff, the mentors personally go largely unrewarded either by time, cash or qualification inducements.

Although some mentors may work within the same organisation, many others do not and generally they work largely independently of one another. Institutions span a large geographical area across London and the South East of England and mentors rarely meet with one another to discuss their role.

There is no substantial proof to suggest that a trained mentor is more effective than an untrained one (Jowett 1998), however, training does enhance an understanding of the stages of a relationship, the mentoring process and it enables critical reflection on professional practice. Conventional mentor training, by virtue of location, time and resources, can only address a small number of aspects of the mentoring process - the tip of the iceberg. Malderz and Bodoczky (1998), take the image of the iceberg further and draw a parallel between the tip, which is out in the air and represents the visible 'good professional' and the main body of the iceberg, which lays unseen and represents all that the professional engages in as an expert in their subject and as a mentor. The submerged part represents the mentor's thinking, planning, and engagement in process, and draws upon their knowledge, understanding, values, feelings and attitudes. The mentor's ability to respond to the student teacher's professional development hinges on their understanding of the role and on their own development as mentors. An analysis of these elements forms the content of the interactive tool.

Project Objectives and Scope.

In its current form, training is administered through a combination of print-based distance material and a single workshop session for some mentors at the beginning of the academic year. Our initial research showed that the majority of mentors would be willing to use IT for training purposes, although we identified a number of constraints; some were institutional such as the limitations of the technical specification of equipment.
provided by colleges (processor speed, CD-ROM drives, soundcards, the ability to play video, etc) and some personal constraints such as knowledge about ICT and confidence in using the computer. The pursuit of a technological solution to provide support and training, independent of time and location was compelling.

In 1998 the Mentor in cyberspace project undertook to produce an alternative means of supplementing the existing mentor training and support. Interactive multimedia, it appeared to us, offered the best chance of developing a range of tools and resources to support mentor processes such as thinking, creativity, self-reflection, problem solving and the development of professional attitudes & approaches over time. At the start of the project only a small number of academic institutions which were not universities had organised individual internet access for their staff. We considered the lead-in time for the project to be sufficiently long to utilise the hybrid function of CD-ROM technology with its ability to connect on-line. Furthermore, the University's online Campus (OLC) was under construction and the idea of extending the range and type of tools available to mentors was attractive.

Learning approaches.

Selecting instructional methods on the basis of the theories has not always been easy because little agreement exists between the protagonists. The constructivists attack instructivist design approaches as formulaic and mechanistic. Defenders of instructivist design have attempted to re-establish its authority at the expense of other approaches. They take a staunch position against the infringements of, in Merrill’s words, “these persons who claim that knowledge is founded on collaboration rather than empirical science, or who claim that all truth is relative” (Merrill, cited in Wild and Quinn 1998, p 74). In much of the current and recurring debate about the role of learning theory in educational interactive multimedia there appears to be a readiness to assert one theory of learning over another - to present one as being deficient and the other as the only credible explanation of learning.

The important issue is to match the instructional approach to learning need whatever the level, whether this is the efficient dissemination and testing of knowledge, the creation of new personal knowledge or the development of opportunities for networking and collaboration. In a professional context where the goal is to encourage the acquisition of reproductive and productive skills and knowledge, a balance must be struck between those methods that appear to work best.

Our approach has been to try to strike a balance between these two ostensibly opposing theories and adapt the technology to suit the perceived learning needs of the mentors. On analysis of the strengths of each learning approach in relation to our purposes, we saw that instead of contradicting and negating each other, these two approaches could be complementary. We perceived that the use of hybrid CD-ROM would combine both learning approaches. CD-ROM is a relatively closed technology, limited by its content and design. Our design here draws upon the strengths of Instructional Systems Design (ISD): its emphasis on presentation, information, structure and reinforcement is useful for the reproduction of knowledge (Boyle 1998) and is suited to interactive multimedia on CD-ROM. Web technology, on the other hand, is characterised by an open, explorative architecture. Accordingly we have used web technology, specifically Computer Mediated Communications (CMC) which supports a more constructivist approach: it is able to provide a set of tools and methods for the mentor to construct new knowledge within ill-structured, authentic, real contexts (Brown, J.S., Collins, A., & Duguid 1989). Hybrid CD-ROM offers the possibility of combining the reproduction of knowledge with the production of 'knowledgeability' (Guile & Young 1998).

This work in progress will report the findings of a pilot study ending in June 2000 with approximately 20 mentors who will have utilised the various tools and approaches during this academic year. The particular focus of the research will examine whether:

- mentors preferred to use the hybrid CD-ROM or the print based material for learning about their role
- one instructional approach or technology was more successful than the other.

I will attempt to draw conclusions about the success of introducing interactive multimedia and whether the use of ICT in this context is an advantage for training and supporting mentors of beginning teachers in VET.

Greenwood J & Recker M. "Networked, Asynchronous Student Evaluations of Courses and Teaching: An Architecture and F

Abstract: This paper proposes an open architecture of Visual Lab on WWW and focuses on scientific experiment for the asynchronous mode of distance learning. Visual Lab is a virtual experiment environment by using video-media. A complete scientific experiment in Visual Lab includes four essential stages: phenomenon observation, experiment process observation, data measurement and experiment recording. In Visual Lab, students can carry out experiments remotely with the toolbox designed on Internet. A system architecture built on World-Wide Web demonstrates the feasibility and flexibility of our idea.

Keywords: Distance Learning, visual lab, scientific experiment, World Wide Web.

1. Analysis of Scientific Experiment in Visual Lab

For a full scientific experiment, there are several essential stages: phenomenon observation, experiment process observation, data measurement and experiment recording. These essential stages are analyzed details in the following.

**Phenomenon Observation:** With such knowledge, phenomenon observation can be divided into two categories

(a) Static Observation.
(b) Dynamic Observation.

**Experiment Process Observation:** It is very important to practice with one's own hands. After experimenting themselves, students can gain much impression.

(a) Traditional Process Observation.
(b) Video Observation.

**Data Measurement:** Data measurement is the key to prove a physics theory.

(a) Equipment Usage in a Traditional Lab.
(b) Usage of Simulation Tools.

**Experiment Recording:** The formats of experiment records have to be designed.

**Problems Analysis of Four Essential Conditions on WWW:** The formats of experiment records have to be designed.

Table 2: Comparisons table of web technologies.

(c) **Experiment Record**: Students can record data what they want to measure and send out these data to teacher. Then teachers can gather all the student learning information via the function provided by experiment record.

2. **Design the Platform of Visual Lab**

In this section, several toolboxes will be discussed. Each measurement and observe components must applied these toolboxes in Visual Lab platform.

**Measuring and Observing Tools**: For a Visual Lab System, measuring and observing tools are helpful to both students and teachers

(a) **Video Controller**: To play some experiments video.
(b) **Scale**: In order to measure the actual length from the experiment video.
(c) **Ruler**: Students can adjust the length of this ruler tool to can get the length what they adjust when they saw in the video.
(d) **Protractor**: Students can measure the angular magnitude.
(e) **Calculator**: Students can input the data and get the result just like a calculator.
(f) **Timer**: A timer is needed to measure time in scientific experiment.

**Components of Visual Lab**: Each learning work is implemented by an independent component, and our architecture can be illustrated as (Fig. 1) shown.

3. **Implement the Visual Lab on WWW**

We designed a platform using open architecture technology. Our purpose is that all of the physics experiments can apply in Visual Lab without any modification. As long as teachers film the experiment and join in Visual Lab, students can experiment in Visual Lab environment and record with Microsoft Excel 2000, as show in (Fig. 2).

4. **Conclusion**

This paper proposes an open and reusable architecture of Visual Lab on WWW. All of the scientific experiments can apply to Visual Lab based on the architecture of Visual Lab had been accomplished. Learners can learn knowledge by experiment in the Visual Lab even they are not at school. Solution for transferring video stream through network should be the next research direction to enhance Visual Lab.
Professional Development Institute vs. On-line Course: Comparing Two Online Collaborations for Designing Technology Integrated Instruction

jsflores@ucla.edu

Abstract. Two groups of teachers, 50 K-12 History teachers from California and 20 K-12 teachers in a Masters program in Massachusetts, participated in an online experience to develop instructional materials which integrate technology into the curriculum. Each groups' level of participation in online communication activities and the method that their instructional design process was developed predicted the quality of the final materials. Recommendations for structuring online collaborative activities for teachers to develop instructional materials are given.

Introduction

This is a comparison of two on-line collaboratives with the same purpose -- to have teachers develop K-12 technology-integrated instructional materials -- but significantly different approaches. The two projects we are using for this comparison are a California statewide professional development project in K-12 History (CH-SSP) and an on-line course in Project Based Learning for a Masters degree program in Educational Technology at Framingham State College in Framingham, Massachusetts.

Key Factor - Participation in Communication Activities

For all participants, developing instructional materials was a process that involved participant to participant, and participant to facilitator/instructor communication using an online space and several forms of electronic communication. There were six different forms -- online chat, face-to-face, online submission of original written material, online response to others written material, participation in the online discussion forums and e-mail. The greater the participation in online activities, the more probable that the lesson plan was completed and the more likely that those lesson plans were of high quality. There were significant differences between the groups in their participation in on-line activities. The professional development group participated significantly less than the online course group. There were two primary reasons for this. Although both groups were required to participate, there was no tangible consequence for not participating for the professional development group. Second, technical resources and technical help were more readily available for the online course participants than the professional development participants.

The greatest disparity between the groups was in the discussion area. The postings for the professional development group were sparse to non-existent. No discussion ever emerged. For the online course, this was unquestionably the most successful communication. The discussions were interesting, in-depth, meaningful and at the Masters level. The major difference between these groups is that the discussion was participant driven for the professional development group and instructor driven for the online course group. We find this to be problematic, as one of the goals of the professional development is to have the participants drive the interaction.
**Key Factor - Instructional Design Process**

An important component of the CH-SSP project was the development of the instructional design process. CHSSP was interested in having the different grade level groups develop their own process for the development of the lesson plans. In the Project Based Learning course, conversely, the instructor strictly imposed the process and the students were, in part, evaluated on how they used this imposed process. We refer to this difference as a self-generated process (CHSSP) vs. an imposed process (Framingham).

The different process experience led to significant differences in the final product. The self-generated process group spent a great deal of time developing the process. As this was a new experience for them, there was confusion regarding what was being asked of them. This detracted from the application of those processes to the instructional materials development. We still feel strongly that we would like to see the process of materials development arise from the teachers that are using the materials. We feel changes need to be made to focus more on the development of the materials themselves.

**Recommendations**

We have several recommendations. There were many difficulties with the professional development institute, most of them centered around participants actively engaging in the online communications, and participants understanding facilitator expectations in relationship to the process of instructional materials development. We would prefer, encourage and work towards that process being developed by the participants themselves. However, many of the participants, from both groups, felt the need for more structure and more direction in how to go about developing the materials. We do not know if this was because they were using a new environment and felt unsure about how to proceed, or if they would have difficulty developing instructional materials without an imposed process in any environment. In the future, in the professional development project, some direction needs to be provided for the development process, however, this process should remain fluid for the participants. In the online course, we would recommend that a portion of the beginning of the course be spent with the participants examining their own practices of instructional materials development.

The professional development institute needs to provide a more concrete reason for the participants to actively participate in the online environment. Providing participants with a 'reward' at the end, such as a stipend, University Extension credit towards salary points, or the like may be an important component to motivate participants. Technical support is also essential. It may be best that technical support be pledged from the district as that is frequently the ISP for the teacher. It also provides a district commitment to the project.

In general, online instructional materials development, in a group, collaborative setting, needs a structure to support it which includes facilitator support for the multiple forms of online communication, technical support, and clear guidelines for the participants process. In addition, participants need a tangible motivation for completing the project, such as salary points or a stipend. These online development projects differ from traditional development projects in that they can be conducted asynchronously and between participants who are at a geographic distance. For the future, we hope that the communities that are formed can continue on, develop further materials and expand to provide online support for other teachers in their subject areas or grade levels.

Using a Wrench to Pound in a Screw:
The Misapplication of Communication Technologies in Education

Eric Wignall
Instructional Design & Educational Media Labs
Purdue University Calumet
United States
Wignall@calumet.purdue.edu

Abstract: This short paper illustrates a framework for examining the application, and misapplication, of media types and contexts in educational settings. It illustrates a relationship between form, format and function that is useful in determining the effectiveness of new media technologies in educational contexts.

Your home has a drawer or box in some convenient place where you can always reach the most useful tools; a flashlight, a ruler, a roll of tape. But there have been occasions where rummaging around in that drawer didn't get you the desired tools. You want to hang a picture on the wall but you can't find a nail, only some screws. You realize that a screw would work for hanging the picture, only to find you don't have a screwdriver. You rationalize that the picture isn't all that heavy so you could just pound the screw into the wall and take care of it, but there isn't a hammer to be found either, only a wrench. This tool, clearly not designed for the task, is pressed into service and with a little effort, hopefully without broken fingers, you indeed hang the picture. You may not have used the right tool for the job but the job was done. Because the picture now hangs over and covers the screw you are also able to hide this odd choice of a mounting device from visitors who would admire the picture.

This short paper is meant as a starting point for examining educational effectiveness of technology applications by matching format, function, and context. In far too many cases today the wrong tools are being used in the wrong context, supporting the educational process in ways that are left unexamined by educational researchers and instructional designers. We are getting the job done with whatever we have available and no one is looking at the inventory of tools in the drawer. The efficiency and effectiveness of technology in educational settings cannot be measured solely through the final output of an educational process. The latest studies of the use of computers for educational purposes, now focusing on the role of the Internet, have provided a confusing mix of contradictory results. Most of the studies are hopeful in tone but unclear about the benefits, or even the overall value, of using the Internet as a medium of education. It can be used, so it is being used.

Educators have a long history of adopting and adapting to new communication technologies as they enter society-- sometimes with great effect. Other communication technologies have been misused in specific applications by teachers and learners and abandoned for all other uses. The awareness that a communication tool can be used in an educational setting is related to the need that could potentially be satisfied by the new technology. If the tool does not immediately satisfy the need, it runs the risk of being abandoned. If the tool can satisfy an educational need even through a use that was unintended, even inefficiently, it will be adapted to suit the purpose. The effectiveness of this use can be improved through an understanding of the educational process, its context, and the effects of communication tools on teaching and learning.

Communication formats and settings

Linking communication environments with educational settings is a valuable starting point for comparing the operational effectiveness of a new technology tool in context. The following six educational/communication environments are based on mass communication theories that grew from research efforts through the 1940s and 50s.

Figure 1. Formats & Settings

![Figure 1. Formats & Settings](image-url)

Figure 1. If the effectiveness of educational technology is to be measured it must take place, necessarily, at one of these levels, and perhaps be used as a tool at several levels. The understanding that different types of communication contexts offer differing levels of interaction with educational material, and thus provide a variable basis for learning, is essential for measuring the effectiveness of the application of technology tools at each level of interaction.
The historical development of multimedia, the combination of moving images, sound, and graphic information, begins with the development of motion pictures and extends to today's subscription television cable systems. The impact of these multisensory media on viewers in the immersive environment of a darkened theater or near the electronic hearth of individual homes is complex and impressive. Multimedia technology has become more sophisticated and multilayered, allowing for multiple languages, commentary, text, and audio input and feedback. This is all the more remarkable in view of the almost total lack of feedback in early silent movie production, mass broadcast television monopolies, and linear videotape media.

Coalescent media is the result of both technology and media convergence. It represents the development of a new, digital, component-based medium. Coalescent media have emerged from the development of computational and data management tools, publishing software, digital audio and media, hypertext, and hypermedia. The linkage of different components occurs in contexts provided by the user in ways determined through navigational choices made on the spot by the user. Today web pages can be built by relational databases on demand. Users select options and the database engine places the requested information in an HTML document using preselected parameters. The limitations of current database technology combine with bandwidth restrictions to limit the potential of this early technology to combine and recombine data, in numerous forms, based on searches of worldwide resources. Coalescent media will be first relational, drawn together through user demand and user selected interaction parameters. Later developments may find hypertextual hypermedia coalescing into forms of communication that extends the capabilities of text, audio, or info-graphics by extending the interactions users have with new combinations of that media. This hyperlinking of other media types, in constantly shifting referential and contextual frames, is creating a new type of medium that demonstrates the characteristics of each level of interaction and uses each previous type of medium. As technology escapes the limitations of keyboards and screens we will see new types of interactions take place in contexts wholly created and invented by the user, not producer, of the content. New technologies being developed are allowing different types of interactions with content in contexts not imagined by the author. We are only beginning to see the curve rise in the growth of computational efficiency and the rise of new computational technologies.

Educational institutions are currently setting learning requirements, and designing the curricula to reach them, through interactions with government, professional and industry interests. These may be anything from international professional societies to locally elected school boards. What will education look like with information age learning requirements and learner-defined knowledge building? If the individualization of economic activity continues, what role will educational institutions play in defining or providing education? Does the personalization of education erode or enhance the role of educational institutions?

Conclusion

Driven by a need for improved commercial skills and abilities learners are rejecting the constraints of semesters and grades for the realities of deadlines and competencies. The growth of asynchronous distant learning systems has been dramatic, reflecting both the new availability of learning through new technologies, and the growing demand for training and education. Knowledge workers need to respond to demands for new, more valuable, knowledge on an accelerating time scale. Traditional educational institutions entering the distance education marketplace are now faced with a similar dilemma; the multifaceted role of information provider, curricular coordinator, skill assessor, and content producer. Institutions are now faced with competition not from other institutions or organizations, but from individuals operating outside of traditional knowledge production frameworks. Without the capital investment needed to create a scriptorium, library, or research lab entrepreneurs can respond to the demands of a new economy in ways that slow moving institutions cannot. Research into the improvement of learning using new media technologies, in different contexts, is not just important. It is vital to the improvement of educational systems that take advantage of each medium.

Formative Evaluation of Learner-Centered Web Course Design: A Strategic Analysis

C. James Wong
Instructional Technology & Distance Learning, Learning Resources Division
Southwestern Illinois College
cjwong@mail.southwestern.cc.il.us

Introduction
A poorly planned and developed distance education program will lead to negative learning outcome. For example, when a Texas college began to offer on-line courses taught by instructors without the skills and experience to teach on the Internet, only about 40% of students who enrolled in the on-line courses completed them (Simpson, McCann, & Head, 1999). From the same logic, a poorly designed Web course interface will have a negative impact on the entire distance education program.

This paper discusses the roles of instructional design and interface design in the development process of a Web course. Although the principles of both instructional design and interface design emphasize the importance of formative evaluation, formative evaluation (which should be conducted to assess the quality of the Web course instruction and interface) is often overlooked or ignored in this process. Formative evaluation involves (1) collecting a third party content expert's feedback to the instruction and target learners' experiences with the instruction and interface and (2) taking these evaluation results into consideration when revising the Web course. The purpose of conducting such formative evaluation is to further improve the Web course instruction and interface to maximize learner comfort and thus their learning outcome.

Instructional Design and Interface Design
In the ideal context of Web-based instruction development, instructional design is a process in which a content expert (the instructor), a distance learning instructional designer, and a course production team (that composes of an editor, a Web programmer, and a multimedia developer) work together developing a pedagogically sound Web course. According to the Dick and Carey systems approach model (Dick & Carey, 1996), the instructional design process involves determination of the instructional goal, analysis of the instructional goal, learner and context analysis, development of performance objectives, development of assessment instruments, development of instructional strategy, development and selection of instruction, formative evaluation, revision of instruction, and summative evaluation.

In this instructional design model, if the instructional strategy has been determined to be Web delivery, then the next stage--development and selection of instruction--will focus on the instructional content level of the Web course, such as choosing the appropriate instructional materials for the intended learners, modifying the existing format, structure and sequence of these materials to which learners are presented, and adding links to Web-based instructional resources.

The literature indicates that an important factor to the success of Web-based instruction is the integration of interface usability design into the development process (Henke, 1997). A Web course interface design defines the surface level of the Web course (that is, the visible structure that helps learners accomplish the goal of content learning). Web courses produced by using HTML coding, Web Course in a Box, WebCT, or other tools appear differently, due to their unique interfaces. An interface includes the following features:
(1) what students will see and hear on a web page within the Web browser (e.g. hyperlinks, text, images, animations, audio and video clips, streaming audio and video media, frames), and
(2) any responses (e.g. feedback, change of web page, error message) to students' actions such as clicking on a hyperlink on a Web page or the "Back" button in the Web browser.

Regardless which Web course production tool one uses (HTML coding or Web course delivery software like CourseInfo, Lotus LearningSpace, Web Course in a Box, or WebCT), it is crucial that a learner-centered Web course interface should address the goals of user-interface design: time to learn, speed of performance, rate of errors by users, retention over time, and subjective satisfaction (Shneiderman, 1998). As mentioned earlier, Wedman is concerned of students' "subjective satisfaction" of his School's on-line master's program.

Formative Evaluation
In the Web course development process, an in-house review of a Web course that can be called an alpha testing (in software engineering, the first test that is often performed only by users within the organization developing the software) consists of instructional designer's initial review and feedback to faculty, faculty's revision, editor's editing, instructional designer's review and feedback to editor, editor's re-editing, programmer's HTML coding, instructional designer's review and feedback to programmer, programmer's revision, faculty's final review, programmer's final revision. What is usually missing is the beta testing which requires a group of learners who are representatives of the target learners due to practical difficulty. Beta tests, usability tests, or formative evaluations (in the instructional design process) have one thing similar--the evaluation of the use of instruction and interface by actual learners or users.
A formative evaluation can be conducted to assess the quality of the Web course interface that includes the Web pages of general course information, and the first two lessons (if time permits, the entire course). The following is an example of an ideal formative evaluation of a Web course based on Dick and Carey systems approach model of instructional design (Dick & Carey, 1996): (1) subject matter expert evaluation, (2) one-to-one evaluation, (3) small-group evaluation, and (4) field trial.

**Data Collection and Analysis**

Technology plays a number of roles in the data collection and analysis processes during the formative evaluation. First of all, for the subject matter expert evaluation, the subject matter expert may live in a remote town away from the institution, so frequent travel to the institution will not be a feasible practice. As long as the subject matter expert has access to the Internet, he or she can review and evaluate the course content on the web, and make comments, corrections, and/or questions in an e-mail message sent to the instructor who developed the course. Through e-mail exchange between the subject matter expert and the instructor when discussing possible revisions in the course, the instructional designer will eventually be notified on actual changes needed for the course based on these two parties consensus.

Second, for the one-to-one evaluation, the technologies used are similar to an interface usability test. The entire evaluation will be taped by using a video camera, and the video tape will be reviewed and studied to observe the learner's facial expression, emotion changes, body language, and spoken language (while the think aloud protocol will be used) which will be also transcribed into words for further qualitative text analysis. The text analysis will make use of a software called HyperQual or a similar text coding/analysis software.

Third, for the one-to-one evaluation, small-group evaluation, and field trial, a web-based testing software (which can be used for survey purpose) like QuestionMark Perception will be used to collect both quantitative data and qualitative data. If a 5-point Likert scale of attitude questionnaire is used, the questions can be entered in Perception. After learners complete the questionnaire, Perception is capable of conducting basic statistical analyses of the quantitative data collected such as mean scores, medium scores, standard deviations, and frequencies. Such data can be also transferred to a statistical software (e.g. SPSS for windows) for further statistical analyses or a database software (e.g. Microsoft Access) for data storage and possible future retrieval for further analyses. Likewise, if the lessons contain some form of objective posttests, Perception can be used to administer these tests, and thus results of student performance can be obtained by looking at the test/measurement analyses Perception conducted and by further analyzing the data in other software packages mentioned earlier.

Perception can also allow learners to enter open-ended information when answering attitude questions or answering subjective lesson assignment questions. The answers will be either kept on the Perception database on the web or sent to the instructor or the instructional designer for grading or evaluation. Again, for responses to attitudinal questions, the responses can be sorted or coded in a text analysis that will make use of a software called HyperQual or a similar text coding/analysis software.

Fourth, for the one-to-one evaluation, small-group evaluation, and field trial, the instructional designer can use e-mail or phone to follow up with the learners to check on the accuracy of the designer's interpretation of their comments, suggestions, criticisms, and/or questions.

**Conclusions**

In order for the Web-based instruction design department to process the same number of courses with the inclusion of formative evaluation, more staff members will need to be employed, and the Web-based instruction design department will need to identify sources that can allocate such money for additional staff recruitment. If it is impossible to secure adequate funding for more staff, a compromised formative evaluation will have to be tailored (that is, to cut portions of the evaluation as outlined above) to fit the existing monetary and human resource structure.

Implementing a Professional Development Program in Instructional Design & Technology

C. James Wong
Instructional Technology & Distance Learning, Learning Resources Division
Southwestern Illinois College
cjwong@mail.southwestern.cc.il.us

Introduction

As noted by Speziale and Kachurick (1996), "advances in technology have provided numerous opportunities for educational integration; however, inadequate professional development programs have seriously limited teachers' knowledge of techniques for integrating instructional technologies." In an effort to solve this problem, instructional technology professional development programs have been founded in many major universities and large community colleges in the United States (Stoloff, 1999).

Recognizing the emerging needs for distance learning and the integration of instructional technology, Southwestern Illinois College has launched a professional development program in instructional design and technology, an innovative service to its faculty, in the summer of 1999. The new program is operated by the Instructional Technology and Distance Learning department under the Learning Resources Division, with a mission to assist members in planning, developing, implementing, and evaluating their instruction and to facilitate innovative integration of instructional technology into their on-campus and on-line courses. This institution-specific case study describes the implementation process of this new program and reports its recent performance assessment.

Program Services and Facilities

The professional development program is led by the instructional technologist/design specialist with assistance from and collaboration with other staff members (including the associate director of distance learning, the Internet systems manager, a Web-based instruction coordinator, a Web programmer, an Internet support technician, and a network technician) in the Instructional Technology and Distance Learning department.

A. Facilities: The long-term goal of the program is to implement a faculty development facility called the "Instructional Design & Technology Center" that consists of a computer lab for training purpose and a multimedia work area for production purpose. To get things started, a computer workstation with a Pentium II dual processor has been built and is available for faculty use. Additional hardware includes: a video capture card, a flatbed scanner, a CD writer, a ZIP drive, a JAZ drive, two digital cameras, a color printer, and a laser printer. Software titles installed are Microsoft Windows NT 4.0 Workstation, Microsoft Office, Microsoft FrontPage, Adobe Photoshop, OCR Software, and other multimedia applications. In addition, a Macintosh G3 computer has been recently included in the Center with some general purpose software such as Microsoft Office.

B. Consultation: The program offers one-to-one consultation to faculty with tailored information about theory and practice in technology applications for instruction. A customized small group session can be arranged when there are two or more faculty members interested in a certain design and technology issue.

C. Training: Hands-on instructional technology workshops on how to use various instructional software are offered to faculty, in addition to pedagogical seminars for faculty to facilitate information sharing and discussion of current issues on design, development, implementation, and evaluation of instructional technology applications.

Program Performance

A. Instructional Design Consultation: To increase the visibility of the innovation—the new professional development program, a small but concise Web site was built in the summer of 1999 to publicize the services and facilities being offered to the faculty. As words about the innovation regarding the professional development program spread out, the number of faculty who came to the program for consultation on instructional design and technology has increased:

- June 1999: 1 faculty on 1 occasion
- August 1999: 2 faculty on 2 occasions
- September 1999: 2 faculty on 2 occasions
- October 1999: 7 faculty on 14 occasions
- November 1999: 4 faculty on 9 occasions
- December 1999: 1 faculty on 2 occasions
- January 2000: 2 faculty on 3 occasions

The average length of a consultation meeting is about two hours. It shows faculty's enthusiasm and willingness to devote their time commitment. Issues faculty members have brought to the consultation meetings are diverse. The following list demonstrates the variety of such topics:

- Developing web pages for a campus course in FrontPage
- Working with WebCT for an online course
- Discussing design issues on Social Science departmental website
- Discussing and planning a Faculty Web Directory
- Designing a welcome template for an online course
- Designing a telecourse support Web site in Frontpage
- Working with PowerPoint to develop a student orientation session
B. Training to Meet Faculty Needs: In order to understand faculty members' needs in instructional design and technology and to prioritize offerings of workshops and seminars, a needs assessment was conducted in the form of a brief survey (Dick & Carey, 1996) to 130 full-time faculty members in August, 1999. The survey included questions asking faculty to rate (on a 1-3 scale, with 3 being highly interested, 2 being interested, and 1 being not interested) their interest in a range of workshop and seminar topics derived from the text by Newby, Stepich, Lehman, and Russell (2000). 68 faculty members returned the survey. The response rate of the survey is, therefore, 52.3%. The top rated topics are listed below in the descending order of the mean of their rating:

Meeting the faculty needs, the program developed and delivered four hands-on workshops and two pedagogical seminars till February 2000. Workshop training materials, with step-by-step instructions and screenshot illustration on how to use the software applications, were produced by the workshop trainer (who is the instructional technologist/design specialist) and pilot tested by other staff in the department. With the intention to reduce faculty's computer anxiety level and not to overwhelm faculty by teaching them every single feature of the software applications, the workshops and training materials were tailored to invite faculty members to practice some of the most commonly used functions to get started. During the hands-on workshops, pedagogical issues such as design principles were discussed before the hands-on practice sessions.

The following table illustrates a brief evaluation of the training delivered from September 1999 till February 2000. The "No." column is the number of faculty who participated; the "Overall" column is the participants' average rating of the overall evaluation of the workshop based on a 1-5 scale (with 5 being the highest rating); the "Usefulness" column is the mean of their rating to the statement "What I learned in the workshop has useful applications for my classroom and/or work".

More workshops and seminars are under development and will be soon offered to faculty members in the future so as to address one of the commonly complained drawbacks of a professional development program according to national findings regarding to professional development: infrequency of training (Speziale & Kachurick, 1996).

Summary

Instructional technology are great tools that offer possibilities for improving the learning process, but such possibilities will not be realized automatically unless the teacher will have to integrate these tools into the curriculum in a way to facilitate teaching and learning (Heinich, Molenda, Russell, & Smaldino, 1999). The professional development program in instructional design and technology fills this gap between the tools and the people by helping faculty use the tools to teach in a more effective and efficient manner.

WALTS: Web-based Adaptive programming Language Tutoring System

Chong W. Woo and Jinwoo Choi
Kookmin University
861-1 Chongnung-dong, Sungbuk-ku
Seoul, Korea
cwoo@kmu.kookmin.ac.kr

Abstract: Many recent web-based educational systems couldn't provide individualized instruction or interactive problem solving, since they are mostly built upon static hypertext. One possible solution for this problem could be adapting existing proven techniques from the stand-alone Intelligent Tutoring Systems (ITS) into the web-based educational systems. Recent web-based ITS research shows this direction by employing the existing ITS techniques minimally. And this needs to be studied further to support more adaptive instruction. In this paper we describe the development of a Web based Adaptive programming Language Tutoring System (WALTS) which is designed by ITS structure primarily, and adapting many successful ITS techniques into the system. In addition, the system adapted CORBA infrastructure to support the user more consistent and reliable performance. Together, the system behaves more adaptive and interactive than the existing static web-based educational systems.

Introduction

Many recent web-based educational systems could not provide an individualized instruction or interactive problem solving, since they are mostly built upon static hypertext. One possible solution might be adapting the existing techniques from the stand-alone Intelligent Tutoring System (ITS). However, most of the recent web-based ITS research show the efforts by employing the techniques selectively (Kay & Kummerfeld, 1994; Brusilovsky et al. 1996; Nakabayashi et al. 1997). And this needs to be studied further to enhance the overall capabilities of the system at the previous stand-alone ITS level. In this paper we will describe development of Web-based Adaptive programming Language Tutoring System (WALTS). The main goal of the development of the system is to provide the first year computer science student a comprehensive instruction for learning C programming language, by porting many successful ITS techniques into the system. In addition, the system is designed to support the user more consistent and reliable performance by employing CORBA (Common Object Request Broker Architecture) structure.

Figure1: The main Architecture of WALTS
Basic architecture of the system

The basic architecture of WALTS is designed by typical ITS structure primarily, including expert module, the student modeler module, and the instructional planning module.

The expert module consists of the object-oriented knowledge base and the problem solver. Since the domain of the system is the C programming language concepts, which may not require any complex causal relationships and only requires mostly simple concepts, we used the frame knowledge representation. The object-oriented approach of designing the knowledge base make it easy to understand and can provide more flexibility for updating or manipulating tutoring strategy in the construction of ITS. The problem solver creates problem table by referencing the problem template from the current lesson unit’s content table, which is the form of hashtable. The solver stores the correct answer, and then it presents the generated questions to the user in appropriate HTML form through the HTML generator. This method can provide different styles of questions for different users even though they are accessing the same lesson unit. Since the column name of the table is object’s name, the planner can reply to the user’s request, such as hint or help, by referencing this table.

The method of building the student modeler is the simple overlay. The modeler keeps all the necessary administrative information on the server, such as initial student’s ID, password, e-mail address, the access time. And the information regarding the student’s learning process is also stored in the student model. And each parameters has unique meanings; for example, the HelpCount, and HintCount can be updated only when the unitLesson is quiz, increase of ReferenceCount means the user is weak at the current unitLesson, the lessonLevel stores information about how many times the user visited the current unitLesson, and so on.

The Instructional Planning

The existing web based educational systems mostly employ the hypertext techniques, which is hard to make hyperlink in every HTML pages, such that it may be inappropriate for adaptive learning environment. Therefore we need to devise a method that can generate adaptive lesson unit dynamically. The instructional planning of the WALTS can be further divided into 3 steps, a curriculum planning, a lesson planning, and a delivery planning. The curriculum planning of WALTS generates a curriculum in tree structure; the curriculum planner extracts information from the knowledge base and creates a curriculum hierarchically in the order of prerequisites. Then the lesson planning sets up the lesson sequence within a single lesson unit. The role of delivery planning is limited to presenting the selected lesson content to the user.

Conclusion

The main goal of this paper is the adaptation of the existing ITS techniques to the web platform. Therefore, we have designed and implemented the system based on the major ITS architecture, and this brings us several advantages over traditional HTML-based educational systems. First, the main knowledge base is created as an object-oriented concept, which can provide more flexibility for updating or manipulating tutoring strategy. Second, the system can generate a problem dynamically by the problem solver and also can solve the problem intelligently. Third, the instructional planning mechanism can generate an instructional plan dynamically. The secondary goal is the designing of the system as a distributed infrastructure using CORBA as backbone. This structure solves the bottleneck problem of previous CGI dependent systems, and also gives some benefits of better performance and also gives flexibility in the case of further enhancement of the system.

Abstract: Online learning communities are an excellent means of integrating collaboration in online learning environments. After a brief introduction we define collaboration and learning communities and address their theoretical foundations. We then discuss the benefits of collaboration and learning communities in online learning environments. Finally, we provide a case study of a new online learning community at Western Governors University.

Definitions and Theoretical Foundations

Learning communities are environments that encourage mutual exchange between the community members to support their individual and collective learning. Learning communities are founded on the aspect of social negotiation of meaning. Collaboration is the key tenet of constructivist and small-group theories (Springer, Stanne, & Donovan, 1999; Grabinger, 1995; Duffy & Jonassen, 1992) that explains the social component of learning and demonstrates that “conceptual growth comes from sharing perspectives and modifying our internal representations in response to that sharing” (Grabinger, 1995, p. 669). Online learning communities provide the collaborative means for achieving the desired “shared creation” and “shared understanding” (Shrage, 1991, p. 40).

Benefits of Online Learning Communities

Collaborative learning and learning communities benefit learners because they encourage shared ways of knowing, promote active participation, improve achievement, contribute to the creation of knowledge, and challenge learners’ cognitive abilities (Springer, Stanne, and Donovan, 1999; Moller, 1998; Lave & Wenger, 1991; Slavin, 1990).

Through new Internet technology, synchronous and asynchronous online collaboration now provides many of the benefits that exist in traditional face-to-face collaborative and learning community environments. Our recent literature review produced evidence that online collaboration and online learning communities:

- Allow learners and instructors to work together to create knowledge constructions from their combined experience (Jonassen, 1998; Reeves, 1997)
- Encourage learners to evaluate complex issues from multiple perspectives and change their perspective based on others’ input (Sherry, 1998; Stone, 1996; Honebein, Duffy, and Fishman, 1993)
- Hold learners individually accountable while striving toward group goals so that students help one another and assess one another’s learning (Springer, Stanne, and Donovan, 1999)
- Provide opportunities for learners to reflect on their learning experiences and upon others’ input (Stone, 1996)
- Demonstrate that meaning and reality is socially constructed and negotiated through the exchange of ideas, information, and feelings among the members of the community (Hiltz, 1998)
- Improve student achievement through increased motivation, peer support and communication, and commitment to participate and finish (Hiltz, 1998; Sherry, 1998; Stone, 1996)

The above evidence demonstrates that online collaboration and online learning communities can impact and enhance the learning process. We have personally witnessed the impact of a self-initiated online learning community at
Western Governors University. Although the WGU online learning community is relatively new, we have already seen positive effects ripple through the community members.

**Case Study of an Online Learning Community at Western Governors University**

In August 1999, Western Governors University (WGU) began enrolling students in its new competency-based Master of Arts in Learning and Technology program (MLT). A cohort of 50 students, primarily K-12 teachers, geographically dispersed throughout Utah were some of WGU’s initial MLT students. In October 1999, a small group of 15 cohort students created their own collaborative online learning community utilizing a listserv since all students had ready access to e-mail.

The WGU online learning community provides a fascinating case study because it was initiated by the students themselves who by and large had no previous experience working together. Of the 15 original members of the community, only five had previous experience working with each other on previous projects; the majority of the learning community members had only met each other briefly at a WGU reception in September 1999.

As we watch the WGU online learning community develop, we are paying attention to the ways that the community members negotiate roles and establish rules and standards for communication, interaction, and entrance into the community. We are eager to compare learning community members’ performance to the performance of students who do not participate in the online learning community. We are also interested in determining why some learning community members remain inactive or decide to leave the community.

**Conclusion**

Salomon and Perkins (1998) state that “learning to learn... fundamentally involves learning to learn from others, learning to learn with others, learning to draw the most from cultural artifacts besides books, learning to mediate others’ learning not only for their sake but for what that will teach oneself, and learning to contribute to the learning of a collective” (p. 17). Collaborative online learning communities provide community members the chance to learn from and with others and to contribute to others’ learning. As a result, they are important means of integrating the social aspect of learning into online learning environments. Our literature review and personal research of the WGU online learning community provide valuable insight into issues surrounding online collaboration and online learning communities’ development, communication patterns, member roles, rules, flexibility, sustainability, and reproducibility.

Abstract: Encouraging effective collaborative learning supported by computer technology requires coordination among faculty, administrators, technical and instructional support staff, and library staff. This paper describes the roles of each of these groups in the design and use of computer technology to support collaborative learning. This paper draws on collective experience from implementing Project Vision and Project Empower, two computer-supported collaborative learning programs in Commonwealth College, Penn State University.

Too often the discussion of collaborative learning and use of computer technology to support instruction focuses solely on the classroom; in fact, successful efforts in the classroom rest on a foundation of collaboration and support from administrators, technical and instructional support staff, and library staff. Over the last several years Penn State University Delaware County has developed teaching methods that incorporate the best features of distance education and collaborative learning in undergraduate education. The two projects most directly responsible for the development of collaborative, technology-enhanced instruction were Project Vision and Project Empower, both programs for freshmen and sophomores in general education courses.

Administrators

Important administrative support issues include motivating, training, and supporting faculty to take on new teaching roles and new responsibilities, since collaborative teaching and use of computer technologies differ significantly from the standard lecture/discussion format. Administrators must make sure that the reward system for faculty recognizes the effort necessary to change from the old to the new model; we provided release time and training for faculty to learn new roles. Administrators are also responsible for making sure that appropriate equipment and software for courses is installed properly and works efficiently. Persuading faculty to work cooperatively with librarians and with technical and instructional support personnel is also an administrative role. Administrators may also be responsible for the selection and orientation of technical and instructional support personnel, who must understand the academic mission and the instructional process. Finally, administrators must be well versed in designing and conducting
collaborative learning in technology-enhanced classrooms, because they are responsible for the evaluation of the quality as well as the economic viability of these efforts.

Faculty

Graduate training seldom includes a component on teaching collaborative, technology-enhanced courses. Hence, faculty must learn how to design, manage, and evaluate collaborative assignments, as well as how to choose appropriate technologies to enhance learning in their specific venues. Faculty must be expert users of the technology in order to explain the technology to inexperienced students who are struggling concurrently with course content. Faculty always balance the advantages of new instructional media against many constraints, including the students' abilities and interests, classroom facilities, and the quality of technical support. They must also balance the time they spend in these activities against other responsibilities of teaching, service, and research. Computer technologies are constantly changing; therefore, faculty who are committed to these pedagogies know that the process of learning new technologies and the balancing act are never-ending.

Technical/Instructional Support Staff

Technical and instructional support staff work with faculty from a wide variety of disciplines, as well as with administrators and students. Math, social sciences, humanities, and business all have different content and different pedagogies. Technical and instructional support staff must understand a wide variety of technologies and software programs appropriate for specific disciplines to help faculty make informed choices. Support staff often advise faculty in designing assignments that make the best use of collaboration and computer technologies. Technical and instructional support staff must understand students' abilities and interests in order to recommend the most appropriate technologies for each particular instructional situation, keeping in mind budgetary constraints. They train faculty and students and trouble-shoot daily problems which inevitably arise. Close collaboration with faculty, administrators, and students requires superior communication skills. A sense of humor doesn’t hurt either.

Library Staff

The new technology-enhanced and collaborative classrooms are changing the roles of librarians as well as faculty. Library staff must constantly keep up to date with emerging technologies, a not inconsiderable task with the rapid development of electronic media. Librarians are responsible for designing systems for accessing information that make sense to users. Increasingly, librarians find themselves acting as coaches and collaborators for instructors who are learning to teach in collaborative and technology-enhanced modes. Library staff also train, coach, and support students in learning to use search technologies to find information. Library staff share responsibility with faculty for teaching critical thinking skills as they teach students to evaluate the quality and usefulness of the information students are using.

Conclusions

Commonwealth College of Penn State University created Project Vision to encourage faculty to redesign courses to incorporate collaborative and active learning strategies supported by appropriate technology in teaching undergraduate education courses. The administration offered release time, extra compensation, and training to prepare selected faculty for the pilot program which was designed by faculty. Over the four years of this program, the faculty tried several models for offering courses. Once all the students took only Project Vision courses for the first year as a cohort; in other years, students took some Project Vision courses and some regular courses. For two years, the faculty offered courses coordinated across two different locations. Usually, the courses were offered as a package. For example, students took Speech Communication to learn how to work in groups, Library Studies to learn how to do research, and Health Science as the content of the research project. The technologies included FirstClass computer conferencing, Eudora e-mail, PowerPoint, and video conferencing.
Synchronized Notes for Digital Class Video

Michirou Yabuki
Faculty of Informatics, Meisei University, Japan, yabuki@ei.meisei-u.ac.jp

Akira Watanabe
Faculty of Informatics, Meisei University, Japan, akira@ei.meisei-u.ac.jp

Introduction

We proposed a method using digital class video for review and self-studying and applied it to some subjects. We believe our method is successful in actual education. Students will make their own notes watching digital class video in the same way they make their own notes during ordinary classes. If students watch digital class video for their study many times over, their notes will be essential. In addition to digital class video, we propose synchronized notes for digital class video.

Digital Class Video

In many educational organizations, networks are used for educational support. On the other hand, there are many traditional classes that have no educational support using computer networks. When one intends to utilize computer networks or the Internet for traditional classes, he/she will suffer from various problems such as time for investigating teaching materials, manpower, arrangements of equipment and preparation of presentation data.

To solve those problems, we proposed a method using digital class video for introducing educational support utilizing computer networks for traditional classes. Our five goals of the proposed method are: the purpose of the method is review and self-studying; the method could preserve the various teaching style of teachers; the method should be simple so that the number of staffs and a budget should not be large; the method is able to be adopted to traditional lectures and computer exercises; more than one simultaneous classes should be supported using the method.

To achieve above goals,

• The scene of a class is recorded on video tape as it is.
• The camera for recording teacher's movements has fixed view and never follows of teacher's movements.
• A written material or a computer screen of the teacher operates is also recorded on another video tape.

These two videos are synthesized to a single image for publication.

As experiments, we applied our proposed method to five subjects in 1998. The experiments are still continued in 1999. The number of total access times to the video was 1300 in 1998. We believe that our educational assistance method is successful.

Synchronized Notes

To study subjects, just watching class is not enough for studying. Students ordinarily make notes on class with a notebook and a pen. (Nowadays, some students use their own lap-top computer for their notes in classes.) When students watch class video on the computer, it is preferable for students to make notes on the computer. To make notes on the computer while watching digital class video is simple because they can easily use another window for a text editor or something like that. In that way, students are able to review
their lessons again, by watching video and their notes. As Notes is, however, "static" information, students should synchronize notes and video by themselves during watching video.

To synchronize notes and video, we implemented a telop function to our MPEG video viewer software. Users are able to put comments or notes to video as a telop just when they are needed. Once users put comments or notes to video, the telop come up on the screen at the designated time whenever they watch video. Fig. 1 shows an example of telop function.

Figure 1. An example of synchronized notes

If user put comments to video, a mark is shown on the scroll bar so that users are able to find where they put their comments. Scroll bar of the MPEG viewer is used to forwarding and rewinding video.

The mark on the scroll bar is also used to find important points of the video. In our method, the entire class is recorded on the video. Usually teachers use a lot of time for thinking, joking or something like that. The mark is used to avoid overhead of watching unnecessary parts of video.

In the same way, not only users (students) but also teachers are able to put comments to video. After the class, teachers sometime notice there were mistakes or insufficient explanation during the class. In such case, teachers are able to add additional explanation or corrections to video as a telop.

Conclusion

We implemented synchronized notes to MPEG viewer. Users are easily able to add comments and notes to class video for their self-studying. After the class, teachers are also able to add additional comments or explanation to their class video. The softwares are implemented as WindowsNT and UNIX (FreeBSD) X-window applications so that students are able to study on any plathome.

Acknowledgement

The Development of Multimedia Kanji Dictionary for Non-Japanese on WWW

Kazuto YAMADA, Shinichi FUJITA, ChunChen LIN, Seinosuke NARITA
Department of Electrical, Electronics and Computer Engineering,
School of Science and Engineering Waseda University, Japan
Narita lab, Sci. & Eng., Waseda University 3-4-1 Shinjuku-ku Okubo, Tokyo, 169, Japan
kazuto@narita.elec.waseda.ac.jp

Abstract: In recent years, popularized technologies such as "Multimedia" and "Internet" came to be used in various fields. The field of education is not an exception either, and these technologies are adopted by CAL (Computer Assisted Learning). Especially, the successful introduction of these technologies into Japanese education is being looked forward to. Since Japanese as the 2nd language is said to be high in the degree of difficulty in acquisition, an improvement in the study efficiency through adopting such technologies is expected. This paper focuses on Kanji of Japanese language education and discusses the multimedia Kanji dictionary.

Introduction & Background

At present, there are many non-Japanese who are learning Japanese in the world. However, with a limited time allocated for study in classes, the present condition does not offer sufficient education for mastering Japanese. For, not only are there problems related to the basic grammar such as the word order in Japanese is sometimes different and the use of the auxiliary verb is more complicated in comparison with other languages but also there are three kinds of characters used: "Hiragana," "Katakana" and "Kanji." Especially, quantity in Kanji is voluminous and the shapes are complicated. Even for Japanese, it takes 6 years to learn over 1000 Kanji characters. Furthermore, so much information is contained in Kanji (for example, reading, meaning, radical and the stroke count, etc.). Therefore, the more efficient Japanese education system is necessary because it is excruciating for people in the countries where Kanji are not used to learn them in a short period of time. When people in the countries where Kanji are not used learn their mother tongue, they emphasize "conversation." Therefore, even when they learn Japanese, they emphasize "conversation." In comparison with Japanese, a one byte code language, in the first place, has a fewer number of characters but has a number of types of pronunciation. Therefore, such a language can be mastered mainly by improving conversation ability.

From such a reason, for people of the countries where Kanji are not used inevitably neglect learning of Kanji. To effectively learn Kanji, the multimedia Kanji dictionary was developed. Since the electronic dictionary facilitates the understanding of Kanji by using animation and sound, it can improve learning efficiency much more than a conventional paper dictionary. Also, the characters of the index are so small that we sometimes become fed up with looking up Kanji in the paper dictionary. However, people will become able to search Kanji more easily by just clicking if they use the multimedia Kanji dictionary. This electronic dictionary is functioning as the dictionary module of an integrated Japanese learning system called "Terakoya."

URL: http://www.narita.elec.waseda.ac.jp/~fujita/terakoya.html

Kanji Dictionary

This dictionary system can be divided into the Kanji searching part and dictionary database part. In the searching part, there are three kinds of functions "Read," "Stroke count" and "Radical." Here, we can find a Kanji character for which we are searching, and we can read out detailed information from the dictionary database that is stored as a CSV file. On the one hand, this system contains detailed information such as radicals and the stroke count for people who want to learn detailed information. On the other hand, this system facilitates easy learning of Kanji by including items for children such as pictures and figures that look similar to Kanji. This system has become an interactive system that has more mobile capability by using animation and sound, which is in contrast to the conventional dictionary system that emphasized text data. Animation is used to display the order of strokes of a Kanji, and voice is used to let the learner hear the data of "Reading" and "Examples." Furthermore, in order to have the users learn a large quantity of Kanji, this system understands Kanji through graphic means by recognizing each Kanji as a picture or a figure to improve learning efficiency.

And, because this system is using WWW, it is not dependent on a particular type of platform. A learner can use it through the Internet from PC regardless of whether the person is at home or in a class. Even if there was no such environment, in such case information of Kanji can be read by printing the contents out on paper as a conventional dictionary. Although this system is developed with Shockwave of Macromedia Company, the browser is not able to function as a printer when the movie that was made with Shockwave is loaded into the browser. Therefore, a page
where Kanji information is transformed into an HTML has been made. If the hard copy of Kanji information can be made, it can be used at places where there is no computer nor a network environment. This function comes from the requests of the Japanese language teachers and also of Japanese language learners.

Future Plans

Although this dictionary system has searching functions of "Read," "Stroke count" and "Radical," these searching methods are used conventionally in the conventional paper dictionary. However, there must be cases where a beginner of Kanji learning has no idea about the reading, the stroke count nor the radical of the Kanji that he/she wants to find out. To this end, we are studying the functions by which a Kanji can be searched through handwritten letter recognition. If this searching method is created, a learner can search for the Kanji by the action that is similar to drawing a picture of the Kanji whose detailed information is not known to the learner. Also, although the present system has registered 80 Kanji characters in the database, in order to maintain coordination with the "Terakoya" system, it is necessary to classify Kanji by the degree of difficulty or by the use frequency in daily life to offer data to the user in an easy-to-understand manner. Furthermore, because there are some cases where the requests of teachers differ from the contents of a dictionary, we should add such function that enables the teachers to freely select the words and pronunciations, etc. that he/she wants to use in the lesson. If there is such a function, a lesson will become very effective. At last, we need to evaluate this Kanji dictionary. This system will be tested by the Center for Japanese Language of Waseda University and the Richmond school in Portland. And, we want to advance to further improvement by asking advices from teachers and students.

Teaching On-line Versus On-site: A Study of Instructional Delivery Modes in Foreign Language Education

Quan Yang
Distance Learning, Troy State University Dothan
qyang@tsud.edu

C. James Wong
Instructional Technology & Distance Learning, Learning Resources Division, Southwestern Illinois College
cjwong@bacnet.edu

Abstract: The purpose of this study was to identify the similarities and differences of online and traditional foreign language courses and to determine the advantages and disadvantages of the online courses. Using a random sample of 20 courses, ten on-line and ten traditional, this study examined the online and traditional courses in terms of five constructs and compared the methods and strategies used in online courses with regular classroom instruction. With a rubric developed for the study, the online and traditional course were rated in a 4-point scale and analyzed with independent t-tests. The findings of the study indicated that online and traditional courses had about the same weight in teaching foreign language and suggested that they each had its advantages and disadvantages. The study concluded that traditional courses had better defined and more specific goals and objectives for both teaching and learning and was more effective in teaching conversation and listening comprehension, while in online courses, students could learn at varying rates and explore material to whatever depth they desire, and Internet technology made it possible for students in different areas and from different countries to access online courses.

Introduction

With the rapid development and fast growing adoption of technology, the use of technology in education has been dramatically increasing over the past few years. In the area of language education, various technologies are being utilized by language teachers and learners in and out of the classroom (Warschauer, 1996). These uses would include the traditional use of audio and films; however they are now being supplemented by computer-assisted instruction and interactive media technologies (Richards, 1996). Computer-based programs, as well as other computer-related interactive technologies, have been specifically developed to provide students with visual and audio support. These applications have shown potential for helping students develop their language abilities and improve classroom performance (Pennington, 1996).

Among a variety of instructional delivery media, the Internet, especially the World Wide Web, has been commonly adopted by many educators in higher education (Khan, 1997; Porter, 1997). However, little research results have shown to support claims for the effectiveness of Web-based instruction (Nunan, 1999). The focus of this study was an analysis of existing web-based foreign language courses and a comparison of the methods and strategies used in online courses and regular classroom instruction to determine the common and unique methods and strategies used to achieve the educational objectives in each environment.

Purpose of the Study

The purpose for conducting this study was to identify the similarities and differences of online and traditional courses of teaching foreign languages and to determine the advantages and disadvantages of the online courses. Methods, strategies, and technologies used in online foreign language courses were examined and compared with those of the traditional foreign language courses. In order to achieve the purpose of the study, the current study addressed the following research questions:
1. Based on the courses examined, what methods, techniques and strategies were used for teaching online foreign language courses and traditional foreign language courses?
2. What were the differences between traditional foreign language courses and online foreign language courses in terms of goal/objectives, strategies, interaction, feedback, and resources?
3. What were the advantages and disadvantages of the online courses?

Method

The sample for this study consisted of twenty foreign language courses, with ten on-line courses and ten traditional courses. Thirty online courses were first identified directly from foreign language courses available on the Internet, which included listening, speaking, reading, and writing courses. The following systematic procedure was used to randomly select ten courses from the thirty previously identified online courses: First, a random list of the thirty online courses was generated. Then
a start point for the selection was randomly chosen on the list. From that point every third course was selected until a total of ten online courses were identified for the study. Among the ten courses that were chosen were two listening courses, one speaking course, two reading courses, two grammar courses, and three writing courses.

With the same procedure, the ten traditional courses used for this study were randomly selected from foreign language courses offered by the Intensive English Programs and foreign languages departments at various universities. The course materials of these ten courses were available at the University of Louisville, the University of Alabama, Southeast Missouri State University, and North Carolina Wesleyan College. They were three listening courses, two speaking courses, two reading courses, one grammar course, and two writing courses, which comprised the traditional foreign language course group for data analysis.

With a rubric developed for the study, the online and traditional course were rated on a 4-point scale and analyzed with independent t-tests.

Results and Discussion

The comparison by means of the rubric indicated that the online courses and the traditional courses had about the same weight in teaching foreign languages in general. Online courses had a total score of 147, while the score of the traditional classroom teaching was 153. However, the independent t-tests, which were performed to identify any possible significant difference between the online and traditional courses, found that significant differences existed between the two types of courses in two of the five constructs measured.

Conclusion

A foreign language acquisition process consists of listening, speaking, reading, and writing skills. In order to facilitate the success of second language teaching and learning, modern technologies have been used in the classroom to promote teaching performance and student learning. Online courses, which have been developed for that purpose, have proved their advantages in foreign language teaching and learning. However, when comparing traditional classroom teaching with online courses, the results of this study suggest that each had its advantages and disadvantages. For traditional courses, better defined and more specific goals and objectives were given for both teaching and learning. Delivering course material through the Web, on the other hand, afforded some advantages over traditional classroom teaching. In online courses, students could learn at varying rates and explore material to whatever depth they desire. There were new ways to guide students through tutorials and to provide them with instant feedback. Using Internet technology made it possible for students in different areas, different countries to use varying computer types to have access to the course.

However, as far as a foreign language is concerned, it is obvious that traditional classroom teaching was better in teaching conversation and listening comprehension courses when students needed face-to-face interactions with the instructor and instant verbal feedback from the instructor. Computer-mediated communication had been criticized as lacking the human social interaction necessary for human learning (Gilbert, 1996) although Lemke (1993) claimed that "cyberspace will be a virtual place FOR human social interaction." It seems that web-based courses might not be able to provide as effective or efficient a means of learning a language as one-on-one human interaction. Without such non-verbal cues as body language and the tone and pitch of one's voice, it is possible to misconstrue messages (Berge & Collins, 1995; Gilbert, 1996).

In summary, neither of the two types of courses is absolutely good or faulty. Each had its own advantages and disadvantages. As an instructional designer, we should be aware of the advantages and disadvantages of both types of courses and make full use of their advantages in the design and development of the courses, based on different student needs, student characteristics, and skill requirements, to achieve the goals of our education.

Abstract: The paper proposes and explains five common mistakes which institutions often make in implementing distance education: using packaged courses and low-level instructors, using one technology to deliver all distance education, not monitoring student satisfaction and retention, assuming that all courses can and should be offered via distance technology, and focusing marketing only on the technology-literate.

Racing along the Road

The shape of distance education is changing daily as more and more institutions embrace the technologies now available to deliver remote instruction. One estimate by Robert Tucker (1997) quoted recently in Forbes, is that about 90% of US four-year institutions will have technology-based distance learning offerings by 2000. Even in 1996, over a million students took distance learning courses of the 14 million attending post-secondary educational institutions. And, although these courses use many different technologies, there is rapidly-increasing focus on Internet delivery. In this rush to get on the bandwagon, the authors, who have been involved with emerging distance education in Texas for the last ten years, have observed several common assumptions which cause great concern. The focus of this paper will be to identify and call into question some frequent phenomena which, we believe, threaten to undermine the success of cyberlearning.

Wrong Turn One: Buy a packaged course and hire a TA or two to run it

One of the driving forces behind the charge to cyberlearning is the common perception that cyberlearning will be a cash cow for traditional institutions, allowing them to cut costs. In a rush to milk, institutions are sometimes choosing to dispense with home-grown courses run by local professors. This choice threatens to result in a world of cyberlearning where there are many institutions to choose from, but all are teaching the same course. Losing the personal enrichment, the personal mentoring and the constant updating which an experienced teacher puts into a course is equivalent to losing the personal voice or identity of an institution. Cyberlearning should increase the diversity of the educational ecosystem, not decrease it.

Wrong Turn Two: Buy one technology and use it for everything.

Because the costs for establishing technology-based distance learning can be large, institutions are prone to make an initial commitment to a technology (VHS with two-way audio, or TV, or compressed video, or web) then force all course offerings to fit themselves to that technology. Institutions have been known to simply buy whatever was pitched to them most intensely in the hopes of not having to face the bewildering array of choices again for quite some time. However, close analysis of student needs, course content, and educational effectiveness has led us to believe that hybrid technologies evolved over time and responsive to
individual courses and student audiences produce superior educational results. Educational needs and goals should drive technology, not vice versa.

Wrong Turn Three: Don't worry about student satisfaction; the learning is fine

Indeed, much past research on distance learning using all kinds of different delivery modalities from correspondence courses to web has indicated that students seem to learn as much from distance courses as they do from face-to-face instruction (Russell 1996). However, we cannot ignore that cybercourses vary enormously in learner-satisfaction and quality. In an ideal educational cyber-marketplace, learner-centered course design will eventually prevail. Courses which use technology well and flexibly to deliver their course content and achieve course goals, and courses which attend to a wide variation in student learning styles will have better success. Convenience of access is not enough; quality matters, too.

Wrong Turn Four: Move everything onto the cyber-track.

With the emergence of virtual universities and entire degree plans available by remote technology, the instinct of many institutions is to think of distance learning offerings as a substitute for face-to-face instruction, rather than an adjunct to it. However, a closer look shows quite clearly that cyberlearning has, thus far, leaned heavily in the direction of engineering, business, computer science and health sciences. (Miller 1998). According to Miller, all other subject matters account for only 10% of cybercourses. In spite of the pronouncement of Peter Drucker (1997) that "Universities, as we know them, won't survive," almost all lower-division and humanities courses continue to be offered in traditional fashion. One reason for this, we believe, is the need for greater flexibility in adapting to the goals of such courses and the needs of students. Cyberlearning should, we believe, offer additional choices to students and teachers--not force them into a course-delivery system alien to them. In fact, we go so far as to argue that cyber courses should, in most cases, have live, face-to-face versions running, too.

Wrong Turn Five: Just market the courses and the students will come

Certainly convenience, accessibility, and low cost are strong incentives for students to engage in cyberlearning. However, issues of equity and market penetration will become ever more pressing as institutions seek to draw increasing numbers of students. Access to computers is increasing daily, as is internet access; however individuals without home computers or internet access may be precisely the ones who most need access to "anytime, anywhere" post-secondary education. Institutions must attend to insuring access at public libraries, K-12 schools and community centers in order to insure equity for all ranks of society and to avoid widening the digital divide. Moreover, some segments of the market will need additional technology training in order to effectively use the access which is available to them, and institutions must provide appropriate training in technology if they are to draw high-school dropouts and retired persons into cyberlearning.

In a dynamic growth period such as we face now, the drive to implement cyberlearning will benefit many students and institutions, but only if decision-makers tread the path thoughtfully and with their eyes open for wrong turns.

Abstract: This paper sought to identify learner-demonstrated learning patterns when undergraduate students were learning to use a computer-based presentation program in a multimedia learning environment without time constraints. Using analysis of patterns in time (APT), a methodology that code event changes over time, the frequencies and the amounts of time of the five learning patterns of the APT codes were calculated. The data derived from the APT codes indicated two major findings: (1) the amount of time used by the participants ranged from 20 to 87 minutes. The amount of time spent did not predict mastery of the product test. (2) Following through error corrections, 'confirming assertions,' and 'trying new steps' were the patterns that did appear to predict mastery, and 'hand on mouse' and 'keeping up step-by-step with the video learners' task engagement' were indicators of learners' task engagement. The findings suggest that it is important to design flexible instruction to facilitate repeated, persistent, and successful practice in order to achieve mastery in a self-paced, computer-based learning environment, regardless of the amount of time spent.

Introduction

This study sought to investigate the existence of any significant temporal patterns of learner-demonstrated sequencing as learning styles that are related to the mastery of a procedurally computer-based multimedia task.

The impact of how different learning styles affect human learning has concerned educational researchers for decades (Bruner, 1966; Gage, 1967; Kolb, 1984; Wang and Walberg, 1985; Tobias, 1993). According to Cronbach and Snow (1977), learning style can be used to predict what kind of instructional methods or strategies would be most effective for a given individual and their task. Such attempts to discover the predictors for content mastery were typified in Aptitude Treatment Interaction (ATI) research. In ATI research, each learner's characteristic related to instructional outcome, and treatment was defined by different values in instruction to the learner (Cronbach and Snow, 1981). However, research to date on this problem has not identified many robust relationships between learning style and instructional method that are needed in order to guide the assignment of instruction to different learners (Snow, 1989). Could this lack of robustness be caused by overlooking the means in favor of the ends of learning? Or perhaps the notion of aptitude needs to be defined differently when the means of learning (or learning process) is considered as a critical component in a learning experience.

Frick (1990) indicates that one of the major issues of ATI is that the linear model approach (LMA) employed by ATI cannot explicitly demonstrate the different means of learning using the computer. The LMA is designed to estimate parameters of mathematical models and is not adequate in dealing with occurrences and relative frequency of temporal events. LMA is best for explaining the relation between two or more independently measured variables, but cannot measure the frequency or density of occurrences of a temporal path (Frick, 1983). This observation directly implies that there is a need for a methodology other than LMA when we investigate the temporal patterns of a learning process, especially with a concurrent attempt to examine aptitude in different ways.

Learning takes time. Learners take different amounts of time to perceive information in order to acquire knowledge. Knowledge is actively constructed through temporal sequencing of meaningful interactions between the individual and the learning context (Piaget, 1975; Dewey, 1916; Bruner, 1972; von Glasersfeld, 1985). But how can we move the learning styles research away from the instruction-centered "how one should learn" to the learner-centered "how one does learn?" In order to make instructional systems more adaptive, researchers need to put more emphasis on learner-demonstrated learning styles, where the relationships between the learning context, time duration, and nature of the media should be carefully examined. This need is especially important now that multimedia, productivity software programs, and the explosive growth of the Internet have allowed students to have more control over their educational capabilities and has caused us to reconceptualize the learning process and to design new instructional approaches (Deffy and Portzinek, 1992).

To understand the student to relate learning styles, it is necessary to comprehend the nature and limitations, of conventional learning styles. Swaff (1985) proposes four popular instruments to measure learning style: the Myers-Briggs Type Indicator (Myers, 1962), the Kolb Learning Style Inventory (Kolb, 1984), the Clifton Strengths Inventory (Clifton, 1986), and the Gardner's Type Indicator (Gardner, 1984). He finds that all of these instruments fall short generally in four areas: (1) no appropriate normative base for the valid interpretation of scores; (2) limited validity due to constructon problem with the instruments; (3) reliability estimators are unstable, though one can argue that the dynamic nature of learning styles makes high test-retest reliability unnecessary; (4) the normative frame of reference makes the interpretation of scores very difficult. Among his suggestions for future research, one suggests particularly interesting the present paper: "Further research could also explore the issue of whether an individual's preferred learning style is modified by the educational environment. For example, do adult students learn better when instruction is adapted to their learning style preferences?" Can people trained to adopt a particular learning style? Do learning styles remain stable over time in the adult population? Does a significant change in life situations result in changes in learning styles? (p.61.)

It is interesting to notice that all four of the above-mentioned learning-style instruments use lists of verbal statements or different visual forms prepared for people to choose or mark. This isolated "one size fits all" approach is decontextualized and artificial, and apparently based on language skills and cultural backgrounds. The predefined assessment tools require people to fit in the limited and selective choices with "I think this is who I am" or "I think this is what I will do or how I will react," which may not predict how one actually reacts to or interacts with a problem in a specific learning situation. This phenomenon has a fundamental reason that only limited reliability and construct validity have been found in existing learning-style studies.

Maybe, as Swaff suggested, human learning styles are constantly modified by the educational environment and social context and are too dynamic to measure on a predetermined and predictable scale. This notion leads the present writer to believe that to survey fully the dynamic nature of learning styles, rather than using artificial instruments, we can observe and faithfully record the event changes of a learner-demonstrated process over time. In other words, the result of this study may not verify that learning style is a stable trait (Bateson, 1979).

Research Questions

1. In the midst of the information explosion, multimedia has become the new learning environment. Learning how to interact with multimedia-based information or instructions has become our daily experience, and it is important to know what multimedia (e.g., video—either text or audio—exploration in a computer program window), (2) iconic (e.g., the screen capture of a computer program window printed on paper), and (3) concrete (e.g., the actual computer program window displayed on a monitor screen). The main questions addressed in this study were as follows: Given the choice of instructional materials in different forms of content, what learning sequences are selected by the learners?

2. Are any of these sequences especially likely to result in overall mastery?

3. Is there a difference in the amount of time spent learning for those learners who achieved mastery and those who did not?

4. In order to increase both reliability and validity in identifying the learning patterns (Dezcuri, 1979; Forman, 1988), a triangulation method was used that involved observation of the learning process and think-aloud interview. "Triangulation" is to use multiple methods in data collection and because (Dennison, 1979; Merrian (1988) indicates that "methodological triangulation combines different methods such as interviews, observations, and physical evidence to study the same unit." An observation system designed and based on the analysis of patterns in time (APT) approach was used to code how and how long students used and switch the instructional materials, and their engagement during the processes of learning. Both the learning processes and the think-aloud interviews were recorded on videotapes for examination and analysis.

Twelve participating students from a midwest regional university were selected through a screening process using Kolb's Learning Style Inventory (Kolb, 1975) where these students were selected extreme cases in each of the four categories identified by Kolb (converger, accommodator, diverger, and assimilator). The participants were expected to create three electronic slides using Axon meals, a multimedia presentation software, during the learning process. They were told that there was no time constraint and that they could freely use the screen just as instructions, the video demonstration parallel to the printed instructions, and the user manual and tutorial. They then created four slide without instructions as the post test. Learning sessions were recorded on video, and participants subsequently watched their own videos and were interviewed using think-aloud methodology. Multiple Observers viewed the videotapes of the learning performances for patterns of interaction, which were illustrated by the think-aloud interviews.

In this study, the interview was semi-structured. The interviews followed the observations and complement the outcomes of the observations, rather than forming a different set of data not related to the observations. The questions asked were open-ended so the students could explain fully and interpret any specific events that occurred during the learning performance.

As soon as the raw data from the interviews were collected, the data gathered from both the observation and the interview on each student were arranged into one case for analysis. As Merrian (1988) suggests, the "simultaneous analysis and data collection allows the researcher to develop a data base that is both relevant and parsimonious.

Next, the data collected from both the observation and the interview were sorted into any repeated patterns that are common to more than one person or identifiable categories or themes. Some patterns and categories were prominent and identifiable. The data was compiled into repeated or identifiable events or sequences from the observation when data from the interviews were reviewed and compared. This step was repeated until all 12 cases were analyzed. Then, an analysis to reduce and refine the categories or patterns among the cases was conducted.

Result

The narrative temporal descriptions of each of the 12 cases were compiled. The descriptions included answers to the following questions: Who was the person (age, gender, race, academic major, Kolb's learning style, mastery of the post test, prior computer experience). What did the student do with the instructional materials during different parts of the learning session? What comments (direct quotes from the think-aloud video) did the person make about what she/he was doing? These thick descriptions (Lincoln and Guba, 1985) illustrated how the participants actually interacted with the instructional materials during the learning sessions. These thick descriptions (Lincoln and Guba, 1985) illustrated how the participants actually interacted with the instructional materials during the learning sessions. To demonstrate the uniqueness of these participants, the following is a complete set of descriptions recorded from one of the 12 students.

Student F

Student F was a twenty-two-year-old male white student. He majored in Secondary Education and had had four years of computer experience. He was a converger (with a tendency toward active experimentation and abstract conceptualization), according to Kolb's learning style. He was judged a master of the post test. He spent a total of 42.5 minutes in completing the learning tasks and the post test.

Student F spent nine minutes on Task 1. He began his learning session by playing the video demonstration while reading the instructions. Student F is rather reserved but well-mannered. Of his choices of instructional materials, he answered, "I started by reading the [printed instructions] and watching the videotaped step-by-step. After a while, I was not even watching, "cause I know pretty much what to do by listening to it." He said of his reading strategy, "After a while, I was just reading aloud, and make sure that I was..."
In a careful review of all the think-aloud interviews in which the learners answered open-ended questions to explain their learning performances while watching the video-recording of their learning AStanard, five learning patterns emerged: (1) following through error correction, (2) confirming actions, (3) hand on mouse, (4) following step-by-step with the video instruction, and (5) trying new steps. Using analysis of patterns in time (APT), a methodology that can code events over time, the frequencies and the amounts of time of the five learning patterns were calculated. The data derived from the APT scores indicated two major findings: (1) The amount of time used by the participants ranged from 20 to 87 minutes. The amount of time spent did not predict mastery of the post test. (2) "Following through error corrections", "confirming actions", and "trying new steps" were the patterns that did appear to predict mastery, and the other two patterns were indicators of learners' task engagement.

The findings suggest that it is important to design flexible instruction to facilitate repeated, persistent, and successful practice in order to achieve mastery in a self-paced, computer-based learning environment, regardless of the amount of time spent.

Suggestions to Practitioners
First and foremost, the implications of these dynamic learning patterns are that the instructional designers and teachers can:

1. Identify the time in which specific methods are used to explain the learning process. However, in a classroom setting and even in corporate training settings, there are time limitations. As such, instructional designers will need to design the time frame so that learners can gain a deeper understanding of the learning materials.

2. Adapt the instructional strategies to accommodate the learning patterns that are observed. The present writer recommends that under such circumstances that the instructional designer needs to develop a mechanism to monitor the learning patterns and apply them to simple instructional tasks on the conduct of the operations (e.g., Windows 95 in this study) and the basic features of the application software program (e.g., the tasks featured in Astound in this study).

3. If those learners who choose to use exclusively the text-to-printed instructions and have problems finding the features, tools, push buttons, or have difficulty finding "where they are" from just a verbal description, then (a) provide series of visual images, or (b) provide a graphical record of the tools and the appropriate screen captures should be added to the printed instructions.

4. Making the video (verbal) and video instruction: A method of teaching and training. (a) Use the computer software program for the course. (b) Use the video instruction to replace the computer software program. (c) Use the video instruction to reinforce the computer software program. (d) Use the video instruction to supplement the computer software program. (e) Use the video instruction to complement the computer software program. (f) Use the video instruction to enhance the computer software program. (g) Use the video instruction to improve the computer software program. (h) Use the video instruction to transform the computer software program. (i) Use the video instruction to develop the computer software program. (j) Use the video instruction to expand the computer software program. (k) Use the video instruction to enrich the computer software program. (l) Use the video instruction to enrich the computer software program. (m) Use the video instruction to enrich the computer software program. (n) Use the video instruction to enrich the computer software program. (o) Use the video instruction to enrich the computer software program. (p) Use the video instruction to enrich the computer software program. (q) Use the video instruction to enrich the computer software program. (r) Use the video instruction to enrich the computer software program. (s) Use the video instruction to enrich the computer software program. (t) Use the video instruction to enrich the computer software program. (u) Use the video instruction to enrich the computer software program. (v) Use the video instruction to enrich the computer software program. (w) Use the video instruction to enrich the computer software program. (x) Use the video instruction to enrich the computer software program. (y) Use the video instruction to enrich the computer software program. (z) Use the video instruction to enrich the computer software program.

5. For those learners who try to new steps, the learning lessons should be flexible. However, for those who do not like to explore new things, more structured jumpstart lessons at the same or at different levels of complexity should be provided.

6. Many participants in this study strongly suggested that more "context sensitive" hints or notes should be made available in both the printed and video instructions because the just-in-time hints or notes given immediately before or after the "problematic spots" helped some learners recover from errors quickly without getting frustrated. Therefore, it is important to observe where in the lesson learners tend to have problems with something, then design and position the "anticipatory cue" directly.

Discussion
In this study, there were five learner-generated patterns identified in a self-paced environment in learning to take part in a computer-based software program. Although generalizations cannot be made for all people in all kinds of learning because of the relatively small and selected sample, the trends found in the data do suggest that a number of these learning patterns would be predictable in mastery in procedural learning. Further studies with a larger randomly-selected sample will further test the character of these trends.

This present study used Kolb's Learning Style Inventory (LSI) as the screening tool to select samples because the LSI is a popular instrument for assess learning styles as a learner. Kolb's 1976 work with a self-paced computer-based learning environment is that regardless of the amount of time spent, repeated, persistent, and successful practice tends to lead to mastery of the post test. This finding echoes the results found by Sbar (1988) that repeated mastery during practice strongly influence students' achievement and attitude in an adaptive computer-based practice environment. Also, it concurs with the Academic Learning Time (ALT) research reported by Berliner (1979) that when students spend more time engaging in a particular curriculum content area, they more likely to achieve higher academic achievement.

It is important to note that the above-mentioned findings strongly support Carroll's (1989) argument that aptitude is primarily a measure of the time required to learn. This argument is in contrast with Academic Learning Time (ALT) research reported by Berliner (1979) that when students spend more time engaging in a particular curriculum content area, they more likely to achieve higher academic achievement.

Bloom, B. S., & Madaus, G. F. (1989). The classical models (based upon theories of intelligence) in which all learners are given the same amount of time to learn, and the focus is on output or achievement. It is important to note that the above-mentioned findings strongly support Carroll's (1989) argument that aptitude is primarily a measure of time required to learn. This argument is in contrast with Academic Learning Time (ALT) research reported by Berliner (1979) that when students spend more time engaging in a particular curriculum content area, they more likely to achieve higher academic achievement.
Does the labeling of links assist user orientation?

Rolf Zajonc & Lutz Schön
Humboldt-University
Invalidenstr. 110
10115 Berlin, Germany
zajonc@physik.hu-berlin.de
www.physik.hu-berlin.de/ger/gruppen/didaktik/a06.htm

Abstract: Hypermedia learning material often makes broad use of links to information which goes beyond the learning objectives. But instead of being additionally motivated some students rather feel too much asked of. Within the Lilienthal project (www.pilotschool.net) links that don't follow the linear navigation are labeled with respect to their relevance for the learning objectives. First evaluations prove that the students welcome this assistance.

Introduction

"Information overflow" or "lost in hyperspace" are keywords, which also are frequently used to describe the difficulties of students using hypermedia for learning purposes. Indeed they give a good impression of what may hinder students from enjoying the new technical possibilities offered by the internet in contrast to their teachers expectations. When creating webpages instructors believe they can motivate their students by offering many links to further interesting or related aspects on the specific subject matter. But e.g. many lecturers report, that rather the opposite effect is shown by their students: learners tend to complain about the number of webpages they are supposed to visit (Dunlap 1999).

The problem faced is, that while the lecturer wants to offer the students the best chances to learn the subject matter as well as possible, the student also has in mind, that he needs to achieve certain learning objectives within a certain amount of time, e.g. to be prepared on time for an examination. Consequently students feel overwhelmed and frustrated by the amount of information, because they cannot differentiate between more and less important links as their teachers can. One possible solution to this problem might be the labeling of the links according to their relevance for the required learning objectives, e.g. by the use of small icons in front of links.

Labeling of links according to relevance

This directly leads to the first question: How to decide on the relevance of a link? The answer can be easy, if the creator of the webpages and the corresponding examination responsible are the same person. But in many cases the learning material is programmed by a team whose members can have different opinions on this question. As this also affects the pages’ content in general, it is necessary, that the complete team agrees on a set of well formulated (e.g. Mager 1978) detailed learning objectives before the actual programming takes place. Afterwards the links can be labeled with respect to these detailed learning objectives.

In order not to confuse the students within Lilienthal it has been decided to restrict the labeling to three icons:
- mandatory, e.g. a link leading to a formula which the student must know by heart;
- recommended, e.g. a link leading to an interesting example which illustrates the effects of the formula in a certain context; or
- nice to know, e.g. a link leading to an abstract about how this formula had been discovered historically.

Of course it still remains the student’s decision whether he follows a link and for how long he stays on the corresponding pages.

Research

Hypermedia material for roughly 80 hours of learning time has been distributed to pilot students of four European flightschools. The material had been programmed after a Delphi-process (Linstone & Turoff 1978) which lasted one year, during which several subject matter experts of all involved flightschools had discussed and finally agreed on a set of detailed learning objectives, each describing 5 minutes of learning time. On this basis, the links within the material have been labeled as described above. The number of links vary per module (9 DLO in average).
At this point in time (March 2000) evaluation of the various data (tests, questionnaires, protocols) has just started. A first evaluation of 208 questionnaires on 11 different modules (average 45 minutes) not only proved that the big majority of students found the labeling of links useful (compare figure 1), but also that there is a strong correlation \((p < 0.01)\) to the statement “the module is easy to operate”. A reasonable interpretation of this correlation is that those students who made use of the additional info of the labeling icons, also felt they had a better control in general.

![The labeling of links (m, r, n) is useful!](image)

Figure 1: Evaluation of 208 student questionnaires on 11 different modules for the statement The labeling of links is useful!

Nevertheless further investigations are required, e.g. because in the pre-evaluation (in total 19 students) 14 out of all 17 students who marked “(strongly) agree” almost immediately added “…but still you click on every link anyway”. This shows a well known behavior of hypermedia users, who only have little navigation experience. The assumption is, that the labeling will have a stronger influence on the ‘click or no click’-decision in the long run.

In this context, although in our case the pilot students certainly form a rather homogenous group (typically male, age 19-23, open-minded for technically related matters, good marks in physics and mathematics), it is still expected, that students are influenced differently by this labeling. E.g.

A students still click on every link,
B students select recommended and in particular nice-to-know links according to the indicated topics,
C students avoid most recommended and all nice-to-know links.

In addition it might well be possible, that a student changes his attitude in the courses process. As has been mentioned before, in particular novices might rather show A behavior, but after a while they are expected to realize, that they need to work more efficiently and become B or C students.

But the labeling should not only influence the decision whether to click but also the navigation on the following pages. A student should be more likely to really explore a webpage if he knows its content belongs to the mandatory level. In contrast he might show scanning navigation (Canter, Rivers et al, 1985) if he knows that he needn’t follow the link before at all. Since so far almost no experiences are reported in this context, these are just reasonable assumptions, which need to be investigated.

SHORT PAPERS
(Work in Progress)
When is an Interactive Learning Scenario a Matter of Interface Design?

Christian M. Adriano, Adriane M. Adriano, Ivan L. M. Ricarte
State University of Campinas, Brazil

Interaction is an important feature a learning activity must promote. Parker (1999) outlines benefits provided by interaction: “Understanding and long-term internalization can only be acquired by communication, reconstruction and reconciliation of information; interaction enables socialization, promotes motivation, and learning commitment; interactive processes foster comprehension and consensus on universal truths”.

In previous research (Adriano et al. 1999), we implemented a computer supported learning scenario by producing content, modeling evaluation, and choosing a proper pedagogical orientation. Our effort resulted in the first version of the CALM platform, which implements a learning scenario inspired by the Goal Based Scenario approach, provides an intelligent tutor, and hosts material for learning Java. In order to guide further effort on interaction, the following problem was posed: When is an interactive learning scenario a matter of interface design? We propose two situations in which developing interactive learning scenarios incurs in interface design. First, when concern fits on one of the items proposed by Marcus (1994): Mental and Navigation Models, Appearance, Interaction, or Metaphor. Second, when the learning scenario, implemented by the resulting interface design, must accomplish complementary definitions for the concept of “interaction”.

Metaphors are fundamental concepts communicated through words, images, and sound. Mental models are data structures, functions, tasks, roles, jobs, and people in organizations of work. Navigation is the process of moving through the mental models. Interaction is all input-output sequences and means for conveying feedback. Appearance relates to visual, verbal and acoustic information.

The designed metaphors (Adriano et al. 2000) were annotation, document, and annotation-place. The design of the interaction item resulted in three annotating paradigms represented by specific annotation-places: Bridge, Inline, and Tree. The Bridge place represents the idea of annotating as adding links. The Inline place supports the paradigm of writing over the text and having the annotation content visible. The Tree place organizes annotations in a newsgroup-like fashion. The mental model comprises the annotation-place model and organization of roles. In the former, a document may contain many annotation-places and an annotation-place may contain many annotations. The organization of roles depends on each learning scenario specification. The navigation model comprises resources to manipulate metaphors. Such resources correspond to: annotation editing interfaces, a search tool, a document composition tool (annotation-places are implemented as applets within Web pages), a tool for repositioning annotation-places due to changes in the original Web page, and a tool to generate workbook-like compilation of annotations. The appearance item relates to types of annotations and annotation-places. The annotation metaphor has four visually different types: doubt, suggestion, commentary and mark.

The discussion scenario comprises theme presentation, individual annotation, group annotation, and discussion summarization. Roles are “moderator” and “commenter”. The theme presentation is a notification that the Web page hosting the text for discussion is available for commenting. After notification, starts the individual annotation phase in which commenters read and make personal annotations on the text. In the next phase commenters may request the annotations of their peers and discuss opinions and acknowledgements, which involves commenting on each other annotations. When discussion is finished, due to a deadline or a common agreement, the moderator compiles annotations into a second text elaborating a summary of the discussion.

The co-authoring scenario includes goal definition, authoring, reviewing, voting, and consolidation. Roles are “co-author”, “reviewer”, and “author”. Co-authors annotate using inline annotation-places and may define when an annotation is ready to be seen by others. Reviewers may comment on annotations made by co-authors. As a co-author decides that an annotation should become part of the underlying text, he/she requires the author to consolidate the annotation. If the author agrees, the annotation is incorporated to the text. The author can also ask for co-authors to vote whether an annotation should be consolidated. An annotation has states such as ready, removed, in consolidation, being voted, and not available.

Some interaction definitions were collected from Vigotsky, Habermas, de Certeau, and Chartier. Vigotsky (1978) deals with the cultural dimension of learning. Apprenticeship is result of interactions among historical subjects and the world. Signs and symbols are the condition for these interactions. People, instruments and signs mediate relations between a subject and physical/social environment. Signs correspond to a representation of reality and refer to remote times and spaces. Interaction is conceptualized as relations among historical individuals,
signs, and instruments. Such definition is satisfied by interfaces that relate individuals as role players, signs as metaphor representations and instruments as tools of the navigation model.

Certeau (1974) states that interaction is based on a metaphor of landmark and on distinctions between place and space. In short, place is static and permanent, while space is dynamic and transient. Landmarks delimit regions (spaces or places), being also classified as dynamic or static. Static landmarks are frontiers, like rivers and fences, delimiting places. Dynamic landmarks are bridges, like doors and windows, delimiting spaces. Bridge-like landmarks represent encounters of action. Moreover, there will be so many bridges as the number of "interactions". Interaction is defined as a bridge separating spaces of action. Such concern inspired the design of annotation-places, whose types provide different bridging between the document space and the annotation space.

As quoted by Prestes (1997), Habermas argues that the communicative action has a kind of anchor constituting background knowledge. Such knowledge fosters interpretations for participants of an interaction. The background knowledge relates to a world of life (Lebenswelt), the horizon on which we move. It is pre-scientific, intuitive, not expressed and not questionable. It constitutes itself not only by cultural convictions, but also by institutional organizations and structures of personality. Habermas uses the daily communicative praxis to guarantee the symbolic reproduction of three spheres; culture, society, and personality. Culture refers to knowledge acervus, over which we formulate interpretations to understand the world. Society refers to legitimated organizations that regulate our bindings with social groups. Personality refers to competencies that enable subjects, capable of language and action, to take part in an understanding process. The following citation of Habermas clarifies these three aspects: "In respect to the functional aspect of understanding, the communicative action promotes tradition and cultural renovation. In respect to coordination aspects, the communicative action promotes social integration and creation of solidarity. In respect to socialization, the communicative action promotes formation of individual identities". Interaction is a space of conflict between a pre-comprehension of world of life and the communicative action. Therefore, when and where interaction happens, the stability of the world of life is disturbed by arguments of the communicative action. Annotation interfaces enabling discussion was a mean to accomplish such vision.

Following a historical point-of-view, Chartier (1997) provides a study of how mankind has been interacting with and by means of the written letter. Medium has changed from papyrus, to codex, to Gutenberg press, and, nowadays, to digital text. Each medium required a proper interaction paradigm suggesting that interaction be also defined by the enabling technological support. In other words, medium defines interaction. Such concept for interaction was accomplished by supporting audio and written media for annotation.

In addition to the five components proposed in Marcus (1994), we suggest a careful study of the interaction concept. The presented discussion stems from project meetings between educators and software developers. A recurring problem faced was the lack of consensus on concepts, accompanied by concerns of presupposing things that needed better understanding before implementation. Interaction conceptualization is one these concerns. We hope the ongoing research will collect further insights to the design of interactive learning scenarios as a cooperative entrepreneurship of educational and computer scientists.

An Interactive System Model of an Online System for Teaching &
Learning Developed as a Scoping / Costing Instrument

Anne A'Herran, Educational Development Adviser (WWW), Teaching and Learning Development,
James Cook University, North Queensland 4811, Australia.
anne.a'herran@jcu.edu.au

Abstract
Although there are strong reasons for purchase of an off-the-shelf system for online
course delivery (including the competitive advantages of reliability, the comfort of a
large client base and scalability), many universities develop a system themselves. These
home-grown systems are often more responsive to specific needs. When James Cook
University undertook to investigate available systems for university wide online course
delivery it was important to explore costs of building a system using university resources.
To this end a system model was designed as an interactive diagram reflecting each part of
the system in prototype http://www.tsd.jcu.edu.au/jcudevelop/jcuproto/jcuonline
The model is both an innovative example of organisational design method and a useful
means of testing user pathways through the system, (use-case), which can assist costing
and project management of the development of such a system.

As part of the search for the most suitable system for use at JCU we set out to determine the costs of
building a system using university resources:
• there was a high level of interest in the JCU community;
• the possibility of economies of production;
• a collaborative venture of this kind with the potential for cross-institution partnerships could be of
  value to the university in the future.

To this end a system model was designed as an interactive diagram reflecting each part of the system, in

The model is both an innovative example of organisational design method and a useful means of testing
user pathways through the system, (use-case), which can assist costing and project management of the
development of such a system.

Discussions were held with the schools of IT and Computing Science. The interactive system model was
felt to be helpful in this process in that it provided, by visible and testable means, a common understanding
of the scope and direction of the exercise. Costing was based in staged development from base level,
adding functionality as we saw a need.

There was found to be no case for developing DIY for immediate implementation:
• the real costs of DIY infrastructure are high for a one-off development which is not amortised over
  other products;
• time of development has to be compressed to keep pace with user needs and technical innovation: to
  compress time requires commitment of personnel which increases costs;
• when a university implements its own system, support for users becomes an internal budget decision
  not externally (market) driven: support is therefore subject to internal budgetary pressures rather than
  the wider driving client base.
Validating a Theory-Based Design for Online Instruction: Aligning Tool Use and Learning Outcomes

Arshad Ahmad
McGill University
1455 DeMaisonneuve
Montreal, Quebec. H3G 1M8
arshad@mercato.concordia.ca

Abstract: This paper provides a theoretical framework for the design of a successful web-based course in Personal Finance. Using an open learning model based on constructivist principles that draw from the literature in cognition and the social sciences, this paper sketches an instructional design model and specifies online tools that mediate between course objectives and desired learning outcomes. In order to validate the model, data generated from tool use and from student performance will be analyzed using confirmatory factor analysis.

Mixed Messages with Multimedia
A growing body of research is exploring the learning effects of multimedia designed environments. Some of this research has attempted to incorporate educational concepts in the design, process and implementation of course production in technology-rich platforms. However, the results are mixed. According to The No Significant Difference Phenomenon (Russell, 1999) which is based on 355 research reports, summaries and papers, the conclusions mainly indicate that the learning outcomes of students using technology enriched courseware are similar to those of students who participate in conventional classroom instruction. Yet, universities are allocating substantial resources towards the development of distance education courses and programs (Brahler, Peterson et al., 1999) to increase access to learning, with the hope that the quality of education will be damaged little, if at all (Ehrmann, 1999) Questions and concerns relating to technology integration are being raised, but as yet have had little systematic impact on the policies that guide educators, administrators and practitioners (Merisotis and Phipps, 1999; Welte, 1997)). Faculty realize that there are certain benefits of technology-based distributed learning environments, but put up considerable resistance to the development of such environments (Rickard, 1999).

Mixing Cognitive and Social Science Approaches
This working paper presents a theory-based design of an undergraduate web-based course in Personal Finance with the aim of addressing some of the issues addressed above in the context of better understanding student learning. Concerns relating to technology integration in educational practice, and technology’s intersection with learning theory are addressed in a design framework that aligns learning objectives, course activities and assessment methods. This alignment simultaneously considers the selection of online learning tools that mediate between design components for Personal Finance. The selection of learning tools also plays an important role in terms of how they will be meaningfully used by students, and how they will affect student performance.

Web-based instruction that is designed on accepted theoretical principles in cognitive psychology opens new doors to designers, learners and practitioners. This is simply because we know very little about best practices arising from the design of courseware that primarily uses this medium. However, in contrast, there is an abundance of theoretical studies in the cognition literature that have increased our understanding of competence in understanding a given discipline (See for example, Anderson, Corbett et al., 1995; Ausubel, 1968; Hatano, 1996; Means, 1993; VanLehn, 1996; and Winn, 1990). Similarly, studies from the literature in social sciences have proposed interactive socio-cultural contexts as a basis for understanding how learning can be constructed, scaffolded and facilitated (See for example, Bandura,
1986; Brown, Collins et al., 1989; Derry and Lesgold, 1996; Lave and Wenger, 1991; Moore, 1994; Shuell, 1993; and Richey, 1994. In his 1999 AERA Presidential Address, Alan Schoenfeld describes the split between cognitive and social science research with references to studies in cognition that excel in fine-grained data analysis but suffer from tunnel vision and points to as many sociological studies that are rich in scope but are weak with respect to validity and reliability constructs. His suggestion to bridge the gap was to “build something to see if it works and then study the hell out of it”.

This study seeks to validate a non-traditional design based on theoretical findings from the cognitive and social sciences literature. The world-wide-web is an obvious choice as the platform for building a design prototype because learners recognize that it is more accessible and convenient than traditional opportunities afforded in the classroom. Combining the web platform and a theoretical basis into a prototype design becomes meaningful when specific learning goals are specified with evidence to link these goals with performance outcomes that are assessed. These links are critically explored and are the focus of this study.

Challenges in the Design Process
The term technology is used broadly to refer not only to tools but also processes and is closely identified with the Greek form techne (art, craft, or skill), which was closely associated with episteme (systematic or scientific knowledge). Its educational meaning is historically derived, bound by specific psychological theories and philosophical underpinnings (Saettler, 1990). Visions of technology look very different depending on the explicit theories of learning that guide their design and implementation. According to The Cognition and Technology Group at Vanderbilt (1996), the challenge for instructional design based on significant technology integration is that learning theory, educational practice and technology interact with each other. To understand the role of technology, one must examine a simultaneous intersection with student learning and educational practice. This challenge is increased since all three areas have seen dramatic change in the past ten years. Thus, changes in theories of learning affect uses of technology, but new technologies such as the world wide web also make new kinds of interactions possible and hence affect theories of learning (Kozma, 1994; Saloman, 1993). Knowledge acquisition in constructivist environments engages learners in drawing meaning from multiple perspectives and through collaborative efforts. Engagement in real world or authentic tasks provides a context for the learner to construct meaning from his/her experiences. Thus, learning is situated in a community of learners who construct personal meaning through dialogue and socialization (See Brown, Collins et al., 1989; Jonassen, 1998; & Wilson, 1995).

Sketching the Design Components
Given these perspectives, different views of how humans learn and how designers approach instruction are incorporated under the umbrella of knowledge acquisition and knowledge construction. In addition, aspects of situated cognition, which emphasizes social and ecological interactions is also included. Parts of the design relies on an information processing view emphasizing course content that hierarchically structures the sequence of information. Using Hannafin, Land et al.’s (1999) open learning model which emphasizes diversity and choice, course material was selected to reflect a variety of print-based, multimedia and interactive web-based tools that could best enable the learner to attain the learning goals set for the course. The importance of constructive alignment between different design components is emphasised by Biggs (1999); they become inextricably linked, so that the course becomes greater than the sum of its parts. These components include a textbook, short vignettes with practitioners who introduce each topic, simulations that forecast your net worth, or your tax bill, interactive practice tests including pre-tests, review exercises, short cases, etc and communication software that allows for threaded discussion, chats, critiquing, posting and other activities consistent with best practices in effective learning communities. Technology has been nested within a constructivist framework to raise the intellectual, social and ethical standards of learners, by empowering them to question, participate, and practice authentic issues in personal finance. Jonassen, Davidson et al. (1995) summarize this approach: “...learning is necessarily a social dialogical process in which the communities of practitioners socially negotiate the meaning of phenomena” (p.9). In addition, feedback opportunities are provided by experts (the instructor as well as practitioners) to ensure accurate knowledge acquisition. Finally, communication strategies are designed to facilitate elaboration of content and solicitation of responses that
reflect what students are thinking. Here, the tools employed include interactive tests, e-mail and bulletin boards, as well as audio conferencing.

Data reflecting student use of designed tools and their performance on assigned tasks will be collected to confirm the validity of the design model. Evidence of learning using Bloom's (1956) taxonomy will reveal the general factors associated with the model. Path analysis will be used to confirm the relationship amongst the design components as they fit within the instructional design model.

Learning Strategies for Multi-Media Instruction

Mohamed Ally, Ph.D.
Athabasca University
1 University Drive
Athabasca, Alberta,
Canada, T9S 3A3
mohameda@athabascau.ca

Abstract: Multimedia instruction must follow instructional design principles that are based on learning theories. This session will share an effective model for designing learning materials and will describe the strategies that should be used when designing multi-media learning materials.

Pre-instructional Activities

Before teaching new materials to students, the lesson must overview the materials so that students can form a mental set for the materials and become motivated to learn the materials. The different types of pre-instructional activities include content map, advance organizer, pre-test, learning objectives, and rationale.

Prepare Learning Activities

Conventional instructional methods tend to use passive instructional strategies. It is important to use strategies that will keep students active so that they will be motivated and will process the information in greater depth. To encourage active learning, it is important to use discovery strategies so that students can find out things for themselves. Instead of teaching a large amount of information to students, we should give students the task and then guide them to find and apply the information. Multi-media and on-line instruction are excellent methods to promote active learning.

Elaborative Strategies

To make the instructional process more effective and efficient, the lesson must provide activities for students to process the content at a deep level. The deeper the information is processed, the better it is learned or remembered. As a result, the instruction should contain elaborative strategies to help facilitate deep processing. Some common elaborative strategies are asking questions during the instruction, asking students to summarize segments of the instruction, requesting students to make their own notes, and asking students to underline or highlight important information. The elaboration process facilitates efficient storage in long-term memory. This is important since the ease of retrieval will depend on the way the information is stored in long-term memory.

It is known that when new learning materials are encountered, they are attended to and transfer to short-term memory storage. After entry into short-term memory, the information must be transferred to long-term memory immediately since short-term memory has limited capacity. As a result, students should be given the opportunity to elaborate on small segments of instruction so that the materials can be transferred to long-term memory immediately.

Presentation Strategies
Most instruction is done in an expository fashion where the learning material is presented in its final form to students. The most common expository methods are rote, inductive, and deductive learning.

The rote method consists of presenting the materials to students and then asking them to recall the materials as presented. For example, the lesson may present a rule and then ask students to recall it. The deductive method occurs when students are given a rule followed by examples to explain the rule. The inductive method involves giving examples on a certain rule followed by the rule. However, to make learning more efficient and effective, discovery strategies must be used. With the introduction of new instructional technologies and multi-media, it is possible to design instruction that contains discovery strategies.

Practice Exercises

Another important component of instruction is practice with feedback. After the presentation of the materials, students should be given the opportunity to practice what they have learned so that they can get feedback on how they are performing and at the same time prepare them for the final test in the lesson. In addition, the practice test acts as a good learning strategy since test questions usually consist of general ideas which act as cues to recall specific details and skills.

Summarize the Lesson

After the lesson is presented to students, they should be given a summary so that they can get a sense of closure for the lesson and gives a general review of the lesson.
Web-Based: Instructional Effectiveness

Nella B. Anderson
Western State College of Colorado
112 Kelley Hall
Gunnison, CO 81231
nanderson@western.edu

Abstract: Training preservice education students on the Internet requires the course to be more structured than would be required to teach the same course without an electronic component (Gillette, 1996). Education students have consistently expressed the need to see technology used by their university instructors if they are to use these tools effectively in their own teaching (Larson & Clift, 1996). Due to both a lack of suitable instruments and the importance of being able to assess web-course effectiveness, the authors developed the Web-Based Survey of Instructional Effectiveness (WebSIE) to meet this need. Forty-one students enrolled in a web-based course were given the WeBSIE prior to and after the completion of the course. Pretest to posttest comparisons showed students improved in their self-reported web-based skills and attitudes in the use of the internet, integration of the internet into instruction, general computer use/attitude and using a computer for communication. Future studies need to replicate these findings and investigate the effects of the integration of technology into more and varied teacher training courses.

The effective use of technology includes rethinking traditional forms of instruction. Instructors teaching online need to maintain the perspective that we learn best "with" technology rather than "from" it (Johnson, 1996). This perspective allows instructors to engage students in active (Copley, 1992; Reeves, 1996; Yakimovicz & Murphy, 1995), authentic (Copley, 1992), challenging tasks (Copley, 1992; Reeves, 1996), and collaborative efforts (Reeves, 1996; Yakimovicz & Murphy, 1995).

A computer-specific introductory course is usually insufficient in modeling for preservice teachers the use of technology as a tool for teaching and learning (Topp et al., 1994). Education professors from various disciplines must begin to use technology as a cognitive tool to mediate and transform the training experiences of teacher education students (Larson & Clift, 1996).

Instructional Design

Training preservice education students on the Internet requires the course to be more structured than would be required to teach the same course without an electronic component (Gillette, 1996). The structure that is embedded and remains consistent throughout each unit of study. The structure of an introductory special education course taught online will be elaborated on in this section by clustering the components into categories and providing a brief description of each.

1. Instructional Design Framework
   (a) Each unit of study is divided into six instructional steps.
   (b) Each of the six steps are divided into instructional components.
   (c) Reference numbers are assigned to each of the instructional components. The reference numbers are depicted using three digits separated by decimals (e.g., 2.3.4 represents Unit 2.Step3.Activity4). The reference numbers are used when discussing activities via e-mail, newsgroup, and/or chat.
   (d) Buttons are located at the bottom of each of the six instructional step pages so that students can go to the "next step" or return to the "unit index", which provides links to all six steps.

2. Curriculum Development
   (a) The curriculum is built upon the principles of active learning, cooperative groups, peer-mediated instruction, and content experts
Active learning is integrated into the course through the use of interactive forms and case studies found on the Internet.

The class is divided into cooperative groups of two based on where students live and their educational major.

Peer-mediated instruction is used through the creation of student homepages and peer expertise pages. These pages allow students to share their work and ideas with each other.

Content experts are utilized by incorporating parents of students with disabilities and personnel in special education field in local public schools into the class discussions (e.g., e-mail, chat, and newsgroup).

All activities taught in the traditional course on campus are incorporated into this online course through the use of e-mail, chat, newsgroup, electronic handouts, forms, and web sites.

Teaching in this virtual classroom in comparison with teaching in the traditional classroom requires much more learning and much less teaching (Peterson & Facemyer, 1996). The dynamic learning environment available online, which is expanding at exponential rates, provides opportunities for students to become explorers and discoverers (Gates, 1996).

Education students have consistently expressed the need to see technology used by their university instructors if they are to use these tools effectively in their own teaching (Larson & Clift, 1996). All students enrolled in this online course had completed at least one required computer-specific course prior to the beginning of this online course. The development of a survey of instructional effectiveness was developed by the authors to measure the effects of learning educational content through the use of web-based technology.

Web-Based Survey of Instructional Effectiveness

Due to both a lack of suitable instruments and the importance of being able to assess web-course effectiveness, the authors developed the Web-Based Survey of Instructional Effectiveness (WebSIE) to meet this need. Expert opinion from individuals with both academic credentials (Ed.D. or Ph.D.) and web-based course experience were sought to develop an original pool of 58 items. This pool of items was subjected to factor analysis. A five-factor model was adopted retaining 30 items: Use of the Internet (8 items); Integration of the Internet into Instruction (8 items); General Computer Use/Attitude (4 items); Using a Computer for Communication (5 items); and web-based Course Effectiveness (5 items).

Using this 30 item survey authors administered 313 to preservice education students and practicing teachers. Cronbach's alpha and split-half reliabilities were calculated for the five scales. Alpha for the whole 30 item instrument was .803, and the five scales were Use = .557; Instruction = .531; Computer Use/Attitude = .415; Communication = .653; and Course Effectiveness = .419. Split-half reliabilities for the five scales were Use = .762; Instruction = .750; Computer Use/Attitude = .726; Communication = .823; and Course Effectiveness = .672.

Forty-one students enrolled in a web-based course were given the WebSIE prior to and after the completion of the course. Single-sample Dependent T-tests were performed on all five scales. An alpha level of .05 was used for all statistical tests. Four of the five scales were significant: Use, t40 = 4.873, p < .001; Instruction, t40 = 4.143, p < .001; Computer Use/Attitude, t40 = 3.797, p < .001; and Communication, t40 = 2.401, p < .02.

Pretest to posttest comparisons showed students improved in their self-reported web-based skills and attitudes in the use of the internet, integration of the internet into instruction, general computer use/attitude and using a computer for communication. These statistically significant gains in web-based skills and attitudes were noted after one education methods course that modeled the use of the Internet in instruction. Future studies need to replicate these findings and investigate the effects of the integration of technology into more and varied teacher training courses. Additional effects of the integration of technology into teacher training programs needs be studied after these preservice teachers become practicing teachers, focusing on how often and in what ways they integrate technology into their own teaching.

The Interaction and Psychological Distance in Educational Situations:
Experimental View

Shaker Hasan Aradi
Institute of Education, University of Tsukuba, Japan
shaker@human.tsukuba.ac.jp

Abstract: This paper reports the findings of a study conducted with an experimental undergraduate-level class. It investigated the differences between learners studying with the teacher face-to-face and learners studying at distance in terms of three dimensions; (1) learners' sense of distance, (2) interaction, and (3) achievement.

Introduction

One of the most important innovations resulting from the remarkable advances in communication and Internet technologies is 'face-to-face at distance education', which is forcing us to adapt new definitions, theories and practices. Physical distance is no longer the limiting factor; "psychological distance" is. Drawing on Moore's work redefining "distance", "interaction" and "transactional distance" (Sewart, 1988 & Moore 1991), the concept of psychological distance (PSD) refers to how close the participants within the educational environment feel to each other in terms of emotional comfort and satisfaction.

As Holmberg (1988) observes "real learning is primarily an individual activity and attained through an internalization process"; thus, learning is the product of internal interaction between the learner's previous experiences and new information obtained from external interaction with the other components of the educational situation, including contents/media, other learners and the teacher/instructor/coach.

The present study focuses on this interaction within the educational environment, in terms of the learners' sense of distance (SoD), as a direct indicator of PSD. Specifically, the main objective of the experiment is to examine the relationships that exist between: a) the learner's sense of distance, b) interaction within the educational environment and c) learners' achievement.

The Study

Twenty-two (only the data from 19 participants was usable) Japanese undergraduate-student volunteers, from a women's university attended four seminars entitled "Introduction to Public Speaking" during spring, 2000. The participants were divided into two equal groups, matched for age and scores for English and Japanese language; a "local group" (LG), which studied with the teacher face-to-face and a "distant group" (DG), which studied with the same teacher at distance. An ISDN-based TV conferencing system was used to mediate communication between the two groups, so that they can study in different places at the same time. Achievement was evaluated by pre-tests and post-tests. The participants were asked to evaluate their "sense of distance" from others (i.e., the teacher, other learners in the same group and other learners in the other group) on a 5-point scale, with 1 indicating very close and 5 very far. The participants also recorded both how often they actually interacted with others, and how often they wanted to, as an indication of the interaction within the educational environment. The classes, as well as short interviews after each class to regarding technical aspects such as sound and picture quality, were also videotaped for further analysis and to improve the seminar contents.

1 Sense of distance is contrasted with “real distance,” as a measure of the distance learners feel to exist between themselves and other components of the educational setting, irrespective of the actual distance.
Findings

The differences between pre-test scores concerning the participant's knowledge of public speaking for the two groups were not significant (average scores were 4.5 and 5.22 for the LG and DG conditions respectively). The scores for the post-test were 16.4 for the LG and 18.66 for the DG, indicating significant improvements in knowledge concerning public speaking for both groups (p < 0.0001). The average scores for both groups also indicate that there were no significant differences between the two groups in terms of achievement at the end of the experiment.

In terms of learners' SoD to the teacher, the average evaluation rating for the LG condition fell from 3.166 after the first class to 1.7 after the last class. In the DG condition, this fell from 4.7 to 3.00. Although analyses (Wilcoxon Signed Ranks tests) indicated that these changes were significant (p < 0.025 and 0.015 for LG and DG respectively), further analyses (Mann-Whitney U test) also indicated that there were significant differences between the two groups after both the first and last classes. In other words, although the learners' sense of distance to their teacher declined significantly for both groups, those in the LG condition felt much closer to the teacher than those in the DG. Reviewing the videos for both sites, we found that although the teacher almost had the same amount of interaction with both groups during the class, he did spend more time talking and explaining to the LG both before and after the classes, and that he was able to give more individualized attention to the learners in the LG condition, which may have contributed in making them feel closer to him.

The data indicated no significant changes in the learners' sense of distance to other learners in the same groups at both sites, which might be due to the fact that the students came from the same university. Examining the learners' sense of distance to the learners in the other group, the evaluation rating fell from 4.62 after the first class to 3.00 after the last class for the DG condition (significant at 4.6% level). However, there were no significant changes in the SoD for learners in the LG condition. This might be due to the initial setting at the LG site, which did not allow learners at the DG site to see their counterparts at the LG site during the first class, which was adjusted for later classes.

The correlation between the learners' SoD to their teacher and the records of interactions was −0.287 (sig. at the .05 level). Although no significant correlation was found between the learners' SoD to their teacher and achievement, the learners' SoD was highly correlated (0.636 sign. at the .01 level) to how important the learners regarded the contents, and how much they felt they had learnt (0.496 sign. at .1 level).

Conclusions

The results of this study suggest that it might be very difficult to acquire the same quality of interaction with physically-distant learners, and that it, therefore, takes more effort in order to reduce their SoD compared to learners studying face-to-face. Despite this, however, the more learners interact with their teachers the closer they feel to them regardless actual physical distances. Moreover, as learners feel closer to their teachers, they tend to regard the study as more important and to feel that they understand it.

Acknowledgement

This study owes its completion to the support and assistance provided by several generous people. I am indebted to Dr. Morio Yoshie and Dr. Ichiko, Shoj from Institute of Education- University of Tsukuba and Noriko Kanakubo from Tsukuba Women's University for their valuable comments, kind considerations, supportive advices and guidance and more for there continuous encouragements.

I also wish to express my sincerest gratitude to all the people and organization that helped me in completing this experiment. Especially, my friends Josh Kirby who kindly taught and prepared all the materials for the classes and Vikash Chandra who help in the experiment's setting and speared no effort to make it happen.
A Generic Pedagogical Agent Architecture That Supports Conversational Authoring

Abstract: Pedagogical agents offer great promise to improve the learning experience of students interacting with educational software systems. This paper describes work in progress on a generic pedagogical agent architecture and an authoring system to support the creation of custom agents by teachers and other domain experts using a natural, conversational metaphor.

The field of pedagogical agents is a recently emergent one which draws from previous work done in intelligent tutoring systems, autonomous agents, and educational theory (Johnson et al. 2000). Pedagogical agents have the potential to offer a wide spectrum of educational interactions with students, including opportunistic instruction, and have been shown to have positive affective as well as cognitive influences on students (Lester et al. 1997).

Several successful pedagogical agents have been designed for a variety of learning environments, ranging from skill-based training systems to more open-ended constructionist environments (Johnson et al. 2000). Currently, however, the task of building pedagogical agents is a non-trivial one which falls within the domains of researchers and professional programmers -- not those of teachers, curriculum designers, and other non-programmers. Authoring tools designed for non-programmers to create customized content for particular agents are under way, but little attention has been devoted to the question of authoring tools for creating customized agents, given a particular computer-based learning environment. It is to this question that we turn our attention in this paper. We will describe work in progress on a project which aims to allow teachers and other non-programmers to author customized pedagogical agents for interactive learning environments. We first discuss the design of a generic pedagogical agent architecture, suitable for use in constructionist learning environments. Secondly we discuss techniques we are developing to allow teachers to author agents based upon this architecture. We require that the architecture be suitable for constructionist learning environments due to their open-ended nature, which raises a greater challenge for the agent designer.

Our generic agent architecture (see figure at http://www.cs.washington.edu/homes/jbaer/pedagent/agentarch.jpg) is built around the Agent Control Module. This module is responsible for processing events received from the learning environment, updating its student and session models based on those events, initiating interactions with the student, and potentially sending commands back to the learning environment. The appearance and user interface aspects of the agent have been separated out into a distinct module. This allows for maximum flexibility in the appearance of the agent. Either the agent can appear in its own window, or the learning environment itself can implement this module, allowing the agent to appear within the main window of the environment, as do many of the existing pedagogical agents described by Johnson and Lester (Johnson et al. 2000) do.

The interaction between the agent and the learning environment consists of the agent receiving events from the environment and requesting state information from the environment or sending commands to the environment. It is up to the environment to define the set of events that will be sent to the agent, as well as the state and control commands that it wishes to expose. A distinguishing feature of this agent model is that we do not require the agent to have complete access to the state of the learning environment. While this can limit the information which the agent has to work with, it allows for interoperoperation with a wider variety of learning environments, all of which may represent their state in different ways.

While the Agent Control Module is the center of operations for the agent, it does not contain any built-in intelligence pertaining to any specific learning environment. Instead, it relies on the Agent Behavioral Control Description (ABCD) for this information. The ABCD is divided into four types of objects: potential student actions,
agent interventions, pedagogical goals, and student concepts. Potential student actions are actions or classes of actions which the student might take within the environment, and which the agent should recognize. These actions are comprised of a series of events, each of which may contain a parameter sent from the learning environment to the agent. The sequence of events and their parameters can be generalized using regular expressions. Agent interventions may be of three distinct types - information presentation using text and images, agent-initiated dialog with the student, or agent-initiated intervention of arbitrary complexity by loading and executing an externally authored program. Pedagogical goals represent general learning objectives, for example, what the most important concepts are for a student to learn, what interaction styles to prefer, etc. Student concepts represent correct or incorrect conceptions that students may hold. Our notion of student modeling is based upon the work of Minstrell et al on educational facets (Minstrell 1992), and our student concept database is a facet base, in their terminology. The student model the agent constructs consists of a collection of student concepts; the agent infers these, and each is weighted with a confidence factor.

Since it is the Agent Behavioral Control Description (ABCD) which makes a particular agent unique, we must allow non-programmers to author it. Its rules are similar to rules in a declarative programming language. However, we do not want to require teachers to think like programmers. Our solution is to have the agent guide the author through the process in a natural, conversational manner. The agent directs the authoring process by asking a series of questions. As the author responds to these questions, the agent modifies the conversational flow and builds components of its ABCD, based on the author's input. In addition to direct question and answer, the agent utilizes generalization techniques from machine learning to allow for authoring by demonstration in some circumstances.

This authoring technique, which we call "conversational authoring", bears a resemblance to the command "wizards" which are found in a variety of applications. However, there are a number of factors that distinguish this authoring paradigm from application command wizards. One factor is that the interaction between the author and the system may be long-lived and span multiple authoring sessions. Because of this, a need exists for the agent to maintain continuity between sessions by being able to summarize the previous session and describe its current state to the author in a conversational manner. This self-description is also important for purposes of agent validation. The conversational authoring tool runs concurrently with the agent and learning environment, so the author can test the behavior of the agent at any point in the authoring process by using the environment from the perspective of a student. However, simply testing the agent may not provide enough validation that the desired ABCD structure has been created. The ability of the agent to conversationally summarize its state at any given point in the authoring process adds another tool that the author can use to validate the authoring outcome.

The work described in this paper is currently in progress. The generic agent architecture has been implemented in Java and integrated into a constructionist learning environment called PixelMath. PixelMath is a recent outgrowth of research at the University of Washington designed to teach mathematical concepts through digital image processing. Additionally, a custom agent has been built on top of the generic architecture by hard coding the ABCD in Java. We are currently in the process of implementing the conversational authoring tool, which will be tested for effectiveness by teachers familiar with the classroom use of tools like PixelMath. A complete description of this project, including current status, is available at http://www.cs.washington.edu/homes/jbaer/pedagent/index.html.

From “Learning-by-Viewing” to “Learning-by-Doing”:
A Video Annotation Educational Technology Tool

Ofer Bergman, Ruth Beyth-Marom, Ahuva Leopold, The Open University of Israel
Doron Hadar, Ben Gurion University, Israel
Amnon Dekel, Interdisciplinary Center, Herzliya, Israel
Synopsis@netvision.net.il

Abstract: Video films are particularly suitable as a way of experiencing the world because they provide a dynamic, although vicarious, encounter through sound and vision. However, the use of video films in their present, mostly passive, form, do not succeed in contributing enough to the learning process. SYNOPSIS was designed to cause a shift from the passive “learning-by-viewing” model to the “learning-by-doing” model while studying with educational films. By utilizing a simple user-friendly interface, the tool allows students to engage, on a computer, in active, reflective, and interactive learning with existing video films. The tool and some preliminary results of an evaluation study will be presented.

Introduction

Video films are particularly suitable as a way of experiencing the world because they provide a dynamic, although vicarious, encounter through sound and vision (Collis, 1996). Moreover, they use a number of technical devices to manipulate that experience. Salomon (1979) called these devices “supplantations”, in the sense that they supplant a cognitive process.

However, the use of video films in their present, mostly passive, form, do not succeed in contributing enough to the learning process (Clark & Craig, 1992). In active learning situations students are able to reflect, construct and interact (Laurillard, 1993, Bates, 1997). In such learning environments, students are expected to comprehend the structure of the lesson, integrate its parts and construct their knowledge through experienc-based actions. Present video-film learning environments do not succeed in providing such a model.

SYNOPSIS was designed to improve the passive “learning-by-viewing” model by reinforcing a shift to “learning-by-doing” while studying with educational films.

SYNOPSIS - An Educational Tool

By utilizing a user-friendly interface, the tool allows students to engage, on a computer, in active, reflective, and interactive learning with existing video films. By allowing students to actively summarize a video film, the tool encourages them to engage in active learning. While summarizing the film, students are creating their own personal model of the movie, its structure, and its contents.

When the observer decides to summarize the film (which is seen on the left side of a computer screen), he/she begins typing the summary. Immediately, the film stops running; the written summary appears at the right side of the screen and the last video frame is attached as an icon to the beginning of the text. Pressing the Esc function resumes the film, and the summary with its icon are framed in a box. Each time the observer begins typing, the film stops running and another summary appears with its relevant icon on the right side of the screen. At the end, the student has a list of blocks in each of which there is an icon representing the place of summary in the film, and a written text which can be printed. This list of blocks can be arranged according to their order in the film, or according to the order in which they were created.

By automatically attaching relevant video icons next to a summary block, the tool provides an easy way of visually remembering and keeping track of, and returning to, important points in the film. This capability encourages students to engage in reflective thinking since relevant sections of the film can be found and seen by clicking on an associated video icon that immediately moves the
film to the intended section. Reflection is also aided by allowing immediate access to relevant sections in the film via simple word searches on the textual summaries.

The tool also allows instructors to prepare interactive questions and assignments pertaining to the film watched. The questions and assignments pop up when the student reaches a pre-specified point in the film.

SYNOPSUS can be used for distance learners and for face-to-face teaching during frontal teaching sessions. By using the presentation mode of the tool, instructors can show predefined segments of a film along with their own headers and annotations.

An Evaluation Study

The Open University of Israel (OUI) is a distance learning institution. Some of the courses offered to students are telecourses which include as learning material a textbook, 26 video films and a student guidebook. A telecourse in psychology was chosen for a study of the new tool. Out of 400 registered students, 100 volunteered to try the software. They received two CDs: one contained the software and the other contained a thirty-minute educational film. The first 60 students who were willing to participate in the study (after experimenting successfully with the software), were divided into two groups of 30 students: In group 1 students received films 1 to 6 on CDs, and in group 2 students received films 7 to 12 on CDs. Both groups received all other films on video cassettes. The two groups were similar in average age, percentage of males and number of previous course credits. This design allows for between and within comparisons regarding the experience with the software and CDs on the one hand and video films on the other hand. A third group of eight students with learning disabilities served for an exploratory investigation into the possible advantages of the software for students with such difficulties. They received the same material as group 1.

A questionnaire will be sent to all three groups at three points in time: (a) after the allocated learning period for the first six films (CDs for groups 1 and 3 and videos for group 2); (b) after the allocated learning period for films 7-12 (CDs for group 2 and videos for groups 1 and 3) and (c) after the allocated learning period for films 13-18 (videos for groups 1, 2 and 3). Group 3 subjects will be interviewed individually regarding their experience with the software and its possible help in overcoming some of their special learning difficulties. At the end of the semester students will be asked to send their summaries to the research team.

The purpose of the experiment was to test learners' attitudes towards the learning tool as well as their learning processes while using it. The design of the experiment permits absolute evaluations as well as comparisons with learners who watch the films on the TV screen without the tool. The following hypotheses will be tested:

1. SYNOPSUS facilitates the process of summarizing the film.
2. Subjects summarize more and better with SYNOPSUS than without it.
3. SYNOPSUS facilitates concentration while watching the film.
4. SYNOPSUS facilitates the process of locating a specific subject in the film.
5. Subjects go backward and forward in the film in order to access specific segments of it more often while learning with SYNOPSUS than while learning without it.
6. Subjects enjoy the film more on a television screen without SYNOPSUS than on the PC screen with SYNOPSUS.
7. Subjects feel they learn more from a film they watched on a PC screen with SYNOPSUS than from one they watched on a TV screen without it.

SYNOPSUS will be presented along with some of the experiment's results that will be available at the time of the conference.

Censorship or self-discipline on the Internet?
Strategies for limiting access to morally undesirable Internet resources.

John Boatright, MA
University of Minnesota
1283 Goodrich Avenue
Saint Paul, MN
boat0011@tc.umn.edu

Abstract: The purposes of the Internet are many; commercial, recreational, informational, educational, communicational, relational. The Internet is a paradoxical universe of structure and anarchy: producing some good and some bad, some beautiful, and some ghastly. There are many, educationally relevant Internet resources. "by the year 2000, anyone in western civilization will be able to get the answer to any question that has an answer" according to influential Byte columnist, Jerry Pournelle. In the 1997 Current Population Survey by the US Census Bureau computer use was surveyed. The study showed that three quarters of the children in the USA have access to computers at home or school - significantly more at school than at home. Children most frequently used home computers for educational purposes (93.3%) and games (83%). One fifth of the children who have home computers used them to access the Internet. For adults, 18 and over, 92 million people used the computer at home or work. More than half these adults accessed the Internet from home, with 80% of them using the web to access government, business, health or educational information. Significant increases on the order of 5-15% were recorded for every category of questioning over the 5 years span between surveys. In all, one of five Americans (ages 3 and higher) used the Internet in 1997.

This presentation/essay concerns controlling a kid's access to "morally undesirable" information. But before we can get to that, it is important to consider the need for such control. In the schools of our nation, our children are using the Internet to reach out of the walls and experience the universe. Free ranging access to the wonders of science and humanity can be had through simply searching the Internet using search programs. Any teacher or student deserves these resources and they deserve to follow the curiosities that are a contingent element of human intelligence. The question that arises involves the various interests of the purveyors of these archives. Some of these interests are illegal and even more are morally undesirable.

Introduction

The purposes of the Internet are many; commercial, recreational, informational, educational, communicational, relational. The Internet is a universe of anarchy and chaos: producing some good and some bad, some beautiful, and some ghastly. There are many, educationally relevant Internet resources. "by the year 2000, anyone in western civilization will be able to get the answer to any question that has an answer" according to influential Byte columnist, Jerry Pournelle. In the 1997 Current Population Survey by the US Census Bureau computer use was surveyed. The study showed that three quarters of the children in the USA have access to computers at home or school - significantly more at school than at home. Children most frequently used home computers for educational purposes (93.3%) and games (83%). One fifth of the children who have home computers used them to access the Internet. For adults, 18 and over, 92 million people used the computer at home or work. More than half these adults accessed the Internet from home, with 80% of them using the web to access government, business, health or educational information. Significant increases on the order of 5-15% were recorded for every category of questioning over the 5 years span between surveys. In all, one of five Americans (ages 3 and higher) used the Internet in 1997.

This essay concerns controlling a kid's access to "morally undesirable" information. But before we can get to that, it is important to consider the need for such control. In the schools of our nation, our children are using the Internet to reach out of the walls and experience the universe. Free ranging access to the wonders of science and humanity can be had through simply searching the Internet using search programs. Any teacher or student deserves these resources and they deserve to follow the curiosities that are a contingent element of human intelligence. The question that arises involves the various interests of the purveyors of these archives. Some of these interests are illegal and even more are morally undesirable.
Illegal interests are pursued and prosecuted in the United States by state and local law enforcement, the FBI, the US Marshall or the Federal Trade Commission depending on which jurisdiction the activity entails. The international nature of the Internet may bring other law enforcement agencies into the investigation and prosecution. In the US there are specific police resources devoted to cyber-crime.

On the morally undesirable side, there is no such concerted effort – in fact there seems to be a fair level of disagreement. While there is much media attention given to (thus far ineffective) efforts aimed at outlawing these undesirable Internet activities, there is a strange avoidance of discussion into exactly which information should be restricted. Consensus has arisen around some pseudo-illegal activities such as distribution of child pornography. But aside from that...almost certainly the literature simply starts off with the assumption that children need to be protected from whatever morally reprehensible activity the writer is imaging but not really describing. And, honestly, aside from acknowledging this vagueness, this writer is not much different.

The generally agreed philosophical rationale is that children from ages 5 to 18 must be protected from this information because they are not ready to contextually understand these darker fantasies and features of our culture. (In extreme cases -- I am wondering who is?) Kids are ignorant to the dangers that may be encountered through their venturing into knowledge unconditioned by experience. A loud debate rages about “how to stop access” to these dark media resources. When the next kids-killing-kids, school shooting incident occurs, our attention will be brought sharply back to the studies that widely implicate media’s influence on a child’s moral development. This research is not clear on the nature of the developmental harm associated with a premature familiarity of the darker side of humanity. We could wish for more specifics as to which type of media, how it specifically affects development and when in the child’s development are they vulnerable to such influence.

For purposes of this essay, it will be assumed that kids need protection from morally undesirable elements of our culture even if adults do not. That further, the special media circumstance of Internet delivery of these morally undesirable archives directly into our schools and homes deserves our special attention. We will assume, as do many others, that an inadvertent curriculum can formulate around these dark and undesirable interests.

Since these fascinations with the darker elements exist in our culture, there is necessarily a developmental time when youth should gain controlled experiences in them. The school however is excluded from that objective – it is left to parents to control this curriculum. There are logical flaws in this plan (e.g. that parents often do not address these legitimate needs) will also be excluded from this essay.

This essay will assume that someday these “morally undesirable” graphical and information archives can be identified through public discourse and reasoning. Something beyond the “we will know them when we see them” criteria. Though there is no theory on whether it really is undesirable for children to be exposed to any of the following areas...and though there is no sharp delineation of the level at which information becomes damaging...the general content areas are well elaborated in the literature and involve concern about the following issues.

Inappropriate sexual displays.

There is a well-publicized and very active pornographic sector accessible through the Internet. These resources may involve text or graphical displays that are developmentally inappropriate for children (and frankly adults!). This area receives much attention by the naysayers of open Internet access. It is said to represent a significant but small proportion of Internet informational traffic (I have seen figures of less than 10% - I cannot seem to find the source right at this moment though) Additionally, these sites often involve unscrupulous schemes to charge the viewer -- while claiming to be free of charge. It is a common family dilemma to have a surprise encounter with the financial consequences of a child’s experimenting with Internet sex sites. Again, research is disappointing here, but in my circle of friends and family, children have spent thousands of dollars in this way. Anecdotally, costs associated with these episodes are confabulated with similar costs charged by cable and phone sex experimentation.

Predatory persons

There is a danger that children may be lured into meeting some predatory person, whose desire is to do them physical harm. While this danger is theoretically real, there is no frequency data available in the literature. It can be assumed though from reports of adults being lured out to meet predatory persons, that children would be also similarly vulnerable to such risks.
Financial Scams
There are a number of financial schemes communicated through the Internet. Pyramid schemes are popular -- so are offers “too good to be possible.” Low interest, poor credit credit card offers are also frequently offered on the Internet. It can be assumed that the limited experience of kids would make them targets for these deceptive or illegal activities. Again, there is no data readily available on the incidence of children being victims. It is sufficient to say, that there are many adults that get scammed. We can be sure that if there were unlimited access to children for the scam artists and a source of credit for the children, there would be a significant level of risk to the financial well being of families and children.

Privacy concerns
The issue here is that children might give out information that could physically target them for predators. Another concern may be that the child, not being aware of the risks, may innocently or out of bravado arrange a connection with an unsavory character.

System integrity and security issues
There might be risks to the stability of the network due to downloading programs that originate from certain Internet sites. There is a fair amount of Internet traffic visible on lists associated with “hacking.” (search keyword “crackers”) The substance of these messages often reflects an interest in illegally obtained software and passwords to various nefarious sites. An easy and more popular invasion of networks involves reflecting junk e-mail (“spam”) from the users domain so that it will appear to be from your computer system. I work for a women’s college in the upper Midwest and we discovered that advertising for a pornographic site was using our domain as a reflector...to the extent that in one night 60,000 emails had been distributed! This, of course, was unacceptable to our network administrators. Protection from this type of hacking has been installed. Another concern is viruses and virus hoaxes. Aside from the damage an actual virus can do to networks, the volume of messages that virus hoaxes can generate is in itself, a plague.

Harassment
It is possible for a predatory person to stalk and harass a person via the Internet. Especially if used in combination with other modes of information accessible through the Internet or other information providers. Phone numbers, addresses, maps may assist the stalker to find their target repeatedly. It is more and more difficult to “disappear” if one needs to. One source listed the costs for information on the a person as $15 for social security number, to $150 for a complete background check.

Internet “addiction”
While dubious as a real disorder, some people spend inordinate, obsessive amounts of time on the Internet. Sometimes this interferes with normal activities of daily living. The fear is, that introducing Internet use in schools give tacit approval for obsessive use of the Internet. There is no empirical data available in the literature, but based on anecdotal evidence (again from families and friends) teenagers are known to sacrifice duties and sometimes sleeping in order to use the Internet. Recently, the American Psychological Association gave some context to the question during a symposia on the topic. They concluded that pathological internet use was possibly an addiction, a disorder or a symptom of depression.

Abuse of credit
A problem not exclusive to the Internet, there cannot be any doubt that the Internet is a good place to spend a lot of money. Many Internet retail and service sites exist and accept credit cards. It is easy to rack up an impressive bill in a few hours of Internet shopping. Amazon.com for books, records, presents; Quill for office supplies; LandsEnd for clothing; EggHead for software; Dell for a computer; Auto.com for a car; ebay for a boat; pretty soon you’ve spent some bucks!

Depression
There have been articles in the psychology literature about a relationship between Internet use and depression. The debate rages on with both side positing credible pros and cons. The crux of the issue here is the chicken/egg problem. That is did the depression preceed the use of the Internet or was depression a result of Internet use? Currently the theory that seems most favored is that use of the Internet is more a symptom than a cause of depression.

Academic integrity
A virtual industry has evolved selling term papers to students. Keyword search on “term papers” revealed 100s of sites devoted to free and for sale papers. Many services offered custom services. According to “Paper-Masters” their custom written term papers are meant to be research to assist you writing your own paper. They conclude that it is not in any way unethical to use their services.
Identity
The relative anonymity provided by the Internet is a challenge to individual identity. This feature also allows people to fabricate an identity that is quite different from their own. The concern is that this fantasy identity may interfere with the identity forming process that is an important in the child.

Community
There are fears that rather than encouraging community and multicultural exchange the Internet actually encourages isolation.

Intellectual property
Many teachers report a cut and paste form of writing where the students simply search out information on the Internet and then copy it directly into their papers without quotation. Additionally copyright infringement rules are very difficult to understand within the context of the Internet.

Social accountability
The anonymity and 2 dimensionality of the Internet does not foster authentic relationships. This issue is the converse of the safety afforded by the electronic distance of the Internet. One concern for kids is the negative role model that this demonstrates. The superficiality of complex individuals as represented on the Internet is also an impression that is unrealistic. On the Internet, as with other media, the distinction between real and imaginary is difficult to detect.

Review of the literature
While this essay is focused on educational issues in American schools, it is interesting to observe that in Europe several countries (GDR, GB and others) have also sought to control certain types of Internet communications. Great Britain actually has a complaint bureau, The Internet Watch Foundation, where consumers can expect to see prosecution of child pornography, and other harmful activities. The bureau expressly stays clear of controversies into items of political or social question though. Internet access is severely limited at the source - the Internet access hub, in several Middle Eastern countries (Saudi and Egypt). All accessible sites are government approved even email is scrutinized.

In the United States, a first Amendment disagreement has arisen over Internet control. The US Supreme Court has made four determinations in favor of free Internet access for anyone able to get there. Though there are plenty of details left to interpretation, the court has made sweeping statements about the freedom of the Internet. Congress continues to contemplate legislative action, intended to circumvent the Supreme Court’s First Amendment rulings and control some types of Internet communications. As stated before, illegal activities are prohibited and prosecuted in multiple ways, the debate concerns pseudo-legal and legal but controversial Internet resources such as child pornography, bomb-building directions, racism, slander, misinformation.

Strategies for limiting the access of kids to morally undesirable Internet archives
Free access to all:
It would seem that this is what we have. This is a common misconception of the Internet. Certain types of information cannot (currently) be transmitted via the Internet. The interface is restricted to materials that are comprised of an audio, visual and/or digital nature. Certainly this covers a lot of ground, but in reality this is a significant limitation from the start. Not everything the human has a capacity to sense can be transmitted by the Internet.

Additionally, and of more relevance to the theme of this essay; illegal activities are prohibited on the Internet. As stated above, several governmental policing agencies monitor and in fact utilize the Internet to investigate and prosecute criminal activities. Email threats are taken quite seriously - the appearance of treasury, secret service officers at a local high school last year to arrest a student for having sent a death threat to President Clinton is lesson enough to prove this point. Drug and firearm enforcement agencies also monitor the Internet for signs of criminal activity.

Direct adult supervision:
There is a tacit rejection of direct adult supervision as a control strategy in almost all the literature. It is felt unrealistic that an adult mentor could monitor a kids Internet adventures, or help them gain context if they bump into something morally undesirable. The literature in this area occasionally mentions that this is an option, but that then goes no further than to state it is simply not feasible for presumably practical reasons. There is, however, agreement that this method of control would be desirable and effective. This writer is not so sure that this is the contingent difficulty with the idea. Challenges here may be more
associated with the problems of communicating with our youth. Adults are really hesitant to talk about morally challenging topics - a sudden view of human sexual interaction might initiate questions and that would lead to a difficult conversation. Teachers should be allowed to have this kind of conversation with our youths, but the onus of responsibility is on the family where it <dismay> rarely occurs.

**User Self Policing - Moral development and the Internet**

It could be left to the user to restrict their own access by virtue of their own experiences. This highly improbable suggestion centers on development of a personally held and derived dislike for morally undesirable Internet resources. It can happen, and most probably does, after the thrill is gone so to speak. The impractical part of this suggestion is not the philosophically sound grounding that exists in allowing people to morally develop, but rather the political impossibility of implementing such a plan in a country founded by the Puritans. Additionally, there is much to be said for the idea that a staged approach with contextualization would need to be implemented to coincide with the developmental capacity of each individual kid. Given the performance record of our public schools...it is utopian to imagine such a strategy could be harmlessly implemented.

**Legislation:**

Communication Decency Act (CDA) and Son of CDA – overturned by the US Supreme Courts. Ruled as unconstitutional by virtue of their violation of First Amendment rights. Politicians continue to bring up legislation that the American Civil Liberties Union defeats in court challenges. Literally millions of dollars have been expended in the quest for legislation that can get through the first amendment tests. Often the problem is that the definitions for morally undesirable materials cannot be specifically measured, and could thus be applied too widely.

**Acceptable Use Policies (AUP):**

As an aide to self control, a signed statement of appropriate internet use AND the consequences of abuse of privileges is used. Samples of AUPs are available on the Internet. AUPs are used in nearly all networked computer labs. It is necessary that some person observe the Internet use in such situations. This can be done by walking around the lab or by looking at the log of Internet addresses that has been accessed on a particular computer. It would seem very possible to automate this observation of a lab by sharing the log with a central teachers workstation, but there was no mention of this strategy in the literature. See references for a link to an example provided by Rice University.

**Rating Systems:**

A strategy familiar to moviegoers is common of the Internet – warning the consumer of adult content. Most commercial (even free) adult sites require the user to physically confirm select their intent to utilize the morally undesirable archives. Some Internet businesses have arisen that claim to restrict the access of minors to their sites by virtue of credit card credentials. Of course, a credit card has little to do with verifying age – these sites are more interested in connecting interested parties (and their credit cards) with their cadre of pornographic vendors. The intent is to protect the inadvertent viewing of these resources, but of course, many curious 15 year olds are undeterred by these warning and click right through.

**Screening Software:**

It would be nice if software could be developed to filter morally undesirable Internet content, but thus far efforts have been only partially successful. Current filtering software can be grouped based on the strategy used to filter. One group uses keywords, taken from a ready made list of dirty words, to eliminate access to undesirable Internet archives. Often the list can be modified by the administrator to add new words or to add in a miss spelling of the particular dirty word of concern. This is effective but suffers from the problem that sometime dirty words also have morally desirable alternative uses. For instance “breast” as a keyword will also eliminate sites concerned with breast cancer. Another approach is to keep a list of either acceptable and unacceptable sites. For instance sites ending with the “.gov” suffix are approved, Disney.com is approved, a list of sites that are not approved is provided and updated by the software company and can be modified by the administrator. Unfortunately, the undesirable element of the Internet moves around a lot, and new morally undesirable sites are launched every day, so it is easy to imagine that something will get past the filter.

**Network Filter programs:**

Similar to screening software, more sophisticated filters can be installed at the network hub. This is the strategy used by those Middle Eastern countries to prevent access to certain internet resources.

**Intranet strategies:**

One strategy taken by some schools has been to simply offer only internal versions of Internet available resources. It’s a sort of smaller, internally stored version of the Internet. WebWhacker whacks entire sites
out of the Internet and stores them on your computer network. This strategy is fine as long as the learner only asks questions available within the limits of the stored information. An encyclopedic resource, and other informative resources are made available. Often access to the external Internet is possible for special situations, and can be more effectively monitored.

**Internet watch groups:**
Another way used in concert with screening software is to have a group of evaluators monitor the moral permissibility of Internet sites. What happens is that a software company or a school enlists the help of a screening committee. Their function is to expand the list of forbidden and permitted Internet resources.

**Free market pressure and industry self regulation:**
Especially during the legislative debate on CDA, many Internet Service Provider companies became concerned over the trouble it might be if they could be held responsible for Internet content. America Online, the largest Internet Service provider, initiated a program of parental controls that allow various levels of access control over the Internet and AOL network resources. Also, they developed a system of “moderators” to monitor kid chatrooms, as well as a responsive complaint system. In other words, they felt it was good for their business interests to allow the user to determine limits on access.

**Conclusions**
So what is the big picture here? First, this is a new experience to all of us, second the Internet needs to be a vital part of the learning experience for kids, Third we will not be able to bring ourselves to restrict anything but illegal activities from the Internet – and even here it's a post hoc analysis.

Clearly the best choice is to design a system where Internet use is closely monitored, but not for punitive purposes, but for contextualizing by adults who are skilled and vested in helping kids see our world, all of it at the right time. Since this is so impossible given our current factory model schools, I would recommend the strategy where much of the information needed by students is anticipated and locally stored on school friendly servers – a second network soto speak. When kids need to venture onto the Internet let them, and be there for them.

There is much research that needs to be done, but some of the important questions IMHO (in my humble opinion) have to do with cultural changes that will come as a result of this new dimension. Questions about moral development, community and diversity seem largely unstudied. Philosophical and psychological issues such as what really is inappropriate and at what developmental age are barely disturbed. Finally, I wonder what the future will hold for new ways to communicate human sensations and feeling will be.

Using Speech Recognition to Support Online Learning of Second/Foreign Languages

Francis Bonkowski, IC Education, Inc., Canada
Quinn Cheung, IC Education, Inc., Canada
Liam Cheung, IC Education, Inc., Canada

This paper presents IC Education’s state-of-the-art pedagogy and technology to support online language learning. IC Education has developed speech recognition over the Internet using a new client/server application that recognizes the voice of user’s without having to install complicated software on a personal computer. The system entails minimal software installation by the user and provides centralization of the speech recognition engine. This innovative technology is a powerful, albeit simple tool used to teach learners proper pronunciation and new vocabulary.
A BUILDING-BLOCK METHOD FOR COURSEWARE DEVELOPMENT FOR LESS-EXPERIENCED DEVELOPERS

Eddy Boot & Yvonne Barnard
TNO-Human Factors, Soesterberg, The Netherlands
Kampweg 5, P.O. box 23, 3769 ZG Soesterberg
Email: boot@tm.tno.nl, ybarnard@tm.tno.nl

Abstract: Although courseware has the potential to increase the efficiency and effectiveness of courses, until now the results of its application is often disappointing. In our research concerning courseware development within the Royal Netherlands Army (RNLA), we investigated some of the underlying reasons for this, and specified an approach to promote its applicability. One of the main problems is the high cost of courseware development, resulting from the long development time and the specific expertise required. We constructed a 'building-block' approach, which enables instructors with limited multi-media expertise to rapidly develop courseware for simple learning objectives, but with the use of advanced multi-media technology. This approach consists of templates that incorporate sound didactical principles, lower the technological complexity of courseware development, and can be used within modern authoring tools. Currently we are implementing the method and are studying how to enlarge the scope of the method towards more advanced learning goals.

The use of courseware

Recently, the interest for the use of courseware within many educational and corporate organizations is increasing in a rapid pace, as it has the potential to increase the efficiency and effectiveness of courses significantly. Organizations want to develop courseware in-house, as in most settings Commercial Of The Shelf (COTS) courseware is not specific enough and currently modern, powerful authoring tools are available. However, in many cases such attempts have been disappointing in terms of contributing to efficiency and effectiveness of (the development of) training programs. For instance, in the last few years, the Royal Netherlands Army (RNLA) has spent considerable time and effort in developing courseware for its Training Centers. This courseware mainly directed at concept learning and procedural tasks. However, the application of courseware has not yet lived up to its expectations. It has never been very cost-effective and (therefore) organizational acceptance or broad adaptation of courseware within training programs is still not accomplished.

Bottlenecks in developing courseware

TNO-HF has been asked to investigate this problem and to formulate, implement and test solutions for it. We found a number of problems concerning courseware development (Boot & Van Rooij, 1999). The development of courseware is mostly done by Subject Matter Experts (SME's) and instructors, using modern authoring tools. Despite the efforts and promises of these tools to reduce development time and the level of required expertise (e.g. Asymetrix, 1998), it still takes considerable time (and therefore costs) to produce courseware. We found that considerable programming knowledge is required for anything more that very simple courseware. Also, much time is required to familiarize with the tools and its many features and the translation of didactical models into courseware is complicated. In the RNLA, the SME's and instructors lack the didactical-, multi-medial- and programming expertise to make optimal and efficient usage of these tools. One can conclude that the development of anything more advanced than very simple courseware programs, remains costly and will be only cost-effective for large target groups.

The building-block approach
If one aims at courseware with advanced technological features (in terms of multi-media usage and interactivity), developed by people with limited programming expertise, a so-called 'building-block' approach can be a solution. This approach pre-structures the development-process by offering templates within authoring tools. Templates consist of empty courseware-structures to be filled with content. These structures incorporate sound didactical principles and advanced technological features. Once connected to each other (hence the name building-block approach) and filled with content (the learning materials), they constitute a complete courseware program. We investigated some build-in pre-structuring features of modern authoring tools that make the same claims, but they are too limited for our purposes. Therefore, our templates should be more advanced and comprehensive, in order to promote proper implementation of didactical models and lower the technological complexity. As standardization, re-usability and exchangeability of courseware(elements) is a key issue, these templates should be embedded within COTS authoring tools.

**Specification and implementation of the approach**

We specified a building block approach for the RNLA, with templates for four levels of courseware-structure (Boot & Van Rooij, 2000);

1. At the top level, templates provide different kinds of navigation through a number of lessons.
2. At the second level, templates provide different kinds of navigation of learning activities within lessons.
3. At the third level, templates provide interactivity within learning activities.
4. At the bottom level, templates provide the presentation of multi-media elements within learning activities.

Altogether, they contribute with standardized screen-elements to the complete user-interface of the program. The didactical functionality, embedded in the templates, is directed at relative simple learning goals; learning facts, concepts, procedures and principles. The instructional strategies that are embedded are based on theories like Gagné's Nine Events and Merrill's Component Display Theory as found in Reigeluth (1983). Technically, the templates are build using Knowledge Objects® within the authoring tool Authorware® Version 5, and are provided with Wizards for guiding the interaction with the developers. For reasons of acceptance and commitment of the future developers, we have involved them during the specification process of the building-block approach. We found that it is important and difficult to balance well between how much templates should prescribe and which freedom remains for the developers.

Currently, we are in the implementation phase; external software developers are building the templates, after which they will be used by some developers within the RNLA. We will start a number of pilot projects to evaluate the application of the approach and the resulting courseware. Based on these results, the templates can be improved and the building block approach will be applied on a wider scale.

**Future developments**

One important aspect of our research is yet unresolved; how to specify a building-block approach that is also directed to more complex courseware? During specifying the described approach, we found that finding a sound theoretical basis is troublesome. It is a challenge to embed didactical models and instructional principles into software-templates that are content-empty. Our future research will be directed at embedding didactical models for advanced learning goals, using principles from learning theories like constructivism and situated cognition. Our goal is to formulate concrete guidelines for the problem-based or case-based approaches from such theories, and implement and test these within an advanced version of our current building-block approach.

Collaborative University Teaching over the Internet

Jacqueline Bourdeau, Department of Education
Université du Québec à Chicoutimi, Chicoutimi, Québec, CANADA G7H 2B1
jbourdea@uqac.uquebec.ca

Abstract: A concept has been developed to achieve various forms of collaborative teleteaching, such as sharing ideas about teaching, using learning scenarios, and engaging in joint teaching actions. Professors play a key role, since they are instrumental in integrating new technologies into teaching. An environment is being developed to encapsulate an instructional design technique to facilitate sharing processes. A database technology provides distributed services over the Internet.

From Teaching to Teleteaching

University teaching has traditionally been defined as an on-campus activity where all players (1 professor and X students) are in the same place at the same time, with or without any media. In fact, all teaching has been based on these parameters. New technology (NT) brings many potential changes to these parameters, since it creates an opportunity for innovative distributed teaching modes. This potential has increased the need for instructional design, and consequently the progressive transformation of traditional teaching modes into instructional design-based teaching. Integrating NT into teaching implies changing teaching practices. Integration has taken various forms in higher education, such as: Web-based instruction, online education (www.telelearn.ca); videoconference-based teaching (Bourdeau & al., 1998); the virtual campus (www.tecfa.unige.ch), or integrative distance learning environments (www.licef.teluq.uquebec.ca). Satisfaction levels in students and faculty vary from enthusiastic to negative. Faculty is being pressured to digitize material in the form of electronic books, or add electronic communication to their classroom teaching. However, teaching continues to be based on the synchronization of professor and students in a given space. There is room for integration modes, which could be better anchored in current practices, while simultaneously fostering greater faculty involvement.

PETRUS: The Concept

Petrus is a new concept developed to integrate new technology into university teaching. The fundamental characteristic underlying the idea is to consider professors the driving force behind educational integration, since they are the agents who design teaching specifically for their own students. The integration of new technology derives its meaning (direction and semantics) from their teaching and personal interpretation. The second one is to consider new technology a catalyst rather than a tool: the spirit of the Internet is all about sharing and cooperation. A good number of professors are clearly prepared to integrate this spirit into their teaching. And lastly, the third characteristic of Petrus is to provide professors with a computerized environment where the groundwork for an instructional design technique has already been laid through scenario-building. Depending on their preferences or needs, professors can use the ScenarioBuilder in Petrus to: 1) assemble dynamic instructional scenarios, 2) gain shared access to comprehensive, validated scenarios, 3) select individual components from scenarios.

Implementation Plan and Work in Progress

Implementing sharing practices requires sharing processes and an environment designed to support these processes. Scenario-building skills can be acquired through a high-quality system where instructional principles have been built into an expert environment. Professors can access, consult, edit or assemble scenarios in the most flexible ways. They also have the option of designing their own teaching environment and learning interface for students. Teleteaching services naturally have to be anchored in current teaching practices and jointly designed with professors. The following plan was designed for a course on learning theories: 1) Collect and analyze a series of syllabi on learning theories; 2) Extract and classify items according to objectives, content, learning/evaluation activities and material; 3) Conduct a needs assessment of useful teleteaching services; 4) Choose software engineering solutions; 5) Develop and test a prototype for one course; 6) Develop and test a prototype for five
courses on distributed sites; 7) Develop a full environment including rights and privileges. The plan is currently under way after a team of professors agreed to jointly design and test the scenario-builder. Steps 1 through 5 have been completed, and a Web-based prototype environment is being developed. The environment will be served by a database that dynamically feeds information into the system. First results will provide information on the quality and level of interest in collaborative teleteaching for a course on learning theories in teacher education programs.

Related Projects

To the best of our knowledge, the concept that comes closest to Petrus is ARIADNE, which stands for Alliance of Remote Instructional Authoring Distribution Networks for Europe (http://ariadne.unil.ch/). The project focuses on the development of tools and methodologies for producing, managing and re-using computer-based educational components and curricula. Collaborative approaches are encouraged, as is the share-and-reuse principle (Duval, 1999). Petrus is radically different in that professors are at the centre of all processes; they are the agents through whom everything passes, and both their personality and teaching style are incorporated into the design. Petrus is not looking to set standards, but seeks diversity instead in terms of intellectual perspectives and teaching styles. Secondly, Petrus contains a scenario-builder that incorporates teaching strategies which can also be shared. The STAR.Legacy project (http://peabody.vanderbilt.edu/ctrs/ltc/) at Vanderbilt University has some features similar to those of Petrus: the learning cycle resembles the Petrus Scenario-Builder and, and the “multiple perspectives” activity in the STAR Legacy learning cycle is characteristic of a team-teaching situation. The working hypothesis underlying the Petrus project is as follows: the successful integration of digital technologies into university teaching must go through the professor – an expert in a particular domain who is responsible for conveying information, inspiring and coaching students to help them achieve their personal, academic and career goals. Professors need to customize the learning environment for their students, and change it as needed. Professors would ultimately be engaging in team teleteaching. Videoconferencing and video servers would provide a multitude of perspectives for students, thus enabling them to acquire greater discernment and critical skills.

Sharing, Collaboration and Teleteaching

In the context of computer-supported collaborative work, sharing is seen as a sub-process of collaboration, which is itself a combination of communication and coordination. Coordination science defines coordination as managing interdependencies, and this concept can be extended to the management of interdependencies among actors (Bourdeau & Wasson, 1997). In the Petrus project, sharing processes can be identified together with their associated interdependencies. The software environment would be built around these interdependencies and provide the means to manage them. Examples of sharing processes include: sharing ideas, scenarios, teaching or coaching activities and lessons learned. Mentoring (at the novice or expert level) can also be considered a sharing process. Examples of sharing principles include: reciprocity, privileges, task distribution, resource allocation, and so on. Software to manage and support sharing processes will be designed when sharing processes are identified and validated, and means for managing interdependencies are developed. Ethical and legal issues will also be taken into account.

Abstract: This paper describes the work of the Carlos III University in the project SEBASTIAN (Educational System based on Internet Technology). The aim is to develop a tele-educational tool, providing to educators/trainers with a simple mechanism that makes possible the use of the network for the broadcast of educational content and enabling the creation of multilingual courses based on XML (Bray, 1998) and SMIL (Stephan, 1998) technologies.

Introduction

As soon as web technologies first became available, they were adopted for educational purposes. Hypertext technologies had already been used in learning systems, and the Internet facilitated the overcoming of distance. Higher education is now undergoing structural changes in terms of the composition of student populations, learning paradigms and curricula. As distance education becomes an integral part of higher education, student bodies are expanding to include more non-traditional students and the contents of courses are richer than before, and incorporate more interactivity.

In this new world, students participate more actively in class and collaboration becomes a more important component of the learning process. These changes have stimulated the development of new ways to represent information (for example: animations, simulation, hypertextual navigation and so on). In particular, multimedia content has been introduced via the medium of the WWW. However, there are problems associated with the variety in present day formats. Facing up to this situation, The Carlos III University of Madrid is working on a project named SEBASTIAN.

System Architecture

The system serves to integrate multimedia learning experiences into the network enabling it to be visualized according to the preferences and characteristics of the student. The courses generated are described in EML 2.0 (Educational Markup Language 2.0). This language is based on XML and includes spatial information (multimedia objects place, presentation size, etc.), temporal information (duration of multimedia objects, scenes, etc.), and information about students profiles (learning styles). The professor will eventually have one tool with three integrated functionalities for the creation of courses, see [Figure 1]. The functions are:

- LG (Layout Generation): Allowing the description of the spatial distribution of multimedia elements that comprise each scene of the presentation. A description language, SLML: Space Layout Markup Language (based on XML), has been designed for this purpose. This functionality will provide the creation of multimedia templates. Initially, some predefine templates will exist, but the object is that professor generated its own templates.
- **STG (Synchronous Text Generation):** The files generated are based on a new language STML: Synchronization Text Markup Language, and provide textual content in several languages. These files contain synchronization labels which synchronize the text with audio or video, as in a karaoke session.

- **CG (Course Generator):** Integrates multimedia files and files generated by the two previous applications. The result is a presentation composed of a sequence of "abstract scenes". Each scene is a compound of the different presentations that may be presented to different students. The view presented to each student depends on their preferences and pedagogic profile. These profiles are generated automatically in accordance with the Learning Style Model (Richard Felder, 1996), the PAPI (Public and Private Information, 2000) and the LOM (learning Object Metadata 1999) specifications.

**Acknowledgments**

The work reported in this paper has been partially funded by the project SEBASTIAN 07T/0015/1997 of the Spanish CAM and the project INFOMEDIA CICYT TEL 1999-0207. We wish to acknowledge fruitful discussions with our colleagues in the Department of Telematics Engineering in the Carlos III University of Madrid.

The Construction and Evaluation of an Internet-Based Knowledge Integration System (IKIS) For a CAI Graduate Course

Mei Chen & Tanya Scott
Department of Education
Concordia University
1455 Maisonneuve Boulevard W.
Montreal, Canada, H3G 1M8
MeiChen@vax2.concordia.ca
TScott@Education.concordia.ca

Abstract: This paper describes an on-going project that involves the construction and evaluation of an Internet-based Knowledge Integration System (IKIS) developed to support a Computer-assisted Instruction (CAI) graduate course. The IKIS integrates cognitive theories of learning and instruction, computer networking technologies, and face-to-face classroom teaching in order to (a) help students build coherent knowledge representations of a great variety of knowledge and skills that are required to design and produce instructional software prototypes and, (b) create a community of practice to aid students in making the decisions concerning the design and production. Our discussion will be focused on two important system features of the IKIS (i.e., the information architecture and communication facilities) that enable us to achieve such goals. A plan for evaluating the IKIS will also be briefly described.

In this paper, we will describe an on-going project that involves the construction and evaluation of an Internet-based Knowledge Integration System (IKIS) developed to support a Computer-assisted Instruction (CAI) graduate course in which students will develop knowledge and skills for designing and producing instructional software prototypes. Understanding of various design concepts and approaches, specification techniques, authoring tools, and development methods is emphasized within this course. Whereas the instructor of the course provides face-to-face lectures, demonstrations, discussions, and laboratory work, the complex nature of the subject can still pose a challenge for students to assimilate and integrate such knowledge. Furthermore, traditional classroom instruction remains an inadequate method in providing timely instruction to each individual student. The IKIS for (CAI) was constructed to (a) provide students with a rich, well-structured knowledge base in order to ensure their active assimilation and integration of a variety of knowledge and skills to be learned, and (b) create a community of practice to aid students in making the decisions concerning the design and production of software prototypes.

The Design of the IKIS

The IKIS integrates cognitive theories of learning and instruction, computer networking technologies, and face-to-face classroom teaching to enable students to use the well-structured knowledge base and diverse tutorial resources to build coherent knowledge representations of the subject-matter knowledge to be learned. The design of the IKIS is based on the cognitive theories of text comprehension that emphasizes the importance of structured knowledge presentations in the construction of coherent knowledge representations (Kintsch, 1988; 1998; Mayer, 1999; 1997), and on situated theory that views social interaction and collaboration as crucial factors in the development of scientific understanding (Lave & Wenger, 1991; Resnick, Levine, & Teasley, 1991). In addition, the cognitive apprenticeship model proposed by Collins, Brown, and Newman (1989) also informed the design of the IKIS. Five principles are articulated to guide the design of the IKIS: (a) providing a rich knowledge base to reflect expertise in the domain of instructional software design; (b) providing a well-organized and transparent knowledge structure to help students construct a coherent conceptual representation of the subject-matter knowledge, (c) employing an effective model of instruction, (d) building a community of expert practice and providing multiple perspectives towards the solutions and, (e) facilitating collaborative learning among students. The theoretical foundation and design principles of the IKIS have been described in details elsewhere (Chen, 1999; Chen, 2000). In this paper, our discussion will be focused on two important system features of the IKIS, namely the information architecture and communication facilities that reflect the principles described above. In addition, an evaluation that we will conduct in the near future will also be proposed.

The information architecture incorporated into the IKIS

The CAI graduate course is focused on the user-centered design for Computer-supported Collaborative Learning (CSCL). A series of topics were identified as important for successful design and implementation of instructional software prototypes. In order to help students construct coherent knowledge representations, the IKIS incorporates...
an information architecture (i.e., a hierarchical organizational scheme) to represent two "layers" of the knowledge to be learned: the first layer consists of various topics, which range from learning theories to web authoring techniques whereas the second layer is a breakdown of knowledge on each topic which includes concept, rationale, goals, methods, example, related issues, trouble shooting and tips, and reflective questions and exercises. Such a knowledge base is expected to enable the students to answer questions concerning what, why, how, to evoke reflective thinking, and ultimately, to create a rich context for students to engage in productive group discussions on the topics via computer-mediated conferencing. Furthermore, some Internet resources and lab tutorials that are relevant to specific topics are also provided to extend the knowledge base of the IKIS. Students can also access a prerequisite-course website to acquire background knowledge if they wish. The information architecture of the IKIS enables the students to learn the topics in a logical manner, meanwhile this architecture is flexible enough to allow each individual to take a different navigation path based on his or her own selection. There is a navigation bar located on the top of the screen that allows students to maneuver through the course topics and breakdown by following either a pre-determined sequence or a selected path. In addition, a bottom navigation bar is available all time to enable the students to access a computer-mediated conferencing facility, newsgroup discussions, and e-mail addresses in the context of reviewing the course topics and breakdown. This bottom navigation bar also provides accesses to the resources and lab tutorials outside of the instructional content that is defined in the IKIS. An on-line help, site map, and search facility are also provided by the bottom navigation bar to enable students to navigate efficiently through the site.

The communication facilities utilized in the IKIS

There are numerous decisions that one must make in the processes of designing and producing instructional software prototypes. No matter how rich the knowledge base is and how well such knowledge base is structured, students may still have unanswered questions. The purpose of proving the accesses to a computer-mediated conferencing facility, newsgroup discussions, and e-mail addresses is to enable students to discuss such unanswered questions with their peers or experts outside of their physical environments. Three communication channels are established to support students' knowledge construction and decision-making: (a) a channel for integrating with the peers: the FirstClass™ software program is used to provide computer-mediated conferencing and chat facilities to facilitate the discussions among students. Each student is required to provide answers to the reflective questions that are proposed at the end of each topic. Students are also encouraged to bring up issues that they wish to clarify and respond to each other's questions. Students can also the FirstClass™ to exchange electronic files that they produced for their group work. The instructor and teaching assistant will monitor the discussion and provide directions and clarifications if needed; (b) a channel for participating in the communities of practice: The IKIS provides students with access to the Internet newsgroups that are most relevant to the topics discussed in the course. These newgroups are organized in a way that is sensitive to the course topics so that the students can be exposed to multiple perspectives on a given issue. Students will also have the opportunities to share their experience and expertise with people who face similar problems and understand the concerns of the practitioners in the community; (c) a channel for communicating with experts: In addition to the communication with the instructor of the course, students can ask questions to some design experts who will serve as the mentors during the course of the semester. These experts will help the students diagnose some "unsolvable" problems and provide suggestions via e-mail. In addition, a list of e-mail addresses of the experts in the fields relevant to CAI design will also be provided to allow students to contact these experts. The communication with these experts may provide students with insights into how experts think and practice. Thus, The communication facilities offered by the IKIS will break the boundary of time and location that is inherited in traditional teaching.

The Evaluation of the IKIS

The IKIS will be evaluated both formatively and summatively. In the formative evaluation phase, a few representative students will be asked to "walk through" the environment and provide "think aloud" protocols for making diagnosis of the system in terms of its usability and learnability. Following the necessary modifications, a summative evaluation will be conducted to determine the effectiveness of the IKIS. Two groups of students will be compared: one that use the IKIS and another that use a print-based version of the same material. An attitude questionnaire will be administered before and after the course to determine the changes in student attitudes. In addition, students' on-line discussions and course work will also be analyzed to determine the levels of expertise developed. The ultimate goal of the project presented here is to understand the ways that computer technologies can be used to enhance student learning of complex subject-matter knowledge and to develop a model of successfully integrating technology into the classroom teaching.

Design decisions in the development of modular instructional content: Describing the transition from local to global learning systems

Paul Cholmsky
Concordia University, Montréal, Québec, Canada
cholmsky@videotron.ca

1. Introduction

Although the increasing sophistication of computer-based learning systems has enabled gains to be made in terms of their pedagogical effectiveness, an undesirable consequence of this sophistication has been a significant increase in development cost. The high cost of these systems has been identified as a principal barrier to their widespread deployment. Increased complexity in learning systems has also led to lengthier development cycles, which has constrained the rate of design evolution and innovation. As a result, there is a pressing need for instructional designers to focus on the efficiency of their development processes as well as the effectiveness of the outputs that are produced by them.

A possible strategy for reducing the time and cost of system development is to create a context wherein whole systems would not have to be designed largely from scratch. A key aspect of such a strategy could be the establishment of cross-organizational standards that would allow developers to reuse content components from other systems, both from within their own organization and from external sources. In essence, this would represent an attempt to leverage the productivity gains from reusability that have been achieved in software engineering into the domain of instructional content development. Over the past year, coordinated proposals have rapidly emerged from several bodies (e.g., Advanced Distributed Learning Initiative, 2000; Anderson, T., McArthur, D., Griffen, S. & Wason, T., 1999) as candidate standards for this purpose. As these proposals are vetted through their initial trials in actual learning systems, it will be important to observe how standards for content reusability affect instructional content development methodologies. Will processes primarily developed in the context of authoring content in small-scale closed systems evolve smoothly into processes for architecting large-scale distributed learning environments where the number of distinct content components may be in the hundreds or thousands? Conversely, if new processes must be developed, which ones will be required, and on what basis do we start their development?

A fundamental issue that needs to be addressed in this regard is the broad function of instructional design (ID) in the development of systems that have a substantial information technology (IT) component. Where does ID stop and IT start? Consider the development of a set of interactive practice exercises that include variable remedial feedback based on learner response patterns. A design decision could be made to use a database-driven approach wherein feedback is assembled from low-level content components that are sourced from a database. If these low-level components include subject-matter terms and their definitions, the same database might be used to drive a glossary function in the learning environment, serving the objective of content reusability. In designing such a system, we would likely not expect an IT professional to author the subject-matter definitions that lie within the database, just as we would not expect the ID professional to design the software that allows the database to communicate within a client-server environment. Appropriate allocation of responsibility for many other design issues, however, is not as clear-cut. For example, is one of these professionals primarily responsible for decomposing the feedback into suitable lower-level components, or is this a joint responsibility - and, if so, how do these professionals collaborate on this task effectively? Of specific concern are the pedagogical implications of successful technical convergence (e.g., the use of database-driven content systems, or the adoption of XML as a markup language): does this form of standardization support research on and development of pedagogical strategy, or does it sacrifice flexibility at this level to achieve the goal of technical convergence? The absence of a clear articulation of the interface between pedagogy and technology in practical terms may prove problematic.

2. Common architectural issues in the design of computer-based learning systems using modular content
To begin assessing the viability of current content development process models in the context of large-scale distributed learning environments, we can examine common categories of design decisions that occur in smaller-scale development projects and assess the possible ramifications of a significant change in scale on them:

- **Modularity:** What is a module, in terms of instructional content? What are the quality criteria for the definition of ‘good’ modules? Do these criteria change as scale increases? How do we use partitions between modules to manage risk in content development? For example, how do we partition a system in order to increase our ability to test numerous content components as they are being developed?
- **Communication and information flow:** What types of information get communicated between modules in a single system? Where are the architectural boundaries in an open content system? How does the information flow in a learning environment instantiate a pedagogical theory of control?
- **Object- and component-based approaches to the development of instructional materials:** How do we determine the right grain sizes for content development? What is the relationship between grain sizes for authoring and the units of analysis employed during front-end analysis? How can the choice of content units facilitate collaboration with software developers during design and production?
- **Reusability:** How is the design of a single reusable content component different from the design of an instructional product out of reusable components? What parts of a learning environment can be reused? How do we move from ad-hoc, opportunistic reuse to systematic re-use? What are the tradeoffs involved? Can there be too much reuse?
- **Interoperability:** At what levels is it feasible to make content interoperable? What goals are achieved by making content interoperable? What is the relationship between reusability and interoperability?
- **System maintenance and evolution:** How do we design system architecture so that it can survive, and indeed facilitate, bottom-up evolution of the system? What kind of evaluation data should the system collect, and how? How do we document system architecture so that it is understandable by those who will be responsible for its maintenance and evolution?
- **Coordination:** What happens when we move from managing individual content development projects in relative isolation to managing integrated content development programs? Which design assumptions are challenged when discrete learning products become parts of continuous learning systems?

3. **The identification and categorization of design decisions**

When a design domain is relatively stable, the explicit articulation of design decisions is less important, since decisions and their consequences are reasonably predictable based on past experience. Process-level issues can generally be resolved on a case-by-case basis in such circumstances. As the transition is made to developing instructional content components for use in distributed learning systems, instructional designers may face a period of domain instability where novel and complex interactions force many tradeoffs to be made unwittingly. Reassessing and evolving processes in light of these challenges will require an understanding of the new design space that instructional content developers are working within. In part, the opportunities and constraints associated with this new context will have to emerge through hard experience. A viable approach for articulating the boundaries and substance of this space in advance, however, is to identify and categorize the macro- and micro-decisions that are made in developing small-scale modular content, and examine these decisions in terms of their scalability to larger, more integrated systems. This is the subject of my current work-in-progress. By examining the development process from the perspective of decisions that are made during design, a top-down, principle-based approach to learning system architecture can be combined with a bottom-up awareness of the individual decisions designers make on actual projects. This is a key stepping-stone in the analysis of the cohesiveness and comprehensiveness of a given set of instructional development processes. The design decisions can also serve to frame, in tangible terms, the relationship between a given pedagogical strategy and its technical implementation.

Interactive Flows in Language Learning on the Internet

Abstract: Concerned with the relationship between interaction and learning, this paper aims at exploring relations between interactive flows in an EFL course offered on the Internet and language learning. The course was produced and is run by the research team of EDULANG, an ongoing research project in language learning on the Web and teacher development for the Web. In this research context, interactive flows are being used to record and analyze the rate and type of interaction in the course, identify units, tasks and course spaces that do not promote expected levels of interaction and plan and promote improvement in course structure, course content and teaching strategies.

Aims and Context

This paper derives from ongoing research in the context of EDULANG, a team project that aims at investigating multiple aspects of language learning and teaching in courses on the Internet. The paper is more specifically concerned with the relationship between interaction and learning and aims at exploring relations between interactive flows and language learning. An interactive flow is here defined as a longitudinal profile depicting amount (no. of messages or interactive turns) and direction (sender and recipient) of synchronous and/or asynchronous participation in an online course. The context of the research is an EFL course offered on the Internet (www.cogeae.uol.com/sal). The course was produced and is run by the research team of EDULANG. Aimed at adults with a basic command of English, its general social aim is to offer students the opportunity to make new acquaintances on the Internet. This general aim unfolds into specific social and language-specific, communicative functions. The course officially lasts 8 weeks but can in fact reach 12 to 13 weeks. The interactive spaces make it possible for participants to a) communicate through messages posted to a virtual Bulletin Board (BB) subdivided into three forums (Classroom, Café and Technical Support), b) display (and re-edit) their interactive production to course peers in a Production Panel, c) send progress tasks and tutorial exercises to the teacher through mail-to-devices on the course pages and d) participate in online Chats. All communication is carried on in English, except for messages left in the Technical Support forum. As an essential element of learning and knowledge construction, interaction must be evaluated for type, effect and efficiency in courses on the Internet. In this research context, interactive flows are being used to record and analyse the rate and type of interaction in the course, identify units, tasks and course spaces that do not promote expected levels of interaction and plan and promote improvement in course structure, course content and teaching strategies.

Method

Data was collected from indicators about sender, recipient, date and subject of 6 groups of students and their respective teachers, in 1998 and 1999, and include a) messages posted in the Bulletin Board, b) messages with ongoing tasks sent to the teacher, c) texts displayed in the Production Panel and d) participation in online chat sessions. All indicators were available within the course system.

Some Findings

Results were organized in order to reveal graphic flows of interaction involving students and peers, students and teacher, teacher and students. These flows reveal trends within each group as well as across groups. Interpreted in
the light of the course context, the graphic flows below have offered support for pedagogical and managerial decisions, as well as for changes in design. Figure 1 indicates that in this course, the amount of student talk tends to be equivalent to or higher than teacher talk. This may mean that in an interactive internet course, students engage in more interaction than students in traditional face-to-face EFL courses. Figure 2 shows that different groups present different types of flows, either with a focus on teacher-student and student-teacher interaction or with a focus on communication among students. In groups where the teacher talks less, interaction among students tends to be higher. In this sense, the amount of teacher interaction with students influences the amount of students’ interaction with their peers. Additionally, Figure 2 shows that groups A, B, C and D (taught in 1998) communicate a lot less in the BB than groups C and D (taught in 1999). This suggests a development of familiarity and comfort with educational contexts on the Web for both students and teachers. However, relatively close averages of participation in the 1998 groups (11.07, 5.53, 8.45 and 11.95) and equivalent participation in the 1999 groups (28.28 and 28.38), suggest that students seem to have a quantitative communicative quota, that they strive to use, regardless of the interlocutors they choose to have (the teacher or a peer). Figure 3 allows an interpretation of the interactive flows in the BB in the light of course content distribution (weeks 1-3 for unit 1, weeks 4-5 for unit 2 and weeks 6-8 for unit 3). A higher state of motivation seems to be associated to specific phases of the course when participants are all getting to know each other (the beginning) or students are trying to close their participation successfully (the official end, the 8th week). Mid course activities have not been able to sustain adequate levels of interaction (notice the relative drop both in the 98 and 99 groups) and are now being thoroughly reformulated. Figures 4 and 5 offer data for interesting observations. Groups A and B seem to reinforce the quantitative communicative quota hypothesis, with task completion and BB message flows in a complementary relationship (lower averages in one flow type complement higher averages in the other). Groups C and D, on the other hand, present opposite results in both types of flows and suggest that teacher management has a big influence on task completion and student participation in the BB. Figure 6 reveals that among students who completed at least 50% of tasks there are more poor “chatters” (23) than good “chatters” (13). However, among the best “chatters” (more than 30 turns) were the best task completion rates. This suggests that completing tasks (a traditional activity) is still favored over other web-typical types of participation and that an intensive participation in chat sessions is usually associated to intensive task completion.
The effects of collaborative, online learning on broadcast journalism students: Perception and understanding of undergraduates at linked universities worldwide.

Marion Coomey
International Centre for Learner Managed learning
Middlesex University
United Kingdom
m.coomey@mdx.ac.uk
marioncoomey@hotmail.com

Abstract: This paper describes a study that is being developed to explore online collaboration between undergraduate journalism students at universities in Australia, Canada, New Zealand, the United Kingdom and the United States. The premise of the study is that by bringing students, instructors and experts together to examine different perspectives of international news stories, learners will develop a stronger understanding of stories that get international coverage. The goal of the research is to develop a consensual and collaborative module that explores international perspectives on global news and to present this module, online, to teams of students at the partner universities. Data will be gathered from online interviews and questionnaires given before and after the module.

Introduction

In the past decade there has been a growing amount of research in journals, books and conference papers in the area of online learning. Online learning, for the purpose of this research, refers to study that is done using computer technologies with the learner at the same location or at a distance from the instructor.

Many established universities, such as Stanford in the United States, Deakin in Australia, University of Twente in the Netherlands, offer online classes to students who live at a distance from campus, to learners studying part-time and to professionals engaged in lifelong learning. These classes may have an international reach but are run and controlled entirely by individual universities. The Open University in the United Kingdom and the University of Phoenix in the United States are two examples of universities that are completely online. All students study from a distance but students are still studying at one university and working within the structure and policies of that system.

Most of the online classes described above, involve students working alone online with some support from instructors or tutors via e-mail but with little collaboration amongst students themselves. Collaborative learning, as defined for this study is: learning in an educational program created by a group of partner universities and in which students and instructors get together to examine course content issues. This sort of interactive, online learning is becoming more widely practised. Medical schools throughout Germany (Friedl, 99) share online resources to study cardiac surgery. An online training for trainers course involved learners in 22 European countries (Leino, 99). Organizations such as the United Nations are using online modules to give professionals around the world a chance to study copyright law (Durant, 99).

So far, in this researcher's literature search, most examples of online collaboration involve engineering, science, medical and business programs and most of the collaborations are developed at one university. Telg (96) noted that in the United States "few collaborative distance education efforts have taken place between American universities and universities in other countries".

In this researcher's area of interest, broadcast journalism, there is little documentation in the literature of any programs using online collaboration as a learning tool.

Study

It is becoming easier and easier for journalists to quickly gather information from any part of the world and disseminate it to any other part of the world but McGregor (98) asks is "the news is better reported with more understanding as a result of the new technologies". We are sending young broadcasters into a world of instant information, instant analysis and instant conclusions about global news issues. One of the questions raised by this study is: do those young journalists, and the
experienced story tellers for that matter, have the enough understanding of global issues to provide clear, non-biased reports?

The premise of this study is that by linking students, instructors and broadcast experts in online discussion and by working in international teams on assignments and presentations concerning global news, the learners will develop a stronger understanding about stories that gain international media attention. The researcher is working in consensus with partner instructors in Australia, Canada, New Zealand, the United Kingdom and the United States to develop a collaborative module that will allow students to examine and discuss international perspectives on global news stories. Students will gather at the module web site that includes: structured and unstructured forums for discussion and debate, a location for students, instructors and industry professionals to interact, links to broadcast networks worldwide plus visual and written content that takes the learner through the module and its assignments step by step.

Data will be gathered using a quiz to examine students' knowledge of global news issues, before and after the module is run. Learners and instructors will respond to questionnaires online before and after the module and will participate in structured and informal taped interviews to elicit personal and anecdotal information. At least ten students from each partner university will participate in the first run of the module in April 2001.

The result of this study will be to establish an international circle bringing learners with different backgrounds and understandings of international news, into an ongoing discussion. The timing is right to examine how online collaborative learning functions within the untested area of broadcast journalism and to determine if there is a benefit for students in using this new teaching/learning method. This study aims to bring issues of online learner effectiveness to light to provoke further discussion research and practise in this area.

Leino, A. (1999) Virtual United: Online courses to 22 Countries by an international team, *Online EDUCA Berlin*, 5th International Conference on Technology Supported learning

Over the next decade, there will be an increasing digital gap between higher education institutions offering and not offering online courses. This will result from the lack of planning by offline institutions in information technology policies, networking and technical infrastructure, and access to remote electronic library resources. This is not an all or nothing situation. Some offline institutions have laid plans for a digital learning future. But compared to online institutions, they have less extensive plans. It takes several years of laying down the technical infrastructure before we see the results in suites of online courses. An institution cannot decide one year to start putting in place such an infrastructure, and then expect to see the results the following year in a dramatically increased online learning.

We mailed 8 questionnaires to 310 colleges, CGEPS, and universities in English and French Canada. 134 institutions returned at least one questionnaire from June, 1999 to April, 2000, for a response rate of 43%. The response rate was good among the 60 universities (89%), but poorer among colleges (35%) and CGEPS (25%). This is due to the inclusion of many very small colleges and CGEPS that had difficulty filling out complex questionnaires. The questionnaires were completed by 8 senior officials responsible for policy and implementation of information, communication, and learning technologies (questionnaires returned are in parentheses): VP or most senior officer responsible for information and communication technology policy (82/134 = 61%); manager or director of networking and technical infrastructure (72/134 = 54%); head of computer support (84/134 = 62%); director of audio-visual services (68/134 = 51%); head librarian (68/134 = 51%); head registrar (69/134 = 52%); director of instructional development or academic or teaching technologies center (75/134 = 56%); and, president of the faculty or teachers' association (47/134 = 35%). The following comments and analyses are based on these data.

INFORMATION TECHNOLOGY POLICIES
VPs of Information Technologies at institutions offering online courses, compared to those not offering online courses, placed more emphasis over the next 3 years in: instructor training in teaching technologies; recruitment of more technical staff; cooperation with other institutions in software licensing; encouragement or requirement of student computer ownership, and provision of open access computers to students. If we expect the information technology gap to close between online and offline institutions, institutions not offering online learning should emphasize these policies at least to the same degree, if not more, than institutions offering online courses. But this is not so. Over the long term this will lead to a growing gap between online and offline institutions.

NETWORKING AND TECHNICAL INFRASTRUCTURE
We asked Managers of Networking and Technical Infrastructure how much they emphasize servers, networking, student computers, and wireless devices in their plans. The data on servers reflects the declining use of UNIX (despite its history and stability), and the rise of Linux and Microsoft NT servers. But institutions offering online courses are more likely to have all three server types in their plans than institutions not offering online courses. This may reflect the greater demand on servers among institutions that offer online learning. However, online courses are not the only demand for servers; they are used for a wide variety of administrative and educational functions. Our question did not tie the server type to a particular online learning use. The data probably reflect a more general difference in information technology configurations between online and offline institutions. Online institutions are also much more likely to expand wired and wireless networking, fast ethernet connections, notebook and other mobile computing devices, and student computer lab capacity. The differences are so large that this kind of weak infrastructure in offline institutions will likely undermine their inability to offer future online learning.

DIGITAL LIBRARY RESOURCES
If institutions not offering online courses expect to catch up to institutions offering online courses, they should reduce their expenditures on hard copy print library resources as much as or more than institutions that are heavily into online learning. In fact, that is not the case. Offline higher education institutions plan to spend more on hard copy print library resources. A greater percentage of head librarians of institutions offering online courses plan to expand electronic library resources over the next three years in contrast to offline institutions. This reinforces the view that institutions already offering online learning are forging ahead with additional plans to develop and extend...
their information technology infrastructure, in this case the library infrastructure, in contrast to institutions not offering online learning. Our data also suggest that most libraries are moving quickly into the electronic age on almost any information technology question we asked. But only about one-third of head librarians plan to emphasize student e-mail access over the next three years. Libraries do not view themselves as centers for providing students with e-mail access; such services and access are available elsewhere on campus and from off-campus.

**SUPPORT FOR ELECTRONIC COURSEWARE**

Directors of Academic Technology and Instructional Development Centers at institutions offering online courses plan to emphasize the following between 2000 to 2003 in contrast to institutions not offering online courses: funding for teaching support and teaching technology support units; funding for free instructor workshops in academic technologies; training instructors in computer literacy and web design; funding for instructional technology projects proposed by instructors, academic programs, and departments; web course outlines; interactive multimedia web courseware with full instructor participation to teach the courses; standalone interactive web courseware with minimal instructor intervention; e-mail in courses; computer conferencing in courses; and, computer-supported collaborative learning (CSCL) in courses. However, those items receiving the greatest endorsement over the next three years among institutions offering online courses are: course outlines on the web; computer conferencing in courses; computer supported collaborative learning in courses; and, training instructors in web design. The least emphasis in plans over the next three years are in user-pay instructor workshops in academic technologies, and funding for instructor release time to work on teaching technologies.

**REGISTRAR PLANS FOR SUPPORTING ONLINE LEARNING**

Among head registrars at Canadian higher education institutions, there is a moderately positive association between the number of online courses offered and plans over the next three years in: student web registration; electronic delivery of student academic counseling; web course evaluations and course outlines; courses geared to job skills; distance education courses; computer conferencing, video-conferencing and e-mail in courses; computer-based training; and, linking electronic classrooms between institutions. There are no plans among registrars in institutions with many online courses to move to general paperless office procedures and web calendars over print versions (already done); student computer competencies (these skills are assumed or picked up as students take online courses); instructor online access to class lists and online submission of student grades; and, information technology in face-to-face courses. There are three areas in which registrars with low numbers of online courses plan to emphasize over the next three years, while registrars at institutions with many online courses will definitely not emphasize: part-time student enrollment; continuing education; and, instructor access to student academic records. It is often assumed that distance online learning goes hand-in-hand with continuing education and part-time studies. This may have been the world of traditional distance education. Online learning has moved out of continuing and part-time studies into full-time studies. We are probably witnessing here a transition in the academic programming of distance education as it moves from offline print correspondence to online learning.

**DEVELOPMENT AND DELIVERY TOOLS OVER NEXT THREE YEARS**

We asked directors of Instructional Development and Teaching Technology Centers the emphasis that their institutions will place on development and delivery software over the next three years. Institutions offering online courses indicate that they will move more strongly in the direction of the top software in the market. Over three quarters (78%) of institutions offering online courses indicated that they will move even more strongly in the adoption and implementation of courses using Web CT. Even among institutions not offering online courses, almost one-third (30%) plan to adopt WebCT. No other software comes close to WebCT in the future plans of institutions. However, there is significant growth potential in Lotus Notes, Centrinity's FirstClass, Macromedia Director and Authorware, Asymetrix's Toolbook, and the Web Board. There does not seem to be much growth potential in Virtual-U, Question Mark, Allaire Forum, Norton Connect, and Web Course in a Box.

**CONCLUSION**

There is little evidence to suggest that institutions not offering online courses will soon catch up to institutions currently offering online learning. They have not prepared their technical infrastructure for offering online courses. Their main hope might be closer collaboration with neighboring institutions that have prepared their own infrastructure for a digital future in online learning.

SUPPORTING A COMMUNITY OF PRACTICE: THE ROLE OF WORKERS AS LEARNERS

Maarten de Laat, Frank de Jong and Julian ter Huurne
University of Nijmegen and the Education and Knowledge Center (LSOP) of the Dutch Police
m.delaat@ped.kun.nl

Abstract: In this paper we focus on the use of computer supported collaborative learning (CSCL) in an organizational setting. The program we use is Web-Knowledge Forum. Although there is a lot of experience in using Knowledge Forum in a classroom setting, little is known about how to implement and work with this program in an organization other than schools. The problem investigated in this pilot study is how a community of practice uses Web-Knowledge Forum as an online learning environment to discuss work-related problems. This study focuses on role of the worker as a learner in an unstructured process of negotiation of meaning in a community of practice. In the study eight police officers participated by forming a heterogeneous group initiated by the Information Management Approach of Criminal Investigation in Police Education (ABRIO) a subdivision of the Dutch police force.

Introduction

A learning organization stimulates the ability to learn individually, in groups and to learn by the organization as a whole. The aim in this is to support continuous learning to combine and develop knowledge in the organization in order to respond flexible to changes that occur in the market (Bolhuis and Simons, 1999). There is a tendency to organize this learning as close to the workplace as possible instead of sending people to courses given outside the workplace (Van der Krogt, 1995; Nonaka & Takeuchi, 1997; Bolhuis & Simons, 1999). Revans argued for action learning. He formed learning teams to work on real organizational problems and to structure their experience in such a way that both useful solutions to these problems emerge and substantial learning occurs for participants (Vaill, 1996). So the employees are recognized as an important resource to the organization. According to Wenger (1999) people in organizations form communities of practice by helping out each other and discussing the latest developments. These communities of practice are bound by a shared practice related to a set of problems. In these communities they share and create knowledge; they learn through participation (Wenger, 1998). Membership to these communities of practice is voluntary, these communities are not bound by organizational affiliations.

In large organizations like the Dutch police force online communities have an advantage in bringing people together independent of time, space and local cultures. CSCL makes it possible for people to participate in communities of practice and work at their own pace and time. One of the programs that support this kind of collaboration is Web-Knowledge Forum. Web-Knowledge Forum is a discussion program designed to form a learning community over the Internet. It’s a product of the Computer Supported Intentional Learning Environments (CSILE) family, developed at the Ontario Institute for Studies in Education (OISE) to support the collaborative construction of knowledge (Scardamalia & Bereiter, 1992). The participants operate in a shared workspace in which they read and write notes. A note is a contribution that can contain text, pictures and links to documents, html pages or other notes in the shared knowledge workspace. Working with this program stimulates the participants to talk about the subject, read relevant resource materials, pose questions, offer theories, conduct experiments, and work together to make sense of new ideas. By working together participants develop greater competence in a particular subject area, using what group members already know as an important component and co-constructing plans of action to extend that knowledge (Hewitt & Scardamalia, 1998). The creation of knowledge therefore is seen as a social product.

Originally this program was designed for use in the classroom to support the construction of knowledge in a social context. The aim in the development was to support an environment that will make it possible for schools to function as knowledge building communities (Scardamalia & Bereiter, 1992). Within knowledge building communities the focus is on knowledge construction. It’s a knowledge-centered community of practice.

The problem we face is how to facilitate the creation and support of communities of practice in organizations that work in a Web based environment and make knowledge building the core of their activity. In the first place there has to be identified a ‘real’ and meaningful problem that exists in the organization. A problem that is owned by the participants and in which solution they are willing to put effort. Second the members of the organization who feel affiliated by this problem have to form a community in which they can participate on a voluntary and functional basis. In this paper we focus on the possibilities of Web-Knowledge
Forum to serve as a meeting place for such communities. A place where participants can work together, undertake collaborative learning activities, sharing their knowledge, aimed at deepening their expertise in the problem to be solved.

Our question is: Can groupware, e.g. Web-Knowledge Forum, support the negotiation of knowledge and understanding in communities of practice in an organization?

We focus on the role of the worker as a learner in an unstructured process of negotiation of meaning in an online community of practice.

The study

This study was conducted to gain experience with participants who were engaged in an online learning community. The community consisted of eight participants who voluntarily joined in the community. They responded to a letter that was sent by the ABRIO to several police departments explaining the problem that has to be solved. The problem was about how to identify and describe general work-processes used in the field of criminal investigation. As a whole the participants formed a heterogeneous group (policy makers, criminal investigators and experts).

During a period of two months they worked together using Web-Knowledge Forum. There was much uncertainty about how to identify work-processes, therefore the participants agreed to start with an open discussion on the subject ‘work-processes’, instead of following a structured plan of action to tackle the problem. Web-Knowledge Forum played a central role in supporting the discussion because all the written contributions are stored as notes in a shared database available to all the participants. The discussion was divided into certain subjects called views in which the participants contributed a note or comment on a note they had read, by writing a build-on note.

Instruments

The way people participated and interacted with each other provides information about the activities of such a community. Web-Knowledge Forum is provided with an analytic toolkit (ATK) that analyses the activities of the members of the community in the database. It creates log files of all the users about how many times they have read, write or edited a note. How many notes are linked to each other and how many ‘build-on’s there are made.

Web-Knowledge Forum is designed to facilitate cognitive and metacognitive activities by providing opportunities to give your opinion, to give a comment, or by making suggestions or providing new information. Because of these possibilities it is important to know more about the nature of the content of the material the community has created together and what kind of activities the participant undertake. Are they trying to advance their knowledge? Veldhuis-Diermanse (1999) developed a coding scheme to gain information about the content of the written notes based on the constructivist view of learning in an educational setting. This coding scheme is still in a design stage and it is the first time this scheme is applied to an organizational community. This coding scheme consists of three main categories: 1 Cognitive activities, 2 Metacognitive activities, and 3 Affective activities.

1 Cognitive activity: Cognitive activities are used to process and acquire insight in the information being discussed. Veldhuis-Diermanse recognized three subcategories of cognitive activities: 1 debating, the accent is on arguing, presenting new ideas or thoughts about the subject; 2 using external information, the accent is on referring to information found in other sources than the database; and 3 linking or repeating internal information, the accent is on referring to information found in the shared database.

2 Metacognitive activities: Veldhuis-Diermanse (1999) describes metacognitive activities as activities undertaken to regulate each other’s learning process or to regulate the goals and direction of the discussion. 3 Affective activities are used to cope with feelings occurring during the discussion among the participants (Veldhuis-Diermanse, 1999).

At the end of the pilot-study we gave the participants a questionnaire to gain information about their experiences working with Knowledge Forum.

Results

The log files generated by ATK gives a description of the activities that has taken place in the database (Tab. 1). The participants contributed 98 notes in the database. That’s an average of 12,25 notes per participant. 56% percent of the notes have been read. This means the amount of notes that have been opened by the
participants. So this might exaggerate the actual reading that has been done. 83% percent of these notes are linked, also called build-on. The log-file only records the activities of the participants, a build-on activity therefore does not have to be content related. Table 1 shows that there are substantial differences between the participants, both in writing and reading. Notice that build-on notes are also a part of the written notes.

Table 1. Participation in the database

The content analysis of the notes reflects the following cognitive and metacognitive activities (Fig. 1).

These results indicate that the participants discuss a lot about the subject. The participants present a lot of ideas of their own and start discussing about that in the community. The participants do not bring in much new information; only seven times they referred to information that can be found outside the database (e.g. book pages). Also they did not make many content related references to the contributions of other participants in the database. Although according to the ATK 83% of the notes are linked. This difference is explained by the fact that the coding scheme only refers to written comments to other contributions in the database. The participants show quite a lot of regulative activities, but in fact two participants are responsible for 66% of the regulative activities. There are quite a lot of affective contributions in the database. The explanation for it is that this way of working was new to them and therefore they were regularly asking for feedback and gave a lot of general reactions to the other participants. This category shows that they did not use this medium for chatting or sending 'e-mails' to each other, that are not related to the discussion. Most contributions even the affective ones were subject related.

The questionnaire provided information about the way participants worked with Web-Knowledge Forum, five out of eight were returned. 60% of the participants agreed on the question if they were collaboratively building new knowledge about 'work-processes', but they pointed out that they need to grow more into building upon the ideas of others. Also they mentioned that there was a lot of confusion about the concepts being used and that they need to clarify the goal of their study, to give more direction to the discussion. 80% of the participants indicated that they were satisfied with the opportunities, provided by the program, to discuss the subject together. The participants (80%) notified to have enough information to be able to take part in the discussion. Answers to the question, what they do if they lack certain information, are searching for relevant information, consulting colleagues at work, and trying to stimulate the other participants to explain certain
issues. Results of the question about what they thought of the quality of the written notes, varies from good to reasonable. In general the quality is good but the discussion became more silent later on. “There is to little structure to guide our discussion, the notes contain valuable information but what does it bring to us?” 40% of the participants indicated that there was to less coordination during the discussion. 60% of the participants pointed out that a more structured or goal directed approach is necessary. They argue that this will help them to achieve agreement and build on that.

Conclusion and Discussion

Summarizing the results it can be seen that the participants show a lot of activity in the database although they read much more than they contribute. Related to the content analysis of the contributions. It seems that the activities the participants undertook are more discussion oriented than building knowledge upon already contributed or new information. However in their perception of working with groupware they appreciate the possibility of knowledge sharing. On the first glance people are willing to work in a groupware environment and share knowledge together. This is promising for the support of working in communities of practice in organizations. The analysis also shows that sharing of knowledge does not happen automatically. Although there are a lot of regulation activities, it turns out that they were mostly carried out by two participants. The questionnaire reveals that the community members desire more structure and support to direct the knowledge building activities of the community as a whole. The use of groupware in communities of practice in organizations seems promising. The participants report that this tool is useful for knowledge sharing but that the actual knowledge building activities needs to increase. They had trouble clarifying the goals and direction of the discussion. Also they discovered that there was quite a lot of confusion about the concepts used by the participants. The main concern was lack of coordination during the discussion. In an unstructured process of negotiation nobody feels direct responsibility to organize and structure the content of the problem studied. The lack of the learning ability in the sense of regulating the content and community processes seems to be crucial for people to become used to share knowledge, deepening their own and common understanding and creating further insights. To compensate this lack one can structure the negotiation of meaning by making a learning agenda. By which participant express their goals, divide certain tasks, and divide responsibilities (e.g. coordinator of the content, someone who keeps the community together or invites new participants when needed, technical assistance). One can also introduce a didactic approach of inquiry analogue to phases of the scientific enquiry process or problem solving.

Abstract: Federal mandates enacted on August 7, 1998 revealed that "Effective 2 years after the date of enactment...any individual with a disability may file a complaint alleging that a Federal department or agency fails to comply with subsection (a)(1) in providing electronic and information technology. (Section 508, "Electronic and Information Technology) "The new rules will apply within a few months to all web sites operated by government agencies...By August 7, 2000, they will extend to vendors doing business with the federal government. "Possibility soon afterward they may extend to every Web site posted in the U.S." (Adam Clayton Powell III). Are ready for August 7, 2000? If not, this paper can provide ideas to help you get started.

Introduction

In PC Week Online, Vaas (2000) notes that between 95 and 99 percent of web sites are inaccessible to the visually, hearing -and/or mobility impaired. Many web developers are ignoring the accessibility issue or just do not know how to making their sites universally accessible. They are bewildered in the face of the vast information available in terms of how to make it applicable to their situation. Three areas can help focus the journey to understanding.

What's What

The law is the driving force behind the need to have universal web sites. There are already been law suits against AOL and Universities for not providing accessible web access. Equally access to information is the key reason that the focus is on web sites. Individuals cannot fully participate in today's complex society based on technology-based information if they do have access to the same information. There are several references to the law at the following web site:
http://www.swt.edu/~df12/summit/LAW.HTM

Who's Who?

This paper will mention just a few of the leaders in the field who are trying to make electronic information globally accessible. The first is W3C. Their mission states "The W3C's commitment to lead the Web to its full potential includes promoting a high degree of usability for people with disabilities. The Web Accessibility Initiative (WAI), in coordination with organizations around the world, is pursuing accessibility of the Web through five primary areas of work: technology, guidelines, tools, education & outreach, and research & development." (http://www.w3.org/WAI/) W3C focus is for experienced programmers and guidelines can be found at the following address:
http://www.w3.org/TR/1999/WAI-WEBCONTENT-19990505/

Accessible Web Authoring Resources and Education (AWARE), mission is to serve as a central resource for web authors for learning about web accessibility. The AWARE Center was launched in April 1999 as part of the HTML Writers Guild's (HWG) annual Web Accessibility Month, a special focus on the importance of designing for universal accessibility. The Center is supported by the Guild's staff and volunteers, and is designed as a resource for all web authors. Ken Barlett co-founded the HTML Writer's Guild with Martin Bayne. The HWG is the world's largest international organization of Web authors with over 130,000 members in more than 130 nations worldwide. The HWG exists to assist its members in developing and enhancing their capabilities as web authors, to compile and

1624
publicize information about standards, practices, techniques, competency, and ethics as applied to web authoring, and to contribute to the development of the web and web technical standards and guidelines.

Disability Access Information and Support (DAIS). Jane Jarras, President, states, "But after we got the ramps and elevators installed, we could think about how to make the teaching that had always gone on in those classrooms fully available to all students. The parallel ends here. While we are scrambling to get the technological "ramps and elevators" in place, we are actively creating new barriers to access on a regular basis. At the risk of stretching the analogy a little too thin, if we don't be careful we will find that when those technological ramps and elevators we installed are finally in place, they only allow for a better view of the opportunities passing by us. We cannot wait to get the technology in place before we start trying to impact on the application of that technology.

Microsoft. The Microsoft Senior Initiative is a program aimed at bridging the digital and generational divides and ensuring that seniors are not left behind on the information superhighway. By providing access to information technology and PC literacy training, the Microsoft Senior Initiative introduces the exciting possibilities of technology to senior citizens. The Seniors and Technology Web site (http://www.microsoft.com/seniors/) is a resource for seniors, their families and communities about the exciting possibilities that can be realized through the use of technology.

**How to?** For people who are just learning how to develop web pages, the easiest way is make a page using a "what you see, what you get editor," then save the web page as text and htm. The problem with this method is that that many people do not do an adequate job of keeping both pages updated. Software companies are starting to make it easier to make web pages accessible through what is called, style sheets, which control the presentation of a document. It is often easier to work in pairs or teems of two to learn this process. There are often many free workshops on the web and in your local area. Perhaps partner with someone who can pay to have a consultant. Design is the first part of "how to." The second part is getting your page validated by a reliable source. Sites can be easily validated using on-line features which require that you paste your URL name in the box and almost immediately you will learn if you have accessibility problems. The top two sources of validation are:

Bobby Accessibility Validator  
http://www.cast.org/bobby/

W3C HTML 4.0 Validator  
http://validator.w3.org/

The complexity of implementation of this mandate can not be fully address with this in progress paper; however, there will a much greater discourse at the Universal Web Accessibility Symposium 2000 (at WebNet 2000) -- San Antonio, Texas, October 31, 2000.

Introduction
Many educators are experimenting with flexible on-line learning; consequently academics have to adapt their delivery, preparation and course administration. This study shares staff and student experiences of participating in a completely remote on-line course, compared to a flexible on-line course where students can attend classroom sessions.

The issues we encountered included ones related to hardware and software, submission of assessments, student communication with each other and the lecturers, as well as student and staff motivation over the holidays.

Existing research documents the pitfalls of teaching on-line and we used these lessons to anticipate problems as we planned our on-line course. This study documents the problems we encountered but hadn’t anticipated.

THE COURSE
Internet and Web Design (IWD) is a popular first year introductory course in the Bachelor of Computing Systems degree. It is normally taught flexibly with lectures and practical classes as well as a self-paced on-line course comprised of notes, exercises, self-assessment questions and a discussion forum (1). In the 1999-2000 Summer School, the course was offered completely remotely and condensed from 14 to 11 weeks. There were no face-to-face sessions except an orientation session, the project presentations and final exam. If students had problems they were requested to post their question on a discussion forum and had no option to ask the lecturers face-to-face.

DISCUSSION
Student issues
No time for a Summer break, condensed time frame, lack of personal tutor-student contact, no option of attending classroom sessions for personal contact with other students and no opportunity to take on a vacation job. Perhaps because of the above issues, there was a higher level of drop outs than normal.

Reasons for students dropping out included: getting a job, workload too heavy and no computer access at home.

Staff issues
Lack of a gap between semesters to attend to the course administration for the previous course. We undertook the course as an extra to our workload, meaning no summer break to recharge and prepare...
for the next semester. Most of the workload consisted of administration and marking and we felt the remuneration we received did not reflect the associated workload.

**Bulletin board issues**

If students had problems they were requested to post their question on the discussion forum rather than e-mail the lecturers, (so that we could avoid duplication of lecturer responses and attempt to mirror classroom communication by allowing students to answer each others’ questions when lecturers were not around). Despite our attempts to encourage participation, the use of the bulletin board was fairly low, with only 140 posts over the whole Summer School. Many students continued to e-mail the lecturers rather than use the bulletin board for questions. Perhaps this was because they didn’t want to look unknowledgeable in front of their peers, or because we didn’t assess the students’ contributions (2,3). Lecturers accessed the bulletin board every other day to check for questions to answer. The lecturer’s often interrupted their vacations to make special trips to cyber-cafes, only to find that no students were seeking help.

**Assignment submission issues**

Students didn’t email their assignments to the correct address, often sending them to our home email addresses and multiple addresses. Issues resulting from this included: lack of software at lecturer’s home; lecturer’s vulnerable to the risk of virus infection; and duplication of administration effort. There was a significant administrative burden for the lecturers who had to confirm receipt by email and print out the assignments. This was exacerbated by the often inappropriately large file sizes of the email attachments, (e.g. one Storyboard Word document was 3.5Mb).

**Group work issues**

Generally, students find it difficult to work in groups. This is exacerbated in an on-line course by having to use the printed word rather than face-to-face interaction. The condensed timescale of the course made this even more of an issue and one of our groups suffered a complete breakdown in communication. During a Semester course it is easier to identify problems with group dynamics and deal with them before they escalate.

**CONCLUSIONS**

The students had a generally favourable impression of on-line learning, but with reservations about the lack of personal contact and the high workload due to the collapsed course time-scale. Reasons for the course’s success included: anticipating possible problems and devising strategies to deal with them; and the considerable amount of user-testing that took place in the prior flexible on-line versions of the course, when semantic problems could be cleared up easily.

However unexpected problems were: inter-group conflicts; a higher than normal drop-out rate that impacted on other group members; higher than normal administrative burden on the lecturers; and serious practical problems with the publishing of student web-sites using FTP (4).

It is important to spend time forming project groups, to let the students get to know each other’s skill-set and interests thereby avoiding problems. This is perhaps even more important in a fully on-line course.

Abstract: Offering video and other rich media content over the Internet is an emerging growth area and represents a new model and opportunity for education. As broadband access increases and advances are made in network caching, streaming servers, video and audio compression, and multimedia databases, delivering streaming video claims unprecedented potential for education. Universities and corporations will continue to look to technology to deliver distance education and web based courses. Determining the pedagogical applications of streaming video is an important area of research. Identifying the strengths and weaknesses from an educational point of view provides an important context to the practical matters of technical implementation. This research intends to investigate both the pedagogical implications and the technical implementation of streaming video.

Overview

Offering video and other rich media content over the Internet is an emerging growth area and represents a new model and opportunity for education. As broadband access increases and advances are made in network caching, streaming servers, video and audio compression, and multimedia databases, delivering streaming video claims unprecedented potential for education. Universities and corporations will continue to look to technology to deliver distance education and web based courses. Determining the pedagogical applications of streaming video is an important area of research. Identifying the strengths and weaknesses from an educational point of view provides an important context to the practical matters of technical implementation. This research intends to investigate both the pedagogical implications and the technical implementation of streaming video.

Often when new technologies, like video, are applied to education they are seen as having the ability to make us all learn better and faster. Some of the questions that need to be answered regarding pedagogy include:

- Does streaming video over the web offer any more promise than standard videotape, the Laser Disc, or the CD-ROM?
- Can the metadata applied to streaming video offer learning strategies and information that was previously unavailable?
- Does the distribution medium, the Internet and a computer, improve the quality or access to instruction?
- What are the ideal tools and methods to develop content and sufficient metadata that make streaming video effective in teaching and learning?
In addition to the pedagogical perspective, there is a highly technical aspect of streaming video that affects price, availability, usability, performance, and quality. The following technical components will be investigated:

- Copyright, Security, and Intellectual Property
- Multimedia Databases
- Servers
- Clients
- Compression
- Network Caching and Bandwidth Issues

Finally, partnerships with industry suppliers, distributors, faculty, and technology solutions will be investigated in an effort to provide business models that can recover the costs of implementing and delivering streaming video content for universities.

Currently, the pedagogical potential of streaming video has not been demonstrated, the technology is so new that it remains largely untested in a learning environment, and content development tools are crude or non-existent. Answering the various pedagogical and technical questions are important outcomes of this research project. Performance indicators of this research will include the application of streaming video technologies to multiple content areas - including campus and off-campus users. In addition, the partnerships developed with industry, such as Akamai or other industry partners, will be measured against the benefits to the institution.

Detailed Description

Applications for streaming video are various. They include: webcasts of special lectures; access to a rich educational video library; video and audio conferencing; the integration of video into course web pages; and the creation of video-based educational objects. The effectiveness of this technology to teaching and learning is largely untested, but none the less the demands to incorporate it into teaching and learning are starting to be met by the technology. Only recently has a distribution medium become available that allows full text searching of video, the application of metadata, interactivity, and other media in ways that make the use of video in education more flexible than ever before. Research into the tools, usability, educational effectiveness, and various solutions benefit current and future teaching and learning at our post-secondary institutions.

The focus is on three main aspects of streaming video. These are quality and performance, pedagogy, and business models. Compression algorithms, the end user software, or client, networking technologies and server solutions impact quality and performance. In order to study quality and performance, various partners around the world are providing and testing content. Other partners, that can provide performance enhancements to streaming video including, cable companies, phone companies, and broadband access providers is under investigation. Various solutions' quality and performance will be compared by individual reviewers and focus groups in several locations. Quality and performance will be tested given different conditions, including connection speed, time of day, distance from server, end-user platform, server characteristics, compression algorithm, and client. Akamai's Free Flow server technology will be tested to compare performance enhancements at a regional and international level. Campus and off-campus user tests will determine quality and performance standards for the main streaming video solutions.

Streaming video, in itself, is like any other video format from a pedagogical point of view. Video, in general, is considered linear and lacking interactivity. If putting learners in front of a video feed was effective, we would learn from home, in front of our televisions, watching a video taped lecture. Clearly, streaming video of lectures over the web does not represent any educational advantage over distributing VHS copies of lectures. However, the potential for the video and audio to contain additional information may provide an educational advantage. Using video taped scenarios that demonstrate procedures and principles can be an effective use of video. Marking up that scenario with additional information, or metadata, may demonstrate clear advantages for teaching and learning. Creating interactivity, allowing the learner to make decisions, search text, navigate non-linearly, and interact with the video may allow a learner more effective access to learning using video than previously possible. Demonstrating the possibilities is not simple. Tools that develop the metadata, and procedures that accommodate
advanced content development for video are crude and difficult to use. In fact, although the need and technology exist, there are no cost-effective methods for creating a transcript of a video without the use of an individual typing what they hear into a computer. The expense of adding this metadata discourages its inclusion. The goals here are to demonstrate its potential and to discover processes and tools that permit the inclusion of metadata for streaming video. It is anticipated that this research will more clearly specify the need for content development software to be developed.

Associated with content development for the metadata of video are the data stores for the video and its metadata. There are several commercial database solutions currently available, and establishing the criteria that matches sound pedagogy for the database is an important outcome of this study. One of the issues is extensibility of the database. Scalability, compatibility, and reusability are all related to extensibility. The momentum of educational objects and IMS metadata standards for education dictate the need for the open, flexible standards and an object-oriented approach. A solution where costs do not prohibit university access to necessary features, while offering security and intellectual property protection will be sought.

The third aspect of this research focuses on the costs, partnerships, infrastructure requirements, and opportunities of streaming video for institutions. In essence, a business model that can sustain the delivery of streaming video for the institution. Costs associated with video production, editing, and compression are high, adding in metadata and storing in it all in large database applications can be very high. Pricing varies widely between suppliers and solutions, and an investigation into the details will lead to recommendations for implementation. Other costs associated with streaming video include servers, licensing fees, and Internet infrastructure. A detailed comparison of these costs against the performance and quality testing will lead to additional recommendations.

In addition to the cost/benefit analysis, the opportunities for collaboration with the private sector are being investigated. Opportunities exist that allow the university and its faculty to recover royalties to its intellectual property and charge for access to its servers. Streaming video over the web could prove to become the best distribution medium available for the thousands of hours of video already produced and owned by our institutions. Developing the types of partnerships and business models that could help support delivery, provide new content, build infrastructure, reach broader audiences, and maintain hardware and software is being prototyped at the University of Calgary.

Summary

The various complex issues from network, to compression, multimedia databases and usability require research, development, and testing to determine the best solutions for the institution. Guided by sound pedagogy, the framework suggested above is meant to get to some of the most important and practical issues, enabling the recommendation and adoption of solutions for the use by a post-secondary institution.
The Impact of Visualisation on Chemistry Teaching and Learning

Abstract: The availability of computers, the emergence of new visualisation and authoring tools and techniques, together with the expansion of web based learning environments and CD-based multimedia applications, offer chemistry teachers new possibilities for bridging the gap in students' knowledge and understanding of abstract and concrete chemical concepts and processes. This paper shows by example how the advantages of both the Internet and the interactive CD-ROMs can be used to improve students' learning at both macro- and microscopic level. We present results of a study of the effects of interactive multimedia teaching units on the quality of knowledge.

Introduction

The old Chinese saying, "a picture is worth a thousand words", has been proven many times by modern neuropsychological studies. Human beings can memorize 20% of what they read, and 30% of what they hear, but 40% of what they see, 55% of what they say, and 60% through active involvement; however, when all of the above sensory channels are used simultaneously, this results in the memorization of 90% of the content (Rose, 1993). According to the Gardner theory of multiple intelligences (Veenema & Gardner, 1996), we possess a number of relatively independent types of intelligences: linguistic, logical, musical, kinesthetic, spatial, inter- and intrapersonal. Each individual has the natural ability to use some of his sensory systems better than others. This shows that many different communication channels have to be used to achieve similar objectives with most of the learners. Spatial intelligence is commonly linked to visualisation and can, like all intelligences, be improved by various activities (e.g. in chemistry through use of models of chemical structures), which should be increasingly incorporated in the teaching and learning process.

In chemistry, three levels of visualisation are defined, which we explain by the example of chemical experiments. At the macro level, the real world is representable by photographs, drawings or video clips of the laboratory experiments. The 3D models of chemical structures or animations of chemical changes represent the micro level. At the symbolic level, chemical change is visualised by chemical equations or graphs. In order to achieve the learning objective, all three levels have to be correlated.

In this paper we present our work on the design, development and evaluation of interactive multimedia teaching units and web based teaching resources to be used at the primary and high school level. They can be used either for individual learning or in parallel with the traditional teaching tools in the classroom situation.

Development of multimedia chemistry teaching materials

In the design and implementation phase of the underlying CD-ROM applications of teaching materials all three different levels of visualisation in chemistry are taken into account. By using video, animations, and simulations coupled with interactive questions, games and problem-solving tasks, the users have, e.g. in the case of a chemical reaction, the possibility to observe chemical changes in reactants and products as well as energy changes, to follow them step-by-step, and then evaluate their observations. We try to simultaneously activate as many of their receptor channels as possible, and the use of nonvisual and static elements is kept to the minimum; the learning and testing
segments are tightly interlaced. Through communication - either live discussion with a teacher or via guided online discussion groups - the concepts learned are further clarified and relevant information is shared among the users.

The use of existing multimedia teaching materials in schools is supported by the intensive in-service training seminars for chemistry teachers. Teachers become prepared for active involvement in the development of teaching materials, produced by the University. To facilitate the needs of teachers and students, a specialized chemistry website named KemInfo was established. It includes a module on the visualisation of chemical structures and processes, together with tutorials for existing high quality educational multimedia CD-ROMs. It also provides the users with original interactive teaching materials, prepared either by teachers, through small-scale projects, or by the university lecturers. The teaching materials vary in size and complexity, the emphasis being on the applications using visualisation techniques (e.g. interactive maps of chemical reactions) and interactivity (collections of interactive exercises and games).

**Evaluation of multimedia chemistry teaching materials**

In spite of the rich assortment of educational CD-ROMs for chemistry, very little has been published regarding the impact of multimedia on the knowledge and motivation of students, let alone the cost-effectiveness of these products. In a research project, our own interactive multimedia CD-ROM, "Light and Chemical Change", was evaluated. The impact of multimedia on cognitive, motivational and motoric development of students was investigated in a qualitative study. The research involved a sample of 50 third-year secondary school students, who were divided into two proportional groups, namely the experimental and the control group. Both groups were pre-tested a week prior to the experiment through multiple-choice and open-answer written tests, so that the initial difference between the groups could be established. The experimental group then worked with the interactive CD-ROM in pairs, and they were given three hours to learn a specific content, presented by video clips, animations and simulations, accompanied by interactive questions with intelligent feedback. This group did not use any other source for knowledge consolidation. Students from the control group were also given three hours, with several course books available, starting with the teacher's explanation of the subject topic. A week after the experiment both groups took a post-test focused on understanding the concepts at the microscopic level of visualisation. The performance of both groups before and after the learning session was compared. Whereas the groups did not significantly differ at the beginning, the results of the post-test show significant difference in favor of the experimental group, which can be largely attributed to the visualisation elements included in the CD-ROM and its interactivity. In our ongoing research project, a study aimed at improving the efficiency of visual elements used in multimedia teaching units is being conducted. We are investigating the correlation between the spatial abilities of the individual students and their ability to correctly interpret different chemical processes visualised by application of the diverse tools.

**Conclusion**

Active involvement of teachers in developing high quality multimedia teaching materials is the key factor for their regular use in schools. The research on the effects of such materials is needed to provide the developers with the feedback. The use of visualisation elements at all three levels is crucial in chemistry teaching, however the learning process has to be supported by discussion and testing.

Abstract:
A unique service organization, consisting exclusively of student employees, exists within the University of Wisconsin's Information and Media Technologies Division. Known as Student Technology Services (STS), this student managed organization is tasked with the operation of various computer, media and technology related campus services. STS employees work in all areas of I&MT including the Campus Computer Labs, Classroom Support, Desktop Support, Help Desk, Network Services, Peer Training, Photo Services, Printing Services, Shortcourses, Technical Resources, Video and Multimedia Production Services, TV Engineering, Distance Education Technologies, Visual Design Services, and Web Maintenance Services. More than 300 students are expected to be employed in STS by Fall 2000.

Student Technology Services (STS):
Student Technology Services (STS) is a student staffed, student managed organization responsible for delivering technology and media-related services to the campus community of the University of Wisconsin-Milwaukee. While empowered student IT workers are employed to provide a service, they are at the same time engaged in a learning experience. They are preparing themselves for their future careers through "experiential learning".

Student employees of STS come from virtually every academic major. Whereas many universities employ primarily technical majors under the mistaken belief that only they can satisfy their campus community's technology needs, STS instead looks for interpersonal skills, drive, and willingness to learn. STS has discovered that customer service and management skill sets have become as important as technical skills in the delivery of information and media-related technology services. Because most STS student employees do not have technical backgrounds, a carefully tailored training curriculum was developed and implemented. The purpose of the curriculum is to empower STS student employees by giving them the technical skills they will need to excel in their jobs as well as important professional and life skills they will need to excel in their future careers.

The STS training curriculum becomes an education when the learning is demonstrated through experience (i.e., implemented on the job) and when the experience is reflected upon (i.e., in an extensive oral and written evaluation.) Because completing the multiple levels of the curriculum, using the skill sets on the job and participating in the evaluation process are all mandatory conditions of employment, STS provides the setting for experiential learning at institutions of higher education. Many of the classes in the STS curriculum are developed and taught by STS students themselves. These STS Peer Trainers do not impose upon the institution's academic teaching mission, yet are an integral part of adding value to the learning experience of STS students. STS Peer Trainers are evaluated after each class they teach and are charged with making the necessary adjustments to their lesson plans.

In addition to the experiential learning provided by the curriculum, STS students are encouraged to transfer to other departments each year in order to learn and practice new skills. The exposure they gain in these other areas strengthens their learning experience and enables them to identify their personal and professional strengths and weaknesses. STS students are required to maintain a portfolio of their diverse work experience and training. The portfolio serves as the reflection piece to the classroom and on-the-job experience, thereby further adding value to TS' philosophy of experiential learning.

STS' focus on experiential learning has been met with welcomed enthusiasm at UW-Milwaukee. STS student employees are sought after not just for their learned technical skills, but also for the maturity and professionalism
that they acquire through on-the-job experience and reflection pieces. UWM department heads specifically request STS student employees to be placed in their departments to troubleshoot and to maintain department web pages.

STS' example of experiential learning is now being introduced to the 26 other campuses within the University of Wisconsin System. Wisconsin's governor recognized the benefits of experiential learning as a means of preparing a qualified workforce in the state that can remain competitive even in the fluid environment of information technology. The Governor's Office recommended increased funding for training IT student workers throughout the entire University of Wisconsin system. His decision was based solely on the UWM STS model and its success. The biennium budget was signed into law in October, 1999 thus propagating the STS model of experiential learning throughout the state.

The STS program has generated strong interest from many academic and non-academic partners. We are exploring relationships with public school systems and with leaders in private industry to provide:

- A pre-college program to create work experience and training in technology for high school students.
- A similar work program focused on the two year technical college in Milwaukee
- Summer internships and potential scholarships for the STS student employees at UWM
- Meaningful industry relationships for students leading to employment upon graduation.

We have met with enthusiasm and willingness by all participants to work together on these new relationships. We look forward to a greatly enhanced student empowerment program when the new partnerships are in place.

The Effect of Level of Technology Training on Teachers' Attitudes Toward Using and Integrating Technology

Ronald Dugan, Jennifer Richardson, & Dianna L. Newman, Ph.D.
Evaluation Consortium/School of Education
University at Albany/SUNY
United States
rd1872@ensvax.albany.edu

Abstract: This paper is a report of an ongoing longitudinal evaluation assessing the effect of level of technology training on teachers' attitudes and comfort toward using and integrating technology into the curriculum. Multivariate and univariate analyses were used on an initial sample of 54 K-12 public and private school teachers from a Northeast state undergoing two levels of technology training who participated as part of a Technology Literacy Challenge Grant. Initial findings support and extend previous research that shows teachers become more comfortable with using and integrating technology, and possess more positive attitudes toward technology, as the extent of training increases.

Introduction

Although over 8.5 million computers are being used for instruction in the U.S., and 85% of K-12 teachers have access to computers and other technology (Survey finds..., 1995), only half of all teachers report using computers for instruction (Hunt & Bohlin, 1995). Social learning theory (Bandura, 1977) predicts that failure of teachers to use computers will vicariously teach students not to use computers. This lack of computer use may be related to attitudes (e.g., anxiety) toward technology (Pina & Harris, 1993). Although 'A of all people who use computers experience some degree of "computerphobia" (Rosen & Maguire, 1990), when teachers experience it, this interferes with their ability to integrate technology into the curriculum (Hunt & Bohlin, 1995). The strongest predictor of computerphobia is experience (Rosen & Weil, 1995). Limited research has shown anxiety towards computers decreases after training and practice (Cambre & Cook, 1987), yet only 29% of teachers report having more than five hours of technology training in the past year (Technology Counts '99, 1999).

The Study

The purpose of this study was to investigate the effect of level of technology training on teachers' attitudes toward, confidence using, and comfort with integrating technology. Attitudes were represented by three constructs: anxiety, avoidance, and fear of stereotyping. Confidence was measured in three areas: software, hardware, and communication tools. Comfort with integration was assessed by participants indicating one of six stages (awareness, learning the process, understanding and application, familiarity and confidence, adaptation to other contexts, and creative application to new contexts). Training occurred at two levels (Level I; 5 days training on using Power Point or Hyperstudio in the classroom: Level II; Level I training plus 3 additional days training in Web page design for curriculum use). Participants were 54 public and private school educators participating in a regional Technology Challenge Grant training program in a Northeast state. Twenty-six educators experienced Level I training while 28 educators experienced Level II training. Over 300 educators are expected to be trained at both levels by the end of this grant year. An end-of-year paper/pencil survey was administered to the first cohorts of educators experiencing both Level I and Level II training so far this school year. Ten items measured attitudes toward technology (anxiety, avoidance, and fear of stereotyping) on a six-point, Likert-type scale (1=strongly agree, 6=strongly disagree). Eighteen items measured confidence in using technology (hardware, software, communication tools) on a six-point scale (1=extremely confident, 6=not at all confident). The Stages of Adoption Scale (Knezek & Christensen, 1999) measured comfort with using and integrating technology into the curriculum.
Findings

A multivariate analysis of variance (MANOVA) was used to analyze the data. The fixed, categorical independent variable was level of technology training (Level I and Level II). The continuous, random dependent variables were confidence with using technology (software, hardware, and communication tools), and attitudes toward technology (anxiety, fear of stereotyping, and avoidance). Findings indicated no significant difference for level of training on confidence in using technology (F=1.26; df=3,37; p>.05). However, a significant difference was found for the effect of level of training on the construct of attitudes toward technology (F=2.83; df=3,50; p<.05). Examination of the univariate Fs indicated a significant portion of the construct was avoidance (F=6.78; df=3,50; p<.05) and anxiety (F=6.61; df=3,50; p<.05), accounting for 15% of the total variance (Wilkes lambda=.85). A univariate analysis of variance (ANOVA) was used to analyze the effect of the fixed, categorical independent variable (level of training) on the continuous, random dependent variable of comfort using and integrating technology (six stages: awareness, learning the process, understanding and application, familiarity and confidence, adaptation to other contexts, and creative application to new contexts). A significant difference was found for level of training (F=5.00, df=1,50, p<.05) on stage of comfort. Strength of association showed that nine percent of the variability in level of comfort could be accounted for by level of training. Those with more training were more comfortable with integration.

Conclusion

These findings support previous research that shows teachers who receive training in using and integrating technology into the curriculum experience less anxiety toward, and more comfort with, that technology. This study adds to existing literature by showing that additional training with more advanced technological software further decreases computer anxiety and increases comfort with integrating technology above and beyond less, and lower-level, training. If teachers are expected to integrate technology into the curriculum and model appropriate technology utilization behavior for their students, they need more training than the levels currently being received by most educators.

Abstract: The Vocational Education and Training (VET) sector in Australia is coming under increasing pressure, both nationally and internationally, to deliver courses in flexible ways that incorporate the latest in information and communications technologies such as the Internet and the World Wide Web. LearnScope is a national initiative funded by the Australian National Training Authority (ANTA). Its aim is to provide professional development support to individuals and work groups in order to develop skills and capabilities for the online environment.

A preliminary study of LearnScope's Virtual Learning Community (VLC) was undertaken using a questionnaire based survey plus analysis of transcripts of forum discussions and published stories. The results highlight the complexity of the role of providing professional development for establishing online learning communities. The major areas of Technical Skills and Computer Literacy, Writing and Communication Skills, issues of Interactivity, and the development of Self-related attributes are identified as important if the VET sector is to build a critical mass of creative, capable instructors to work in the online environment.

The Changing Context of Vocational Education and Training

As the geographical boundaries of Vocational Education and Training (VET) in Australia become blurred, both nationally and internationally, the competitive edge of providers, Registered Training Organisations (RTO’s), will not only be the courses and training programs they offer but the quality of instructor support and service provided to the learner. Information and communications technologies (ICT) such as the Internet and the World Wide Web has seen online interactivity emerge as a critical factor in delivering learning materials and supporting learners and instructors. A series of Australian National Training Authority (ANTA) reports (1994, 97 and 98) provide details to developments in this area.

Traditionally VET practitioners, in particular those in Technical and Further Education (TAFE) Colleges, have been provided with professional development to update their skills. In recent years this has been through work based learning using a range of processes such as mentoring, coaching, workshops, discussion groups, conferences and site visits. In the area of ICT, professional development programs have primarily focussed on technical skills development, that is, learning how to use the technology without focusing on the 'deeper' level of critically understanding the benefits and restrictions of using these tools in the learning environment.

LearnScope and its Virtual Learning Community

LearnScope is a national professional development initiative that is available to work teams and individuals within RTO’s. It is focussed on the development of skills to deliver training in increasingly flexible ways using new ICT’s. The LearnScope home page provides more details: http://www.learnscope.anta.gov.au/cover.html

For the individual instructors it is LearnScope’s Virtual Learning Community (VLC) that provides a range of activities in several zones. These activities include:

- **About LearnScope** – an information about the national LearnScope project, guidelines and application forms and contact people within the project.
- **Key Issues** – an information area which provides clustered groupings of key issues relating to flexible delivery. This includes resources, text, access to software, people or web sites.
- **Project Gallery** – the area where LearnScope teams publish their plans, interim and final reports.
- **Expert Spruik** – an area to introduce key people who will contribute to the LearnScope VET community.
- **RantZone** – an area for people to practice their publishing skills, request information or make a statement.
- **Evaluation** – an area for the LearnScope’s project evaluator to submit information about evaluation issues.
- **What’s New** – a frequently changing area which provides a summary of key information for all users.
- **Forums** - an area for both public and private discussions.
- **Chat Room** – an area for planned synchronous discussions.

While the VLC is primarily for the support of LearnScope project teams, anyone interested in the application of new learning technologies to achieve more flexible learning and professional development within the vocational education and training sector is welcome to register and participate.

**The Survey: Methodology and Sample**

Data was gathered in 1999 during two rounds of LearnScope projects and in two formats: a questionnaire, and forum discussions and published stories (Weathereley, 2000). A total of 58 questionnaires were distributed and 33 were returned giving a response rate of 57%. A total of 153 postings to 5 forums (average 14, range 10 to 21 participants per forum) as well as 336 published stories were also collected. These data was then used to:

(i) Identify the reactions, feelings and thoughts to using a virtual learning community in the context of the national VET system and to gain insight as to the level of experience of users.

(ii) Identify how VET practitioners used an asynchronous forum area set up specifically for learning.

**Findings and Recommendations**

It is recommended that for instructors or professional development planners who are engaging in developing online learning plans that the following areas of skills development and capabilities must be addressed:

(i) **Technical Skills and Computer Literacy**: To achieve the best possible learning environment it is necessary to go beyond the simplistic operational understanding of ICT. It is important to have the capability to make critical judgements about its appropriateness and to develop ideas about teaching and learning within the environment. The challenge for the national VET system is getting more people involved in a professional community which as Spitzer and Wedding (1995) says "...requires the active and willing participation of teachers in the process of examining, reflecting on, experimenting with, and ultimately changing the way they practice – in the context of a professional community that allows them to enrich their understanding of subject matter and to consider issues about how students learn.”

(ii) **Writing Skill and Communication Style**: For online learning communities to be successful, the writing and language skill must be conducive to the audiences ability so that group interaction, sharing and participation can lead to an environment based on relationship development.

(iii) **Interactivity**

(iv) Understanding the range of interactive possibilities and promoting an environment which encourages active interaction online between people is vital. Understanding the significance of the human medium and the levels of interactivity will provide teachers with the potential to make critical judgements about student learning.

(v) **Self-related attributes**: Developing self-related attributes is significant in professional development for the online learning environment. Teachers need to identify, develop and model these attributes. Self-related attributes should also be an important aspect of learner development.

(vi) **Teaching and Learning**: Knowledge building in order to gain maximum benefits of an online community and to provide a quality learning environment, requires a range of strategies. Based on the constructivist model where learning builds on previous professional and personal experiences, the importance of linking practice with discussion, dialogue and debate in this new learning field is critical. Professional development activities need to incorporate pedagogical dimensions. These recommendations must be incorporated into instructor’s professional development plans otherwise a quality online learning environment will not be achieved.

Integrating WWW Technology into Classroom Teaching: Students' Perspectives of the Usefulness of their Course Web sites

Manal A. El-Tigi
Syracuse University
330 Huntington Hall
Syracuse, NY 13210
maeltigi@syr.edu

Abstract: The purpose of this study is to explore students' perceptions of the use of World Wide Web (WWW) technology as an instructional resource specifically customized to support teaching and learning practices on campus-based classes. While there are many efforts to design meaningful learning environments there is very little current instructional design literature on fostering and support of Web-based environments. This study examined college students' perspectives on the usefulness of specific Web site functions used for teaching and learning purposes, in an effort to optimize the use of Web-based instructional support resources.

Review of Relevant Literature

The 1999 Campus Computing Project’s (CCP) national annual survey of information technology in higher education reported that many higher education institutions are providing more services via the WWW (CCP, 1999). For example, more than half (69.5%) of these institutions provide online undergraduate applications on their Web sites. More than three-fourths (77.3%) make the course catalog available online. A quarter (25%) of the institutions make library-based course reserves readings available online and almost a half (46.5%) offer one or more full college courses online via the Internet and the WWW. Similarly, the percentages of college courses using the WWW in the syllabus rose from 7% in 1995 to 28% in 1999 (CCP 1996). This number quadrupled by 1999 meaning that more than one in every four classes has a Web page. In fact, compared to e-mail and general use of Internet resources, use of Web pages has shown the highest rate of increase over the six-year period. E-mail had already been in use in 1994 rising to 54% by 1999 up from 44% in 1998, and 20% in 1995. Khan (1997) provided a definition of Web-based instruction used for the purpose of this study.

Web-based instruction (WBI) is a hypermedia-based instructional program which utilizes the attributes and resources of the World Wide Web to create a meaningful learning environment where learning is fostered and supported. (p. 6)

At a university level, the Syracuse University Faculty Syllabus Web site available at http://syllabus.syr.edu is an example of a growing list of campus-based course Web sites. For the purposes of this study, a preliminary analysis of 175 Syracuse University Web sites was conducted during the fall 1998 semester.

Theoretical Framework

A conceptual framework was developed to ground and guide the research conducted in this study. There is evidence from research findings that certain principles exist in most successful teaching and learning practices (Chickering and Gamson, 1987, 1991). Second, there is evidence in the literature that the application of instructional design principles to the teaching and learning practices leads to more effective learning (Gagne’ 1975, Gagne’, Briggs, & Wager, 1992). One of the important measures of effective instruction is how students feel about the instructional process (Dick & Reiser, 1989). Based on the above premises, one can make the assumption that a well-designed instructional Web site can support and facilitate good teaching and learning practices and therefore can be perceived as a valuable instructional resource for both faculty and students.

Purpose of Study and Research Questions

The purpose of this study was to examine the opinions and perceptions of college students' use of the course Web site as an instructional resource for classroom-based teaching at a private university in the northeast of the United States. The focus of the study was on the identification of Web site functions that students' perceived as supporting and enhancing of their learning experiences by exploring students' perceptions of the usefulness of the various Web site functions. The following question was posited: How useful did students perceive their course Web sites?
Method

142 primarily undergraduate students enrolled in nine courses that employ Web sites as course resources responded to a questionnaire on their use of their respective course Web sites. Initially, all Web sites were first screened using an instrument developed by the researcher to evaluate the Web sites' instructional quality and design based on principles of instructional design. On the student Web site perception questionnaire (SWPS), functions pertaining to the Usefulness dimension were construct validated using confirmatory factor analysis. Two indexes were constructed for the Usefulness dimension using items that loaded (>0.60) on these two factors: GUIDE and PREPARE. The first represents practice, elicitation, and feedback functions. The second represents functions that facilitate recall of prior learning and enhance retention and transfer through communication, enrichment and remediation. All functions are derived from Gagne', Briggs, and Wagers' (1992) nine events of instruction and Chickering and Ehrmann's (1996) principles of good teaching and learning practices using technology as lever.

Results

Results showed that most functions were useful with a mean score for the PREPARE index (n=132, M=1.87, SD=0.74, scale 0-4 where 4=highly useful) and a higher one for GUIDE (n=131, M=2.20, SD=0.71, scale 0-4 where 4=highly useful).

The PREPARE index consisted of functions including: (a) the use of pictures, tables, diagrams, etc. to recall or present new information (n= 78, M=2.79, SD=1.00); (b) the additional links and information on the course Web site for further study (n= 96, M=2.43, SD=1.16); (c) the links to review/pre-requisite material to help recall (n=91, M=1.87, SD=0.74), and (d) overall usefulness of the course Web site (n=132, M=2.63, SD=1.13).

The GUIDE index consisted of functions including: (a) the opportunity to ask questions online (e-mail, listservs, hypermail, etc. (n= 112, M=2.74, SD=1.00); (b) posting graded assignments/Home Work on the Web (n=64, M=2.66, SD=1.30); (c) online practice assignments (n=47, M=2.64, SD=0.85); (d) online feedback on various assignments (n= 73, M=2.60, SD=1.00); (e) situations, case studies, formulas, problems, simulations, etc. posted on the course Web site to improve learning (n= 65, M=2.52, SD=0.99); (f) online self-assessment quizzes (n= 49, M=2.51, SD=1.23); and (g) instructions on how to navigate the Web site and download software, get an account, subscribe to a listserv (n= 100, M=2.30, SD=1.10).

Discussion

Key findings from the study are indicated below using Chickering and Ehrmann's (1996) seven principles of good teaching and learning practices for undergraduate education and Gagne', Briggs, and Wager's (1992) nine events of instruction as the framework for discussion. Findings for the PREPARE index related to assisting students to recall information and to transfer new knowledge were supported by functions representing two principles: (a) Good practice gives prompt feedback and (b) Good practice encourages contacts between students and faculty in that the most useful functions were those that enabled students to communicate with their instructors and to receive timely feedback. Electronic mail, computer conferencing, and the WWW increase opportunities for students and faculty to interact and communicate much more efficiently than before. In addition, the nature of communication becomes more thoughtful, deliberate, convenient and safe. Moreover, the negative aspects of face-to-face confrontation are lessened. Findings from the GUIDE index indicated that Gagne’s et. al. (1992) instructional events pertaining to presentation, practice, feedback, and elicitation of new knowledge and skills were overall most useful functions. The multimedia capabilities of the Web allow for an almost seamless integration of email capabilities, video clips, sound, images, and animation thereby allowing for multiple modes of communication through feedback and assessments. In conclusion, in terms of theoretical implications, the study supported the usability of Gagne's events of instruction in particular the ones related to presentation, practice, elicitation, and feedback, as a viable means of designing course Web sites to support teaching and learning practices. The study also provided empirical findings to support Chickering and Ehrmann's (1996) principles of good teaching and learning practices in particular the ones related to prompt feedback and student-faculty interactions. It is recommended that course Web site design could be optimized to include more instructional functions such as elicitation of responses, practice, feedback, and increased student-faculty interactions using the interactive and visual and auditory display capabilities of the medium.

Evaluating Motivational Aspects of a Web-based English Language Course through the Website Motivational Analysis Checklist (WebMAC)

Anise D'Orange Ferreira
Graduate Program in Applied Linguistics
Catholic University of São Paulo
Brazil
anise@pucsp.br

Abstract: This work in progress short paper is a report on subjects' evaluations of a web-based language course's motivational aspects through WebMAC, Website Motivational Analysis Checklist, developed by Small and Arnone (1998). The subjects were 26 adult students who participated in a basic online English course for Internet users, focused on informal asynchronous and synchronous writing and communication skills, called Surfing and Learning. This course is designed by teachers and researchers of the EDULANG research group. The instrument measured the level of four motivation factors which provided the results for two dimensions within an Expectancy-Value framework: Value and Expectancy for Success. The evaluation results showed a high level of Value dimension and Expectancy for Success, although factors linked to Expectancy for Success, such as Organisation and Ease of Use showed more variation in scores than those linked to Value, such as Meaning. Although WebMAC seems to be sensitive to student motivation, other kinds of data are required to a complete course evaluation. It will continue to be used for the ongoing evaluation of Surfing and Learning and other courses offered by EDULANG.

Introduction

Most researchers agree that motivation is a difficult construct to work with (Weiner, 1990). Wlodkowski (1999) says that beyond the general understanding of motivation as a concept that explains why people think and behave as they do, "any specific discussion of the meaning of motivation brings in a cornucopia of differing assumptions and terminology" (p. 1). According to Dörnyei (1998) motivation is a "process whereby a certain amount of instigation force arises, initiates action, and persists as long as no other force comes into play to weaken it and thereby terminate action, or until the planned outcome has been reached." (p. 118). He also agrees with the idea that motivation is a multifaceted factor and no theory has yet been able to represent it in its total complexity. Despite difficulties, instructional designers continue to seek motivational frameworks in order to achieve a better design in technology based learning environments such as the WWW (Cornell & Martin, 1997). Duchastel (1997) elects two main models. One is Keller's ARCS model, considering four factors in motivation to learn: (a)ttention, (r)elevance, (c)onfidence, and (s)satisfaction. The other one is Malone's CFC framework for intrinsically motivated instruction, which involves three factors: (c)hallenge, (f)antasy, and (c)uriosity. ARCS guided interventions reduced the drop out rate, by half, of a Master's degree distance course intended to prepare adult students for careers in the areas of instructional design, job performance improvement, etc. (Chyung, Winiecki and Fenner, 1999). Also influenced by the ARCS model, the Website Motivational Analysis Checklist - WebMAC (Small & Arnone, 1998, 1999) was designed to assess the motivational quality of a website. Small (1997) claims that, although the ARCS model is rooted in a number of motivational theories, its main basis is the expectancy-value framework in which motivation to behave is the sum of individual's expectancy for success in a given task plus the value attributed to success in the task. Website quality is measured within expectancy-value framework: the user is motivated to remain in the website if it has value and if the user expects to be successful in the website environment. Dörnyei (1998), surveying motivation in second and foreign language learning (L2) research shows that researchers have adopted and empirically validated some concepts originally introduced by motivational approaches in mainstream psychology, such as expectancy-value theories, goal theories and self-determination theory. Therefore, WebMAC was chosen here to evaluate motivational aspects in a L2 web-based instructional design. This evaluation is part of a major research project in which the analysis of interactive flow is also considered (see Collins' paper).
Methodology

The subjects were 26 students, male and female, age 29 to 64, who participated in a web-based language course in 1999. The course, Surfing and Learning (http://cogeae.uol.com.br/sal) offers a basic English for adult Internet users, focusing on informal asynchronous and synchronous writing and communication skills. It was designed by English language teachers, members of EDULANG research group, under the coordination of Heloisa Collins, in the Graduate Program in Applied Linguistics of the Catholic University of Sao Paulo (LAEL/PUCSP). WebMAC versions 3.1 and 4.0 were translated into Brazilian Portuguese and edited into a HTML format, so that the students answered the checklist anonymously at the end of the course and submitted it through a CGI implemented web form. The answers were scored according to WebMAC scoring guidelines. Both versions were used and the scores obtained from 3.1 version were adjusted to version 4.0 factors. WebMAC is composed of assertions or list items to be rated by an evaluator on a 4-point level of agreement scale. The 32 items in version 4.0 measured 4 factors: 1) Stimulating; 2) Meaningful; 3) Organized and 4) Easy to use. The sum of first two equals the Value dimension level; the sum of the other two equals the Expectation for Success dimension level. Zero to 8 points for a factor means the site needs much improvement on this factor; 9 to 16, it needs some improvement, 17 to 24 means the site is highly motivating. Version 4.0 contains four additional unscored items: two yes/no assertions and two open questions. Most of list items are the same in both versions. However, they are not related to the same factors. In both versions, each subject provides two main scores that are plotted on a bidimensional grid: 1) Low Value to High Value and 2) Low Expectation for Success to High Expectation for Success. The score position reflects the motivational status of the site in terms of Value and Expectation for Success. (fig.1)[figures at http://www.anise.f2s.com/anise-edmedia.html]

Preliminary findings

The results (fig. 1) show the scores on the average to high-level area of Expectation for Success and Value. Only two students showed low Expectation for Success and only one gave low scores to Value dimension factors. The individuals' scores under each of the four factors (fig.2) show less variation for the Meaning factor than Organized and Easy to Use factors. The answers to WebMAC open questions presented in 4.0 version revealed some students' satisfactions and dissatisfactions. Despite high levels of Value and Expectation for Success, the amplitude of scores in each of the four factors suggests that the course can be improved in Organization and Ease of Use factors. The interaction in communication areas of the course was pointed out by students as a particularly strong aspect of the course design. The complaints about tools and dictionaries seem to confirm comparatively lower scores of Organization and Ease of Use factors. Future work should consider the use of WebMAC during the course. These results can be discussed in terms of guidelines for motivating language learners (Dörnyei, 1998). Although the present instrument seems to be sensitive to student motivation, other kinds of data are required to complete the course evaluation, such as the interaction flow analyses. The ongoing evaluation of Surfing and Learning and other courses offered by EDULANG, such as Reading and Listening Comprehension for public high school teachers, will continue to use WebMAC.

Abstract: UWired created the web-based Catalyst initiative to support innovation in teaching through technology. To scale beyond early adopters, Catalyst has developed a new strategy centered on collaborative partnerships with campus teaching practitioners—learning, technology, and teaching research centers, libraries, and departments—to disseminate innovative uses of technology in teaching through the Catalyst website.

The Problem of Supporting Innovative Teaching with Technology

In 1994, three top-level administrators at the University of Washington were charged by the Provost to “do something about technology.” Collaborating with faculty, librarians, technologists, and students they quickly moved beyond a small pilot, rounding up partners and gathering resources from wherever they could to focus on bringing technology into the service of teaching and learning. Today the organization they formed—UWired—has a permanent budget, a staff of eight professionals and over 60 students, and has extended services and support to thousands of students and faculty.

As higher education institutions have scrambled to keep pace with rapid changes in information technology, many campuses have established faculty technology centers, offering workshops and training to interested educators and perhaps even supporting faculty technology projects to transform particular courses. These efforts have generally targeted "early adopter" faculty who are eager and willing to teach themselves how to use and implement new technologies. Resources are thus devoted under the assumption that early adopters will play the role of Johnny Apple-Seed, spreading innovation throughout their home departments. Indeed, UWired inaugurated its Center for Teaching, Learning and Technology (CTLT) to foster and support instructional innovation in this manner.

For the most part, however, this strategy has had a negligible impact on educational transformation through technology. Beyond the few early adopters are legions of "wary adopters" who look for easy ways to improve their teaching through technology but are unwilling to match the time commitment of the “early adopters.” The classic early adopter is drawn to technology for its own sake, reveling in the "gee whiz factor" of new technologies, but "wary adopters" are pragmatic. Representing the mainstream of higher education faculty, "wary adopters" will use technology only when it can be demonstrated that doing so will add value to their teaching without significantly reducing time already allocated to teaching, research, and service activities. Needless to say, the CTLT found it
Creating a Catalyst for Innovative Teaching with Technology

The need to expand support to a much wider audience—and to do so without a major infusion of new staff or relocation to a larger facility—was clear. How to do so was not. In fact, the CTLT faced four major obstacles posed by the needs of "wary adopters": (1) the absence of a coherent framework for faculty Web publishing, (2) the absence of well explained, compelling examples of enhanced teaching and learning through the Web, (3) the absence of convenient, in-person support located in departments, and (4) the absence of a clear incentive for faculty to explore the use of technology in their teaching. After an intense period of reflection and wide ranging conversations with campus stakeholders and faculty focus groups, the CTLT's leadership team developed a new framework for faculty support. The framework depended upon an instructional support Web site that would provide faculty with anytime-anywhere resources and also serve as the foundation for redesigned instructional workshops and one-on-one consulting.

The Web site, Catalyst, was launched in 1999 to provide this support while placing pedagogy and student learning at the center of the discussion about technology. Catalyst is based upon four assumptions: (1) faculty want just-in-time learning and support; (2) they prefer to learn at their own pace, in their local environment; (3) the Web is or will become the vehicle of choice for just-in-time information and learning; and (4) distributed support personnel are best suited to make the critical decisions about local infrastructure and local support. Given this, the key function for Catalyst—the value add—is in capturing, focusing and disseminating ideas, resources, and tools that allow both faculty members and local support personnel to make innovative use of new technologies in teaching and learning with a minimum of duplicative effort.

Scaling Innovation through Partnerships and Collaboration

Through Catalyst, UWired can easily identify promising practices from within the campus and then use them to address enterprise-wide educational needs. As an easily navigable clearinghouse for information on the use of the Web in teaching and learning, the site has met faculty needs and drawn repeat visits, creating a center of gravity for innovation in teaching with technology that far exceeds the physical reach of UWired and the CTLT. Catalyst has four basic types of content: (1) profiles of educators and programs that provide a vehicle to share ideas and experiences with technology, humanizing its use and, hopefully diffusing teaching innovation; (2) guides to instructional methods and technology tasks that provide a map to a wide range of individual documents geared towards improving learning; (3) dynamic content and frequently updated information on news and events relevant to teaching with technology; and (4) instructional tools that provide a standard mechanism for faculty to create interactive, Web-based instructional modules in any computing environment using only a Web browser.

As envisioned, departments and college support personnel who have developed materials specific to their local computing environments—for instance how-to documents on a particular Web editor or "one-off" Web-based instructional tools—have been eager to see their work repackaged and made available to a much larger audience. More, through a partnership with a university-wide initiative, the Program for Educational Transformation through Technology (PETTT), UWired now has the capacity to conduct research on the science of learning and disseminate information via Catalyst, thus promoting the thoughtful exploration, development, assessment, and dissemination of next-generation technologies and strategies for teaching and learning.

Catalyst not only extends UWired's reach, but it also improves the overall quality of faculty support, providing department support personnel with a set of resources they can draw upon, freeing them individually tailor services to their faculty. By aggressively profiling the efforts of campus educators, Catalyst makes faculty innovation visible and contributes directly to the vitality of the teaching community on campus. In its first year, the Catalyst Web site logged half a million page views; it now averages 100,000 page views per month. On the UW campus, over 1000 faculty and instructors from departments ranging from Anesthesiology to Urban Horticulture have implemented Catalyst tools.

Abstract: Social pressures are creating the necessity for a system of lifelong learning. Electronic distance education appears to be the optimal system for meeting the educational requirements of learners. While educational needs have shaped the development of the electronic learning environments there has been little attention paid to the physical and psychological health issues for the electronic learner. Athabasca University (AU) has used questionnaire and focus groups to examine the implications for learners using AU's electronic environments for learning.

INTRODUCTION

Distance education is often identified as a panacea for adult learners as it overcomes geographical barriers that often prevent students from attending universities to study. With the advent of the Internet as a readily accessible medium, web-based courses have become immensely popular with providers of distance education around the world. It clear by the enthusiasm with which computer-based distance delivery has been embraced that society is willing to rely on computer technology for learning.

At Athabasca University, where the mandate is distance education, students are distributed not only across Canada where the University is located, but also across North America and the rest of the world. For the past five years Athabasca University's Centre for Computing Information Systems and Mathematics (CCIS) has offered 20 undergraduate Computing Science courses over the World Wide Web (WWW). In 2001 it will be offering a Master of Computing and Information Systems over the WWW. The Center for Nursing and Health Studies (CNHS) has offered a Master of Health Studies (MHS) degree over the WWW since September, 1999 and in less than a year has over 200 graduate students enrolled in the program.

The needs and capabilities of the learners are our first considerations in the development of an electronic learning environment. In our developments we have focussed on involving the learners to optimize the environment for learning (Holt, Stauffer & Jelica, 1999). However, until recently we did not look seriously at health related issues. Marcoulides, Mayes, and Wiseman (1995) have suggested that the use of computers in the workplace can result in anxiety. Similarly, technology-based learning may result in added stress among learners. There are other potentially negative implications for students who rely on computers for learning. According to Faulkner (1998) these may include psychological factors such as alienation, inadequacy, lack of privacy, loss of responsibility and damage to self-image. Furthermore, Dix et all (1998) noted that physical problems include repetitive motion strain, postural fatigue, eye fatigue and less frequently, skin rash, reproductive disorders, and cataracts.
In order to examine health issues related to the use of computers for learning, we decided to survey graduate students in our Master of Health Studies Degree and undergraduate students in Computing Science. Questionnaire data has been collected on general computer-related habits, any health problems encountered, and their ergonomic awareness related to design of workspace, posture, usage, and exercise. This was a large exploratory study with a questionnaire of 19 items distributed to 1310 CCIS Students and 145 CNHS students. More in-depth data will be gathered by focus groups which are underway--the results and will be reported more fully at EdMedia 2000. The more interesting questionnaire results analyzed to date are presented in this session.

CNHS students and CCIS students differed on a number of dimensions including graduate versus undergraduate, continuous monthly enrollment versus semester, discipline, and different WWW-based learning platforms. Since the purpose of the study is to consider ergonomic factors in the design of electronic curricula for both CCIS and CNHS students, we have not focused on inferential statistics and differences between the groups but upon useful descriptive statistics within each group.

The return rate was low for CCIS students (150 of 1310 questionnaires). It was higher for CNHS students (41 of 145 questionnaires). The low return rate makes the results more difficult to interpret as students with health related problems may be more likely to respond giving us a biased sample. Nevertheless, computer usage was reported to be very high among respondents. Both CNHS students (80.5%) and CCIS students (85.3%) had high rates of computer use in general and relatively high use for education other than the current courses (43.9% and 72.3%). The mean time using computers was 24.2 hours per week for CNHS students and 32.2 hours for CCIS students.

There was a wide range of usage but it would appear these are high-use groups at risk for computer related health problems.

CNHS students and CCIS students rated themselves respectively as somewhat or informed (75.6% and 63.4%) about ergonomic issues. However, a majority of all students did not make use of special ergonomically sound furniture and at least half of both CNHS students (53.7%) and CCIS students (50.0%) did not take any regular breaks while working at the computer. As high usage groups these students ought to be more aware of ergonomic issues and in ideal circumstances, practice more ergonomically sound computer usage.

Both CNHS and CCIS students reported some physical problems related to computer use (26.6% and 26.8% respectively). Problems reported include carpal tunnel syndrome, eye strain, and back strain. Ironically, although both groups reported low rates of psychological problems (9.8% and 6%), they did report considerable levels of anxiety about their use of computers. Interestingly, the most intense anxiety was associated with issues of privacy and security with 70.7% of the CNHS students and 65.1% of the CCIS students reporting slight to high levels of anxiety in this area. Other areas of anxiety included the cost of computer technology (46.3% and 57.7%); keeping current with software (46.3% and 40.3%); loss of data (43.9% and 60.8%); keeping current with technology (34.1% and 40.3%); and keeping up with the information glut on the Internet (36.6 and 47.7). High computer usage does appear to affect these students' social/family life--36.6% of the CNHS students and 34.7% had complaints from family members about their computer usage. This finding is hard to interpret in lack of comparison with students learning by other methods of education but it certainly warrants further attention.

Of the CNHS students 32.5% reported that the electronic courses aggravated old problems, 50.0% said they created new problems, and 51.3% had suggestions for course design. Of the CCIS students 12.7% reported that the electronic courses aggravated old problems, 16.7% said they created new problems, and 30.7% of CCIS had suggestions for course design. When students listed concerns most of them were related to computer use or course design rather than to health related problems explicitly (other than perhaps related to stress). This could be a function of students being so engrossed in their use of computers for learning that they are relatively unaware of health problems. We are conducting further focus groups to further investigate the factors and underlying situations that contribute to students being in undesirable physical and/or psychological danger and other ameliorative approaches they might use. On the basis of findings to date we are implementing a Java/XML based printing utility and highlighting ergonomic tips in the course materials.
DESIGNING SYNCHRONOUS INTERACTIVE LEARNING TELECONFERENCES: Digital Field Experiences at the Columbus Zoo, an Informal Science Contextual Setting

Tamara J. Garcia-Barbosa, 
Andrea K. Balas, 
Dr. Barbara S. Thomson, 
The Ohio State University 
249 Arps Hall, 1945 N. High St. 
Columbus, OH 
garcia-barbosa.1@osu.edu

Abstract: The Columbus Zoo has a Distance Learning Interactive Field Experience Teleconferencing program (CZDLIFE) to provide a vehicle to enhance standards-based math and science instruction in Ohio’s schools. The use of interactive technology in schools can increase the ability to use contextual settings in education which add a level of reality to classroom learning. Making connections through planned partnerships outside the traditional classroom promotes curiosity, creativity, and exploration. Learning in an informal setting helps students connect and transfer their knowledge base as they engage in new learning opportunities. Zoos can provide an excellent informal context to ground distance learning interactive field experiences.

The Project
The goal of the Columbus Zoo Distance Learning Interactive Field Experience (CZDLIFE) is to offer educational and scientific resources to enhance standards-based math and science instruction using two-way audio/video interactive technologies. The CZDLIFE provides an exciting and meaningful curriculum that incorporates a variety of activities for all students at the distant site. The instructional design of the project was grounded in contextual teaching and learning theory and situated learning environments (Brown et al. 1989, Balas, 2000). The design emphasizes the use of several pedagogical strategies blended with contextual experiences that promote real-time problem-solving interaction. These experiential activities are designed to promote knowledge creation through interaction with zoo facilitators and other learners (Thomson, B., et al. 1999). The field experience was constructed using six key areas: 1) considerations to connections to the curriculum, 2) connection to multiple content areas, 3) inclusion of non-formal educators in the design phase, 4) developmentally appropriate activities, 5) professional development activities, and 6) follow-up activities (Francis, 1999).

Research Problem and Question
The Columbus Zoo has experienced a great deal of success implementing on-site and outreach educational programs. The recent advent of the use of two-way audio/video interactive teleconferencing as a means of sharing the zoo resources has added a new and complex medium for educational content delivery. Interactive teleconferencing is a unique medium that requires different and diverse pedagogical approaches than those regularly used with on-site visitors and outreach populations. The main benefit of two-way interactive teleconferences is that the nature of the system provides a level of intimacy in communication that is not apparent in other forms of distance learning. Two-way real time video transmission of information implies a new definition of real-world context, in which the learning environment, although video-mediated, is indeed the actual environment with which the learner interacts (Jonassen et. al. 1995). Another strength of the technology lies in its synchronous nature; the teacher and learners experience parallel delivery and reception of information without a time delay.

In order to add to research based design, the main question of the study is How do you design effective standard-based two-way synchronous teleconferences from an informal education setting?
Research Design and Procedures

Background research in the development of interactive teleconferences in contextual settings such as the zoo is almost non-existent. The study involves the Columbus Zoo, in Columbus Ohio, and four distance learning sites throughout the state. The four sites were divided among three schools in New Lexington, Stark County, and Richfield, Ohio; and one community-based after-school enrichment program, which used the Cincinnati Zoo as their teleconferencing facility. Five elementary school teachers, one principal, four technology coordinators and seven classes were used for data collection. The student population ranged from second to fifth grade with a combined total of 140 students. This population is representative of Ohio’s urban, suburban and rural students.

Qualitative data was gathered through surveys, interviews, observations, field notes, and researcher reflections. Surveys were collected immediately after the CZDLIFE, and interviews were conducted with the teachers and technology coordinators prior to and after the CZDLIFE teleconference. The qualitative data was interpreted through the development of common themes generated from the interviews and is being synthesized into assertions about the nature of the experience.

Preliminary Results

The CZDLIFE teleconferences use a view of learning that encourages knowledge creation rather than a knowledge delivery. For most learners having tactual contextual opportunities is critical to accommodate for their learning styles (Thomson, B., et al. 1999). The CZDLIFE program has been effective in providing an opportunity to:

1. Bring to the zoo a wider student audience.
2. Help meet the needs of students who are unable to attend on-site programs.
3. Provide real time face-to-face interaction between classrooms and zoo educators.
4. Involve outside speakers who would otherwise be unavailable to regular zoo visitors.
5. Provide an opportunity to “export” unique exhibits such as the coral reef or some of the endangered animals that can not be used on regular zoo outreach programs.
6. Allow “real time” 2 way audio and video contact between students and the facilitators at the zoo.
7. Incorporate the use of experiential learning activities, live action and pre-recorded video to present interactions carried out at the zoo which are not available to the general public.

Implications

The results and conclusions of this program help provide a better understanding of design process for interactive distance learning field experiences in informal science settings. The study also serves as one of the few studies that examine the outcomes of using two-way interactive distance learning between elementary classrooms and an contextual learning setting.

Abstract: This presentation reports on our current and on-going R&D efforts towards the design and development of multimedia, web-based courses suitable for use through the Internet. We discuss the process that has been adopted in designing the interface and the tools used. An important issue for the implementation of the courses is the use of streaming technology for the reliable transmission of multimedia content material over the Internet. This technology allows us to transmit multimedia data in a more efficient way and to introduce interactive elements using SMIL (Synchronized Multimedia Integration Language).

Introduction

Until now, the traditional educational system has assumed that all students learn identical materials via the same delivery mode. However, it is known that each student's intelligence profile and learning style is unique and therefore, the traditional lecture-based method of classroom instruction cannot accommodate the large number of diverse learning preferences. In this context, the Internet has emerged as a new means for meeting the needs of individual learning diversity and has introduced significant opportunities for the improvement of the educational process.

However, although significant investments have been made for the technological support of this new educational environment, similar steps have not been taken towards the creation of noteworthy educational software. Thus, although a vast amount of electronic educational material currently exists on the Internet, it is usually in the form of simple text occasionally combined with some graphics. Undoubtedly, there is a lack of genuinely qualitative educational content. This is due mainly to the fact that the current Internet infrastructure is incapable of transmitting high-quality multimedia content (a problem which can partially be addressed by the use of streaming technology). In addition, the significant expense and time required for the development of such material are serious prohibiting factors.

This paper discusses our efforts towards the design and development of interactive multimedia, web-based courses suitable for use through the Internet. The primary characteristics of the material developed are the following:

1. It is dynamic and interactive.
2. It supports the concept of collaborative learning i.e. it offers opportunities to simulate real situations of collaboration among various groups of users.
3. It can be transmitted efficiently to users.

Designing the interface

The appropriate design of the interface depends on the specific context that it is intended for. To this purpose, an effort was made to create an interface, which would be used by adult graduate and post-graduate students and would use unambiguous “metaphors” for the effective and consistent delivery of specific concepts to learners. The screen was divided into three vertical frames, the left of which always displays the contents of the course. The middle frame presents each individual course in the form of text while in the third frame, accompanying graphics, video or animation, can be viewed by the user, depending on the requirements of the specific material being worked on. It is important to emphasize that that each lesson is available in several
different forms of delivery i.e. text, narration, etc.

Implementation of the educational material

On a technical level, the implementation of the courses was based on the use of:

a) Streaming technology
b) HTML, JavaScript, VBScript, XML (SMIL), ASP

Streaming technology for the efficient transmission of multimedia elements

One of the basic problems encountered during the implementation of a multimedia, web-based course is undoubtedly the limited bandwidth of the Internet. This is perhaps one of the main factors that justify the lack of extremely high-quality multimedia material. The greatest amount of educational software existing presently on the Internet is in the form of simple text, frequently enriched with some graphics. This form, however, proves to be inadequate.

Streaming technology addresses this problem in the following way:

Although, the conventional way of transmitting data through the Internet requires that the entire file (e.g. a video file) be received before it may be viewed by the user, this is not a necessity when streaming technology is the adopted method. In the latter case, the information is presented to the user (e.g. the video file begins to "play") even though the remaining information is still being received and it becomes possible to view the multimedia elements almost simultaneously with the appearance of the rest of the HTML document.

A primary advantage of this kind of technology is that it is possible to transmit very large multimedia files in an efficient and reliable way thus resulting in the preservation of the learner's concentration.

Streaming technology makes use of the RTSP (Real Time Streaming Protocol) instead of the HTTP protocol. The product selected to deal with the difficulties associated with the network infrastructure of the Internet was the RealServer created by Real Networks. RealServer makes it possible to incorporate high-quality multimedia elements (RTSP is designed to stream clips that have time lines) within a web-based course. Whether the learner has an ISDN line or accesses the Internet through a low-bandwidth connection, s/he may still view a course that comprises a variety of multimedia elements. There is also a possibility for the dynamic detection of different connection speeds between the client and the server so as to achieve improved transmission.

Emphasis should be given to the fact that it is possible to include additional interactive elements within the educational material (sound, video, animation) through the use of the SMIL language.

Interactivity

An additional item of concern was that the educational material should be enriched with a variety of interactive elements. To this extent, SMIL (Synchronized Multimedia Integration Language) presents notable interactive characteristics.

Based on XML, this language reacts upon the multimedia elements of the course, which are transmitted through the use of streaming technology.

The main reasons that make SMIL so important are:

a) It can integrate and co-ordinate many diverse types of multimedia information. We can capture events that are generated from the interaction between the learner and the multimedia element. This is achieved through the use of callback methods.

b) It can be considered as an "open", platform-independent technology, which is based on W3C XML.

Denmark
Lg@dlh.dk

Abstract: Based on case-studies of edutainment Multimedia programmes this study is exploring the affordances of the contextual elements of narrative in relation to interactive Multimedia programmes, the possible cognitive costs that lack of canonical narrative elements may have for the user and the particular possibilities they may offer in a learning environment in which meaning, experience and motivation for further exploration are key elements.

Narrative and the user's construction of meaning
Educational or edutainment Multimedia programs are offering new environments for learning and communication (Gjedde 1999a) but often these programs are not employing the canonical narrative elements that can be found in popularization of complex information in television, magazines or in books. Instead there has been a natural interest in exploring the non-linear possibilities that the interactive media is offering. This has been done while letting go of the canonical narrative elements and schemata's that typically has a beginning including a notion of time, place and a protagonist, a development and an end (Bartlett 1932 1995; Labov 1972). Research on the relationship between narrative structure and cognitive processes like memory and comprehension has indicated that there tends to be better memory and comprehension for texts that employ a narrative structure than texts that do not use a narrative structure.(Thorndyke 1977; Mandler 1984). Narrative theories are furthermore pointing to its importance for experience, identity and communication. (Schank 1990, Schank and Abelson 1995; Schank 1997).

The structuring and communicative elements of narrative are often not used in educational or edutainment Multimedia programs, which are often encyclopaedic in structure and if using other structures as a motivating factor, tend to use games that often do not have the basic narrative elements. They are not embedding the information offered in the context and structure of a narrative, but it is instead presented in an abstract cyberspace, or in an encyclopedic structure that does not provide the same cognitive and experiential level of support for the user. This lack of narrativity can have consequences for the ability of the user's to construct meaning from the seeming chaos gathered by experiencing information that is presented out of a context or a known and comprehensible universe.

This can be found in the edutainment/educational genre, where the user may be particularly vulnerable to the lack of cognitive support for the organization of the material, that a narrative structure may provide.(Plowman 1996; Plowman 1998)

The user may also lack the involvement, which the narrative can create through an experiential dimension, through the unfoldment of a narrative, with the possibilities for emotive and identificatory involvement and a narrative logic with an explicit causal structure. These factors may be of importance for the learner's motivation and construction of meaning, particularly the possibility for making a connection between the information they may gather through the program and their present experiences and knowledge structures. (Sarbin 1986; Schank 1990; Gjedde 1998b)

Previous research in this area, has looked at various CD-ROM's in the edutainment and educational genre (Laurillard and Taylor 1994; Plowman 1998). There are indications that a non-narrative or encyclopedic structure tends not to support the user's construction of knowledge or perception of global coherence to the extent that the narrative that may be found in books and television typically does.

An empirical research project with an experimental design, the MENO-project (Multimedia in Education and Narrative Organisation) has experimentally employed different types of structure in an interactive educational program. (Laurillard and al. 1995) (Plowman, 1999 ). It was however focused on the structural manipulations and not on a narrative embedding of the material through a consistent main character that provided a focus for identification, or the point of view of a narrator.
This type of narrative embedding may be found in several successful popular science productions. An example of this is the best-selling novel by Jostein Gaarder about the History of philosophy: *Sophies World* (Gaarder 1992), which became the world's most sold book in 1995. A CD-ROM production was made on the basis of this book within the genre of edutainment, which was based on some radically different structures. In the CD-ROM version some of the canonical narrative elements have been replaced by a NLP-generator, which is capable of having a primitive dialogue with the user; and with a number of game elements.

Based on a pilot project with a case-study of some users of this CD-ROM I have identified some potential problems that will be further explored in a study that will involve other CD-ROM's of the same genre that are using narrative. The results from the pilot study are indicating that it might have implications for the user's experience when the basic narrative element are replaced by other elements, which do not support the process of narrative construction, by the user. The narrative is seen as fundamental for the user's experience of meaning and global coherence.(Bruner 1990; Schank 1990; Schank and Abelson J.1995) the narrative is furthermore of importance for the dimension of experience.(Gerrig 1993).

Without the narrative which affords an embedding context the user tends to experience the options offered in the interactivity as lacking in coherence and meaning. This must be seen in relation to the genre of edutainment and that the target group's users, are not supposed to have much previous knowledge about the particular field that the CD-ROM is presenting.

The study is being done in a naturalistic mode, with a high degree of ecologic validity, using natural users of the CD-ROM's with a mobile usability lab. This set up allows for a video-recording to be done with a video of the user as well as a documentation of the activity on the screen through a scan-converter. The study uses a qualitative methodology that involves user's narratives about their experiences with the program and their construction of meaning from it. Using both video-observation and qualitative interviews as well as a questionaire allows for a comparison between the different sets of data.

The focus of the project is to explore the user's experience through narrative and how it translates into a potential greater sense of motivation and possibly cognitive capability for construction of meaning, in relation to the non-linearity of the media.

**The aims of the project:**

- To provide a greater understanding for the qualitative aspects of narrative in relation to interactive Multimedia and the particular possibilities they offer in a learning environment in which meaning, experience and motivation are key elements.
- To explore the relationship between the contextual elements of a narrative. In particular these which are offered by the elements that constitute a beginning in a canonical narrative (Labov 1967, 1997; Mandler 1984) - and the cognitive implications for the user in terms of experience, understanding and interest for the subject and motivation for further explorations into the subject.
- To look at possible connections between the narrative elements in the interactive program and the user’s process of narrative construction and focus on the relationship between the narrative organization of the material and user's level of processing.(Laurillard et al. 1984, 1997)
- To explore gender specific preferences in the relation to narrativity (Gjedde 1998b) and multimedia.(Adam 1998).
- To inform the producers of educational multimedia about the implications for using narrative structure and other narrative elements in relation to specific groups.

School of Human Movement Studies
Queensland University of Technology
Brisbane, Queensland, 4001, Australia
g.kerr@qut.edu.au

Abstract: The aim of the current project is to design, develop and implement a teaching strategies model and a multimedia template which crosses over curricular boundaries and responds to a wide variety of learning styles of students. The Conversational Framework model as proposed by Laurillard formed a starting point in examining the place of a multimedia template in Academic Learning while the design of the template has been guided by the need to establish reusable resource materials. Key characteristics of such a template were deemed to be accessibility, cohesiveness, supportiveness, flexibility and quality.

Background

According to Laurillard, the teaching - learning process is an interaction between teacher and student operating at two intermingling levels:

<table>
<thead>
<tr>
<th>Level 1 - Discursive Level - the level of theory</th>
<th>Level 2 - Interactive level - the level of practice</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 stages to reach consensus:</td>
<td>The way the student acts in the world</td>
</tr>
<tr>
<td>1. Teacher articulates the subject matter</td>
<td>1. Teacher sets task</td>
</tr>
<tr>
<td>2. Student joins dialogue - asks questions, practices etc</td>
<td>2. Student acts</td>
</tr>
<tr>
<td>3. Teacher re-expresses their point to clarify and elaborate. * Teacher uses student understanding to adapt interactive activities and elaborate theory to those appropriate to student needs</td>
<td>3. World responds - includes teacher, other students, experts etc. * Teacher uses student understanding to adapt interactive activities and elaborate theory to those appropriate to student needs</td>
</tr>
<tr>
<td>4. Student has another attempt at representing the theory</td>
<td>4. Student modifies action to improve their performance (adaptation and reflection).</td>
</tr>
</tbody>
</table>

The teaching model is designed to provide a framework for the teacher and student for all steps in both levels whilst the multimedia matrix plays a role in only part of the total process. A balanced mix of multimedia resources, face to face interaction, online communication and practical activity could form the components of a complete learning experience.

Teaching Plans

It is the intent of the designers that the multimedia template act as a guiding mechanism for the teacher in order to facilitate the mapping and selection process for the teaching sequence. Through thorough analysis of the learning objectives, the resource selection, interaction planning and assessment strategies are developed and a mapping of
strategies is undertaken. Once all aspects of the teaching mix are determined, then the multimedia elements are produced and assembled and supporting technologies are weaved into the virtual learning environment.

A typical analysis by a teacher in planning the learning experiences may be as follows:
* Concept Map is produced showing the interconnecting curriculum and content elements
* Identification of feasible interactions that best achieve learning outcomes
* Development of plans for each interaction eg multimedia matrix, face to face discussion, practical excursion etc
* Topic in Context material is assembled and Themes and associated Activity sequence is determined and designed
* Media Resources are gathered for supporting problem solving as required by activities
* Computer tools are assembled for use by students in carrying out activities
* Delivery proceeds with monitoring and feedback loops built in to the interactions - Evaluation data is gathered and used in review of the model and matrix.

In teaching academic staff to utilise the matrix tool, the above sequence forms the basis for a workshop. This enables the intertwining of a pedagogical and a technological focus and is punctuated by a management theme ie all three focuses become a part of the teaching plan.

**The Multimedia Matrix**

The matrix template consists of a number of "cells" which may be populated with content or resources which are required for the student to carry out their study of a particular topic. These are as follows:
A) Topic in Context - an overview of the topic and its place in the whole curriculum. The relevance of the topic to the profession is also a key aspect.
B) Topic resources - these are not directly linked to any one theme or activity but rather are more global to the topic eg Extended readings or digressions may be placed in the resource area
C) Themes - In order to create a single environment for students that is self contained but has interconnecting parts, the template allows for the creation of several themes. A concept map highlights the links between themes.
D) Activities - these are the problems and instructions that guide students through the resources and learning experiences designed for them.
E) Tools - These include Glossaries, Concept Map generators, Text editors, Analysis tools and a launch pad for applications that are common place such as word processors and spreadsheets.
F) Media - Video, Audio, Graphics and Text elements can be used in the template - these are dropped into any matrix and become a part of the application.

**Progress to date**

The use of the matrix in teaching the concepts of movement through the specific idea of "gait" has been planned. A plan for the main phases of teaching the sequence has been established and each matrix in a sequence multimedia support applications is being developed. These include Biomechanical, Bioenergetics, Diversity and Neurologic perspectives on gait. Rather than examining gait in each of these aspects separately, the planned sequence moves from an exploratory view through each of these perspectives in order to establish core understanding and then evolution of ideas both quantitative and qualitative from a combined view. To illustrate, a typical activity may require a student to make a series of observations that will lead to understanding of both diversity and biomechanical principles and their interrelation. Use of a common visual resource in supporting such an activity ie the same video sequence, also reinforces this cross curricular notion. The template itself is in BETA phase and has been used to assemble the first of these applications.

The staff development program that is essential in establishing the model for achieving maximum effectiveness of implementation of the Conversational Framework model has begun and a network of colleagues from one faculty group who are in close proximity, has been set up. This is a key feature for staff development in an area that requires complete rethinking and restructuring of teaching and its planning. **Collegiality and support** cannot be underestimated in their power to catalyse best practice teaching. We envisage that the notion of a learning matrix both in terms of the multimedia application itself and of the curriculum structure will provide a clearer view for both students and teachers. In this way the path through the study of a discipline may be made more transparent and flexible. In supporting a student-centred approach to teaching, the initial effort has been significant, however the revolution that will follow will show energy levels that pale these efforts into insignificance.
Being Social in an Anti-Social Environment: Is Cooperative Learning Possible Using Computer-Mediated Communication?

Joseph G. Gregg  
Jones International University  
United States  
jgregg@international.edu

Abstract: The purpose of this study is to investigate which experiences of adult learners in an online cooperative learning environment contribute to the expected evolution from an aggregate of strangers to a group capable of high performance. There is a clear need for a thorough qualitative study focusing on the development of online relationships required for successful cooperative learning groups. The interview, observation, and journaling methods will provide information to address impression formation, social presence, group development and the conditions of ambiguity and detraining. In addition, the results of this study will help provide a palette of best practices for designers of online learning environments utilizing similar instructional strategies.

Introduction

Providing opportunities for students to take distance education courses is becoming commonplace in higher education. It should come as no surprise that this growth fosters change and with change comes resistance and criticism. Yet, perhaps it is time to listen to that criticism. Historian David Noble, professor at York University, wrote a series of articles criticizing what he characterized as the unmindful haste by higher education institutions to adopt the Internet and World Wide Web for course delivery creating nothing more than a technologically-slick updated version of the correspondence course (summarized in Noble, 1998). Nobles’ primary fear is that we are creating courses devoid of any true interaction between the student and instructor.

Course developers and instructors recognize the importance of designing interactions into courses offered by distance education means. The importance and validity of these interactions is amplified in numerous studies in which students reported that their individual success was due, in large part, to a high-level of interaction, typically learner-instructor (Eastmond, 1995; Wegerif, 1998). Likewise, many learning theorists do describe the integral role that interaction plays in the level of learning attained by students (see Reeves & Reeves, 1996, for review). Most studies on communication using computer-mediated communication (CMC) or asynchronous learning networks (ALN) have examined interactions resulting from tasks requiring some type of online discussion (Eastmond, 1995; Hiltz, 1994; Wegerif, 1998) Yet, very few studies have looked at the social aspects of group processes in online environments using cooperative learning techniques.

Reports from distance learning students in collaborative or cooperative learning groups using computer-mediated communication (CMC), specifically, asynchronous learning networks (ALN), indicate that there is a crucial moment in their experience in which they cross a threshold from outsider to insider or from newcomer to old-timer (Eastmond 1994; Wegerif, 1998). Crossing this threshold is crucial for increased positive attitude leading to continuation of the course and higher achievement. Failure to cross this threshold often results in the student dropping out of the course. How does a collection of strangers move from being an aggregate of people to a group capable of high performance using computer-mediated communication (CMC), specifically asynchronous learning networks (ALN), as the sole means of communication?

It stands to reason that understanding interpersonal communication across asynchronous learning networks is crucial to designing and implementing effective cooperative learning. Results from laboratory research led to a set of interpersonal CMC categorized as the “Cues-Filtered-Out Approach” (see Walther, 1994, for review). Essentially those theories postulated that the reduction of nonverbal cues leads to communication that is task oriented and impersonal, resulting in more equal communication among group
members but the possibility of very negative interactions ("flaming"). Initially, Walther (1992) stated that the communication process observed within CMC follows that found in face-to-face groups only the time required for certain behaviors to emerge is of much longer duration. In addition, an individual's perception of anticipated future interaction with group members leads to more social relational behavior. His most recent work showed that computer-mediated communication can run the gamut from impersonal to interpersonal, and finally to what he calls hyperpersonal (Walther, 1996).

There are major discrepancies for prescriptions on how to establish and manage groups and cooperative groups, whether face-to-face or online. For example, the need for an individual to identify with the group as a prerequisite for intimacy, affection and social orientation (Bales, 1950) appears to be contrary to the identification of heterogeneous groups as the most successful for cooperative learning (Johnson, Johnson, & Holubec, 1994). Furthermore, there are conflicting theoretical approaches and even haziness in single theories about the ongoing development of thriving groups in CMC. Specifically, there are conflicting indications of how one might go about creating, facilitating, and managing online groups using cooperative learning communicating via ALN/CMC. How can these discrepancies be resolved?

Proposed Research

This study examines the key aspects to consider when using cooperative group instructional strategies for distance learning mediated by text-based Internet communication. Based on components derived from research on small group development, cooperative learning, and relational behavior, instructional strategies are recommended and a set of research questions are proposed.

Understanding the cooperative group processes when using CMC that provide for the development of successful interpersonal communication leading to close interpersonal relationships will 1) provide information for instructional designers and instructors of online courses to guide their design and 2) delivery efforts in terms of group composition, group activities, and facilitation strategies, and guide design of better interfaces and software to enhance effective communication interaction.

Keep facilitating pupils and English teachers appropriately

Bo Han
Foreign Languages Department
National Teachers' College
Inner Mongolia P.R. China
hanbo49@hotmail.com

Abstract: This paper describes a research project on primary school English teaching and teacher training in Inner Mongolia P.R. China where the financial situations of the schools and pupils vary, and English teachers' levels differ greatly. The research group has developed a course, which has a set of kernel textbooks, and there are eight different combinations. This article describes why certain media are chosen and how they are used in order to make sure that teachers can be trained properly and the pupils can get the most possible benefit.

Introduction:

There is no doubt the use of technologies in learning is gathering pace around the world. The use of the multimedia as learning/teaching is changing the way the world thinks and acts. Multimedia has the potential to make teaching and learning more effective but can we use them everywhere? This article describes the research project on primary school English teaching and teacher training in Inner Mongolia and why certain media are chosen and how they are used. Future plan is mentioned and suggestions for improvement are longed for.

Analysis and schemes:

The demand for learning English is greater and greater in this fast developing world. This research project is aimed to meet the need of this demand. To plan for flexibility and adaptation right from the start is very important, if we aim to get good learning results for a long period of time (Griffiths, Heppell, Millwood, & Mladenova, 1994). The following aspects are what we considered when we tried to work out a proper plan:

There are not enough English teachers in Inner Mongolia. Some schools may have one; some other schools may have more. The teachers' English levels and teaching experience vary; Inner Mongolia is a region with different nationalities. The main languages are Mongolian and mandarin which have sharp differences. Mongolian pupils learn Mongolian and mandarin in primary school, so they can only learn English for one or two years in primary schools to make sure that they may not be overloaded; Some schools may have tape recorders, others may have overhead projectors. Video player, etc; locations: Inner Mongolia is a vast area. Primary schools scatter all over the area. To train all the teachers face to face is impossible; Some pupils cannot afford expensive textbooks and tapes. Some schools cannot afford expensive teaching aids; Although Inner Mongolia is a backward region, it is also changing rapidly. The numbers of English teachers in each school will change, the facilities in schools will change, the home appliances will change; How can we use different media for the pupils and teachers in the most appropriate way? (Collis & Deboer, 1998; Griffiths et al., 1994)

After all the above aspects besides teaching methodology being considered, certain media are used in the way as the following: Kernel textbooks and supplementary textbooks have been developed to make sure that the pupils who can only study one or two years may have basic knowledge of English before they go to middle schools and other pupils who have the opportunity to learn more in primary school may well informed. Eight teaching plans with scientifically related teaching materials have been designed to make sure that all the pupils can benefit most efficiently. The textbooks are designed black and white and special revision exercises are designed to make pupils paint the textbooks with colorful pencils by themselves. Therefore the textbooks not only attract
pupils' attention more and the pupils may remember more of the teaching materials but at the same time the price of the textbooks is cut down; Two sets of tapes are designed. One set is that one tape is offered each term to help the pupils to learn at home and to keep a low price for those pupils who cannot afford two tapes. The other set is that two tapes are offered each term. This is to make sure that there are enough feedbacks and interactive exercises to do, and it makes preview and review convenient. At the same time, these tapes can also be convenient for teachers to prepare their lessons. A special tape is designed only for teachers to check pupils' assignment. In this way pupils do not have to buy that tape and teachers will not have trouble with the questions and answers. Transparent sheets for overhead projectors: Two sets of transparent sheets are designed. One is black and white; the other is with color to meet the need of different schools. In this way, teachers may have teaching aids even in schools with limited budgets. We made videotapes for pupils and teacher training so that teachers from remote areas can also have the opportunity to watch other teachers' teaching and understand the theories of teaching. Schools with video players can play the videotapes to their pupils and pupils with video players at home can watch the videotapes to learn better.

Learning should be immediate feedback as many educators have already recognized. However, the above media which have been used are quite limited in the aspect of interactive activities. This means that a lot of potentials from the teachers and pupils have not been cultivated. What should we do to accomplish our goal then? In order to work out our future plan, let's first see what will happen in this part of the world in the near future?

The future plan:

In the near future, more and more schools in Inner Mongolia will also have computers. Since Internet connection in China is still quite expensive, most of the families in Inner Mongolia will not be able to get access very soon. But the perspective of using Internet in schools is great. A significant number of schools will have the capability to interact online. It means that teaching materials designed to be used with computers may help more and more teachers and pupils to teach and learn more effectively. The key to successful interactivity, is not simply offering educational access to preexisting networked materials. Rather, a more valuable role is to offer a collaborative environment where users can create, and share information of their own with other users. It's an opportunity that many teachers won't let slip by them. It means that we're reaching a point where teachers can't be competitive in other words, prepare today's children for the university and the modern workplace without the Web. Therefore, our future plan is divided into three steps:

1. To put the teachers' books on the Internet first and build a forum for teachers to share their teaching experience. In this way, teachers will be well informed and share their experience in teaching, and with the latest version of teachers' books, they can always try to teach their pupils better.
2. To put teaching materials with more interactive activities on CDs. In this way schools with computers and pupils with computers at home can use these materials to teach and learn more efficiently.
3. To establish online courses for pupils to learn. Besides textbooks with interactive activities, a reading series can be developed. In this way, pupils with Internet access not only can learn the textbooks well but can also learn by their own pace to develop their abilities in reading, listening, speaking, and writing.

The above are our plan for the near future. We are eager to ask you, the specialists in the conference to offer us suggestions in order to make this ideal into reality. All your advice would be greatly appreciated.

Course Production Applying Object Oriented Software Engineering Techniques

Ronald Hartwig, Huberta Kritzenberger, Michael Herczeg
Institute for Multimedia and Interactive Systems
University of Luebeck
Seelandstr. 1a, D-23569 Luebeck, Germany
Hartwig <hartwig, kritzenberger, herczeg>@informatik.mu-luebeck.de

Abstract: Developers of educational material like web-based training and online courses face well known aspects of classic software development processes: Reusability of course units; Supporting cooperation and resource sharing between the members of the design process, like content authors, designers, multimedia producers and quality managers and Quality management. Therefor, software engineering techniques like object-oriented analysis (OOA) based on a central database to be used in iterative design processes will also be useful for the development of educational material. This considerations are the background for our work and experiences in the project Virtual University as described in this paper.

INTRODUCTION
The Project “Virtual University of Applied Science”
This paper reports work done in the project “Virtual University of Applied Sciences” (period of duration 1998-2003, see http://vhf.de). It aims at establishing a location independent university with a curriculum for computer science of multimedia systems and for business engineering (Bachelor, Master). The authors of this paper are involved in the production of web-based courses, in the design of user-adequate learning spaces and in the support of the design process. Their focus is on usability recommendations and quality management for the course material during the development process. Other aspects like teaching strategies, learning processes or technical issues concerning the course production are supervised by other dedicated consulting groups within this project.

Adressed Problems
During the first months of course production for the virtual university several problems got obvious:

- The lack of a appropriate context of use description.
  Practice showed that the developers of course material had only an incomplete mental model about the needs and abilities of the intended user groups, like previous knowledge, learning style, preferences in teaching mode, motivation and other information that would be important to adapt the teaching strategies and delivery of hypermedia structure and content accordingly (Kritzenberger 2000). The mental models about this user group and the assigned attributes even differed during development phases.

- No stable base for the quality management
  Quality management (e.g. of learning processes, functional correctness, usability) suffers from a lack of basic information about design and implementation requirements.

- Consistency of content information and re-use of contents
  Another problem is that the content or the structure of the course units may get inconsistent during workflow. While the content author has her or his version (e.g. a linear MS-Word-Document), the hypermedia producer has to transfer content and structure to web formats (HTML and sometimes JAVA Add-Ons). Changes in the linear version have to be manually transferred to the hypermedia version. This is a source of errors and often prevents maintanance, because of the extra effort it will take. Keeping such a training unit up to date often requires to start all over again (e.g. with updating the Word-Document) and repeat former development steps.

DESCRIPTION
The main idea is to overcome the problems mentioned above by introducing a central information base which is used by all participants during the design process: content author, designer, producer and quality manager (see figure 1). Using a simple relational database combined with a powerful web frontend seems to be adequate. This database should include all
the context information as well as the content of the teaching units. In a first step these informations are only presented to the involved persons but no contents are automatically generated.

For database organization object oriented techniques are used. Classes of information like "user attributes", "organisational requirements", "content", etc. are identified and then may be freely combined into "views". These views are role dependent, for example the content author may concentrate on the analysis data and the contents. Whereas the producer, who has to implement the learning unit, may need additional design rationales added by the designer. A quality manager can base his evaluation of the system on the requirements identified and documented during the analysis phase.

As the size and the number of the learning units is difficult to handle, techniques of the OOA are used: abstraction, inheritance and generalization. If for instance many different user groups are to be considered, they may be ordered hierarchically: "All users" → "users of the teaching unit" → "A special group within these user group". Attributes of the most general object ("All users") are inherited by all following objects and then, e.g. the designer's view includes all attributes, from the general to the specific ones. OOA techniques, like underspecification and refinement make the handling of large object sets easier and allow all participants to start with rather raw data and to refine them during the lifecycle of the developed system using OOA techniques based on a database has several advantages. The database supports the complete lifecycle of the course unit and makes all information and design rationales available again for maintaining or updating the course. As the contents are HTML-based they can be included into the courses with less manual effort. Furthermore, the connection of each unit to the position and role in the database is kept. Additionally for each production phase there is appropriate additional information available, like design rationales and the related context informations. Updating a content in the database automatically updates the course and avoids inconsistencies.

Current and future work
Currently two major tasks are to be solved: First the different object classes (content and context objects) and views needed for the educational systems must be identified, validated and implemented. Second the database tool has to be implemented and tested.

As the described method is similar to a special OOA technique currently under development in our institute as well (project "TAToo") see (Herczeg 1999), we reuse implementation resources from that project. Actually the database frontend and the needed JAVA/JDBC/JSP-Interface will be the same in both projects.

A Framework for Evaluating the Usability of Political Web Sites: Towards Improving Cyberdemocracy

Shahizan Hassan
Department of Management Science
University of Strathclyde, Scotland, U. Kingdom
shahizan@mansci.strath.ac.uk

Feng Li, PhD
Director of Postgraduate Research, Department of Management Science
University of Strathclyde, Scotland, U. Kingdom
feng@mansci.strath.ac.uk

Abstract: In an Internet environment, users' expectations are diverse due to its on-line characteristics. Internet can be assessed by any user of any age, group, race, nationality, and gender all over the world at any time and at any place. Considering these, web site designers must adhere to certain design standards and properly evaluate their sites to ensure its usability and effectiveness. Despite abundance of studies on web usability, very few of them focus on the political web sites. Using political web sites in Malaysia as an empirical base, this research intends to identify factors affecting the use of political web sites; and then based on the analysis, develop a framework for evaluating the usability of political web sites. The main purpose is to contribute towards the improvement of cyberdemocracy in the information age.

Introduction

The central focus of the debate on the success of a democratic political system is people participation in election, political discussion, and the process of governance. In order to participate, people should possess sound knowledge about political and social issues affecting them. Traditionally, people are mostly dependent on mass media mainly newspapers, magazines, television and radio as sources of political information. Indeed, mass media has been very influential in shaping public opinion about political and social issues in any democratic country. Today, the advent of the Internet has revitalized the whole concept of communication media. Ideally, it does not only provide an alternative source of political information, but it can also be used as an effective political communication medium between and among citizens, public leaders and political parties. This development certainly provides opportunities for the enhancement of democracy whose main emphasis is on citizens' freedom to actively participate in politics by debating and exchanging views on key social and political issues.

Cyberdemocracy and Current Practice

There is little agreement on the exact definition of cyberdemocracy because of its uncommon usage. Clift (1997) states that cyberdemocracy is about the use of online communication tools for many-to-many civic discussions among citizens and public leaders. It is based on the belief that opens communication and participation is the foundation of democracy. According to Alexander and Grabbs (1998), cyberdemocracy refers to the optimized use of Internet-based communication technologies by government agencies, interest groups and non-profit organizations to promote public participation in the process of governance. In general, cyberdemocracy is defined as the use of the Internet technology such as World Wide Web (WWW), File Transfer Protocols (FTP), electronic mail (email), conference facilities and net chatting for dissemination of information and exchange of ideas between and among government, political parties and public leaders with the general public. There are a number of examples of efforts carried out by government, political parties and voluntary bodies to establish cyberdemocracy. Minnesota e-democracy project (http://www.e-democracy.org), established in 1994 by a group of volunteers, held the first online debate via email among candidates for governor and United States Senate and launched the MN-POLITICS email
discussion forum. Another example is United Kingdom Citizen Online Democracy (http://www.democracy.org.uk), a non-partisan effort, that began work before the 1997 national election. It hosted a number of topical events on such topics as European monetary union efforts and online delivery of government services, and it held an all-party debate during the election.

Web Usability and Research Focus

Usability is basically a very broad concept in system design and difficult to define. In this research, usability refers to how easy, effective and useful it is for a person who uses a political web site to achieve their goals. According to Nielsen and Mack (1994), and Shneiderman (1998), there are 5 main aspects of usability: ease of use, efficiency, satisfaction, rate of users' error and retention over time. The primary focus of this research will be on the usability issues of web sites used as political communication medium. These issues are grouped into seven main factors: Screen design, Content, Accessibility, Navigation, Media Use, Interactivity, Consistency -- abbreviated by the researcher as SCANMIC. These are the generic factors of web usability based on an analysis of current web design guidelines and literature.

Research Question

In an Internet environment, users' expectations are diverse due to its on-line characteristics. Internet can be assessed by any user of any age, group, race, nationality, and gender all over the world at any time and at any place. Considering these, web site designers must adhere to certain design standards and properly evaluate their sites to ensure its usability and effectiveness. Despite abundance of studies on web usability, very few of them focuses on the political web sites. Yet, usability has become one of the most important aspects that determine the success of web sites regardless of their category. With this in mind, this research will address three major questions:

a) What are factors that affect the usability of political web sites?
b) How to evaluate the usability of political parties' web sites?
c) What is the level of the usability of web sites in current cyberdemocracy efforts in Malaysia?

Conclusion

The above research questions will be used to achieve the following objectives:

a) To identify factors that affect the usability of political parties' web sites.
b) To design a framework for evaluating the usability of political web sites. The framework is designed for both technical and non-technical people who are involved in political web site development.
c) To test the applicability of proposed framework.
d) To propose a guideline for developing a usable political web site.

Biggs’ Constructive Alignment: Evaluation of a Pedagogical Model Applied to a Web Course

John Hoddinott  
University of Alberta  
Biological Sciences  
Edmonton, Alberta, Canada, T6G 2E9  
john.hoddinott@ualberta.ca

Abstract: Biggs’ (1996) proposed a pedagogical model where “performances of understanding” specified in course objectives are used to systematically align teaching methods and assessment practices. The model was applied in a plant physiological ecology course delivered at a distance over the web. Students and instructor thought the course format helped learning and that the assessment model, the SOLO Taxonomy, was good. Everyone also concluded that the course workload was too great in spite of ample feedback to discourage such excess. The course may be viewed at: http://www.biology.ualberta.ca/courses.hp/bot431.hp/bot431hp.html

Evidence based good teaching practice seeks to enhance “deep learning” by emphasizing active learning strategies, high expectations, time on task, prompt feedback, respect for diverse ways of learning and student-student and instructor-student interaction. Deep learning is supported by a constructivist pedagogy that argues that it is the learner’s activities that aid their construction of meaning to bring about learning.

Biggs (1996) has articulated a “Constructive Alignment” model that is the marriage of two ideas: constructivism as a framework with the learner's activities as central in creating meaning and the instructional designers emphasis on the relationship between the learning objectives and the targets for assessing student performance. In his model, the "performances of understanding" nominated in the objectives are used by the instructional designer to systematically align the teaching methods and the assessment activities.

Biggs and Collis (1982) previously developed a 'Structure of Observed Learning Outcomes (SOLO) Taxonomy' that analyzes the cognitive level of students’ written work. It identifies five categories:

1) prestructural - no understanding of the topic,
2) unistructural - nominal understanding of one, or a few, points,
3) multistructural - several aspects understood but used separately,
4) relational - components integrated into coherent wholes,
5) extended abstract - the integrated whole is reconceptualized at a higher level of abstraction.

The taxonomy provides a scheme that served as a basis for giving feedback to students on their written work.

The Constructive Alignment model was applied in a distance delivered web based course for senior undergraduate and graduate students. For each week of the course, the course web site gave details of the learning objectives, required reading, optional supplemental reading and web hyperlinks to resource sites. The web site also provided an extensive background on the pedagogical principles behind the course, the nature of the SOLO Taxonomy, sample responses to a problem and their assessment according to the Taxonomy, and advice on preparing portfolios of evidence that the learning objectives had been achieved.

Students were invited to assemble their own portfolios of evidence that they had achieved the learning objectives. Portfolios were submitted by e-mail and assessment feedback was provided in the terminology of the SOLO Taxonomy. Students had access to a password protected conferencing system that allowed them to interact with each other, the teaching assistant and the instructor in a virtual, asynchronous group environment. An on-line chat room was also available through the conference system. Private communication between participants was available through e-mail.

The course opened with a telephone conference to allow the students to meet each other and interact with the teaching assistant and instructor. The students and the teaching assistant then moved to a computer lab where all
students had the opportunity to demonstrate that they were familiar with the computer and software skills required to complete the course work.

Student assessment in the course was based on the submission of three portfolios of evidence of meeting the learning objectives through the term. Take home mid-term and final exams were also given. These exams were integrative of the material in the portfolios and gave the students considerable discretion in selecting the context in which the questions were answered. Exam feedback was again based on the SOLO Taxonomy. As the eight students in the course had no previous experience of distance education or portfolio assessment, they were invited to maintain a reflective journal that was read three times during the course by the instructor. Marks for keeping the journal were given on a credit/no-credit basis.

At the end of the course students were asked to evaluate the course and their learning experience. Evaluations were submitted to the TA who cut and pasted the anonymous student comments into an e-mail message to the instructor.

The evaluations showed that the students thought the course format helped learning, they developed independent learning, time management and communication technology skills, that the web materials on the SOLO Taxonomy were good, that the web material on the course philosophy was good but only in retrospect and that the learning journal material was very helpful.

In the future the students thought that workload in the course should be reduced, feedback increased, course notes provided, more texts should be placed on reserve, a lab should be included and a TA with a background in physiology would be preferable.

Students thought that future offerings of the course should retain the chat room, group camaraderie, learning objectives, the SOLO Taxonomy, and the instructor's understanding.

The instructor's evaluation concluded there should be a reduced workload, more frequent feedback, greater use of an on-line seminar facility and continued use of the SOLO Taxonomy and learning journals.

Workload was an issue for everyone. Despite the feedback given on their portfolios, the volume of evidence provided on each of the three submission dates increased steadily. Students were spending more time assembling evidence and the instructor was spending more time assessing it. Conversations in the chat room emphasized the concern that everyone shared and a phone conference was organized to discuss the problem in real time. Despite encouragement by the instructor to pay attention to the quality of the portfolio contents rather than the quantity, the problem persisted.

Providing more regular feedback would have spaced out the assessment workload for the instructor but it is not clear that it would have helped reduce the pressure the students placed on themselves to submit a large mass of evidence of their learning. The conferencing tool (WebTeach) had a seminar facility where students could have posted questions for their peers relating to the learning objectives. Responses to questions posted by their peers were not readable until participants had submitted their own answer. This facility remained unused although it might have been a vehicle to model the depth of material that was reasonable in a portfolio. It is also possible that students would see use of the seminar facility as even more work.

Everyone involved in the course was satisfied with the SOLO Taxonomy as a framework for assessment. It allowed the students to align their portfolios to the learning objectives and the assessment criteria. Students found preparing a learning journal to be useful. Evidence of concern over workload was recorded in the journals along with recognition of the feedback they were getting on what was anticipated. However, recognition of the issue and a discussion of solutions did not solve the problem.

The learning objectives were well received by the students. However, some continued to think that course notes would have helped. It seems that even these senior students were uncomfortable in assuming a large degree of control over their own learning. It is worth noting that some students commented that the material on the pedagogy behind the course was only useful "in retrospect". If these various opinions were expressed by the same set of individuals, it might suggest that more quickly coming to terms with the pedagogical background might have compensated for the lack of the course notes.

In conclusion, Biggs' pedagogical model of Constructive Alignment is suitable for application in a web environment.

A Multimedia Resources Bank for Teaching and Learning

Vincent Hung, Jacky Pow
Centre for Learning, Teaching and Supervision
Hong Kong Institute of Education, Hong Kong
vhung@ied.edu.hk, jpow@ied.edu.hk

Winnie So
Department of Science
Hong Kong Institute of Education, Hong Kong
wiso@ied.edu.hk

Abstract: This paper introduces an attempt to make use of Information Technology to facilitate teaching and learning in a teacher education institute. A multimedia video bank was being developed to provide with teacher educators and student teachers necessary video clips that could be made use to produce computer-assisted instruction programs that fit the local context. All the videos are intentionally to do without any narration or background music to allow flexibility for the subject teachers to present their materials and to better communicate with the students.

Background

In the First Policy Address of the Chief Executive of the Hong Kong Special Administrative Region (HKSAR) Government, a firm devotion of the Government to develop information technology (IT) in education was first revealed. However the education community in HK is still striving to seek the direction of IT in education that matches the local context, a unique culture of the East and the West. Most of them, especially the primary school teachers are puzzled simply because they do not know how to start with teaching with IT.

Objective

With the aim to facilitate teaching and learning with IT that fits the local context, this project attempts to build up a multimedia resources bank (MMRB) for teacher educators and student teachers in the Hong Kong Institute of Education (a publicly-funded teacher education institute) to develop their own computer-assisted instruction (CAI) programs or to use as part of the teaching materials. It works towards a direction to encourage and promote innovative teaching approaches with an effective use of IT in classrooms.

Multimedia Resources Bank in General Studies

Despite of the resources put in acquiring computer hardware and software, there is hardly any quality interactive CAI program in “General Studies” being developed because there are difficulties facing by the primary school teachers:
[1] The heavy workload does not allow them to have location shooting and video editing that are both needed in developing the CAI programs in “General Studies”.
[2] It is not worthwhile for the primary school teachers to heavily involve in video production, as it is not their profession in this aspect.

However, there are enthusiastic primary school teachers who are willing to produce their own multimedia teaching materials provided that there is enough support (Pow, So and Hung, 2000). With this in mind, we therefore tried to build a MMRB in “General Studies” for the primary schools teachers and let them to make use of the resources to tailor make their own CAI programs to facilitate teaching and learning. With the cooperation between a lecturer from Department of Science and education technology professionals from the Centre for Learning, Teaching and Supervision in Hong Kong Institute of Education, the team has produced about a hundred video clips according to the syllabus of the “General Studies” to be put on the MMRB. We chose “General Studies” as the starting point for MMRB as it is a new subject that integrates science, social study and health education in primary school curriculum, and hence at hand resources are still lacking.
The content of the video clips covers a broad area of topics from Hong Kong community services, transportation, housing, etc. to scientific experiments such as the property of magnet, heating, etc. The videos are classified, edited into a reasonable length and stored onto a video server for easy retrieval and viewing. All the videos are intentionally to do without any narration or background music since we would like to allow flexibility for the subject teachers to present their materials and to better communicate with the students. Although it is the Institute that owns the copyrights, staff and students can use it freely in their own works or teaching. Staff and students can instantly view the video clips of their choice at any computer that is linked up with the Institute's Intranet or download these media clips for their own use later on. This MMRB is expected to be able to save up valuable time and resources for those who want to try out teaching with IT but do not have enough time and resources to produce the media on their own. It is hoped that this could contribute partly to promote innovative use of IT in teaching and learning, not just within our Institute but also to the education community at large.

The Effects of PBL Authenticity on Learning and Motivation

Myunghee Kang  
Educational Technology Department  
Ewha Womans University  
Seoul, Korea  
Mhkang@mm.ewha.ac.kr

Nari Kim  
Educational Technology Department  
Ewha Womans University  
Seoul, Korea

Abstract: The purpose of this study is to examine the effects of learner's PBL authenticity perception on achievement and motivation. There are two major research questions. First, is there a difference on learner's achievement between high and low perception level of authenticity? Second, is there a difference on learner's motivation between high and low perception level of authenticity? The results show the following: (1) There is a significant difference in the learner's achievement between low and high level of authenticity perception ($t= -3.42$, $p<.05$) (2) There is a significant difference in learner's motivation ($t= -3.34$, $p<.05$).

Introduction

In recent years, with the advent of the Information Society, the focus of educational paradigm has been shifting from “teaching” to “learning”. This signifies a move to a learner-centered education where the student becomes an active participant in the learning process. Korea's educational reform committee has established a goal to build a learner-centered educational environment to prepare Korea's students to be competitive in 21st century.

"Web's Cool" program has been planned since 1998 to support the learner-centered education system in Korea. Subject areas such as language arts, math, science and ESL (English as a Second Language) for middle school students have been developed on the Web. Since the Web was considered to be an effective medium for learner-centered approach by applying the constructivist principles, PBL (Problem Based Learning) strategy were applied to provide students opportunities to participate in the learning process actively.

While the Web’s Cool has been developed, we wanted to investigate the fact that whether the problem we were using as an authentic task has any effect on learner’s motivation and achievement. In order to measure the authenticity of the task, the expert's as well as student’s perception level of the authenticity toward the task has been scored by using a 5 point scale. Two tasks were selected as high and low authenticity level of perception by both 10 experts and 10 students to investigate the effects.

The purpose of this study is to examine the effects of the authenticity perception on learner's motivation and achievement. There are two major research problems. First, is there a difference on learner's motivation between high and low perception level of authenticity? Second, is there a difference on learner's achievement between high and low perception level of authenticity?

Research Method

Subjects
Subjects for this study are 51 students of the middle school students. Two learning tasks perceived low and high authenticity are selected.

Results

The results are as follows:

1. There is a significant difference in the learner's achievement in general between low and high level of authenticity perception (t=-3.42, p< .05). A significant difference was found in the learner's authentic achievement between low and high level of authenticity perception (t=-4.54, p< .05). However, no significant difference was found in the learner's logical achievement between low and high level of authenticity perception (t=-1.75, p< .05).

Conclusions

Based on the results of the study, following suggestions were made: (1) Measuring scale of authenticity of the learning task has to be further validated through many different situations and various subjects (2) Authentic assessment of the authentic learning environment has to be studied further.

Teaching WAP Technology as a Part of a Multimedia Course

Harri Keiho, Jari Lahti, Jari Multisilta

Abstract: Wireless Application Protocol (WAP) provides a universal open standard for bringing Internet and Intranet content and advanced Value Added Services to mobile phones, PDA’s and other wireless devices [1]. The production of WAP applications and content requires new software professionals on the area. In this paper we describe our experiences from the multimedia course where students developed WAP applications as their project work[5].

Background

WAP is an industry standard whose purpose is to achieve universal mobile access to Internet based information services. The application is independent of the underlying digital wireless network technology [1]. WAP applications are developed with Wireless Markup Language (WML) and WML Script. [2]. WML applications can be developed with special toolkits, for example Nokia WAP Development Toolkit, Ericsson WAP development kit or UP.PHONE development environment. These toolkits include smart editors and debuggers, phone simulators and help system. However, its is possible to develop your WML applications using only a simple ASCII editor. The students developed simple WAP applications in the laboratory work and implemented a larger project work in the end of the course.

Wireless Markup Language Specification and WML Script

The Wireless Markup Language specification describes the markup language, WML, including the document semantics, Document Type Definition (DTD), and encoding extensions. WML is a markup language based on Extended Markup Language (XML) and is intended for use in specifying content and user interfaces for narrowband devices, including cellular phones and pagers. All information in WML is organized into a collection of cards and decks [3]. WML Script is a scripting language that makes it possible to implement dynamical elements in the WML application.

Student’s WAP projects

The students were required to design and implement a real WAP software and document the code in the end of the course. The topic of the project was free and many of the students chose to implement a game in WAP phone. In this chapter we will present three WAP games, namely Moonlanding game, Lucky Wheel, and Jackpot. The idea of the Moonlanding game is to land to the surface of the moon by controlling the fuel consumption of the rocket (Fig. 3). In the Lucky Wheel game your mission is to find out a secret word or words by guessing the missing characters. Jackpot is the WAP implementation of the old casino game (Fig. 3). Some of these applications are being developed furthermore and will be published in the commercial WAP service by the national mobile phone operator.

The first step in the project was the learning of the WAP development environment. The Nokia Wap software toolkit was used in the projects. In general, programming in WML and WMLS is similar than programming in almost any other environment. It is possible to use the toolkit as a stand-alone environment or with Nokia WAP gateway in order to simulate real wireless connections [6]. In our case, it was not required for the students to test their software in real phones. During the development of their software the students find out several problems. One of the most significant problem was the differences between the real phone and the simulated phone. Of course the
toolkit itself was beta-level software and was not very reliable. In addition the real WAP phone does not fulfill the WAP specification [4]. For example, the Nokia 7110 WAP phone does not support table feature in the WML content and the WAP applications can use only a little memory - the memory size in the phone is appx. 2 KB.

Figure 3. The moonlanding game and the Jackpot.

Positive aspects in the project were that the project was very motivating, the simulator makes it possible to develop software without the real phone, it was easy to learn to program with WML and WMLS because they are similar than HTML and JavaScript and students used actively WAP discussion groups in internet.

Conclusions

Increasing global competition, digitalization of content the general use of HTML and WML languages and the adoption of mobile broadband data transfer will require software specialists with new skills. In the future content producers, telecommunication companies, IT companies and media companies need workers with good knowledge technological convergence and good ability to use the new content producing technologies like WAP. This is a demand for the educational institutes and universities. We should provide up-to-date technological education and be prepared to modify our curriculum to follow the latest technological innovations. In this paper we have discussed about WAP as a new technology to implement wireless content services. The students at Tampere University of Technology studied the WAP technology and implemented simple WAP applications as their project work. The applications were developed using freely downloadable Nokia WAP development toolkit. The most significant problem was the differences between the real WAP phone and the simulated WAP phone. From our point of view the projects succeeded well: some of these applications are being developed furthermore and will be published in the commercial WAP service by the national mobile phone operator.

Enhancing Total Patient Management Skills in Dentistry with Interactive Multimedia Simulation

Mike Keppell
Biomedical Multimedia Unit, Faculty of Medicine, Dentistry & Health Sciences

e-mail: k.kan@dent.unimelb.edu.au, l.messer@dent.unimelb.edu.au

This paper examines a project which aims to improve dental clinical management through case management of medically compromised dental patients. During the past few years, it has become increasingly difficult to access suitable patients, especially child patients, for dental students and consequently for them to become sufficiently experienced in treating patients with medical conditions. Multimedia simulation provides a means to fill this gap and allows interactive learning in a non-threatening environment. This paper examines the design, development, project management and evaluation of the first module – congenital heart disease.

Teaching dental students to treat patients safely and efficiently presents many challenges. The declining availability of suitable patients attending the teaching clinics of the Royal Dental Hospital of Melbourne prevents students from developing a range of experiences in total patient management. A disadvantage of traditional preclinical laboratory teaching is that students are not able to integrate theoretical and practical skills. Consequently there are concerns that dental students are not competent in combining preventive and restorative management philosophies while integrating diagnosis and treatment planning (Suvinen, Messer, Franco, 1998). Multimedia case simulations were considered to be a viable alternative as they replicate the dental clinic without requiring ‘live’ patients. These modules provide an opportunity to develop and consolidate the concept of integrated patient care.

During 1999 the first module, congenital heart disease (CHD) was designed and completed. During 2000 further funding will allow three other modules to be developed: diabetes, Down syndrome and cleft lip and palate. These medical conditions were chosen as they are the most likely medical conditions to be encountered and are least understood by a dentist in general practice treating children. Each condition will follow the existing template developed for the CHD module except for the diabetes module which will use a 3-D Dental surgery to enhance interactivity. The CHD module contains a description and review of the medical condition, considerations of medical management and dental management. The student is then presented with a case scenario of a child with CHD. The student constructs a treatment plan and management approach after considering a range of treatment options. The module series will replace some tutorial and lecture content for both 4th and 5th final year dental students. The modules will not replace valuable clinical practice; but prior learning from the modules will enhance students’ ability to perform clinical work. The modules will also be used for post-graduate students and in Continuing Dental Education programs for dentists.

Design and Development
In designing and developing the CHD module, the project team followed the model utilised by the Biomedical Multimedia Unit (Keppell, 1998). The design phase of the project focussed on developing the macro-structure for the module in the form of a concept map (Novak & Gowin, 1984) and completing the micro-structure in the form of a ‘planning grid’. The content experts for the project were experienced specialists and educators in the field of paediatric dentistry. They worked with the instructional designer to develop the concept map and planning grids for the project. Figure 1 http://www.medfac.unimelb.edu.au/Ed-Media2000/ outlines the resultant concept map which provided a scaffold for the development of the planning grids. The process used to develop the concept map and planning grids followed the Content Production Process (Keppell, 1999). A specific form of storyboard or ‘planning grid’ has been developed to provide a ‘communication tool’ for interfacing between the instructional designer, content expert and graphic designer/programmer (Keppell & Buschgens, 1995). The planning grid is useful in streamlining communication and providing a common ground for discussing the multimedia project. The planning grid
is analogous to an 'architectural blueprint', which can be applied or 'engineered' by the graphic designer/programmer (see Figure 2). The graphic designers developed the interface for the congenital heart disease module and the subsequent modules (see Figure 3).

Project Management & Evaluation
The project management focused on carefully scoping the project, providing a detailed planning grid to the graphic designer/programmer and establishing the "look and feel" of the interface. England and Finney (1999) suggest that each project will define its "own quality priorities" (p.17). In this project the priorities of target audience, subject, budget and the time available impacted on the project management of the project. England and Finney (1999) also suggest that "design quality for media projects = content and treatment agreement" (p.17). These treatment parameters were carefully considered in the initial stages of the project conceptualisation. The first module was targeted to be completed within an hour by undergraduate users. The macrostructure for integrating the subsequent modules was also considered as an essential characteristic of the project. In order to analyse project costs and as a means to plan for the future modules, the total work hours were tracked for this module. A total of 390 hours was required to produce the CHD module (see Table 1). The CHD module was completed in November, 1999 and was evaluated with a group of 15 recent graduates (interns and postgraduate students) at the School of Dental Science in December 1999, using a Likert-style questionnaire. Table 2 shows the distribution of responses to questions concerning content. The majority of all responses were either "strongly agree" or "agree", with most modal responses being "strongly agree" (Table 3). Most respondents correctly identified the deliberately placed distractor, "confusing". In general appraisal, the majority of respondents rated the module as "good" or "excellent", and "very easy" to operate and navigate (Table 4).

Discussion
Computer-assisted education in dentistry is in its early stages (Yip and Barnes, 1999). Developments are occurring very rapidly, and educators must evaluate modules developed internally or purchased externally (Mercer and Ralph, 1998). Sound instructional design indicates the goals of instruction must be made clear, so that users know what is expected of them in operating and navigating a module. This may not have been so in the instance of one respondent. Nonetheless, it is concluded that computer assisted instruction was enthusiastically received by most of the recent graduates. Experience in focus groups has shown that participants valued the tutor discussions that were held at the end of the module, which allowed extension of learning and further professional role-modelling.

Abstract: At the George Washington University teacher candidates in the master's program learn to apply technology in teaching and learning within the context of methods and curriculum courses and school-based practicum and internships. Teacher candidates acquire skills and understanding as they prepare presentations, develop curriculum materials, teach lessons, assess student learning, and reflect on practice. This short paper describes the ways in which teacher candidates' development of multimedia electronic portfolios to assess their ability to implement a variety of instructional models assists in learning to use a variety of hardware and software for instructional purposes. It is expected that teacher candidates will, on some level, transfer their proficiency in using technology to the secondary students with whom they work during their teaching internships.

Why Electronic Portfolios?

Performance assessment in teacher education programs commonly includes development of a teaching portfolio during the teacher internship. The purposes of the portfolio are to document professional growth (Campbell, et. al. 2000) and to cultivate outstanding teaching and learning (Wolf, 1996). Fulfilling these purposes requires that the portfolio is a dynamic, flexible documentation of student growth. Emerging technologies facilitate creating electronic portfolios that support flexibility rather than traditional portfolios constructed in 3-ring binders that tend to be collections of artifacts. The electronic format offers several advantages: the ease of storage usually on a computer hard drive or some sort of removable media (floppy disk, Zip disk, CD); easy access to information; portability is enhanced; multiple copies can be created at low cost; the opportunity to add sound, pictures, graphics, and even video make an electronic portfolio more attractive and interactive than traditional style binders; in the process of developing portfolios, students gain valuable technology skills as they create and edit this multimedia document. These skills can be transferred to 6-12 students during the internship and as the successful teacher candidate moves into classroom teaching.

Development of the Electronic Portfolio

A group of teacher candidates in the secondary education graduate program at The George Washington University are expanding their technology proficiencies through developing an electronic portfolio. The primary purpose is to provide teacher candidates with technology related skills that they can transfer to middle and high school students and use to support their teaching. A secondary purpose is to enable teacher candidates to demonstrate their teaching competencies using an alternative method to the binder-style portfolio currently in use in many teacher preparation programs.

The conceptual framework used to develop the portfolios is based on the Interstate New Teacher Assessment and Support Consortium Standards (Darling-Hammond, 1992) and the National Board for Professional Teaching Standards (1991). The domains addressed include: 1) commitment to students and their learning, 2)
knowledge of the subjects taught and how to teach those subjects to students, 3) establishment and management of
student learning in a positive environment, 4) assessment of student progress and adapting instruction to improve
student learning, 5) commitment to reflective practices, and 6) professionalism. Several indicators are provided to
students within each domain specifying ways in which each is exemplified in teaching or in course work.

Those participating are currently enrolled (spring 2000) in a class that teaches application of instructional
and classroom management models. The instructional models reviewed include Direct Instruction, Inductive,
Inquiry, Integrative, and Cooperative Learning. Each of the models represents a cognitive perspective of learning
which views learners as active investigators of their environment. In these models, teachers are directly involved in
guiding learning through questioning and discussion. Candidates construct a number of products to show their
understanding of concepts and theory and their ability to apply them in a teaching-learning situation.

Specifically, teacher candidates learn how to use various technologies as they learn pedagogy. In the
course, they will practice using technology to: present information; research content; organize and store data; track
and record their development as teachers; and reflect on their teaching behaviors as a process for solving problems
and growing professionally. For example, they will learn to use PowerPoint in the context of learning how Howard
Gardner’s Theory of Multiple Intelligences applies to the teaching of science, math, English, social studies or ESL.
Each candidate will design a presentation that outlines how each of the 8 intelligences is used to frame curriculum
development of a specific unit topic. Candidates select topics according to their content specialization. Each will
focus on the utility of the theory in: 1) designing curriculum, 2) engaging and motivating students, and as 3) assessing students’ learning.

In demonstrating their understanding of and ability to apply instructional models, candidates will teach
lessons they develop to other members of the class. They will be videotaped using a digital video camera. After
receiving feedback from peers and the course instructor, the teacher candidates will view the video and reflect on the
effectiveness of their teaching. As a part of the reflective process, they will edit their video to capture those portions
that exemplify what they have learned about their teaching and will include this shortened version in the electronic
portfolio. In the process of creating the portfolio, teacher candidates will learn how to create a personal website.
The goal is to expand their portfolios as they move through the graduate program. Unlike what typically occurs in
the binder approach to portfolios in which students organize a collection of artifacts during the teaching internship
which illustrate their best work, the approach taken here will concentrate on documenting growth as teacher
candidates develop their knowledge and skills in both pedagogy and content. This means that candidates will begin
assembling their work during their initial experiences in the program and, the work included in the portfolio will not
necessarily showcase their best products. Rather, the final product will reveal the ways and extent to which each
candidate has grown as a beginning teacher.

Conclusion

One major area of emphasis in the teacher preparation program at the George Washington University is to
prepare teachers who will serve as leaders in the schools where they teach. An important aspect of that leadership
role is technology. As our students develop their proficiency in this area, they will be encouraged to explore the
connections to teaching in middle or high school. The ways in which technology use can enhance teaching and
learning is of particular importance. Specifically, through the development of electronic portfolios, these teacher
candidates will consider how the use of technology can assist secondary level students in: learning content; present information; conducting research; and, reflecting on their development as learners.

Abstract: This paper is based on experiences with the production of web-based training (WBT) courses for a course of studies in medical computer science. Course production is regarded as software development process, which starts with conceptual models shaping the design and defining the way the software product is presented to the user. This paper reports experiences with conceptual design models and shows the danger of being insufficient or incorrect.

INTRODUCTION
Our project “Distance Education in Medical Computer Science” (started in January 1999) aims at providing a complete course of studies for the specialization of students in medical computer science, offered at a virtual university. Our responsibility is to transfer the linear text documents (mostly MS-Word format) into hypermedia networks and multimedia courses, which means practicing reverse engineering for WBT course development.

PROBLEMS WITH CONCEPTUALIZING WBT COURSES
The transfer of a text document to hypermedia means transformation of format, gain of flexibility, interaction capabilities and so on. Hypermedia and multimedia courses can be used in ways beyond the intentions of the content author. On the other side, people occupying other roles in the development process, like multimedia designers, or quality managers do not know about the content domain or didactic aspects. The static version, which the content author had in mind, has only one dimension of presentation. Accordingly, the semantic (content) structure and the didactic structure of the course are intertwined. Most authors are not able to separate both structures in a way applicable for hypermedia production and vice versa the multimedia experts are normally no experts in the semantic domain or in didactics, therefore, they can hardly explain their needs to the content authors. This lack of knowledge in each others domain results in unintended course structures, unnecessary restrictions or other mismatches. A similar problem arises if the author for example has to start with specifying a semantic model and then would have to design for different learner groups.

Furthermore, we found in our projects, that media designers, producers, and content authors often have insufficient, incomplete, and partly incorrect models about the learners, the task and the situation of use. The models vary at different times during the period of course production.

COURSE PRODUCTION AS SOFTWARE DEVELOPMENT PROCESS
Our approach to course production as practised in our projects is to regard the production of hypermedia and multimedia WBT courses as a software development process. As for many other software systems, it is also true for the development of WBT courses: To realize a user and task adequate human-computer-system, developers have to take into consideration all system components: user, task and situation in order to form a conceptual model that is as adequate as possible [1]. The conceptual model of the developers shape the software product, in our case the WBT course, and therefore, will decide how usable and user-friendly the WBT course will be and how adequately it will support learning processes.

Figure 1 shows the different models we have to deal with in the context of WBT course production. First of all there is the developer’s mental model the design process starts with. In the case of WBT course development we have to deal with diverse developers. In our project there is the conceptual models of the content author, of the designer, of the HT/MM producer and of the quality manager. Furthermore, there is the learner’s mental model about the application domain, how the WBT course is implemented and how it supports learning processes. And last but not least, there is the system’s model, which contains the way the application domain is implemented and sometimes information on the user’s interaction with the system. Each model represents the complex domain of interaction with WBT courses from a certain perspective and in a specific way.

1679
Mismatches between these models lead to usability problems of the software product. Above all, the importance of the developer's conceptual model for shaping the software product has been noticed for other kinds of software applications for a long time [2], [3]. According to our view, this holds true for WBT courses as well.

CONCEPTUAL MODELS OF DEVELOPERS
A fundamental problem for the development process is, that the developers need substantial and relevant information about the user, the task and the situation of use. They need this information from the very beginning of the design process in order to specify the requirements and shape the WBT course adequately. However, in practice content authors start course production in the traditional way and produce a linear document that includes their conceptual model about domain knowledge and about teaching strategies. This production methods corresponds to the production of traditional lectures for classroom teaching. These courses will not match the situation of use in the virtual university of the future. Lectures on demand have to serve the needs of different user groups and different situations of use. The attributes for users, the task and the situation of use will differ [4] and should have an adequate representation in the conceptual model of all authors. A severe drawback with this situation is, that it is impossible for a content author (and also for the other developers) to take into consideration all these attributes at one time.

In some way, of course, the author is aware of the situations of use and the complexity involved. This might be the reason, why the conceptual model about the user group and the assigned attributes differ from phase to phase of the development process. This is a problem as well. If the conceptual model of the developers includes a prospective mental model of the user and if the design is based on this model, then it will be clear that varying the conceptual model during the development process will result in an inconsistent WBT course, which will be hard to understand and will not support learning processes.

FUTURE WORK
The conceptual models of the diverse developers shape the WBT course and determines the way the educational system is presented to the user and determines if it supports learning processes. Therefore, it is important for the developers to have sufficient and appropriate knowledge about the user, the task and the situation and it is also important that the conceptual models of the diverse authors can be communicated and complement each other during the design process.

With this background we are working on methods to adequately represent conceptual knowledge for the design process [5]. We also want to offer ways to communicate relevant knowledge components between all developers through the whole development process.

Students' Acceptance of Videoconferencing in the Lecture Context

Patrick Kunz
Network for Educational Technology NET
Swiss Federal Institute of Technology (ETH)
Zürich, Switzerland
kunz@diz.ethz.ch

Abstract: The goal of this work was to develop a set of recommendations for the use of videoconferencing in large classrooms. The students' acceptance of synchronous videoconferencing, the role of the instructors as well as the influence of videoconferencing on motivation and interactivity were in the focus of this study. Based on the statements of 178 evaluated students there are three main recommendations that can be made: (1) The didactic approach of the course must concentrate on an more active involvement of the participants. (2) The instructor must be willing to adapt his teaching style to the integration of new media. (3) Technic has to be so perfect, that it guarantees the first two aspects: an undisturbed transmission with possibilities to interact for all participants and support of the instructor to make teaching easy.

Introduction

A lot of studies report about the benefits of videoconferencing in the context of small classes with active student participation. Videoconferencing in small classes has been shown to increase student motivation as well as interaction among students and lecturers often leading to a redefinition of teaching (among others Abotte, Dallat, Livingston, & Robinson, 1994; Bramble & Martin, 1995). Experiences with videoconferencing in the large classroom context however differ at least in part in some of these results. Increased inhibition to speak in front of others and lowered spontaneity seemed to be real problems (Knox, 1997). Further, an improved motivation or satisfaction was not found (Fillion, Limayen, & Bouchard, 1999). The purpose of this study was to find out, which aspects are the most crucial for the use of videoconferencing in large classrooms.

Method

Equipement
The videoconferencing facility used in this evaluation is a synchronous system based on ATM. Its theoretical bandwidth of up to 155 Mbits/s allows the simultaneous transmission of three audio- and video-streams with high quality and perfect audio-video synchronisation between two and more connected sites. The system provides full interaction possibilities to all participants at all connected sites.

The setting in the examined lecture is a two-point configuration consisting of the following components:
Remote classroom: Three screens, projected by beamers, with 1.) the instructor, 2.) the PowerPoint slides and 3.) the other class.
Local classroom: Two screens, projected by beamers, with 1.) the PowerPoint slides and 2.) the remote class. For further technical details see (Walter & Hänni, 1998).

Participants
The examined sample consisted of totally 178 participants of a two year course in pharmaceutical chemistry (86 students in the locat classroom; 92 students in the remote classroom). Gender representation was not equal (139 female and 39 male).
Control data (normal course without videoconference) were collected from students of both locations during summer 1999. The experimental data resulted from the first half (13 weeks) of the academic year 1999/2000.
The constructs and its components consisted of items which were measured using a five-point Likert-type scale (1=strongly disagree to 5=strongly agree).
Results and discussion

The following presented results were based on a minimum level of significance of $p<0.001$.

Acceptance and Motivation
As expected, students in the local classroom accepted with $M=3.3$ the videoconference better than remote students ($M=2.7$). Furthermore there was a significant difference in the acceptance which is correlated with the infrastructure: While in location 1 the auditorium used for the transmission consisted of a permanent equipped room, location 2 had to build up all equipment for the lecture every week.

In contrast to studies who reported about increased motivation, the measured motivation construct (consisting of subject interest and self-efficacy) remained the same with versus without videoconference. Nevertheless, with $r=0.57$, motivation was one of the strongest predictor of the acceptance.

Influence of the quality of the transmission
The participants rated the quality of audio ($M=3.9$), the level of synchronisation ($M=3.7$) as well as the quality of the transmitted videos (picture of the lecturer ($M=3.8$) and projection of the slides ($M=4.1$)) more than satisfying. Only the video of the remote auditorium was assessed average ($M=2.9$). The quality of transmission seems to be so good, that there were no correlations greater than $r=.34$ with the acceptance or the motivation.

Role of interactivity
The largest impact on the acceptance of a videoconference-classroom exerted the possibilities of interaction. Students assessed this kind of lecture in comparison with a normal classroom less stimulating for discussions between them and the lecturer ($M=2.5$). This variable had with $r=.61$ the strongest correlation with acceptance. The hypothesis, that students were more inhibited to ask questions during the class, can be accepted. However, the level of inhibition was lower than expected ($M=3.5$). With $r=-.27$ ($p<0.002$) the correlation between inhibition and acceptance never reached the expected level.

The possibilities of spontaneous intervention were even rated slightly higher than in the traditional classroom setting ($M=3.2$) and did not coincide with the students' actual hesitance. This high rating is most likely due to the lecturers' efforts to integrate prepared questions in their slides. Its correlation of $r=.43$ with the acceptance underlined the importance of the possibility to interrupt the speaker at any time.

Role of the instructors
The correlation of $r=.38$ between the acceptance of videoconferencing and the performance rating of the lecturers (with $M=3.6$ both were assessed above average) emphasized the important role of the instructors.

It is encouraging to note, that the implementation of videoconferencing had positive side effects on teaching: The cooperation of the two involved professors lead to an overall improvement of the curriculum with better structure, more goal orientation and the integration of prepared questions.

Recommendations
Based on these results, the following guidelines are proposed for the use of videoconference systems in the lecture context with groups consisting of more than 20 participants on each side:

1.) Lecturers have to consciously plan possibilities to interfere and to create an atmosphere that motivates students to undertake a more active part.
2.) The instructor must be above average and be willing to accomplish an extra effort.
3.) The technical infrastructure must guarantee a clear transmission of video and audio as well as the possibility of interaction at anytime for all participants.

Understanding collaborative learning in CMC: A research in an elementary classroom

Qing Li, University of Toronto, Canada

Abstract: This study is intended to understand collaborative learning in a context that enables communication by computer text messaging. Particularly, the study seeks to determine the level of collaboration in a classroom that uses computer-mediated communication (CMC), as well as to examine the relationship between the language functions associated with CMC generated messages and the collaborative learning process. In this study, "language functions refer to ways we can use language to achieve a communicative purpose" (Olsen, 1992). It is what people "can do with language" (McDonell, 1992), or "what people want to do with the language" (Finocchiaro & Brumfit, 1983, p.13), such as: requesting information, requesting confirmation, making suggestion, apologizing, etc.

The study is prompted by following questions

1. What are the levels of collaboration (in terms of interactivity) in the classroom that uses CMC?
2. Are there any patterns in people using of language functions in relation to the degree of collaboration (in terms of interactivity) in the context of CMC? If yes, what are the patterns?
   a). Are there any patterns in people using "requesting information" in relation to the degree of their collaboration (in terms of interactivity)?
   b). Are there any patterns in people using "requesting confirmation" in relation to the degree of their collaboration (in terms of interactivity)?

Computer-mediated communication (CMC), is an effective electronic means of connecting geographically dispersed learners using computers, in order that they may collectively participate in a learning experience where the interaction is mediated. Despite it relatively short history as a distance medium, a great deal of interest has been shown in this technology.

Courses offered by CMC are gaining favor in schools and institutions of higher education. Students can interact at a time and in a place that is personally convenient, discuss issues as fully as desired without constraints (Henri, 1995). CMC promotes interactive activities such as active dialogue and sharing of information and knowledge, which help develop a sense of community among participants (Burge, 1993). The CMC can be used as a powerful tool for group communication and collaborative learning (Crook, 1995). The collaborative learning environment promotes active mental engagement in the experience (Grabowski, 1990). Despite the large body of literature on peer learning and teaching, there are few acknowledgments of how well CMC may support collaborative learning. Although cognitive and social psychology have already provided much information about how students communicate and its relationship with collaborative learning, the context has usually been the traditional face-to-face setting with its paralinguistic cues to facilitate communication. What we do not yet know in published detail are how people learn collaboratively and how this collaborative learning relates to the communication in the CMC context. In addition, O'Malley (1995) calls for studies of collaborative learning that "focus more on the processes involved in successful peer interaction, rather than just on learning outcomes".

Therefore, this study seeks to understand how people learn collaboratively and how their collaborative learning relates to the communication in the context of CMC. By asking these research questions, I assume that if we, as educators, know more about the process of collaborative learning in a computer-mediated-communication environment, we have a better chance of developing practical guidelines for facilitating learning. In addition, the information obtained from the study may contribute to the present understanding of students learning in CMC environment and may suggest future studies in the area.

For instance, numerous studies (Johnson & Johnson, 1989) dealing with collaborative learning have suggested that students need appropriate social skills in order to be successful in their collaborative learning. Johnson and Johnson (1989) emphasize that collaboration is the most important and basic form of human interaction, and the skills of collaborating successfully are the most important skills anyone needs to master. Coelho (1992) explains that good social skills can promote collaborative learning and some negative behaviors can shut off future collaboration. In addition, the literature on collaborative learning emphasizes the need to teach social skills. Students need assistance in acquiring those social skills and many of these social skills can be regarded as...
communication skills. For example, Olsen and Kagan (1992) state that "social skills include ways students interact with each other to achieve activity or task objectives (e.g., asking and explaining) and ways students interact as teammates (e.g., praising and recognizing)."

However, all these conclusions are based on the works that have been done in traditional face-to-face settings. Are the conclusions still true in the CMC environment? This remains to be answered and it raises important questions in the field of collaborative learning. This study will try to understand how students go about communicating and learning in the CMC environment. Once we have this understanding, we might then compare the CMC learning strategies with those reported for face-to-face classroom contexts in order to search for new practices to facilitate collaborative learning and better suited to the CMC context. And only when we have a better understanding of computer mediated learning, we can make a better use of CMC.

The subject of this study will be a grade 5-6 classroom in an inner elementary school in Toronto.

Combining Instructional Models and Enabling Technologies
to Embed Best Practices in Course Instructional Design

Paul M. Malone, Germanic and Slavic Languages, pmalone@artmail.uwaterloo.ca
Catherine F. Schryer, English Department, cschryer@watarts.uwaterloo.ca
Vivian Rossner-Merrill, Lt3 Centre, vrmerrill@lt3.uwaterloo.ca
University of Waterloo, Ontario, Canada

Introduction and Overview

Two distinct fields of educational activity should inform instructional design of courses using teaching technologies. These are cognitive theory and instructional theory. Cognitive psychologists tend to analyze cognitive structures and processes at a conceptual level without due regard to how these may be implemented in the instructional setting. Conversely, content designers and instructors do not often recognize the value of undertaking the analysis of content and teaching practices from a cognitive analytic perspective (Reusser, 1993). We propose that one means to combine the best practices of both fields in teaching and learning is to ensure that the instructional design process integrates both perspectives. Three principles inform the proposed framework of design.

- Selected models of instruction that best support the teacher's purpose for mastery of content, and the selection of enabling technologies that mirror the selected model of instruction are combined in the design process.
- Models of instruction and enabling technologies are selected according to the nature of the content to be learned, the teaching styles and preferences of instructors, and the learners concerned.
- Promoting and supporting development of the active nature of the learner underscores the entire design process.

The development of this framework took place through a recursive process of experimentation and teaching in two different university courses. The campus course uses concept-mapping software as a teaching aid and as a study aid for students needing to master the more difficult and abstract content areas in the study of German Thought and Culture. The software used was chosen for its ability to mirror the 'meaningful learning' model of instruction developed by (Ausubel, Novak & Hanesian, 1978) and (Novak, 1998). The online course, Introduction to Academic Writing, uses a Web site as the primary teaching tool and its design mirrors the 'expert instructional scaffolding' model of learning developed by (Hildyard, 1996). This model supports the need to ladder content into instructor supported incremental steps that allows modeling of best writing practices through interactive feedback processes.

Using Visual Organizers and Meaningful Learning to Teach Cultural History

Students unfamiliar with cultural history are frequently presented with a huge number of facts and dates that have little significance to them, encouraging – if not forcing – them to acquire as much as they can through rote learning. The nature of the assignments and examinations often further reinforces rote learning and tends to discourage the synthesis and creative application of the material. The use of visual organizers coupled with instructional design based on a model of meaningful learning permits the student to see how the information communicated in the course is interrelated internally, and also how it is connected with students' prior knowledge. Relationships and interrelationships can be seen and apprehended quickly and easily when represented visually.

Concept mapping conveys information by reducing it to concepts (perceived regularities in objects or events) and propositions (significant combinations of concepts), which are then structured hierarchically and linked by means of lines representing the relationships between concepts and labeled accordingly. Each concept is thus already presented in a contextual relationship with other concepts. This device can be used either as a visual aid in teaching or more actively as an aid to learning. Novak's strategy of concept mapping is based on Ausubel's principles of meaningful learning designed to promote retention and subsequent related learning. These principles include the following:
• The learner must have prior knowledge related to the new information to be learned
• The new material must be relevant to other information and must contain significant concepts
• The learner must choose to learn meaningfully, rather than by rote.

We focus on concept mapping as the most viable strategy to link prior knowledge with relevant new conceptual material, using the CMapTools software package to support this strategy. The software has the features needed for the strategic learning practices outlined above; it is downloadable as freeware and it is easy to learn and use.

Using ‘Expert Scaffolding’ and the Web to Teach Academic Writing Skills

The purpose of this course is to provide the foundation for scholarly writing that students can build on through further, related coursework and through application of their writing skills in other university courses. Because writing skills are best acquired sequentially, the material in this course is scaffolded into linked, incremental units that build on each other. Throughout the course, the instructor provides expert modeling through feedback as evaluative discourse. Using WebBoard as a vehicle for threaded discussion, students interact with an experienced writer who supports them until skills are mastered at each level. Drawing from (Langer and Appleby, 1986), four design principles for scaffolding were used to inform teaching practice and design of the Web site
• Students were encouraged to assume ownership of their writing tasks
• The assignments were designed to address students’ incremental levels of knowledge
• The assignments were designed to support the sequence of skills acquisition in the course
• The instructor and tutors supported students in a facilitative manner

Successful teaching in a course of this nature requires providing ongoing feedback using multi-faceted dialogue with students through commentary on writing and involvement in peer editing sessions. Feedback comes from the instructor and tutors and from other members of the student group. The course begins with a shared basis of readings – reading groups which present their interpretation of texts – and continues with discussion groups which assist writers to refine and elaborate their thoughts, and concludes with peer revision and editing groups. Thus evaluation is embedded in the design of the course and specifically with the design of the assignments. The assignments and final project include interactive exercises, instructor and peer commentary and editing, and online areas for discussing course content.

Conclusion

To date, we have successfully demonstrated in two courses that instructional theory and enabling technologies can be combined in a useful framework to inform instructional design of a given course. The next step is to design research studies that address the impact of using this framework on teaching and student learning.

To teach remotely by controlling the didactic interaction of a student with a multiapplication environment

Nathalie Masseux
Auvergne University Institute of Teachers Training
20 av. R. Bergougnan
63039 Clermont-Ferrand Cedex 2, France
nmasseux@auvergne.iufm.fr

Conceptual approach

The TeleCabri practices can be articulated with the whole of the experimental studies led these ten last years on remote teaching (Dessus et al. 97) in term of situated learning. The teachers seldom intervening in the realization of the computer-based environments that they use to teach remotely, the purpose of this research is to specify the cognitive influence (Balacheff 91) of the mediation of these environments on the student/teacher interaction. The computer-based didactic systems, with the constructivist meaning of the didactic theory of the situations (Brousseau 86), are its object of study. It is built according to the interactionist approach in HCI (Pochon & Grossen 97) considering these systems as a semiotic mediator by way of the didactic concept of computer-based milieu (Chevallard 92). A computer-based milieu is regarded as knowledge carrier aimed by the learning. We are particularly interested in the milieu which include microworlds or simulators characterized by a significant epistemological validity and a capacity to support a learning guided by the discovery (Masseux & Michau 96). It can thus include a computer-based tool identified like software or/and hardware support of a learning. Here, we center our study on the environments including several educational applications. This study aims at specifying the strategies of didactic regulation engaged by the teacher modelled before in the theory of the didactic situations. These strategies are analyzed using cognitive models (Anderson et al. 90) of action/feedback between a user and an application who are declined for the student and the teacher. The finality of this research is to develop tools which help the teacher to diagnose in real time the learning activity of the student. It lies within the scope of study of computational didactics applied to mathematics (Balacheff & Kaput 97).

Functional integration of a platform to teach remotely

The functional integration of the platform is based on the capacity of a system to bring answers to the specific constraints of the students and teachers. The functionalities of the platform bring a technological response to the complexity of management of distributed human resources and of which the availability is unforeseeable.

The student/teacher interaction through PCs articulates three types of functionalities:
- functionalities allowing an autonomous work of the student (educational applications)
- functionalities of synchronous collaboration (video, audio, shared applications)
- asynchronous functionalities of interaction (email, sending of files)

Cognitive influence of a multiapplication environment on the remote student/teacher interaction

With TeleCabri, the student and the teacher interact remotely by way of three applications, each one considered here as didactic milieu and each one characterized by an epistemological validity specific to the stake of learning:
- an oral milieu, supported by the videocommunication,
- a milieu Web on the geometry, including a base of exercises, definitions and properties,
- a milieu (CabriGéomètre) microworld of direct interaction with geometrical objects provides as a solving board of problem.

To control the student/environment interaction

The regulation which the teacher carries out is conditioned by the sequential organization of the various stages of use of the platform by the student. This sequential organization can be schematized as follows:
- an autonomous stage of work for the student which precedes the stage by videocommunication with the teacher,
- a stage of videocommunication during which the student requests the assistance of the teacher to solve his difficulties by sharing its applications

The regulation processes of the teachers on the student/environment interaction

The observation underlines the didactic contribution of the property multiapplication of the environment. This contribution is observed through the diversity and the accuracy of the regulation processes carried out by the teachers. Those try to exploit the epistemological complementarity of the three milieu within the limit of their own functional and cognitive control of the environment.

In short, to control the student/environment interaction, the teachers proceed according to two types of interaction:
- co-operative interactions on the geometrical objects with the interface of CabriGéomètre when the teacher focuses himself on the diagnosis while the student concentrates on the autonomous experimental solving of the problem,
- collaborative interactions to create, to modify and to remove objects with the interface of the microworld when the teacher wants to destabilize a balance of action/feedback of the student with the environment.

The process of destabilizing used by the teacher consists in questioning the student on the inaccuracies or the cognitive disjoinednesses which arise from the interaction of the student with the three milieu. The regulation in the oral milieu in term of formulation, reformulation in the linguistic reference frame of the Euclidean theory, takes into account the collaborative interactions.

The Total Student Experience

Paul McKey
CTO NextEd Ltd
paul.mckey@nexted.com

Abstract

With the advent of online education the Universities of the world are for the first time exposing their wares in a public space, the Internet, in direct competition and comparison to similar commercial offerings.

While the argument for the University offering as being one of 'accredited academic quality' is easy to win against its unaccredited training and professional development competitors it is not necessarily as easy to suggest the university offering is always a better 'product'.

Universities typically have little experience selling their wares in a commercial environment where price, service and immediacy matter. It then comes as no surprise that when a mature adult learner is shopping around universities are often being overlooked for education alternatives more in tune with the requirements of a modern lifestyle.

The Total Student Experience offers a conceptual framework for the discussion, delivery and measure of an online educational system from the student’s perspective. It suggests a model with four distinct layers, which individually and collectively, effect the learner’s overall satisfaction with the system. The four layers are presentation, function, education and administration with a number of key variables occurring within each layer?

This paper will discuss the use of this framework and the importance of the underlying assumption that the university ‘product’ in the online environment will be measured not only by its traditional hallmarks but also by the key elements of the medium in which it is offered. When that medium is the Internet these elements are convenience and relevance, service and value, and the antithesis of the mass production era of education, personalisation.

Telematic Post-basic Nursing Education at the University of Pretoria in South Africa:

Salomé M Meyer
Lecturer: Nursing Education
Manager: Telematic Education
Department of Nursing Science
University of Pretoria, South Africa
e-mail: smeyer@medic.up.ac.za

Abstract: This paper is on the Telematic Education (TE), which is not the mere use of the television set as a teaching tool/aid. It should be viewed and managed as a strategic resource. TE refers to a comprehensive system of flexible learning. It emphasises the use of technology that will enhance the teaching and learning environment. Nurses/lecturers have been confronted with the fast development of technology for many years, but mostly in clinical practice. The Department of Nursing Science of the University of South Africa is providing in the learning needs of professional nurses in certain rural areas of the country by means of TE.

1. Introduction:
Broadcast television has been a solution to educational requirements such as the widely distributed campuses of some countries such as Australia and Canada, or even the widely distributed student populations of universities (Laurillard. 1993: 113). To be of any value to a student television education must be interactive in nature. This implies that student and lecturer must be able to communicate during a lecture that is being broadcast by means of television. This brings to mind the concept of Telematic Education (TE), which is not the mere use of the television set as a teaching tool/aid.

2. University of Pretoria (UP):
No university is immune to the impact of technological change. Organisations can benefit tremendously by exploiting technological change. It should be viewed and managed as a strategic resource. The deployment of the Technology Plan of the UP has already borne fruit. The establishment of the unit for Telematic Teaching
and the subsequent virtual campus initiative are direct benefits of the Plan.

3. **Telematic Education:**
Before one should attempt to understand what (TE) is, it is important to know what is meant by ‘flexible learning’. According to Dr. Tom Brown of the Telematic Education Department of the University of Pretoria, TE refers to a comprehensive system of flexible learning. It emphasises the use of technology that will enhance the teaching and learning environment. TE is mostly delivered over a distance. The dependent learner will be more directed by the lecturer whereas the autonomous student who are capable of self-study will be able to employ the higher technological learning facilities. In the educational setting, all the dynamics of the traditional classroom are preserved, regardless of the distance separating the locations”. This is the ideal situation to which finances and available sources not always lend it.

4. **Interaction:**
The structure of a typical teaching session must have two parts. During the first part of the lecture the lecturer delivers the lecture, i.e. passing on knowledge to the students. The second part of the lecture can be in the form of a discussion/question session with high interaction between the lecturer and the students (Jameson, Hanlon, Buckton, & Hobsley, 1995:114). The need for students to have back up videos/copies of broadcast stems from the fact that some students might not be able to attend broadcast sessions due to employer demands, technical failure or such like reasons (Jameson et al. 1995:45).

5. **The Nursing Education Situation:**
Nurses/lecturers have been confronted with the fast development of technology for many years, but mostly in clinical practice. Telematic education (TE) is employed in nursing education (NE) for post-basic programs. Post-basic programs imply that people who have already registered as professional nurses at the South African Nursing Council (SANC) are continuing and furthering their skills and knowledge regarding certain specialities in the profession. Continued education for post-basic nursing requires a
distance education method that will serve as an academic solution to professional nurses in rural areas of South Africa. The Department of Nursing Science of the University of South Africa is providing in the learning needs of professional nurses in certain rural areas of the country. Jack Yensen (1996:213), who calls this method of teaching 'telenursing', is of the opinion that the two key dimensions are distance and electronic mediation.

6. The Lecturer:
Lecturers who teach by means of telematic education must be skilled, self-confident, understand the uniqueness of the rural students and should be flexible. They should keep the concepts of adult learning in mind and respect the authority of experience that many students bring to the classroom. Lecturers who have not taught by means of this method need sufficient training. They do not need technical courses, but training on how to adjust their method of teaching as well as teaching aids to that of the telematic medium (Yeaworth. 1996:150). The use technology influences educational innovation.

7. Closing Remarks:
The twenty-first century will see many changes, the first of which will be the end of extensive emphasis on classroom teaching. Teachers, students, and preceptors will come together in dialogues to question, to demonstrate, and to participate actively in the learning process. Nursing will hopefully develop a 'world view'. "Remember, the information revolution will continue to roll on – with or without you. So, get on board and begin changing" (Simpson. 1997:27).

Abstract: The greater prevalence of computer technology in the daily lives of middle school students is impacting their learning environment. Students of both genders and different levels of socio-economic status are well on their way to becoming part of the digital culture. This paper suggests that the gaps that once existed with regard to computer access, use, and perceived expertise are narrowing significantly. These findings are based upon survey data from 512 middle school students in three areas: (a) self-perception of computer skills and their acquisition; (b) exposure to technology at home and at school; and (c) media style and content preferences.

Introduction

Media and digital technology are pervasive in our lives. The advent of technology into the lives and culture of adolescents is not one of choice but of certainty. If we understand the influences at work among our youth, then perhaps we can address their educational needs in ways that maximize what we already know about how to structure effective content. Are there any signs of technology acculturation at work? Have computer presence and increased proficiency translated into any appreciable closing of the previously documented digital divide with regard to gender and socio-economic variables among middle school students?

The Study

Based on a series of small focus groups with middle school students, the authors compiled a 68-item questionnaire, both closed and open answer, to cover students' preferences and practice using different types of media. Students answered the paper and pencil questionnaire during either a science or computer technology class period. Typically, the questionnaire took 30 minutes to complete.

Between October 1998 and April 1999, 568 middle school students were surveyed from eight different metropolitan-area public and private middle schools covering four different school districts. The students ranged in age from 11 to 15 years (M = 12.59, SD = 0.66). Students who did not report essential demographic information were dropped from the analysis for a final sample of 512 students. Of the final sample, 43.4% were male (n = 222) and 56.6% were female (n = 290). Schools were recruited to obtain a diverse student population representative of urban and suburban schools, as well as all ranges of socio-economic status (SES). The final sample contained 31% high disadvantage students (n=158), 33% middle disadvantage students (n=170), and 36% low disadvantage students (n=184). Within each SES category, male and females were represented nearly equally.

Findings

The digital divide separating the confidence levels of male and female adolescents with regard to computer use is narrowing. While some significant differences emerged, the patterns of computer use and the purposes of use were remarkably similar for males and females in our sample. As recently as 1994, one study by Sakomoto indicated
that among fourth through sixth grade students considered "heavy users" of computers, the ratio of boys to girls was 4 to 1. Our results indicate that this gap is closing as we found no gender difference among those who could be identified as heavy users of computers. Additionally, when looking at the use of computers for identified school subjects, we found similar levels of self-reported computer use between males and females.

In contrast to previous research, both males and females indicate that games dominate the home use. Even in the school environment, games were one of the prime uses. Games remain an important part of adolescents' computer repertoire. These findings, in particular, argue for ways in which to infuse the gaming format with sufficient intellectual content to make the "game" a valuable learning tool. Some educators have already seized upon this notion and are producing more substantive Internet games that incorporate accepted learning theory. The theoretical framework of curriculum built around problem-based or case-based learning could lend itself to a gaming environment. Crucial issues of how intrinsic the problem is to the game scenario and how well do learning objectives translate into an appealing hypermedia format are all ones that would need to be explored.

Conclusions

While the content of educational web sites targeted for middle school students is still an issue for debate, the data from this survey point clearly toward web sites as an effective delivery mechanism. Access, use, and perceived self-confidence in navigating the Internet are less constrained by gender-related concerns than they were less than a decade ago. In addition to the rapid rise in adolescent female participation in technology, the data also echo the research of others in highlighting the prominence of all types of media in the life of adolescents.

The recent Kaiser survey (Kaiser Family Foundation, 1999) found that the average amount of time each day spent using all types of media for children from 8 to 18 years olds was 6.43 hours. The influence of all media in youth's life was reinforced by our survey participants' choices of "your favorite famous person." Of the 512 responses, 74% were performers or musicians. The remaining types of persons named could be categorized as 18% athletes, 3% historical figures, 2% religious figures, and 4% other.

Media of all types are playing a larger role in children's lives; however, it is mostly a solitary experience. Our data indicate that children are largely using the Internet and computers at home free of supervision. It also may not be the case that the computer is replacing other forms of media in adolescents' lives, but rather it is being "added" to the existing repertoire among those who are already "heavy users" of media.

One of the challenges before us is the creation of sufficient quantity and quality of digital materials to attract and retain adolescents' interest in an unsupervised environment. The materials must be free of gender-bias and bridge the gulf that currently exists between how kids learn and communicate on their own and how they are taught in school. Can the production of high-quality, educationally-grounded, and content significant materials attract adolescents to the world of learning via the Web?

Abstract

This evaluation project examines the required elements for a standardized instrument for the evaluation of educational technology. The project will survey current users of educational technology and seek common threads and patterns in a successful evaluation. This study will attempt to answer this question: What should we be collecting, measuring and examining when evaluating technology in an educational setting? This project is the first step in a multi-stage, two-institution evaluation study that will develop a standardized evaluation instrument for use in the evaluation of education technology. The project will enlist the assistance of two post secondary faculties, clients, developers and students. Each group will be surveyed using an online form. A representative sample from each group will be interviewed in a focus group setting. Expected outcomes of this first stage include the collection of responses from users, developers and clients of educational technology. The survey responses (n=81) have provided a unique opportunity to share and compare educational strategies and concepts between post secondary institution faculty, users and developers. Common patterns were evident within and between groups relative to concepts of educational technology evaluation and important aspects of instructional design.

Introduction

This evaluation project will examine the required elements for a standardized evaluation instrument for educational technology tools and applications. The project will survey current users of educational technology and seek common threads and patterns amongst user groups for the design of a successful evaluation instrument. The goal of this project is to determine what users and developers deem important, valuable and relevant with respect to instructional design and the evaluation of technology in the post secondary arena. The survey data collected will be used to create a standardized evaluation tool. This evaluation tool will assist developers, instructors, teachers, and learners in the design, construction and use of an instructional design model and template suitable for use in the post secondary field of education.

Project Rational and Purpose

First, the research in this area has focused on the application of technology. Evaluation studies on educational technologies have traditionally focused on the particular technology tool and its impact on the learning environment. While useful in producing data for that tool or application, generalizability to other technologies or application is not possible due to the design of the instrument. Typically these instruments survey specific program issues and fail to consider the larger pedagogical issues of technology (this link provides examples of about 50 instruments of evaluation used in educational technology)\(^1\). Such programs as the Annerberg's Flashlight Project\(^2\) and McMaster University's EVNet\(^3\) have been leaders in educational technology project, but have failed to develop a standardized instrument, useful in evaluating all types of projects, across multiple users in various circumstances.

Secondly, this project is the first step in a multi stage; two-institution evaluation study dedicated to the development, testing and dissemination of a standardized instrument for educational technology evaluation. The first stage is a necessary step in determining what should be evaluated when examining technology in the education field of study.
Several studies have identified survey instruments and other collection tools for use in educational technology\(^4\)\(^5\). While useful in assessing individual programs for a specific outcome, these types of instrument are difficult to generalize to educational technology, regardless of platforms, users or programs. Determining what should be evaluated in a format that can transferred across technologies and application is a critical next step in valuing educational technology's contribution to learning.

**Conclusions**

The first step of this multi-stage evaluation project produced an extensive database of information on what users, developers, clients, and educators think about educational technology and its application to learning. The collection of data ranges from attitudes towards technology to perceptions of technology and its affect on learning. It also provided a resource in the development of a standardized tool for evaluation educational technology.

From this study sample, it is clear that respondents agree on a number of issues in terms of importance and relevance to instructional technology. It is also important to note that there are some differences between respondent groups relative to the evaluation process for educational technology. This information supports previous research in educational technology that has identified key concepts and factors of educational technology.

This first stage of the project provided an opportunity to validate the survey instrument, by seeking some responses to confirm that the evaluation of educational technology is an important aspect of the instructional design process. These findings can be used to development a survey instrument designed to evaluate the important constructs of instructional design with the use of technology.

This first stage of this project provided a unique opportunity to share and compare educational strategies and concepts between two post secondary institutions. It is hoped that the two institutions will share a common ground with respect to the development, application and delivery of educational technology.

Using Mobile Computer Technology and Internet Tools to Promote Constructivist Teaching

Chrystalla Mouza
Teachers College, Columbia University
United States of America
cpm12@columbia.edu

Introduction

This paper investigates how continuous access to laptop technology and telecommunication tools can promote a student-centered, inquiry-based, problem-solving teaching practice. The purpose of the study is to deepen our understanding on how technology and Internet tools can best be utilized in K-12 classrooms. We present an Internet-based project that utilizes laptop computers in a sixth grade classroom.

Research Questions

We explore how laptop computers and Internet tools are used by a sixth grade teacher who has extensive experience with technology and multiple opportunities for professional development. The overall questions that guide this research are as follows: a) What are the teacher’s beliefs about teaching and learning? b) What is the nature of students’ assignments? c) What is the role of the teacher and the student in the classroom? d) How are laptops being utilized in the curriculum? e) How is the Internet being used in the classroom?

Methodology

This study began in September 1998 and takes place in urban elementary and intermediate schools in New York City. The primary data collection techniques that are utilized include classroom observations, teacher interviews, and document analysis. These activities have been carried out during school visits since the academic year of 1998-99. Participants for this initial research effort include a sixth grade teacher and her students. All students in the class are minority students; the teacher is a white female.

The classroom is part of the Laptop Project, which was initiated by the school district in 1997. All students in the project have been issued a laptop computer. The classroom is also part of the Eiffel Project, a major effort of the Institute for Learning Technologies (ILT) at Teachers College, Columbia University to assist schools and teachers integrate computers and telecommunication tools effectively in their classrooms. ILT provides teachers with technological and pedagogical support, as well as with opportunities for communication and collaboration with other teachers and researchers involved in the Eiffel Project.

Project Design and Preliminary Results

Mary, the sixth grade teacher participating in our experiment, started teaching for the first time using laptop technology during the academic year of 1997-98. That first experience provided her with valuable training on the use of computers in teaching. Mary was ready to try new ideas, experiment with different projects, and go beyond traditional instruction. Therefore, she volunteered to participate in the Reach the World (RTW) project.

RTW (www.reachtheworld.org) is a virtual expeditionary venture that uses the world circumnavigation of Makulu II, a sailboat, as an interactive tool for classroom teaching in the United States. RTW utilizes the Internet and other...
telecommunication tools to bridge the student classroom with different cultures of the world. The crew of the Makulu II communicates with students regularly via satellite email. Since September 1998, Mary accommodated her social studies curriculum to the RTW project. Soon after she started participating in the project, she became the most active teacher. Some of the lesson plans she developed are posted on the RTW web-site as examples for other teachers.

Nature of Student Assignments

Planning an Itinerary. In this project students were asked to form groups and conduct research in order to identify possible sites that the Makulu II should visit on their trip to Singapore. Each group researched different attractions and recommended sites of interest. Students used travel brochures to locate tourist attractions, maps to figure out distances and ways of transportation in Singapore, and historical information from the Internet to identify museums of interest. When the final itinerary was put together it was sent out via email to the Makulu II crew. The Makulu II crew completed the tour and sent back relevant information and pictures to the students via email and air-mail.

Comparing religions of the world. Students studied different religions using information and videotapes that were sent by the Makulu II crew. In sequence, students formed groups and selected one religion to study in-depth. Final reports were presented to other sixth grade students in the school using PowerPoint slides.

The Role of the Teacher and the Students

Teaching was organized around two types of pedagogies: Collaborative knowledge construction and direct verbal instruction. Direct instruction did not represent the dominant mean of communicating knowledge to students. Students were rarely asked to memorize facts. They were instead asked to locate facts using CD-ROMs, books, the Internet, and other resources. The information was then analyzed in order to complete projects and solve problems.

The teacher was mostly a facilitator of learning and a “guide on the site”. Students were given opportunities for self-directed inquiry. In many cases they were asked to generate their own questions and search for the answers. Laptops were very helpful because they put a lot of the resources into the hands of the students.

Utilization of Laptop Computers and Telecommunication Tools in the Classroom

Laptops were a vehicle to support the curriculum and expand the classroom’s walls. Students typically used application programs such as a word processor for typing and editing documents, databases for organizing information, and graphics packages for developing multimedia presentations. Email was also used extensively in the classroom for communication purposes. Moreover, all students used First Class, an Intranet service that allowed them to communicate with their classmates and teacher after school hours.

Laptops were effective in promoting collaborative work and problem solving. Very often students were required to work in groups and create projects. In collaborative projects, students were required to perform research, collect information, analyze it, synthesize it, and produce a final product.

Conclusions

This paper presented an effort to integrate technology in the classroom. Laptop computers and telecommunication tools were used to provide students with authentic, meaningful, and motivating experiences. Learning became a challenge and students exhibited increased levels of control and creativity. Successful use of technology in the classroom depends, however, to a great extend, on the teacher. Therefore, in any implementation effort, adequate time must be devoted in helping teachers become comfortable with the equipment and absorb the new teaching principles associated with the use of the new technologies.

We currently work with a number of teachers in the New York City area assisting them with their technology implementation efforts. Many teachers use laptop computers and Internet tools for instructional purposes. Therefore, we continue our research by observing what is happening in these classrooms and analyzing changes in the instructional beliefs and practices of the teachers.
Scenario Building to Design a Distance Learning Program

Lisa Neal
EDS
3 Valley Road
Lexington, MA 02421 USA
lisa.neal@eds.com

Abstract: Scenario building is a process that can be effectively used to design a distance-learning program. It begins with the identification of the key stakeholders, who are typically students or participants, course developers, teachers or facilitators, support staff, and administration. Then, for each perspective, the relevant characteristics are identified, followed by a determination of what is required to meet the needs of a person in that category. The process also has the benefit of being a group activity that can facilitate team-building and commitment. We have used this process with multiple organizations and report on these case studies.

Introduction

Distance learning programs are designed in many ways: some evolve from individual efforts, some are designed using available technological capabilities, and others, more recently, are purchased from or co-branded with e-learning providers. Scenario building provides a systematic process for the group of people involved in planning and implementing a program to work as a facilitated team to design a program. The process can be used for any type of organization, including a university or business. It involves a number of steps: determining who will be involved in developing, delivering, supporting, administrating, or taking courses, and prioritizing these to order the next phase. Starting with the most important perspective, usually that of the student or participant, the relevant characteristics of members of that category are determined by the group. This may include computer and Internet literacy, work environment, and time commitments. The group then determines what happens when a representative of that category carries out their role, i.e., taking, teaching, or supporting a class. This results in a list, which is then prioritized, of the needs and requirements from that perspective for the distance learning program. Subsequent perspectives are usually easier to consider after the first, and the entire process leads to requirements analysis and planning for the program. This process has been used for a number of organizations that are planning distance learning projects, including the University of Puerto Rico.

The University of Puerto Rico

The Puerto Rican government funded an ambitious distance-learning program at The University of Puerto Rico. To help get the program underway, the university called on a team of EDS consultants to structure and support the program's essential planning and implementation processes. The team began with strategic planning to determine the tasks and responsibilities needed to ensure the program's on-schedule readiness. During this process, it became clear that the distance-learning concept conjured widely different images for members of the steering committee depending on their knowledge of its theory and practice. Many assumptions were based on the association of distance learning with the room-based videoconferencing that dominated distance education prior to the introduction of Web-based technologies in the mid-1990s. Some of these images did not account for the level of interactivity and engagement that students and teachers experience using state-of-the-art distance-learning technologies or failed to accommodate the important differences between learning and teaching in traditional and technology-mediated settings.

The team proceeded with scenario building, an activity designed to help the program's steering committee understand, envision, and specify technology's role in the new distance-learning offering. Scenario planning began by determining the roles that people will play in the university's distance-learning program; those roles are student, professor, teaching assistant, and a number of support and administrative positions. The scenario-planning work led
to each role being assigned characteristics that are relevant to the how a person in that role operates in a distance learning program or that give the role dimension and interest. Characteristics of a student, for instance, included age, family/home situation, educational background, technology literacy, Spanish and English literacy, and typing skills.

The goal was to agree upon the role of technology, the specific types of technology, and the support requirements for technology in the distance-learning program. To achieve this goal, we developed a prototypical member of each role in order to envision, as a group, what a day in that person's life would be like. We carried this to the level of detail of which relevant activities they were engaged in, where they carried out the activities, and what technological and human support was required. There were implications from some of the characteristics of a role; to discuss the activities of a person in a day, we needed, for instance, to know if there was access to a computer and, if so, under what conditions or with what possible distractions it would be used. If there was no access, then a staffed computer room must be available during reasonable hours. Additionally, we considered the implications of atypical but plausible cases for each characteristic, such as the ramifications if a student was older and returning after a period out of school.

Conclusions

The scenario-building process uncovered many issues, concerns, assumptions, and previously unarticulated misconceptions, which led to constructive discussion that culminated in a consensus about technology's role in the project and about the people who would manage and support it. Equipped with the scenarios' insights, we completed a thorough analysis of the program's specific technology needs, identifying and prioritizing the components of the supporting technology. In subsequent discussions, we continued to refer to the prototypical characters, and found that they continued to help clarify issues since the group could look at that person's specific (imagined) needs. Ultimately, the process of identifying each role's relevant characteristics and the hypothetical activities and interactions of a person in that role pointed directly to the criteria against which the entire program will be evaluated, ensuring that the overall effort's success will be measurable and more easily repeatable.
Initiating and Sustaining Collaboration in Technology: Critical Elements

Paula Nichols and Stephenie Yearwood
Department of Educational Leadership, Lamar University
pNichols@tenet.edu; yearwoodso@hal.lamar.edu

Abstract: Collaborative technology projects require new types of relationships and distinctive management strategies. This paper outlines three critical elements in creating and continuing such partnerships: common vision, a reward system, and consensus.

Technology ventures often demand collaborative efforts which bring together personnel, financial resources, needs and solutions from diverse entities. Older models of cooperation worked within top-down power structures; new structures of collaboration are complex and require long-term thinking and conflict management. Furthermore, sustaining collaboration is critical because the payoffs of such efforts are often long-term. We identify here three elements critical to building and sustaining collaboration: common vision, a reward system, and consensus operations.

Common Vision

Diverse groups who collaborate in technology ventures always face semantic difficulties, terms are defined differently and goals are stated in language only the originators understand. As a result, common definitions of terms and in-depth discussion about problems, solutions, and common issues are essential (Winer 1994). In this initial establishment of common understanding, group members must adopt a posture of tentative knowing, a non-judgmental stance which reserves value judgments and allows for continuing conversation. Although individuals may be experts in their domains, they need to drop their "know it all" perspective when they work collaboratively. Rarely does any entity get all it wants, but group members must be honest about what
they are willing to put into a collaborative effort as well as what they wish to get out of the collaboration.

A Reward System

Different entities have different currencies and rewards. Rewards must come to group members in the currency valuable to them in their system, be it promotion, tenure, credit hours, test scores, or bonuses. Furthermore, different stakeholders define accountability differently, as staying within budget or positive publicity (Report 1997). As specific rewards are discussed, entities must spell out to whom and how they are accountable and how that will affect their participation.

Consensus

In diverse collaborative groups, absolute agreement is rare. Thus it is essential to establish that the group will operate by consensus and to establish a process for achieving consensus and resolving conflicts. Even when members do not agree on an outcome, if they have subscribed to a specified process which has been followed consistently, they will be able to accept the result (Winer 1994). Once established, conflict resolution needs to be called into play quickly when problems arise. Difficulties which drag on are much harder to deal with.

Clearly collaborative ventures in technology are neither simple nor easy. However, the power of successful collaboration is synergistic. Collaborative groups which are able to sustain their efforts can achieve a whole which is indeed greater than the sum of the parts.

Integrating Learning agents in a virtual laboratory

Roger Nkambou and Yan Laporte
Département de Mathématiques et informatique
Université de Sherbrooke, Sherbrooke, J1K 2R1
Canada
roger.nkambou@dmi.usher.ca

Abstract: This paper presents a system called Cybersciencel dedicated to distance education. The learning interface of Cyberscience includes a component consisting in activating an interactive multimedia simulation in which the student can carry out direct manipulation tasks making the simulation a virtual laboratory (virtual lab in short). A virtual lab for genetic study is currently realized. As an intelligent distance learning system, Cyberscience includes a number of intelligent learning agents that operates in the space of the virtual lab in order to help students to achieve their goals. This paper presents an overview of those agents.

Introduction

There is already a lot that has been said about software agents, especially intelligent agents’ technology. While this is a really a current trend in software engineering. The concept of intelligent agents is at the same time simple in principle and complex in classification (Jennings and Wooldridge, 1998; Nwana, 1999) While intelligent agents systems are widely being developed, most of the frameworks available simplify the architectural and technical aspects and provide relatively no support to implement agent behavior. The goal of this research is to provide people with a strong basic architecture and shell to handle the complex task of implementing intelligent behavior in software agents. The tools provided must have a fairly generic aspect so they can be applied to a wide variety of problems and systems while still being able to adapt sufficiently to a problem to provide relevant intelligent features. It should be possible to achieve such capability by building a set of general-purpose agents that would be easily customizable and reusable.

A set of multiple agents

The first part of building such a set of agents is to determine a set of feature that are desirable and that are sufficiently high level to be reusable. The current proposal includes a planning agent, a decision making agent, a data mining agent, a rule-based reasoning agent, a data extracting agent and a case based reasoning agent. These agents cooperate in the context of CyberScience in order to: create an action plan for the current instructional objective associated with the selected course or theme, according to the student model, select the relevant resource the student will use to achieve the goal, update the student state of knowledge, help the student during the learning process and so on. In the following, we describe each of the agents.

Data Mining Agent. The Data miner has a high probability of being highly useful to many different applications. Basically, this agent’s purpose is to retrieve useful information from databases and electronic documents both on a local machine, a network or even the Internet. Of course it can mean only search for certain keywords but it is also possible to implement more complex and advanced intelligent search algorithms. It remains to be decided how it is most convenient to interface with such an agent. It is also to be considered if such an agent should be mobile or not or even if it should decide whether it should move itself to a different host system to be able to accomplish it’s job more efficiently.

Rule-Based Reasoning Agent. The rule-based reasoning agent acts mostly as an expert system. Expert systems have proven over time to be efficient to a large number of tasks. The goal of this agent is to derive conclusions from a knowledge base consisting of facts and knowledge. It needs an engine and a set of

---

1 This project is funding by the University of Sherbrooke.
deductive rules. It needs an interface to specify the content of the knowledge base. An interface also needs to be defined to query the truth of undefined facts. The engine would be most likely based on the Rete algorithm that is already well known and extensively used and tested.

**Case-Based Reasoning Agent.** The case-based reasoning agent on the other hand compares the different cases and makes generalizations out of them. When the case-based reasoning agent is invoked on a particular situation it tries to find already known cases that are similar to the current one.

**Planning Agent.** The planning agent is software capable of making plans. The goal is to come up with a combination of actions to be executed in the future in order to achieve a desired behavior. The interface to the planner agent is a bit more complicated than previously discussed agents, but this is expected considering the complexity of planning problems. First it needs a way to specify an initial state and a goal specifying the desired task to be achieved. It also needs a set of specifications of the actions feasible by the system. Finally it needs a planning strategy, a starting plan and a set of bound parameters both in time and space. The agent’s engine would be most likely to base on SIMPLAN because of its capacity to operate in highly variable environments (Nkambou and Kabanza, 1999). This agent will generate a plan of actions repairing the plan given in input that best satisfies the goal from the initial state, given the restrictions implied by the bound parameters.

**Decision-Making Agent.** Finally the decision-making agent and the knowledge extraction agents are making extensive use of previously discussed agents in this paper. They would probably encapsulate specific instances of these. The decision-making agent, as its name implies, takes decisions about the different tasks to be done and how they must be accomplished effectively. It would work by using the rule-based agent to generate a goal as of what to do. A planning agent starts to search how to best achieve the goal by calculating a new plan while case based reasoning agent tries to find a relevant plan that was previously used in a similar situation.

**Knowledge Extraction Agent.** The knowledge extraction agent finds relevant information from different digital data sources. Like the decision-making agent, the knowledge extractor uses a combination of three internal agents. It obviously uses a Data Mining agent to retrieve pieces of documents or database information related to a subject requested by an internal rule-based reasoning agent. But a case-based reasoning agent also tries to find similar cases as where relevant was found to help the data mining agent. Once it is retrieve the information can then be used by the system.

**Conclusions**

The development of the set of intelligent agents involved in CyberScience will lead to a shell to easily implement intelligent learning agents systems. Most of the required features for each agent have already well known solutions. There are also numerous frameworks that already offer facilities to create agents and to give them mobility abilities. It is expected that a higher level of intelligence in behavior of the system would be achieved by close collaboration of these agents. It has to be defined how it should be organized to provide a generic functionality that would be reusable. Also, it must be established how would the specification for a custom system based on these agents would take place. With this shell the use of intelligent learning agents system is likely to widespread. But the first application it is used on, as a test case, is the Cyberscience virtual laboratory. While it could merely be used as a replacement for current expert system to add them a higher level of intelligence, adaptability and interaction level, it is also expected they could be applied to new breeds of problems directed at a less specialized category of users. It can be easily assumed how this system could be used to create assistants or coaches in a context of an Web-based intelligent tutoring system.

SGML BASED COURSE DEVELOPMENT: BALANCING INSTRUCTIONAL DESIGN AND TECHNOLOGICAL REQUIREMENTS

Solvig Norman, MA
Coordinator of Instructional Development
Open Learning Agency, Canada
snorman@openschool.bc.ca

Abstract

The Open Learning Agency in British Columbia, Canada, is involved in a multi-year project aimed at producing a number of courses that are derived from structured SGML documents. Presently, fourteen courses are being delivered on-line in 33 School Districts throughout British Columbia. This paper describes the use of structured documents for course development with a focus on the benefits and challenges of balancing technological and instructional design issues.

Background

The Open School, a division of the Open Learning Agency, is involved in a multi-year project aimed at producing a number of courses that are derived from structured SGML documents. The goal is to offer innovative and current educational resources for students and teachers that are directly linked to the government’s curriculum and provide flexibility through delivery of alternative formats within a distributed learning environment (e.g., for use in a classroom environment and also within an independent self-paced learning environment). Fourteen Grade 11 and 12 courses were developed within a structured document environment using SGML (Standard Generalized Mark-Up Language) technology to meet Open School’s goal. These courses are presently being delivered to about 1200 students registered either in one of the nine Distance Education Schools or within one of the regular classroom-based schools in British Columbia.

Open School has traditionally developed large print-based courses with some complimentary wrap around media such as text, video, or audio. Development time from the planning stage to delivery took, on average, two years to complete. Once a course was delivered, it was cumbersome and time consuming to update and maintain. Courses were seen as being out of date, too large, too much work, and provided primarily a singular pathway for students to learn. Open School had some previous experience with developing courses for on-line use, but realized the need to change their course development processes in order to develop more timely and flexible content. The implementation of SGML as an underlying course development tool for planning, development, production and delivery was identified as a means to an end. This technology can facilitate the following:

- creation of courses from instructional design to deliver,
- creation of assessment types and mechanisms,
- identification, association, and categorization of resources within,
- identifies the course architecture,
- creation of custom views of materials for different types of learners,
- storage and management of parts and pieces of course materials,
- output to both print and web, as well as to other media.

SGML has roots in the high tech and publishing industries and is the international standard for representing electronic text in a mark-up language. The mark-up provides a means for interpreting the text. SGML is not dependent on any specific hardware or operating system SGML provides a consistent approach to...
identifying the components of a document and how they relate to each other. The process permits explicit tagging to identify the components of a "course": lessons, learning outcomes, glossary terms, activities, online resources, etc. There are an infinite number of document structures that can be defined depending on the specific requirements. SGML is a descriptive mark-up language rather than a procedural mark-up language. A descriptive mark-up language uses codes, called elements, to name and categorize parts of a document. Procedural mark-up language, like that of HTML, is often used to represent text in a certain style like bold. SGML also includes a DTD: Document Type Definitions. The DTD defines the "allowed" elements and specifies the order in which the elements may or may not appear. The authoring process must produce documents that conform to the specifications of the DTD.

The Marriage of Instructional Design and SGML: The Benefits

Open School, as part of the Open Learning Agency, has a long history and experience with implementing sound instructional design practices for developing learning materials. Fundamental stages of instructional design including needs assessment, learner analysis, planning (review), development (prototype, formative evaluation), production (evaluation), delivery, and summative evaluation – all have been at the heart of course development practices for over twenty years. Various instructional technologies have been used over the years and have often been perceived as tools whether they were word processing software programs, computer conferencing systems, videos audiotapes, and more recently the World Wide Web/Internet.

However, with the implementation of SGML, instructional design methods became more explicit as part of the structured process dictated by the technology. Open School’s SGML based courses have been developed with very explicit Document-Type-Definitions that lay out the architecture of courses from the instructional design planning stage to the delivery stage. This process has permitted course developers to explicitly examine the contents of their courses in a more detail manner that was never before possible. A course basically "grows" from an instructional design plan (e.g., consisting of learning profiles, learning outcomes, resources, proposed activities and assessment) into a fully authored final product (e.g., completed modules with lessons including narrative, instructions, content, activities, and assessment). Because of the structured information approach to course development, “bits and pieces” (e.g., granules, learning objects) of a course can be re-used and re-purposed for other learning situations or outputted to different formats (e.g., print or the Web). Developing 14 courses for on-line and in the print at the same time would not have been possible without the use of SGML as an underlying tool.

The Marriage of Instructional Design and SGML: The Challenges

Although there are many benefits in the implementation of SGML as a course development framework, Open School has also faced a number of challenges. Here is a list of the main challenges:

- Adopting a new technology that entailed a whole new infrastructure (e.g., with new hardware, software, additional staff, extensive training for internal staff, new procedures to follow).
- Reviewing and analyzing existing processes and products in order to come up with consistent structures and language for different course architectures (e.g., deciding on what constitutes a course, a module, a lesson, an activity, etc).
- Designing content to be used in different learning situations. With a database as a backbone, SGML files can be used by other course developers to re-use existing content. There are issues around designing content to be stand-alone (e.g., learning objects). How granular can content be (e.g., a paragraph or a lesson)?
- Ensuring that content which is designed in “bits and pieces” (e.g., learning objects) is pulled together into a cohesive manner which provides an effective learning environment for students.
World Wide Web Course Delivery in Developing Countries: A South African Perspective

Shaun Pather  Geoff J. Erwin
School of Mathematics, Information Technology & Computer Science
University of Durban Westville, Private Bag X54001
Durban, South Africa
spather@is.udw.ac.za  erwin@is.udw.ac.za

Abstract: There is increasing international usage of the World Wide Web for course delivery. The current South African education system is still structured as a legacy of the apartheid system. The South African government currently promotes the uses of technology to enhance access to education and to foster resource-based learning. The authors report findings of a survey of Web-based course delivery at South African tertiary institutions, including problems being experienced by academics in adopting Web-based techniques.

Introduction

The Internet and the World Wide Web (WWW) are part of a shift away from traditional classroom based course delivery methods (See for example Pilgrim & Creek, 1998, p. 189; Kinzie et.al., 1996 p.59). The South African situation does not reflect this trend. South Africa is characterized by a transforming education system that aims to address imbalances brought about by the apartheid era. Disenfranchised sectors of the South African population have historically had limited access to higher education (Christie, 1986).

Background

The South African Department of Education promotes the use of technology (including the World Wide Web) to enhance and widen access to higher education and to foster resource-based learning. The Department of Education is actively engaged in promoting technology-enhanced learning. It has initiated a five-year strategic plan, through the National Centre for Educational Technology, to build an infrastructure to support technology-enhanced learning (Department of Education, South Africa). The current social and education systems are still heavily influenced by inheritances from the apartheid political system before 1994. For example, the majority of South Africa's population (mainly black) do not have access to the Internet (Webcheck National Survey, 1999). Potential university students have no experience in the use of information and communication technologies (ICTs). Currently, only 0.02% of South African schools have an Internet connection (IDRC, 2000). Their ability to use Web-based education is limited. The lack of telecommunications infrastructure, combined with low levels of technological literacy of the population is a major obstacle to deployment of Web-based material.

The Survey

A survey of academics from fourteen South African tertiary institutions was conducted between June and September 1999. A non-experimental survey method, using a structured questionnaire, was used to investigate the following: The extent of usage of specific WWW features for course delivery. In particular the authors assessed to what extent current adopters have used the WWW to move away from traditional teaching methods. Specific features listed in the survey were: Use of Email, posting of syllabi (dynamic & static), detailed course information updated regularly, distribution of lecture notes, links to external sites, feedback mechanisms to students, online chat-room, streaming video, multimedia online lectures, animation, submission of online homework, testing and examinations. Problems that exist at tertiary institutions that are impeding the implementation of WWW technology. Specifically the survey examined areas of availability of human and physical resources, organizational conditions, and the attitude of academics to the use of WWW as compared with traditional classroom based methods.

Findings
1. Current and intended usage of the WWW by South African academics:

Figure 1 (see http://is.udw.ac.za/staff/research/web/figure1.htm) indicates that current levels of adoption of the thirteen WWW based activities listed in the survey fall into two broad categories. The first category reflects a relatively high level of use. The seven activities in this category (e.g. Email, syllabus postings, distribution of lecture notes) are activities that are widely used and are those that support traditional styles of teaching. They do not necessarily change the actual method of classroom-based delivery. A possible reason for this could be that such activities could be implemented at a low cost and with no need to spend a large amount of time doing in-depth planning and design. The second category reflects very low or non-existent levels of use (six activities). This category involves activities (e.g. Chatrooms, multimedia online lectures, online testing) that would significantly move away from traditional teaching methods. These are activities that require intensive planning and design, and are also dependent on a high availability of a technological infrastructure supported by adequately trained staff. There is an increased level of usage. Respondents also indicated an intention to increase level of use of activities that fall into the second category listed above. This is a positive indication, since the activities that fall into this category are those that will realise a paradigm shift away from traditional course delivery methods to a student-centred, constructivist approach.

2. Comparison of level of South African tertiary institutions with international usage

The WWW features listed in the survey echoed those from an international survey that was conducted by an American university at the end of 1998 (Peffers & Bloom, 1998). Figure Two (see http://is.udw.ac.za/staff/research/web/figure2.htm) provides a comparison between the South African tertiary educators surveyed and those of the international survey. The similarities in the trends are noted in the paper. However, it must be noted that this not imply that the broad state of WWW adoption for course delivery in South Africa is at the same levels of usage as our international counterparts.

3. Existing difficulties in the implementation of Web-based course delivery.

Staffing problems: The results of the survey suggest that academic staff do no have the necessary skills to implement Web-based courses. The situation is further compounded by the absence of support staff needed to run Web-based courses. Organizational conditions: The Survey suggested that the organizational conditions such as time and flexibility in respect of work commitments do not allow academics (especially if they are novices at implementation of Web technologies) to experiment with WWW technologies. Financial Restraints: The problem of shrinking financial resources is affecting service delivery at all levels of education in South Africa. The survey indicates that current budgets do not allow them to invest in Internet technologies.

Conclusion

The desire for on-line teaching at South African tertiary institutions is increasing. The survey indicates that academics acknowledge the positive role of the WWW in course delivery. Key recommendations are: Adopters of Web technology in the classroom need to be encouraged to utilise the Web for more than merely support of traditional lectures; Management at the faculty and institutional level should be encouraged to create the possibility for and invest in adequate training of both academic and support staff. Heads of academic units support the adoption of Web technologies by providing incentives to staff. Tertiary institutions should investigate possible collaboration with external partners in the private sector as a means of alleviating high costs. Some of the issues that require further research and investigation are: international experiences and collaboration with counterparts; Development of guidelines for designing Web-based courses; the long term effectiveness of Web-based teaching on students; the role of academics in developing Web-based courses; and user-friendly authoring tools.

Abstract: This paper looked at the variation of structure and participations for online conferences. Four different structural models were used in designing the conferences, which were (1) Open-ended discussions by expert, (2) Scaffolded discussion with facilitated follow-up, (3) Scaffolded discussion without facilitated follow-up, and (4) Open-ended discussion without facilitated follow-up. Data were collected on frequency of messages, word count of messages, and key word analysis for themes. The findings will provide comparative and descriptive data related to conference structures, participant variables, and levels of participation for future research in online conferencing.

Use of Online Conferencing as a Vehicle for Training Special Educators

There is evidence that materials designed to assist teachers in working with students with behavioral problems are currently in high demand. The design and development of the Internet as a delivery medium for such continuous training in both preservice and inservice teacher education has been documented in special education (Smith, Martin, & Lloyd, 1998). A team of researchers, funded by a U.S. Department of Education grant, has been hosting a series of online conferences for preservice and inservice educators under the auspices of the Virtual Resource Center in Behavioral Disorders (Fitzgerald & Semrau, 1998-2000). These virtual conferences involve the participation of national experts in the behavioral disorders field for the purpose of providing in-depth discussion of topics and social discourse regarding the application of the information.

Design and Structure of the Virtual Conferences

Four different structural models were used in designing the online conferences. Each conference ran for two weeks, but the degree of openness and structure, involvement of the online expert, and the use of discussion facilitators differed across the conferences.

Conference #1: Open-ended Discussion by Expert. 95 participants; 477 messages.
One expert online for two-week duration with all participants in one large discussion group; no required pre-conference preparation or readings; messages not organized by themes or available via archives.

Conference #2: Scaffolded Discussion with Facilitated Follow-up. 105 participants; 283 messages.
One expert online for first week with all participants in large group; participants grouped into four smaller discussion groups directed by project facilitators for second week; required writing of a case scenario; suggested readings offered via web site; messages organized by themes and available on web archives.
Conference #3: Scaffolded Discussion without Facilitated Follow-up. 37 participants; 155 messages. One expert online for first week with all participants in large group; participants continued discussion for second week without expert or facilitators; pre-conference self-evaluation encouraged; suggested readings offered via web site; messages organized by themes and available on web archives.

Conference #4: Open-ended Discussion without Facilitated Follow-up. Three national facilitators for first week with all participants in one large discussion group; participants continue for second week without national or project facilitators; no required pre-conference contributions required; free CD-ROM provided prior to conference containing suggested software and resources for viewing; messages organized by themes and available on web archives; greater mix of field teachers participating with preservice teachers.

Preliminary Findings & Importance of the Work

The findings reveal equivalent levels of participation regardless of prior computer experience, teaching experience, access to equipment, typing skills, learning styles, writing anxiety, or frequency of e-mail and Internet use. Writing anxiety may play a role in length of message but not frequency of responding. Graduate students demonstrate significantly higher levels of participation compared to undergraduate students. Less structured conferences allow participants to initiate more of their own topics of concern. Instructors have an important role in providing technical assistance. Instructors and course requirements impact participation and authenticity of involvement of preservice participants. Readings provide common ground for discussion. Written scenarios can be requested from participants, but they emerge naturally. Structure and facilitation provide an even level of participation and ongoing discussion. Messages must be archived by threads for asynchronous access.

This research provides a comparison of online participation during conferences that differ in open-ended vs. scaffolded features and the use of facilitation. Online conferencing appears to be a valid and valued method of providing preservice and inservice training, but the variables of designing and running virtual conferences are more of an art than a science at this stage of research. These studies will provide comparative, descriptive data related to conference structure, participant variables, and levels of participation to guide future research in this mode of instruction.

Introduction

In medical education, Problem-Based Learning (PBL) is becoming appreciated more and more. The design and implementation of a problem-oriented medical curriculum, however, is very time-consuming for the educational staff. Case-based, Web-based training systems can help the educators to develop, implement, organise and reuse well-structured multimedia cases. For students, such a system can be used to improve and test their problem-solving competence. With respect to heterogeneous learning environments, the system should be flexible and adaptable. CAMPUS tries to meet these requirements by covering the needs of different user groups (e.g., students, educators, physicians) in different application scenarios (e.g. self-study, presentation, learning groups) to get maximum benefit of integrated medical cases. With the CAMPUS player component (learner’s front-end), users can work out medical cases in a simulative - and therefore realistic and interactive - way or let the system present a case in different manners. Users can get help via expert comments or context-sensitive systematic knowledge which is available in addition to the case data. With the CAMPUS authoring component, medical experts can feed the system with cases from any medical field. CAMPUS, part of a comprehensive virtual university project, is going to be integrated in a reformed medical curriculum approach at the University of Heidelberg.

Methods

The idea of CAMPUS is to develop a case-based, Web-based training system in Medicine including a broad variety of usage modes with the aim of minimizing acceptance problems and maximizing the effectiveness and efficiency of case-data input, which is time-consuming and still one of the central problems of case-based systems. To achieve such a functionality, CAMPUS provides the following features:

a) Integration of medical cases from any medical field
b) Storage of case data in a very detailed manner in a relational database
c) Presentation/treatment of cases in different adaptable ways

The degree of interactivity/realism of a case presentation/treatment is optional. The most interactive form is 'decision', where the student has to treat a case in a realistic, simulative way leading to a maximum of active knowledge processing. The user has to ask questions of anamnesis, order physical, lab or technical exams, make diagnostic decisions and propose a therapy. In the form 'compact' the student only has to make diagnostic decisions and propose the therapy. The results of the different tests are shown en bloc. If a user is only interested in medical case data he can choose the form 'total', where the whole case is presented at once with no interactivity at all.

With these different forms of application the user can look at a case the way he likes and is able to. For example, if a user does not want to do the anamnesis on his own for any reason, he may choose the form
If, on the other hand, he wants to concentrate his learning activities on the physical exam, he may choose the form 'decision'.

d) Expert comments on demand
It is very important to explain certain things about a case, e.g., why a diagnosis has been made or why a particular exam has been done. Hence, for every particular point within a case the CAMPUS author can define an expert comment.

e) Questions if wanted
Questions are - besides other things - an important aspect of interactivity and active knowledge processing. Thus the case author can define questions of different types on every definable point within a case, e.g., after or before the user gets the answer to a certain question of the anamnesis or after or before the whole physical exam. The user can choose if he wants to see only case-dependent questions, case-dependent and case-independent questions or no questions at all.

f) Distinction between case data and systematic knowledge
Every user has a different state of knowledge. Therefore, every user needs help at different points when working on a case. Hence, CAMPUS shows context-sensitive systematic knowledge only on demand. The knowledge can be internal (integrated by CAMPUS authors) or external (using external knowledge sources from digital libraries over the internet).

g) Detailed case search
Cases are searchable by defining symptoms or diagnoses. For example, one could look for cases with fever, shivering and chest X-ray abnormal. Such a specific search is possible because of the detailed database.

h) Execution over the internet/intranet or locally
To acquire platform-independence, permanent actuality and world-wide access along with all capabilities of a programming language, CAMPUS is implemented in Java as a Browser applet. For users at home, it may be better to have a local application to save time and costs. Therefore, CAMPUS is also executable locally using a local database.

In order to avoid the structure and vocabulary of cases varying from author to author, a case has a well-defined structure and has to use a defined vocabulary for anamnesis questions, exams, diagnosis (ICD-10) and therapies. Every case has the following structure: anamnesis, physical exam, suspected diagnosis followed by one to many passes of a therapy loop with examinations (physical, technical, lab), working diagnosis and therapy. That means that, unlike many other case-based training systems, CAMPUS doesn’t stop at the first diagnosis given by the user but considers a case in a more detailed and realistic way. To give the user an easy to understand user interface, we implemented a so-called situated learning environment, where the ‘situation’ is a physician’s room.

Conclusion

CAMPUS implements a new dimension of flexibility of a case-based, medical Web-based training system. It can be used by different user groups in different learning environments. Therefore, the effectiveness and efficiency of the time-consuming case data input has been improved. CAMPUS offers the chance to develop a case-database with well-structured multimedia cases to be used by students as well as educational staff (especially in problem-oriented curricula) who can use and - more important for the educators - reuse cases in several scenarios. A first prototype is available and is going to be integrated in the reformed medical curriculum at Heidelberg at least. A comprehensive evaluation is taking place in June/July 2000. An international version of CAMPUS is planned.

Evaluating the Effects of Web-based Collaboration in a Distance Education Program

Paul Rodes, Haejin Chung, Dennis Knapczyk, Carrie Chapman
School of Education, Indiana University, Bloomington, USA.

Abstract: To study the effects of asynchronous web-based collaboration in an existing video-based distance education program, the authors structured coursework to enable evaluation of differences in cognitive and emotional aspects of learning between those using web-based collaboration and those completing assignments through traditional independent methods.

Educators have increasingly recognized the important role collaboration can play in learning. Asynchronous web conferencing has been identified as a unique tool in promoting such collaboration, particularly when applied in distance education coursework [Knapczyk, Chung & Baik 2000, Moller 1998, Duffy et al. 1998, Bonk & Cunningham 1998, Ernest 1995, McMahon, O'Neill & Cunningham 1992]. In the past three years we have integrated web conferencing into our existing video-based distance education program at Indiana University to promote collaboration and ownership among learners [Rodes et al. 2000, Rodes, Knapczyk & Chapman 1999, Chung, Rodes & Knapczyk 1998].

While we have been pleased with the results of web conferencing in our program, we recognize the need to evaluate its effects in verifiable terms. In fact, although much has been written about the benefits of asynchronous web conferencing, few studies have been conducted to verify these findings. The education literature typically offers descriptions of programs and effects, with little controlled study or verification. Furthermore, little has been written on the possibilities of web conferencing when integrated with other distance education technologies. To address this lack, we have been conducting a study in Spring 2000 to investigate the effects of asynchronous web-based conferencing on both cognitive and emotional aspects of learning.

The Collaborative Teacher Education Project at Indiana University offers graduate-level special education coursework to cohort groups of teachers in rural Indiana communities. Classes are delivered via two-way video and are supplemented by e-mail, fax machines, and web-based conferencing using the SiteScape Forums web conferencing system [Knapczyk et al. 2000, Knapczyk, Rodes & Chung 1998]. In the Spring 2000 semester we offered a single course on behavior management to in-service teachers at six sites.

For the current study we divided our course content into four units. The independent variable of our study was the use of asynchronous web-based conferencing. For each unit, we developed two parallel sets of assignments and activities: one set was to be completed individually with collaboration taking place at the learners’ discretion; the other set was to be completed collaboratively in web-based learner teams. During each unit, learners at three sites completed their work using web-based collaboration, while learners at the other three sites completed their work using the “traditional” assignments.

To facilitate direct comparison, during every unit each web-based site was paired with a non-web-based site to meet for a video-based course once a week. In this way we ensured that the sites to be compared received the same instruction. After each unit the roles assigned to the groups were reversed. For example, learners in Tell City were linked each week with learners in Spencer in a video session originating from the IU-Bloomington campus where the instructors were located. For the first unit of the course, the Tell City group completed assignments in web-based teams, while the Spencer group completed assignments individually or using informal collaboration. For the second unit of the course, these roles were switched, and so on. By pairing sites in this way, by switching the assigned roles at the end of each unit, and by repeating this full cycle two times during the semester we aimed to minimize the effects of any differences among learner characteristics and environments across the different sites.
The dependent variables we have been investigating reflect both cognitive and emotional aspects of learning. We are evaluating the following three elements of content learning [Bloom 1956]:

- acquisition--through product evaluation and content-based tests
- application--through product evaluation and field reports from learners
- retention--through follow-up tests and surveys on content issues

In the emotional domain, we are using both immediate and follow-up surveys to evaluate learner satisfaction, which is a particularly important factor to consider in working with adult learners [Galbraith 1998].

A specific grading rubric was used to ensure uniformity of evaluation and to be sure products were assessed for issues of applicability as well as acquisition. To facilitate clear comparison, all surveys, testing, and product evaluation have been linked to the four individual units of the course. In this way we can compare the results at each study site not only to the linked cohort site using the opposite approach, but also to the results at that same site during other units, to track any differences as learners moved from web-based to non-web-based activities.

By completing this study we hope to have gathered reliable data on the effects and the effectiveness of web-based collaboration when combined with other distance education technologies. We anticipate that our findings will contribute to an understanding of the importance of collaborative learning and web-based conferencing in distance education programs, and for education in general.

Abstract: Edubox® is a system, built at the Open University of The Netherlands, that supports educational innovation processes in higher education. The system allows maximal flexibility in that it enables educational designers to model an instructional system completely after their ideas. In this paper the phases of the design, development and implementation of an instructional system are described with particular attention to Edubox®.

Introduction

Edubox® is a system, built at the Open University of The Netherlands, that supports educational innovation processes in higher education. The system allows maximal flexibility in that it enables educational designers to model an instructional system completely after their ideas, unhindered by implicit didactic beliefs similar systems often harbor.

An instructional system is here defined as the assembly of 'objects' that collectively assist a student in acquiring a set of learning objectives. At a more concrete level, an educational system features such items as people (e.g. teacher, fellow students, experts), tools (e.g. word processor, browser), knowledge sources (e.g. books, videos, cd-rom's), and activities (e.g. writing a paper, peer-assessing a fellow student).

Design Stage

Edubox® is able to provide the educational designer with such freedom and flexibility because it makes use of a didactic metamodel embedded in an Educational Markup Language (EML) - a generic XML-based language - as described by Koper (1999).

In principle, everything the learner or teacher will experience in Edubox® has to be modelled by the designer. In contrast with traditional electronic learning platforms it does not make any (implicit) assumptions (Onstenk & Meijer, 1998; Dabbagh, Bannan-Ritland & Silc, 1999) on preferred didactic scenarios, thus providing the designer with a didactic "clean slate".

Decisions on the Instructional System

The instructional system to be developed may be modelled at several levels: the micro-level (e.g. module), meso-level (e.g. course), and macro-level (e.g. curriculum). The designer has to make up his mind about the main level for...
his design activities. Subsequently, the designer has to opt for a pedagogic approach, taking into account several ingredients of his instructional system:

- educational objectives and prerequisites, (aimed at the acquisition of knowledge, skills, attitudes, competences, complex cognitive skills) and target group
- relations between the stated educational objectives, prerequisites and the structure of the instructional system
- the context in which the education takes place (roles, sources, instruments, on-the-job)
- situational experiences and domain specific information in education
- individual differences
- co-operation and collaboration
- communication
- the use of different educational materials
- assessment
- the kind of activities which have to be performed to assure learning processes
- the learning process and transfer processes passes off
- stimulating motivation
- sequencing activities

Decisions on the Delivery Medium

The educational designer has to make a decision on how the educational system will be delivered to the learners. For example: will the product be a book or will it be delivered on the Internet? Depending on this decision and the level of implementation of the instructional system, the designer will have to design a style sheet for the lay-out of a book or an entire graphical user interface (G.U.I.).

Development

Developing the Instructional System

In the development phase the whole instructional system has to be structured using the Educational Markup Language (EML). For specific pedagogical orientations (e.g. problem-based learning, case-based learning), ready made EML-templates may be available. EML knows the following main elements (Tab.1):

<table>
<thead>
<tr>
<th>element</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata</td>
<td>all general data concerning an educational object</td>
</tr>
<tr>
<td>roles</td>
<td>the different roles persons can have within an instructional activity</td>
</tr>
<tr>
<td>objectives</td>
<td>(learning) objectives which are related to an instructional system</td>
</tr>
<tr>
<td>prerequisites</td>
<td>prerequisites (e.g. in terms of knowledge, personal characteristics, instruments available to learner) related to an instructional system</td>
</tr>
<tr>
<td>content</td>
<td>all components (defined within the elements ‘activity’ and ‘environment’) which are conditional for the acquisition of (learning) objectives</td>
</tr>
<tr>
<td>activity</td>
<td>a stimulation of the learner to perform certain behavior</td>
</tr>
<tr>
<td>environment</td>
<td>components (e.g. tests, knowledge sources, instruments) which are conditional for the acquisition of (learning) objectives</td>
</tr>
<tr>
<td>method</td>
<td>structure, didactics and processes within an instructional system</td>
</tr>
</tbody>
</table>

Developing the delivery medium

In the development phase the necessary features for publication to the medium chosen during the design phase should be developed.

Implementation

Because of the richness of EML and the flexibility of Edubox®, different designers may implement similar ideas in very different ways.

Technological Tests of Educational Theories: A Research Role for the Generative Virtual Classroom

Dr. Lynette Schaverien
Faculty of Education, University of Technology, Sydney
PO Box 222,
Lindfield NSW 2070 Australia
Lynette.Schaverien@uts.edu.au

Abstract: Throughout history, technological advances have led to scientific breakthroughs. Computer-mediated learning environments have the potential to function similarly: as technological tests of educational theories. Here, this unexplored research role, for one such learning environment, is illuminated. The Generative Virtual Classroom, a web-delivered virtual classroom for teacher education, is demonstrated and preliminary research findings with respect to theory advancement reported. Some emerging implications for computer-mediated learning and for the generation of educational knowledge are discussed.

Cultural development is littered with striking examples of technological advances that have led to scientific breakthroughs. The successful building of European cathedrals provoked the development of a detailed engineering science (Bronowski 1973/1992). In our own time, pioneering brain-imaging technologies have brought important new neuroscientific insights (see, for example, Carter 1998 and McCrone 1999). Similarly, technological tools for learning, especially those designed on particular educational principles, ought to expose the worth of those principles. In action, such technologies may well constitute a potent and, as yet, unexplored research tool by means of which educational theorising can be advanced. In this work-in-progress paper, I explore this research role for one such technological tool for learning: the Generative Virtual Classroom.

The Generative Virtual Classroom

This paper begins by demonstrating the Generative Virtual Classroom itself, so as to elucidate its educational principles. Emerging from a series of classroom studies of learning and learning to teach (in particular, Cosgrove & Schaverien 1996 and Schaverien & Cosgrove 1997), this web-delivered learning environment attempts sophisticated computer-mediated teacher education in elementary technology-and-science. Its design embodies a generative view of learning in which learning is conceived as a generating and testing cycle (after Minsky 1986, Wittrock 1974, 1994 and Plotkin 1994, 1997). According to this view, learners generate ideas that they then test on their value, keeping those that survive their tests (Schaverien & Cosgrove 1999, 2000). In a nested pair of virtual classrooms (a virtual elementary one and a virtual tertiary one), Education students can develop their views of learning by observing exemplary learning by young children from an archive of pre-recorded digitised video excerpts. They can formulate their thoughts about these excerpts and communicate with others about them, considering others’ views of them, including, in particular, a generative view of learning. As an environment in which learners can develop a generative view of learning, in ways consistent with such a theory, the Generative Virtual Classroom is poised to be a powerful technological test of this generative theory itself.

Do Learners Learn Generatively in the Generative Virtual Classroom?

Already, pilot research conducted in the Generative Virtual Classroom affirms the fruitfulness of viewing learning generatively. For example, in a nine-month autobiographical study of the development of her views of learning in the Generative Virtual Classroom (Allard 1998), an Honours Education student was able to establish her conceptual progression, for herself, and to identify what she still needed to understand. On analysis, this student’s learning was well explained in generative terms; and, as well, on the basis of her experience, minor
alterations were able to be made to the learning environment itself. Such studies suggest the value of proceeding to larger scale tests of the worth of this theory. Consequently, a large-scale collaborative research trial of the Classroom is now in its beginning stages. In this trial, a full cohort of First Year Education students (n=100) has begun to work in the Generative Virtual Classroom, yielding early data on the nature of the learning of a diverse range of individual students over a semester. Students' text contributions to the Classroom's community database and e-mail discussion group will be collated, described and analysed for evidence of generativity, in an attempt to assess the worth of such a theory in making sense of what they did.

Implications for Computer-mediated Learning and the Generation of Educational Knowledge

Clearly, the recent proliferation of technologically mediated environments in which learners can teach themselves has brought new opportunities to explore the nature of learning. Even more recently, such writers, inter alia, as Alexander & McKenzie 1998 and Hannafin, Hannafin & Oliver 1997 have begun to insist that these new learning environments be explicitly grounded in educational principles. From these positions, it is a short but significant step to conceiving of computer-mediated learning environments as instruments for the testing of educational theories, an idea whose time has come. Once crystallised in these terms, such a research program has the potential to redress long-standing dissatisfaction with the apparent lack of theoretical progression in Education in particular (Thagard 1992) and in the social sciences in general (Ziman 1978/1991). The paper closes speculatively by discussing the implications of such a re-conceptualisation for computer-mediated learning and for the generation of educational knowledge.

Abstract: This paper draws on data gathered during a year-long ethnographic study of graduate education classes in a 2-way audio 2-way video distance education classroom. Cultural analysis of transcript excerpts indicating student reactions to their experiences in the technologically mediated classroom highlight the anxiety and confusion they experience in making the shift from the familiarity of traditional classroom culture to the uncertainty of a new, often strange environment. This transition phase in classroom cultures, what Turner (1969) calls the liminal phase, is a time of high anxiety but also of high learning. Our data suggests that instructors who take on the role of technology guide and provide students the opportunity to vent anxiety and learn about the technology, create environments that significantly increase the comfort levels of students and receive much higher ratings from them.

Introduction

Distance learning, via web based and two-way interactive video classes has changed the market areas of educational institutions from how far faculty are willing to drive to how far the Internet or phone lines will reach. Given this new global market, institutions of higher education are rushing to fill the niche. Students are recruited, new learning environments are created and faculty are suddenly asked to teach classes in front of computer screens and cameras. Although the literature encourages the use of instructional design principles when teaching this way (Moore & Kearsley 1996), in the rush to stake out new territory, such classes are often thrown together with little planning and less understanding.

According to Willis (1993), “research suggests that distance education and traditionally delivered instruction can be equally effective if the distance educator puts adequate preparation into understanding the needs of the student and adapting the instruction accordingly” (p. 22). But how does one do that? How can students and teachers anticipate their needs in a substantially new learning environment? Are these new learning environments traditional classrooms with a few technological add-ons where the assumption can be made that student’s needs are little changed? Or are they complex new environments that require descriptive and analytic illumination by researchers such that student needs can be assessed and then addressed? Our research suggests the latter.

It is our contention, that the situation people face in distant classes is, from a cultural perspective, radically different from the traditional classroom. The enculturation process that occurs during years of schooling solidifies in the learner norms for the role of the teacher, for methods of classroom communication, and for student interaction that lasts a lifetime (Henry, 1955). The entire dynamic of teaching and learning, which is deeply grounded in traditional classroom culture, is changed in complex and nuanced ways when the class becomes technologically mediated. The study on which this paper is based used the approach of ethnography and the perspectives of cultural anthropology (Geertz 1973) and social interactionism (Mead 1934) to uncover these changes in classroom culture and illuminate changes in the teaching/learning dynamic.

In this brief paper we can do little more than present fragments of interviews to show how descriptions by students of their distance education experiences and an awareness of traditionally based student expectations can
inform a deeper understanding of the needs of students. This understanding then becomes the basis for strategies that instructors can use to help learners through the cultural transformation process and to have more successful learning experiences.

The Study

The study is based on data gathered for an ethnographic case study of graduate education classes during the inaugural year of a 2-way audio 2-way video interactive distance learning classroom. Courses included in the study varied significantly in teaching style, course objectives, course content and student responses. Traditional ethnographic and qualitative research methods facilitated data gathering and analysis (Agar 1996; Maxwell 1996). Data gathering involved more than 400 hours of participant observations in classrooms, formal interviews and informal conversations with students and faculty, weekly e-mail correspondence, open ended surveys, focus group interviews, and video of all classes. Thematic coding, frequency counts, and frequent debriefings between ethnographers L. and R. Schmertzing contributed to interpretation and ongoing analysis of the data (Spradley & Mann 1975).

The Data

Excerpts of student comments from e-mails and interview transcripts introduce the complex culturally based issues that students face in the interactive televised classroom. All of the following passages were written by students in response to questions from the researchers regarding the students first night in the distance classroom. We will present the excerpts in the data section and comment on them in our discussion.

When I saw the room set up I was in shock, actually. It was my first interactive distance learning class and I walked into the room thinking "why did I sign up for this?" At the sight of all these different video screens and cameras all around the room, I didn't think that the grades would be the same. I thought they would favor the class that had the most physical interaction with the professor. I became sort of jealous of the other campus and resented the fact that she (the instructor) was there. I felt like I was at the main campus where the professor should have been. If the other class was at a branch campus, they should have primarily been in the distance learning aspect of it. My GPA is very important to me. I feel that the grade I earn will be affected by how much time I will have to spend watching her on a monitor. There were so many distractions, it was hard for me to stay focused. Also, there was so much zooming in and out with the video cameras, I honestly got motion sickness and walked out of class feeling sick to my stomach with a headache. I did not like it. The cameras were set up in awkward angles and you couldn't see the professor's head when she was talking. We got great views of the back of her head.

Many students made similar comments, although the attitudes of others were more like the following who noticed the difference but struggled to adjust.

I was really surprised at my reaction. I've taken a web-based class before and I have seen the equipment for this classroom before. I didn't think I would feel any different, but I did! I was surprised at how I looked on camera and feel that I will have to work on this so that it doesn't impact my participation. Also, I forgot several times, where to "look" so I would be facing the remote group when I "spoke". I also found that as the night wore on, I kind of avoided responding to questions 'cause I felt like I was monopolizing the session. I did like being able to "face" the other group and do not feel that the experience effected my learning. I found myself "concerned" about the remote site when we had a few technical problems and am concerned about the learning experience when the instructor goes to the other class and I am in the remote site, having to rely on the technology.

For some students the two-way audio/video class they participated in was an entirely positive experience. “After the first night of class I am totally satisfied with everything. I especially enjoy being able to take the class at this campus and am excited to have the opportunity to be a part of this class.”

Other students cited particular elements of the technologically mediated classroom that fed their anxieties and complicated their ability to focus in the classroom. “I’m just much more aware of asking questions and making contributions, because I have to do this mechanical thing.” The necessity to physically encounter technology in
order to participate in class confused students and contributed to a magnified concern for the value of their own comments. “You don’t have the ability to just sit there and say, ‘Wait a minute;’ you’re on camera now, you’re on air-time, and so if you have what you think may be a little question, you’re wasting class time [if you ask it].”

Discussion

The variation in student responses points toward the diversity and complexity in their perspectives. Students from each class all have different ideas about their experiences in their new classroom environment. They all, however, enter the classroom with an understanding of the way a traditional class works and quickly confront the differences. Students expect the classroom to look a certain way; they expect to focus on a teacher standing at the front of their classroom; they expect to have easy means to speak and be heard. When these culturally based expectations are not met, students are often left with a sense of anxiety and feelings of uncertainty. We found that complex technologically mediated interactions between learners, instructors, and content forced the re-construction of the way participants had previously “done class.” Learners, caught between the old way and the new way, moved through a liminal state (Turner 1969) to find a balance that provided enough comfort with the environment so that distractions were minimized and learning maximized. The student need indicated in this paper is the need to be guided through this liminal state, the need to be helped through the adjustment phase. In such a context, the new role for the instructor is as a guide.

Instructors that we observed to be successful guides used various strategies to speed up and enhance students’ adaptation to the new classroom. Students found balance more quickly when instructors recognized, articulated, and showed sympathy for the “awkward,” “uncomfortable,” “surprising,” “overwhelming” state of the learner. When instructors talked to their students in an “up front,” “understanding,” “sensitive,” (from student transcripts) manner about the strangeness of having class in the new environment, students were more responsive to instructions on how to use the technology to accomplish class goals. When learners were allowed opportunities to express their feelings about the environment without fear of repercussions, they appeared to overcome the added burden of “hiding [their] anxieties” about to taking a distance class and became more “willing” to work with the new technologically-mediated environment. The instructor who provided students the opportunity to “vent” through both class discussions and online threaded discussions achieved the highest rating for classroom interaction of all the instructors considered in this study and did so in the least amount of time.

The style, manner, and attitude an instructor established the first night of class was also a key factor in how long it took students to learn the technological system and for the ease and speed with which they learned to function effectively. First class meetings rated highly by students were those that were characterized as “fun,” “calm,” and “slow enough to understand.” Instructors who, in early classes, laid ground rules for communication, clearly and completely explained the technology of the classroom, gave students an opportunity to use the system in a non-threatening manner, and provided a thorough picture of what would be expected throughout the semester built bridges between participants and the technology. Once the bridge was built and the connection made, the environment felt “safer” and interaction took place more easily.

These are a few of the insights and strategies that have emerged from our analysis so far. We expect that our continued analysis will produce many more.

Introduction of a New Media Concept for a Teaching Profession Degree in „Computer Science“: A Formative Evaluation

Axel Hunger, Stefan Werner, André Bresges and Frank Schwarz
Gerhard Mercator University Duisburg, Department of Dataprocessing
Bismarckstr. 81, 47057 Duisburg, Germany
e-mail: {hunger | swerner | bresges | schwarz}@uni-duisburg.de

Abstract
Within the scope of the development of a new multimedia education concept for the teaching profession "Computer Science", the strengths and weaknesses need to be constituted already during the development-phase and weaknesses need to be eliminated if necessary. Therefore, the concept is examined within the formative evaluation on its tangibility and effectiveness.

The newly developed education concept, which was developed at the Gerhard Mercator University Duisburg under usage of new media, aims at creating new possibilities for differentiation and decentralized learning by a multimedia teaching and learning concept. The didactical new conception of the course is supposed to take the students different learning prerequisites into account. Thus, procurement methods are striven for that enable individual preparation, consultation and practice dependent on the students educational background.

Introduction
The teaching profession with the vocational field “Computer Science” at the Gerhard Mercator University Duisburg can be attended by students with different main subjects. Students can combine the specialized professional field “Computer Science” with different main subjects, e.g. mechanical engineering, chemistry technique or textile and clothing technique. So a teaching concept had to be developed due to the different bases in the information technical education of the different courses. It has to consider the heterogeneous foreknowledge of the students and offer according intensive procurement methods.

The developed concept is used in the basic course "Fundamentals of Computer Science" as first trial phase. The course covers topics such as the Boolean algebra or switching algebra, the technical implementation of logical operations, which are based on the Boolean algebra and finally the fundamental digital circuits and systems as well as simple digital computers, which are based on these operations.

The procurement of contents and the conversion of the quoted objective requires the completion of the course forms so far by means of a suitable concept on computer base and the transfer by means of multimedia technique. The interactive, multimedia teaching and learning software is set up in such a way that the different learning methods of the students are taken into account. Therefore, different points of entry are available for the software.

One entry point runs over the content structure, here the student can choose his learning path in accordance with the content of the lecture. The course so far included exercises for practicing and applying the taught methods. This exercise part is also integrated in a suitable form into the interactive learning concept. The second entry point clarifies the interaction between the acquired knowledge and the latter practice on the basis of a descriptive task. Thus, a learning goal oriented or res. a problem based learning is enabled. The student receives an course of action. A detailed description of the concept is given in (Schwarz, Hunger, Werner, 1999).

Initial Considerations for Evaluation
Sources of information that are available for a study group are on the one hand conservative sources such as books, scripts and patterns, the instructor and laboratory/experiment device. Additionally, fellow students also count as information source, since notes, sources of information and interpretations can be exchanged with them.
New media can take the place of an information source (book) and the place of an experiment device (simulations). It can also partly take over the role of a teacher, by answering standard questions and checking exercise results, as far as the exercises are machine controllable. Furthermore, new media creates more extensive communication possibilities (Dweck, 1988). The entire focus during the introduction of new media in complex, problem based learning situations is determined and already distributed on different learning tasks. The attention can not be increased by the introduction of new media! In the case of new channels being available, the individual must redistribute its bandwidth and thus its attention on the available channels. A rearrangement takes place on expense of other channels. Refocusing might lead to a favoring of channels due to improved accessibility of information through new media, which enables individuals to receive information more easily and thus the attention on other channels is encouraged. We can speak of a positive modification of the social behavior induced by introducing new media, if both possibilities deal with the channels which the individual use to interact with other members of the group.

Formative Evaluation

The concept is evaluated in several steps. In the first step, the teaching and learning processes are evaluated by observing and interviewing the participants. The experiences of students from different subgroups are of importance and thus raised in particular. The members of the group are interviewed by using a questionnaire. This questionnaire ranks important data through accordingly formulated questions on socio-metric matters for the 4 partitions of the theory model (economy of attention, social behavior, motivation control, accessibility of information). The behavior and movements of the user is recorded at the same time. Thus, it is to be determined, whether the mapped mental model is applicable on the learning group and whether weaknesses in the navigation and comprehensibility can be discovered. The results flow directly into the development. Furthermore, an expert workshop is set up in order to determine suitable scenarios of different emphasis. The expert workshop primarily consists of professors of the respective field.

The evaluation leads to the following results:
70 participants were interviewed, among them where 25% that use MODULO regularly. The participants hardly use MODULO for stringent reading, but rather for the direct search of information. This functions well to outstanding; students indicated that finding information under usage of MODULO is substantially better. The links between exercise and lecture were considered as helpful. The complex scenarios, which are supposed to clarify the application of knowledge in vocational practice, are considered less helpful for understanding the material. Most students rather find the scenarios helpful at ranking the material into vocational practice.

In a further step, a summative evaluation will take place after final completion in order to elevate the acquired knowledge of numerous years and using it for advancements of the concept.

Summary and Prospect

In this article a new concept for supporting the theory of the teaching profession course "Computer Science" and an appending formative evaluation was presented. The concept aims at media-technical editing of the disposition, the development of a training concept and the development and implementation of a WEB-database with dynamic access. This concept holds the advantage of being able to go into different needs, previous knowledge and learning methods of students, due its modular structure. It enables a self-controlled learning, promotes media competence and offers demanding possibilities of acting.

The first evaluation which accompanied the development of the system had positive results and constructive criticism. The entire system is to be completed by September 2000, so that the summative evaluation can be started in the winter semester 2000/01.

Art Department 
California State University, Los Angeles 
United States 
psemrau@calstatela.edu 
bboyer@calstatela.edu

Abstract: CSULA was charged with assisting the NSA in the research, development, documentation and the necessary expertise to convert a traditional face-to-face platform course to a multimedia web-based course. We converted a platform-based course taught by the NSA called "EEO 100: Equal Employment Opportunity Law and Diversity Training for Selection Boards." To accomplish the task, an interdisciplinary team of graduate and undergraduate students from Instructional Technology, Art Education, Computer Science, and Design collaborated on producing the website.

Constructivism

Recent studies in education have promoted the constructivist approach to learning "...where students develop their knowledge through team collaboration, discuss different interpretations of a problem, and negotiate and synthesize ideas drawing from various disciplines" (Boyer & Semrau, 1995, 14). Technology can play a significant role in this process by having students become more proactive in their own learning and more independent in their search for knowledge. Students using technology have access to ongoing real world problems, on-line dialog with scientists, and access to the latest technological advances. Ultimately, students will be engaged in their learning, see relevance in it, and take on an ownership in it. To meet the needs and interests of students, education must emphasize problem solving and application of information, instead of memorization of facts. Roberts et al state, "...students need to be able to find and use relevant information, share and discuss data and ideas, and collaborate on problem solving" (1990, 116).

Year One of Project

July of 1998, California State University, Los Angeles (CSULA) began a 3-year project sponsored by the National Security Agency (NSA) entitled "NSA Partnership with Cal State L.A.: Courseware Conversion and Evaluation Project."

CSULA was charged with assisting the NSA in the research, development, documentation and the necessary expertise to convert a traditional face-to-face course to a multimedia web-based course. CSULA students were selected to work on the project with a focus on collaborative group work and a constructivist approach to learning. An interdisciplinary team of graduate and undergraduate students from Instructional Technology, Art Education, Computer Science, and Design were brought together under the direction of two faculty members.

In this project we are converting to the web a platform-based course taught by the NSA called "EEO 100: Equal Employment Opportunity Law and Diversity Training for Selection Boards." EEO100 is directed to employees who serve or who may serve on boards, panels, or committees charged with the responsibility of
rating workers for selection purposes. The course is designed to provide participants with an understanding of the extent to which their rating activities are subject to applicable civil rights laws, and to appreciate the value and contributions of every candidate. Students after taking this course will be able to:

1. Understand the requirement for EEO 100
2. Understand legal rights and responsibilities for fair and equal treatment in the decision-making process
3. Gain a common understanding of "diversity"
4. Recognize "blind spots" and conditioning from society, and how these factors impact decisions
5. Provide a hands-on opportunity to improve the decision-making process
6. Appreciate the value and contributions of every individual

Training was provided to the CSULA student team on the basics of html, Adobe Photoshop, Premiere, and Pagemill in order for them to be able to undertake the task of courseware conversion to the web. They were also trained on the use of WebCT for developing the website, uploading of web pages to website, and designing of web pages. WebCT is an online Internet authoring tool for web-based courses. The students were guided regarding the overall layout and screen designs. For a foundation in working collaboratively in building a website the students first designed a demonstration site on streaming media—RealAudio and RealVideo. The demonstration site was developed for sharing our research and for communication among the students and project faculty. Focus was placed on developing an educational website demonstrating various applications of streaming video and audio in education as well as being a source of research data and instruction for creating streaming video and audio for web-based training.

The students investigated the hardware and software requirements for streaming media, selected examples of streaming video, and html coded web pages documenting their gathered data about streaming media and its role in web-based training. The WebCT course site also offered additional built-in communication features including e-mail, chat rooms, a bulletin board, and white board. Students used the bulletin board to provide help to each other and to assess each other's web pages.

For the foundational first part of our collaborative work, the students researched and structured their content on streaming media into the following sub-areas:

1. Introduction to Streaming Media
2. How Does It Work--Streaming Video?
3. How Does It Work--Streaming Audio?
4. Aesthetics of Streaming Video
5. Aesthetics of Streaming Audio
6. Educational Applications of Streaming Media
7. Our Examples of Streaming Video
9. About Us

Each student was charged with the design, structure, research, and development of one content sub-area.

Year Two of Project

During the fall, 1999 we moved onto converting the EEO 100 course content into a web-based course. We followed the pattern established in the prior year where each student was assigned full responsibility for the research, design, development, and coding of a topic. The EEO 100 content was subdivided into the following main topic areas: Current requirements, additional requirements, definitions of discrimination, disparate impact, harassment, affirmative action review, and tools. Each student studied and learned the EEO 100 course content and was then individually tested on it. In the process of understanding the content, they realized that it would be necessary to rewrite and revise the content, as well as integrate multimedia to accommodate a web-based learning environment. Next they html coded the EEO 100 course content and thus begun the creation of the web-based course. One of the students developed the screen design incorporating American Disabilities Association (ADA) guidelines.
They developed new test items for the content. They researched websites and selected appropriate ones related to the content and created external links to these websites. We designed draft layout for structuring the menu and content. And, we investigated, selected, and adapted a quiz format for use in this website to set up pop quizzes that were integrated within content areas.

In the winter of 2000, the students analyzed a video that was a tape of an original face-to-face traditional approach to teaching the class, which was provided by the NSA. They made a list of the video clips matching the content they were responsible for. Before we started digitizing the content, we inspected the length and filesize of each video clip to determine how to reduce the size of very large clips. We came up with several solutions which included digitizing only the audio for certain clips and accompanying the audio with still diagrams of key points and cutting up the longer clips in to shorter segments. Next the students captured the video using Adobe Premiere and the Osprey 100 video card in a Dell Precision 401 computer. They edited down the clips using Adobe Premiere. The audio was captured and edited with SoundForge. Next, the clips were streamed with RealProducer and html coded into their relevant web pages of content.

To polish off the interface design, we brought on an art student who was charged with developing an easy to use menu of topics and navigational system.

In the spring of 2000, it is our intent to synthesize various course components (content, video, test items) into a final course website and to design visual learning aids (diagrams, charts, and pictures) and tools (glossary, law books, and court cases) to enhance learning of the course content. We are preparing to design and incorporate simulations into the website. NSA has been encouraging and supportive of this idea as an extended project.

Conclusion

The new web-based version of this course will make the content accessible to more NSA employees located in various places throughout the world. Plus, the online version will include interactive pop quizzes with immediate scoring and feedback as well as streaming media lectures to complement the course content, which is presented as text on the web pages.

Through this project the students became constructively involved in their own learning and have acquired in-depth experiences in collaborative learning. The students became empowered to be creators of their own curricular materials and web pages instead of being passive viewers of others'. In this project all of Bloom's higher level taxonomies are implemented. Students are analyzing websites, synthesizing criteria that they have researched, applying their book readings, comparing and contrasting their criteria, designing and producing their own web pages, and more.

The Internet Chemistry Set:  
Web-based Remote Laboratories for Distance Education in Chemistry

Frederick A. Senese  
Dept. of Chemistry, Frostburg State University, USA (senese@antoine.frostburg.edu)

Christopher Bender  
Dept. of Chemistry, Frostburg State University, USA (bender@antoine.frostburg.edu)

Abstract: The convergence of modern data acquisition technologies with the Web's interactivity, connectivity and multimedia capabilities presents an exceptional opportunity for distance education in the physical sciences. Web-mediated access and control of laboratory equipment can improve utilization of expensive and specialized instruments, facilitate collaborative data sharing and analysis, and provide essential practical experience in physical science courses delivered at a distance.

This paper describes a remotely controlled experiment for determining the rates of fast chemical reactions. The experiment is not a simulation; it involves actual equipment controlled in real time from remote locations on the Web. The experiment is the first in a series designed to provide a pedagogically on-line laboratory experience for Web-delivered general chemistry courses. Students use the experiment's Web interface to collect data, to obtain interactive technical support and background information, and to display and analyze results. Each experiment is designed to encourage sharing of data and collaboration with users at other institutions, providing students with a valuable first look at work in a distributed laboratory environment.

Introduction

Chemistry is an experimental subject. Chemists construct knowledge by systematically examining quantitative data for patterns. Patterns suggest hypotheses, which in turn form the basis for theories. Theories are then critically evaluated in the light of new experimental data. This is the only sanctioned approach for progress in science. Pedagogy that is not founded on the interplay between theory and experiment poorly serves students by not involving them in the essential process of science.

The experimental nature of chemistry presents severe challenges for teaching the subject at a distance. Many current online chemistry courses either have no laboratory experience at all or use simple kits or 'kitchen chemistry' experiments that can be performed with household materials. Obtaining accurate, quantitative data from which relevant and interesting conclusions can be drawn is difficult with such simple equipment.

Online chemistry courses often make heavy use of simulations. While simulations can be quite effective, they are theoretical constructs that cannot substitute for practical experience. For example, students regarded the output of simulations in a statistical analysis experiment at Oxford University as "pretend" data (Cartwright, 1998). They sometimes failed to carry over the lessons learned from analyzing simulated data to data collected in actual experiments. Concerns about the pedagogical quality of the simulations were addressed by the development of a simple, economical "optical rig" (Cartwright, 1999), which allows students to collect and analyze actual data over the Internet.

This project addresses the problem of practical experience in Web-delivered courses by providing students with remote access and control of real equipment. A remote-control reaction kinetics experiment suitable for chemistry students at the undergraduate or advanced secondary level is described. The apparatus monitors the course of a fast chemical reaction spectrophotometrically using a simple continuous-flow method. Students can use the data they collect to determine the rate laws for the reaction under a variety of conditions. By collaboratively analyzing the results of a large group of experiments performed by peers, students can propose mechanisms for the reaction. While the experiment is conceptually quite simple, it involves specialized apparatus that is unavailable in most undergraduate laboratories. Rapid data acquisition can allow many users to perform experiments in real time, and
nearly spontaneously.

Method

The experiment is an adaptation of a classic continuous flow method for studying the rates of fast reactions (Dalziel, 1953; Roughton & Chance, 1963). The apparatus can be used to determine the rate of any sufficiently fast reaction that produces a colored product, although practical considerations limit the choice of reaction (Shoemaker, 1974). Pilot investigations studied the formation of FeSCN$^{2+}$ (an orange complex that absorbs at blue light at 455 nm) and "Prussian blue", an intensely colored complex used in blueprinting, paints and inks (Sharpe, 1976).

A schematic diagram of the apparatus is shown in (Fig. 1).

Reactant solutions are forced from large reservoirs into a T-shaped chamber, where they mix completely in less than 1 millisecond. The reacting mixture then travels down a long capillary tube. The product of the reaction is intensely colored and strongly absorbs a characteristic wavelength of light. Product concentration rises as the mixture moves along the tube. Seven light sensors placed at fixed positions along the tube monitor the increase in concentration. Monochromatic light is passed through the capillary at each position using a fiber-optic cable. High sensitivity photocells placed on the opposite side of the tube record the intensity of transmitted light at each point; the intensity drop caused by absorption of the light by the complex is simply related to the concentration. A flow rate sensor allows the position of each of the spectrophotometers to be associated with a reaction time.

Data from the sensors is acquired by "sanzone", a 500-MHz PC equipped with a National Instruments data acquisition card. A LabView program collects, labels, and writes the absorbance, temperature, and flow rate data to an "outgoing" queue. The program then checks for requests in an "incoming" queue. If one exists, a new run is started. Otherwise, the system is flushed and the valves are closed to avoid unnecessary waste of reagent solutions.

A Webcam collects pictures of the apparatus during the run. The camera view includes the reservoir manometer and a digital thermometer, so it is used for data collection as well as for helping students monitor the progress of the reaction. The Webcam is attached to a second PC to avoid contention.

A Unix Web server (Marie) mounts Sanzone's hard drive across the local network. Perl scripts running on Marie fetch data from the outgoing queue, interpret it, and prepare the results for display.

Students perform the experiments via a "smart" instrument panel served from Marie, displayed in a standard browser. The instrument panel recreates the actual look and feel of the remote experiment. Operators immediately see the results of their actions via the Webcam, as well as on a rich data display. The panel's panic button launches a conferencing connection with the system's caretaker via Netmeeting during working hours and by email at other times. The panel monitors and interprets student activity to diagnose and correct conceptual problems and to prevent
actions that could damage or tie up the apparatus for long periods of time.

The instrument panel front end is implemented in JavaScript and Macromedia Flash. When students submit a run from the instrument panel, backend Perl scripts label and process the request and write it to an "incoming" queue on Sanzone and the expected time of completion for the job is displayed on the panel. Jobs complete within a few seconds when the incoming queue is empty. Queues are intelligently managed by consecutively scheduling jobs with similar operating parameters and by assigning lower priority to non-local IP addresses (to prevent 'walk-in' users from monopolizing the experiment).

Future versions of the experiment will allow students to manipulate additional parameters, such as reagent concentrations, pH, temperature, ionic strength, and flow rate. Data from different groups can then be pooled and analyzed. Students will then use these results to evaluate proposed mechanisms for the reaction. Further developments will be outlined on the project home page at http://antoine.frostburg.edu/chem/senese/inetchemset.

A Distance-Learning Model Based on Web Mining

Ruimin Shen
Qijun Wang
Dept. Of Computer Science and Technology
Shanghai Jiaotong University, Shanghai, 200030, P.R.C
Email: rmshen@mail.sjtu.edu.cn

Abstract: Distance-Learning based on WWW has become a trend for the development of education. But the distance-learning site based on WWW is static, the designers of the courses don't know whether the design of courses is rational or consistent with the teaching law. While there is a lot of students' information accumulated in the web site, and the information is useful for our course designers. In this study, we present a distance-learning model based on Web Mining, which can take advantage of those students' information accumulated in the web site.

1. Introduction

Distance-learning based on WWW has become a trend for the development of education. The available distance-learning model based on WWW is discussed in (Xuejun Li 1999). But recently the distance-learning site based on WWW is static, and the designers of the courses don't know whether the design of courses is rational and consistent with the teaching law. While there is a lot of students' information accumulated in the web sites, such as students' access patterns and registration and communication data information, and these information is useful for our course designers and teachers.

In this study, we present a distance-learning model based on Web Mining, which can take full advantage of those students' information accumulated in the web sites.

2. A Distance-Learning Based on Web Mining

The model integrates the Web Mining technology into the available model base on WWW. It's architecture is shown (Fig.1). In this model, we add the Web Mining module into the available model. The Web Mining model is located in the server-side and performs in the server-side.

According to our special system for distance learning, the Web Mining process as shown in (Fig.4). The Web Mining module has three phases (Robert cooley et al. 1998): Preprocessing(Yilin yang et al.1999), mining process and pattern analysis.

3. Conclusion

Our model has following points: The course designers can reconstruct a Web sites in order to better serve the needs of students of a site according to these information such as the students' access patterns and page access frequency statistics; it can provide individualised page or different course content for individual student; and it can provide teachers the students' feedback, and teachers can redesign their teaching plans, too.

Introduction

The aim of this paper is to illustrate and demonstrate the value of a user-centered method for CALL systems development. We accept the argument of Hubbard (1996), Levy (1997) and other the deficiencies of current CALL system can be attributed to the lack of a systematic methodological theory guiding their design. Accordingly, a CALL design method has been developed which draws on recent developments in the field of human-computer interaction regarding scenario-based design and prototyping in relate to the user-centered design of computer-based learning material.

Scenario-Based Prototyping

The main features of the method include the use of scenarios to identify user requirements (Carroll, 1995), the development of prototypes embodying key design issues, and a series of formative workshops to evaluate the prototypes. The overall results confirm the general validity of the user-centered, scenario-based methodological approach.

There were three cycles of prototyping process in this research. Each cycle was based on a set of User Satisfaction Scenarios. The scenarios were used to build prototypes in two different ways: user dissatisfaction scenarios were used to define existing problems that have been found from the current CALL products; and user satisfaction scenarios were used to clarify possible problems that could be found in the CALL product to be built. A template for scenarios is proposed for the educational environment. The template include the user environment (i.e., age, school, class, user's conception toward CALL system, motivation of using CALL software, software type), learning environment (i.e., classroom, self-studying, group-studying), and narrative user interaction scenario to define features user satisfied/dissatisfied. Overall, this paper is to suggest the method of use of scenarios explicitly for designing CALL systems, not to show the results of prototypes which have been constructed and evaluated.

Developing prototypes is an integral part of iterative user-centered design process because it enables designers to try out their ideas with real users and to gather feedback. There were three major cycles of prototyping process with different prototypes embodied different design issues, which is based on user-satisfaction scenarios. The main design issue of the first prototype systems was to find how user-control could affect to achieve high quality CALL systems in terms of both educational and technical value. Two comparative systems were built for this initial stage: one was a high user-control (learner-based) system, and the other was a low user-control (teacher-oriented) system. According to the feedback from a series of formative user workshops, it has been found that the effectiveness of user-control were dependent on learners'...
experience in CALL systems and their learning environments. Based on the feedback from the first workshops, the user satisfaction scenarios were revised to find the design issues for the second prototype.

The second prototype system was a hyperlink system between three different systems: Tutorial system for listening skills with low user-control, Main Lesson system for practicing listening skills with high user-control for experienced users, and a sub-system called Speaking Dictionary to provide learners linguistic help. The user response about the hyperlink system was that it would be better to have a different user-control by learning stages concerning user experiences. Users also showed positive opinions about the user satisfaction scenarios because they agreed that scenarios make it easy to visualize the real-world environment and to comprehend users' perspective toward CALL systems. On the other hand, users responded that learners need more support to control their learning process more effectively.

Therefore, the third prototype constructed was focused to investigate the effectiveness of Teaching Agent to support learners' learning process with respects of HCI aspects and educational achievement. At this stage, we argue that TA should have domain knowledge (i.e. English), Training knowledge (i.e. listening skills), and Specific pupil knowledge. Here, the specific pupil knowledge is the most significant to advise learners what to do next. While the knowledge of domain and training are static and independent on student or teacher, the knowledge of specific pupil depends on followings: how well is the learner doing?; what listening skills have been used?; what personality does the learner have?; and what is the learning goals? The TA system called Magic Mirror has been developed to apply those aspects based on the revised user satisfaction scenarios, in which learner personality and learning goal of specific pupil knowledge were not considered. The result from the third workshop with teachers was positive towards the concept of TA in general, but some teachers questioned how TA could act as a substitute for a teacher. On the other hand, learners showed more positive attitude towards the TA because they compared the TA with Help functions in other CALL system, not with their teachers. The conclusion is that TA could make CALL systems more effective if all the aspects of the specific pupil knowledge are regarded on the development.

Conclusion

The essential elements of this user-centered method for designing CALL systems are scenarios, prototypes, and formative workshops. Prototyping helps designers to make user-oriented decisions by eliciting information from the formative evaluations of users, and scenarios are useful to articulating new design concepts like TA. In HCI practice, *scenarios of use* are increasingly being used to help set overall design objectives for guiding various aspects of the design process. Carroll (1995) argues that if we believe the scenario approach to be a valuable enhancement of current development practice, we must ask how the use of scenarios in system development can be evoked, supported, and brought to bear on various activities within the system development cycle. Overall, this user-centered method is very effective regarding the following aspects. Firstly, Scenarios are used as a bridge between designers and users to define learners' or teachers' needs and learning environment in order to achieve learning goals. Secondly, prototypes are used to apply design issues and to demonstrate the expected learning environment concerning pedagogical value. Finally, user workshops are held to investigate user satisfaction to evaluate design issues and principles in terms of both technical and educational value.

Abstract: Design of electronic books should take into account the diversity of learning styles, intelligences and preferences of each user. This project main aim is to provide high level of electronic book interaction and flexibility by matching different categories of electronic pages (graphic page, talking page, hypermedia page and web page) to the different learning styles. Each page exhibits programs and activities that attempt to cater for each learning style. The same content in each page will be presented in four different presentation modes. In addition to the technical system development, a conceptual model of children's electronic textbook will also be proposed. This model is based on Howard Gardner's theory of Multiple Intelligences and Philip Barker's generalization of electronic books model.

Introduction and definition of electronic book

Educational environment stresses the importance of reading materials: textbooks, reference books, encyclopaedias, magazines and newspapers as media of knowledge carriers. Hence converting printed publications especially textbook into interactive electronic form should prove to be extremely useful and helpful. There are various definitions of electronic book (e-book). Bonime et al. (1998) described any kind of information ranging from a CD-ROM title to an online interactive database including collection of web pages as electronic book. Barker (1998) defined e-book as essentially a computer-based information storage that embeds a book metaphor. More precisely (Barker, 1999), e-book is usually considered to be composed of a collection of reactive pages of electronic information that are organised in a thematic way and that exhibit many of the characteristic features and properties of a conventional book. Barker categorises e-book into ten types depending on the types of information embedded: textbooks, picture books, talking books, moving picture books, multimedia books, polymedia books, hypermedia books, intelligent books, telemedia books and cyberbooks. While Barker categorises ten types of e-book, Landoni et al. (1993) classified e-book according to three different criteria: books which are portable (e.g. personal digital assistant), books which preserve the logical structure (i.e. chapters, sections and subsections) and lastly, books that support both the physical and logical aspects of a paper book. In context of this project, definition of an e-book will be defined when the study is completed.

Research Question

Children learn in different ways. There are many theories on how people learn and one example is the Multiple Intelligences (MI) theory proposed by Howard Gardner (1993). This theory states that there exist seven intelligences (thus seven learning styles): verbal/linguistic, logical-mathematical, visual/spatial, bodily-kinesthetic, musical, interpersonal and intrapersonal and intrapersonal (to date, two more intelligences have been added). Based on this theory, Armstrong (1994) wrote a book on how to apply this theory into the classroom environment. He identifies that each child could learn in any one of these ways or through a combination of several ways. With these different learning styles, design of e-books should take into account these diversity and attitudes of each user particularly young children. Thus, one question can be extracted: how to give young children better flexibility so as to cater their differences?
Proposed Solution: Giving E-Book Flexibility

There are many methods to give flexibility in e-books. One example is by providing tools or facilities, which can be used by users while consulting the e-book. Landoni et. al (1993) in her project provided users with facilities such as personalisation (highlighting, bookmarking, note taking), searching through TOC table of content and index, and printing. Other examples include providing system adaptivity, supporting for group-based learning, considering the likelihood that teachers will use the program in class and including different levels of contents in the books.

It is the intention of this ongoing project to suggest that another method to achieve flexibility is through flexible presentation modes that include programs and activities which match each learning style. The following gives few examples on how to match MI theory to the existing e-book model:

(a) Verbal/linguistic – Is matched with e-book concept of hypermedia page through programs such as letting users create essays, read aloud and include storytelling.
(b) Visual/spatial – Is matched with e-book concept of graphic page through programs such as letting users draw and paint and allowing users to read and see information as graphics, maps, charts and diagrams.
(c) Musical – Is matched with e-book concept of talking page through programs such as combining stories with songs and letting users sing along.
(d) Interpersonal – Is matched with e-book concept of web page by including programs, which need two or more users at the same time and group project or discussion.

Proposed electronic book model

Page = Contents + [Object A + Object B + Object C + Object D]
Object A = Graphic page + {Program G1 | Program G2 | ... | Program Gn}
Object B = Talking page + {Program T1 | Program T2 | ... | Program Tn}
Object C = Hypermedia page + {Program H1 | Program H2 | ... | Program Hn}
Object D = Web page + {Program W1 | Program W2 | ... | Program Wn}

Conclusion

In conclusion, our e-book shall exhibit four different concepts and include a number of presentation modes and styles, in order to provide readers with a high level of flexibility. Users can choose between the four different presentation modes when he/she opens any page. Upon completion, this project will be used to prove these assumptions:
H1: It is possible to address diverse learning styles by providing users with flexible presentation modes of each page.
H2: These flexible presentation modes are probably more appropriate to use and as such give e-book high level of flexibility.
H3: It is then possible to suggest that due to this high level of e-book flexibility, users are more likely to prefer this type of e-book.
H4: If H1, H2 and H3 are proven, then we could postulate that an additional desirable feature for e-book would be to present contents by mixing many presentation modes.

What Is So Revolutionary About The Internet In Education?

Peter B. Sloep, Ellen Rusman
Educational Technology Expertise Center, Open University of The Netherlands
The Netherlands
peter.sloep@ou.nl; ellen.rusman@ou.nl

Abstract: The Internet is making inroads into almost all quarters of our society. Education is no exception to that, nor should it. Exciting new ways of building content, of delivering it, of interacting with our students, indeed of managing our educational ‘industry’ can be seen to evolve. Even if one may not wholeheartedly support all these innovations, particularly for all those with an inquisitive mind it is inspiring to see education being rethought in so many and fundamental ways. Or is it?

The Internet revolution clearly is a technological revolution. It pushes developments in various fields, education being no exception to that. However, are the new technologies used to innovate education, that is, to bring about a genuine transformation; or do they just substitute older technologies for new ones?

An educational model that is widely implemented these days - although it doesn't alway go by this name - is that of the extended classroom. As the name suggests, an extended classroom takes the ordinary classroom as its starting point and extends it, mainly spatially. So the dominant didactic model here still is a teacher who addresses a group of students; students and teacher are simultaneously present; the teacher takes the lead; students may ask questions but those only serve to clarify the exposition of the teacher; students seldom interfere with the choice of content, which is the teacher's exclusive realm; students hardly ever have a say in the didactics used, this also is the teacher's prerogative. In the extended classroom, teacher and students may be in different locations, the distance being bridged by television, videoconferencing, audiographics and similar technologies. Put extremely, with the extended classroom one aims to mimick a regular classroom to the largest possible extent. Hence the call for ever larger bandwith, for systems that allow for 'natural' interactions between the teacher and the remote classroom, etc.

However cleverly designed our communication systems, however large our bandwidth, extended classrooms will always be second best, a substitution for the real thing, only useful as a means to reach out to the remote student, perhaps to serve larger groups of students and achieve some economy of scale. Lecture notes that are being put on the web as a service to the students, or e-mail and newsgroups that deliver additional support only serve to underline the main conclusion: in the extended classroom technology is used to substitute or augment existing teaching modalities.

Obviously, there is nothing inherently wrong with this. Technology is a means to an end and should be used accordingly, that is, how we see fit. However, if it is our lack of imagination or if it is the rigidity of our institutions that prevent us from using technology in more creative ways, then we should not rest content. We should reexamine our educational practices and ask ourselves to what extent they were limited by existing technologies and to what extent the new technologies empower us to innovate. And indeed, it is our claim that we only stand at the beginnings of truly innovative educational practices and genuinely new didactic principles.

Distributed learning is a term that is often used in this context. In distributed learning systems, there are no classrooms anymore, no teachers offering students prepackaged chunks of education carefully aranged to conform to the needs and capacities of the average student. Students now occupy center stage, assembling and arranging content that fits their specific needs; they take it in in when and where it suits them best, perhaps in a didactic style that optimally matches their learning style. The role of the teacher now is not communicating knowledge, but to make it available, to empower students via intakes and assessments and help them assimilate knowledge, to offer custom support. In distributed learning, technological innovation is not the push behind educational innovation, as is the case in the extended classroom. Rather, the converse holds true, educational
innovation pushing technology. And indeed, distributed learning requires specific technologies that extend beyond the mere facilitation of communication. Technologies are needed for creating learner centered content, for the delivery of such content, for flexible intake and assessment procedures, for portfolio management, etc. In our presentation we will discuss these technologies at some length.
Online Mentoring: A Case Study Involving Cognitive Apprenticeship and a Technology-Enabled Learning Environment

Kathleen Snyder, Applied Learning Sciences, IBM T.J. Watson Research Center, U.S.A.
ksnyder@us.ibm.com

Robert Farrell, Applied Learning Sciences, IBM T.J. Watson Research Center, U.S.A.
robfarr@us.ibm.com

Norma Baker, Project Executives Programs and Support, IBM Global Services, USA
njbaker@us.ibm.com

This paper describes a study aimed at investigating the impact of a technology-enabled training program for Project Executives (PEs) in the IBM Corporation. The program is focused on a mentoring approach to learning whereby PEs considered to be experts in specific skills coach less experienced colleagues in the development of critical skills. Since job demands prevent ongoing face-to-face mentoring relationships, technology which enables collaboration at a distance is implemented to support the mentoring relationship. Of interest in this study is the effectiveness of instructional design approach, the impact of the technology-enabled learning environment on sustaining mentoring relationships, and the nature of online discussions between experts and students.

IBM PEs are responsible for managing large information technology contracts. These professionals deliver on commitments to customers, ensure customer satisfaction, secure business opportunities, and mentor other project executives. Their role of mentor is critical to the professional development of less experienced colleagues. While traditional face-to-face mentoring is desired and encouraged, job demands often prevent mentors and students from sustaining the type of relationships needed for the transfer of critical skills.

In the current study, a combination of face-to-face instruction and a technology enabled learning environment is used to develop and sustain mentoring relationships among expert PEs and less experienced colleagues. The face-to-face instruction includes a two day workshop consisting of five sessions led by the expert PE’s. The purpose of the workshop sessions is to 1) initiate a mentoring relationship among expert PE’s and a group of colleagues and 2) to begin the mentoring process which includes the transfer of a specific set of problem-solving skills.

At the conclusion of the workshop participants are introduced to e-mentor, a Lotus Notes discussion database which can be accessed using a Lotus Notes Client or a Web browser. The discussion database is used to provide an online learning environment in which the mentor-protégé relationship is preserved. Mentors post mini-lessons on topics relevant to the development of complex problem-solving skills needed in customer situations. Participants respond to the lessons in discussion format, post questions and collaborate with one another in solving customer problems. Mentors are available to assist participants with appropriate strategies for addressing customer problems.

The instructional design approach used in the workshop and online is based on cognitive apprenticeship, an instructional approach developed by Collins, Brown and Newman (1989). Cognitive apprenticeship focuses on the development of higher level thinking skills such as problem-solving. Because of its focus on the teaching of cognitive and metacognitive knowledge, cognitive apprenticeship may be a more appropriate instructional design model for online mentoring than more traditional instructional designs such as a lecture approach. Whereas text and lecture-based instructional design models focus on teaching concepts, facts, and procedures in non-situated environments, cognitive apprenticeship focuses on teaching the processes and strategies used in expertise and how this knowledge is used to solve real-world problems. Snyder (2000) demonstrated the effectiveness of cognitive apprenticeship as an instructional design approach for teaching technical skills in an online environment.

Collins, Brown, and Newman (1989) and Collins (1991) identify four aspects of cognitive apprenticeship learning: content, instructional methods, sequencing of instruction, and sociology. Content refers to the
different types of knowledge required for expertise and includes domain knowledge and strategic knowledge. Domain knowledge consists of concepts, facts, and procedures; strategic knowledge refers to knowledge which underlies an expert's ability to make use of concepts, facts, and procedures to solve problems.

Instructional methods are the learning activities used during instruction to help students construct, use, manage, and acquire new knowledge (Collins, Brown, & Newman, 1989). Seven instructional methods are recommended. These methods include teachers "modeling" skills, "coaching" learners as they attempt to mimic expert skills, providing "scaffolding" in the form of support for learners, and gradually "fading" support, as learners become more proficient. Learners are also encouraged to "articulate" their knowledge, "reflect" on their problem-solving processes, and "explore" new approaches to problem solve on their own.

Sequencing involves the staging of learning whereby tasks are presented in increasing complexity and diversity so that students develop a broad understanding of the domain of expertise. Sociology deals with the authenticity of the learning environment. Technological, social, time, and motivational characteristics of real-world situations are designed into the learning environment so that students will learn when, where, and how the knowledge applies to other situations (Collins, Brown, & Newman, 1989).

The PE workshop in this study and the e-mentor database are designed to incorporate the four aspects of cognitive apprenticeship learning. In the workshop, learning takes place in the context of solving a variety of real-world complex customer problems. Mentors begin sessions with an introduction a complex customer problem. Facts and concepts about the customer environment are presented (domain knowledge) and followed by modeling of the strategies and processes used to solve the problem. During this activity, mentors use think-aloud protocols to model the strategic thinking required to solve the problem. Next, tips and techniques (scaffolds) for remembering the processes and strategies are provided to students. Students are then assigned to small teams of six and work together to develop a solution to an existing customer problem. The problems used in this exercise are real-world and are brought to the workshop by students. Students are required to articulate the processes and strategies used to address the customer problem and then briefly explore alternative approaches to problem-solving. At the conclusion of this exercise, mentors model their thinking with respect to solving the team problems. When the two-day workshop ends, the mentor-protégé relationship is maintained using the Lotus Notes discussion database. Workshop participants use the database to request help from colleagues and mentors regarding problems experienced in the workplace. Mentors use of the cognitive apprenticeship method when responding in the online environment.

The results of this study to date have been successful in that this combination of face-to-face and online mentoring has enabled a community of IT executives who are geographically dispersed to form working relationships and share knowledge on a regular basis. This model has also provided participants with an environment for continuous learning on a just-in-time basis, convenient to their demanding work schedules. The instructional design approach has been notably successful in providing an effective way for PE's to learn new skills. Participants in the workshop quickly adopted the habit of thinking about problem-solving from a strategic perspective (that is, identifying the processes and strategies needed to solve customer problems and using reflection and exploration techniques before identifying a solution). This learning approach has also provided a common ground for PE's to work together to solve customer problems. Results of a survey administered to participants of the workshop indicated high ratings with respect to the methods fostering working relationships among PE's, the value of the content of the workshop, its structure (instructional design approach) and the value of the e-mentor database in providing a continuous learning environment which facilitates collaboration.

An Online Environment that Scaffolds Moving from Novice to Expert Collaborative Learners

Brigham Young University

Abstract: This work-in-progress paper describes a pedagogical approach to designing an online collaborative learning environment that scaffolds learners in becoming better collaborative learners. This environment is based on Collaborative Problem Solving (CPS) instructional theory. The paper will overview the need for the environment, and the design principles used to design and develop it.

Need

As online education becomes more prevalent as a system for distance education, a need arises for an online structure that supports instructors and learners engaging in small group collaborative problem solving or project work at a distance from one another. Particularly, there is an increasing need for online learning environments that support effective, efficient collaborative processes, such as those used by expert group problem solvers.

When online environments impose restrictive structures or do not account fully for these processes, they may hinder the flow of learning, and curtail effective, efficient problem solving. Most online environments that attempt to use collaboration as a learning strategy incorporate a smorgasbord of communications technologies that are not structured according to research into the most effective ways to scaffold effective collaborative interactions. Furthermore, the applications included in these systems (such as email, threaded discussions, and file storage) are generally lower-level communication tools as opposed to tools that could support robust collaboration. Because they do not use a guiding theory that is pedagogically based, the resulting interaction often do not adequately address the social, intellectual, and logistical complexity of effective collaborative learning. This is partially due to the fact that until recently, no comprehensive theory capable of support effective online collaboration existed.

Specifically, the weakness of these approaches is their primary reliance on a document-based paradigm (such as Lotus QuickPlace or Hyperwave), conferencing-based paradigm (such as Microsoft NetMeeting or Lotus Sametime), or room-based paradigm (such as BioMOO or Diversity University) (Miao, Fleschutz, & Zentel 1999). For the design to fully support a cohesive collaborative learning approach, the strengths of each of these approaches must be synthesized into a context-based system that allows for a more flexible combination of people, places, tools, documents, and interactions than these other types of systems afford, thus providing robust support for the communication, collaboration, and coordination necessary to learn effectively as a small group.

Proposed Solution

We propose to design, develop, implement, and evaluate an online collaborative learning environment that both supports pedagogically sound instruction and provides appropriate scaffolding for moving learners from novice
to expert collaborative learners. It will be based on Collaborative Problem Solving (CPS), an instructional theory designed for effective, efficient small-group problem solving (Nelson 1999). This theory outlines a detailed collaborative learning process derived from a series of carefully documented case studies of expert learning groups integrated with findings from current research in areas such as small group dynamics, cooperative learning, and problem-based learning. The goal of this theory is to provide step-by-step scaffolding to both instructors and learners that will help learners make the difficult transition from novice to expert collaborative learners.

Unlike existing tools that merely provide a collaboration platform, this online system will be designed to serve as a robust teaching and learning environment that will provide guidance for both instructors (in designing their instruction and in appropriately monitoring, supporting, and assessing the learners’ progress) and learners (in developing effective collaborative skills while learning at a distance). This learning environment will be capable of scaling to any number of small groups and will support instruction in a variety of disciplines desiring to engage learners in project- or problem-based learning around complex, real-world problems. Its structure will afford support for every phase of effective small group collaboration, from building readiness to providing closure, by providing all the collaborative learning spaces, tools, and resources necessary to do so, such as “just-in-time instruction” for learners as they progress through the given project or problem scenario.

Project Goals

The goal is to create an online learning environment that has the following features and characteristics:

- Teaches and supports the nine phases, not just isolated activities, of Nelson’s effective collaborative problem solving process, which includes: building readiness, forming and norming the groups, determining a preliminary problem definition, defining and assigning roles, engaging in an iterative collaborative problem-solving process, finalizing the solution or project, synthesizing and reflecting, assessing products and processes, and providing closure to the learning experience,
- Employs proven pedagogical theory and arrays tools around this theoretical structure,
- Responds to the needs of the users by being flexible, customizable, and reconfigurable,
- Runs entirely on open standards-based Internet protocols,
- Enables distributed groups to learn and work together at least as effectively as co-located groups,
- Provides guidance for both instructors and learners in effective collaborative learning, and
- Archives the work of small groups for both the group’s reference and for research analysis.

Project Design

Our design approach is to translate each element of CPS theory into a corresponding aspect or structure of the environment, such that it both implicitly and explicitly supports effective, efficient collaborative problem solving philosophy and methods. From this blueprint, we will work with a software designer to create a data model. From the data model, the software designers will create a database-driven, internet-based collaborative environment that will scale to any number of small teams. Simultaneously, we will begin a paper prototyping phase to determine the initial visual design, working with a target user pool of instructors and students at the two distance education entities. We will then employ a rapid prototyping method to improve our visual design and address the usability issues of instructors and learners testing alpha versions of the system. Once we have a beta quality environment, we will conduct pilot studies with instructors and learners in diverse content areas and geographical locations. Finally, we will evaluate case studies of the system fully implemented in a variety of learning, work, and research settings and use the data to refine a final version that we will release for use on the local servers of any interested partners.

Abstract: This paper describes the implementation of a pilot project involving the formation of networked technology learning communities designed to nurture the growth and sharing of expertise in meaningful uses and integration of technologies into teaching and learning among college faculty members, student teacher candidates and classroom teachers. The paper focuses on issues related to the establishment of technology learning communities and includes brief studies of selected members of the learning communities.

Introduction

Recent studies (Trotter, 1997; U.S. Department of Education, 1998) indicate that a large majority of classroom teachers in the U.S. continue to feel inadequately prepared to integrate technology into classroom instruction. This work-in-progress paper describes the implementation of a pilot project that focuses on ways to address this problem. The project involves the formation of networked technology learning communities designed to nurture the growth and sharing of technological expertise among college faculty members, teacher candidates and classroom teachers in the integration of technologies into teaching. The project studies potential for such communities to enlarge the number of technologically proficient current and future teachers by increasing the number of college faculty members who model the use of technologies in their teaching, the number of teacher candidates exposed to technology-proficient college and classroom teachers, and the pool of technologically proficient classroom mentor teachers. Ultimately, the goal for this project is to support a cycle of increased meaningful integration of technology into teaching.

Technology Learning Communities

Technology learning communities provide “a culture of adult learning and mutual support” (McKenzie, 1999, p. 71) that enable individuals with different skill levels to assist each other in the learning of ways to integrate technologies meaningfully into teaching. Technology learning by members occurs in both informal and formal settings, with support and expertise provided when requested by members of the communities. These communities sustain the different learning styles of the members. The strength of a learning community lies in the emphasis on members teaching each other what needs to be learned and at a pace that meets individual needs and preferences (McKenzie, 1999). Emphasis in the pilot learning communities is on supporting projects that have a direct impact on teaching and learning.

Inherent in the formation of learning communities with membership from diverse groups, i.e. college faculty, college students, and classroom teachers, are many challenges. If a learning community is to be successful, membership must be “flat and non-hierarchical” (McKenzie, 1999) in the sense that all members are
equal partners. Ideally, the learning communities should have an impact on education that radiates beyond the communities. The focus of each member of a community must be on ways to use technology to improve teaching, not simply on the development of individual technological expertise. Members of a learning community must accept the responsibility to take the acquired skills and knowledge back to their circle of professionals. Each member must be willing to build on acquired skills and knowledge, even after the pilot project ends.

Each ten member learning community in this project is composed of college faculty members, teacher candidates, and preK-5 teachers, with varying degrees of technological expertise. Criteria for membership were established prior to the formation of the learning communities. Student members were selected based on meeting those criteria and documented faculty support for their membership. Faculty members and K-5 teachers meeting the criteria and having a range of technological expertise were identified and invited by project leaders to participate in the project. The members of the current learning communities appear to have successfully established a non-hierarchical relationship partly due to the selection process. Each member of the learning communities is equipped with a laptop computer and Internet access to facilitate collaboration.

In the initial meeting of the learning communities, members were surveyed on their levels of technology expertise and discussed their learning expectations. This information assisted the coordinator of the learning communities in planning group learning sessions. In addition to these face-to-face meetings, members of the communities interact using email and a discussion list. The discussion list, TechTalk, provides a mechanism for members to share and request resources, and to obtain fast response to technology-related inquiries. With support from learning community members, the college faculty members are increasing technology use in the courses they teach. The teacher candidates have the opportunity to assist in the implementation of technology-based lessons, to design lessons and materials to be used during student teaching with preK-12 students, and to work with the college faculty members as they integrate technology into courses. The classroom teachers are sharing and expanding their expertise in integrating technology into the preK-5 curriculum.

Members of the learning communities have formed partnerships as reflected in interviews done with one student and one faculty member in the communities. Faculty Member A is a beginning technology user, though she is knowledgeable about the Internet. As a college history professor, she wants to explore the use of the Internet not as an electronic library reflected in the web sites that she includes in her syllabus bibliography, but as a vehicle to encourage her education students to think critically about events in history. She finds the learning communities helpful in learning about social studies issues important to elementary teachers but receives the most help from one-on-one tutoring from individual members. She is especially appreciative of the help from Student B, an above average technology user, who acquired many of her skills at the college. In addition to tutoring Faculty Member A, Student B is helping two classroom teachers in her learning community to teach their students HyperStudio. She finds that the learning communities aid her goal of being a teacher because through this collaboration she is spending time in a classroom setting working with children.

Evaluation of the progress being made by members of the learning communities in meeting the initial goals of this pilot project is encouraging. This project is providing the groundwork for modification and expansion of future technology learning communities.

Four Challenges for TeleTeachers in Rural Schools

Ken Stevens, Memorial University of Newfoundland, Canada

The introduction of telelearning in schools in Canada, as in other developed countries, has been particularly noticeable in rural areas and has been influenced by declining school enrolments. There are four challenges common to the technological enhancement of rural schools: the building of appropriate infrastructures, the location of appropriate technologies, the development of pedagogy for teleteaching and the need for on-going professional development.

Challenge One: Building Appropriate Structures (Digital Intranets)

By constructing web-sites both teachers and students in a rural school can enable people located almost anywhere to connect with them and learn about their programs and activities. In Canada regional and national educational networks link classes in schools on dispersed sites. Stem-Net in Newfoundland and Labrador in eastern Canada is the provincial arm of the federal SchoolNet System. These federated electronic structures enable teachers to extend the curriculum available to learners in dispersed and, often, very isolated sites. Schools in rural Canada are developing open and flexible academic and administrative structures as they electronically link with one another. These new structures exist within the traditional and, by comparison, closed school systems in each school district. In the open educational structure of teleteaching within digital intranets, constructed to link schools for the delivery of specific courses for some students, participating institutions academically and administratively interface for that part of the school day during which classes are being taught. This is a very different educational structure from the traditional and, by comparison, closed educational environment of the autonomous school with its own teachers and its own students. In Canadian networks such as Stem-net, each site becomes an inter-dependent part of a virtual school, without which it could not provide all the courses that local people are increasingly accessing.

Challenge Two: Finding Appropriate Technology

As schools become teaching and learning sites within digital Intranets, there is increasing demand for adequate technological support and co-ordination. Few teachers have the skills to provide adequate technological support for the increasing numbers of computers and computer users in their schools. The result is that the emerging teaching and learning infrastructure in many places is often very fragile. An essential aspect of the development of open electronic classes is the coordination of both hardware and software between schools. Without coordinated technology, schools cannot fully participate in electronic networks. However, the purchase of appropriate hardware and software is a matter of confusion for many principals, teachers and School Boards who seek support and advice. Many rural schools with open electronic classes realize that the successful administration of a network requires local technical support. Unless adequate technical support systems can be established, electronic networked classes could be curtailed by teachers who could argue, with justification, that there is insufficient back-up to justify their investment in telelearning. The need to have people in schools, or available to schools, to maintain information technology hardware and software is, for many teachers, a matter of growing
importance. In geographically isolated communities the assurance of adequate technical
backup is, however, often particularly difficult to provide for teachers and principals. In
schools in Newfoundland and Labrador, the majority of which are designated rural,
telelearning often depends on the goodwill of one or two teachers with enough
knowledge to keep computers going when they mal-function.

Challenge Three: Pedagogy for TeleTeaching

In the changing technological environment, teachers often have a choice of teaching face
to face and, for part of a school day, providing or receiving instruction for their students
at a distance. This can be done in synchronous or asynchronous mode, with a range of
technologies, and with a range of learners. The use of information technologies in schools
has been vigorously promoted by the federal agency, Industry Canada (Information
Highway Advisory Council, 1995; 1997). Students often have more independence in
managing their learning in open electronic classes but most have to be assisted by
teachers in the setting of goals, the meeting of deadlines and in evaluating their progress
(Stevens, 1996). Teachers are effective in open electronic classes if they can be flexible
in ways that they allow students to participate in on-line lessons. Strategies and protocols
for on-line teaching have to be developed between participating schools if all students are
to be able to fully participate. The introduction of a rural school to an open electronic
network considerably improves its resource base for both teachers and learners, but does
not solve all of its problems. It is often difficult to coordinate the timetables of networked
schools and a considerable measure of inter-institutional and intra-institutional
cooperation is required to develop detailed and effective plans for collaboration. The
need for rural networked schools to have a close relationship with the suppliers of
technology has become increasingly apparent to schools, school boards and to technology
retailers. Rural schools with telelearning infrastructures require expert advice and support
from technology suppliers at the network rather than at the individual school level. There
are several immediate pedagogical challenges to be considered for effective teaching in a
digital Intranet:

1. Teachers have to learn to teach from one site to another. This is fundamental to the
   success of teleteaching. Teaching face to face and on-line are different skills.
2. Teachers have to learn to teach collaboratively with colleagues from multiple sites.
3. Teachers have to judge when it is appropriate to teach on-line and when it is
   appropriate to teach students in traditional face-to-face ways. These judgements have
to be defended on the basis of sound pedagogy.

Challenge Four: Professional Development for TeleTeaching

A difficulty many teachers face in Canadian schools is simply finding the time in their
busy days to learn about information and communication technologies. It is impossible
for some teachers to do this, let alone reflect on how new technologies can be integrated
into their classrooms and their professional lives. There is not only a widespread need for
professional development for teleteaching; there is a need for it to be provided on a
continuous basis. A second challenge facing many teachers is finding effective ways of
integrating information and communication technologies, including the Internet, into
teaching and learning. It is not difficult to add information and communication
technologies to any classroom but it requires considerable planning to integrate
technological developments so that both teaching and learning are enhanced. A third
challenge for the professional development of teachers is to be able to justify, on the basis
of professional judgements, why the Internet and other technologies should be used in
teaching and learning at all.

Conclusion

The introduction of inter-school electronic networks has added a new dimension to rural
education in Canada and in other developed countries. In Canada and in many other
places, teachers and researchers are seeking appropriate ways of using existing as well as
emerging technologies to enhance teaching and learning. The teachers and researchers
who are collaborating in the development of new electronic structures for delivering
education to dispersed, rural sites in Atlantic Canada are very conscious of being
pioneers. Both realize there is a lot to learn about both teaching and learning in this
new environment.

Abstract: The paper presents an experimental validation of learning effectiveness of three different types of group interaction for computer mediated collaborative learning and problem solving. The assumption underlying this research is that the form in which knowledge is shared in collaborative learning is a substantial for cognitive construction and reconstruction. The experiment revealed that the learning effectiveness is influenced significantly by the mode of group interaction that depends on the extend to which students share their learning not only as results but also as a process of knowledge acquisition and creation by a direct interaction.

Theoretical background and research question

Rapidly changing technologies generate new requirements for creating computer environments that support learning in the broad context of global networking communities. Different theoretical perspectives emphasise collaboration as a successful and powerful activity for learning and problem solving.

Collaboration creates an extension of the internal cognition of the personality in outside world (Perkins, 1993). According Salomon (1993) the individuals' and the shared group cognitions interact with one another in a spiral-like fashion whereby individual inputs, through students' collaborative activities, affect the nature of the joint, shared system, which in turn affects their cognitions. It is emphasised that reconstruction of individual cognition requires a profound and mutual understanding of collaborators' perspectives and shared interpretations of the problem. Only the knowledge that is meaningful for individuals could be internalised.

The assumption underlying this research is that the form in which knowledge is shared in collaborative learning is a substantial for cognitive construction and reconstruction. The main research question is: Is the mode of group interaction a predictor of learning effectiveness in a computer based collaborative problem solving design?

Collaborative scenarios

Three scenarios of problem solving group interaction have been designed, based on the assumption that knowledge exists in three forms: as individual mental constructs and precepts, as knowledge in action, and as knowledge embodied in artefacts (Hedlund & Nonaka, 1994)

1. Distributed interaction. Group members work autonomously and produce intermediate artefacts embodying their knowledge and visions, which are passed to the other members. This circuit is repeated until all group members reach a common vision of the problem. The process of knowledge acquisition, creation and internalisation is individual.

2. Moderated interaction. Interaction process is facilitated by a group moderator (the role is taken by one of the group members) adjusting individually produced artefacts until a common group vision is reached. The representations of individual cognitive structures are not directly accessible but group members are involved in the process of negotiation of meanings and ideas that take place between them and the group moderator.

3. Shared interaction. Group members interact directly by synchronous activity and common efforts to solve the problem as a group. They share their knowledge in action. Knowledge is communicated in the process of its acquisition and creation and is not mediated by intermediate artefacts. Collaborative actions of students are the individual inputs toward shared cognition.

Experimental validation
The learning effectiveness of the three modes of group interaction was tested experimentally. The experimental design was a random assignment pre-test post test control group. The independent variable was the mode of group interaction with three levels – “Distributed”, “Moderated” and “Shared”. The dependent variable was learning effectiveness operationalised as individual learning achievements in terms of: fluency (number of concepts representing individual understanding of the problem), flexibility (variety of concepts and ideas), knowledge acquisition (number of new concepts acquired), individual-to-group transfer (individuals’ inputs in the group solution), group-to-individual transfer (concepts derived from the group solution), reconfiguration (changes in the concepts’ structure), retention (contra indicated by the reduced concepts), and creativity (new concepts and ideas generated individually after the collaboration).

Twenty-six students (6 groups) of University of Twente, Faculty of Educational Science and Technology, enrolled in “Linear and Hypermedia” course, were selected as experimental subjects and were randomly assigned to the three collaborative scenarios. The group task was formulated as an open-ended problem. Concept mapping technique was chosen for representation and communication of knowledge because of its effectiveness as a tool for externalisation and representation of cognition. (Stoyanov & Kommers, 1999). Data was analysed applying one-way ANOVA procedure by SPSS 9.0 statistical package.

Results and Discussion

The results are significantly predictive for the learning effectiveness of the three group interaction scenarios. The mode of group interaction influences significantly the knowledge fluency (Sig. = .047), concepts acquisition (Sig. = .045), and group-to-individual transfer (Sig. = .004). On these criteria students in Shared groups scored significantly higher than students in Moderated and Distributed groups.

All three scenarios enabled students to present and incorporate their knowledge in the group process. No significant difference was found on individual-to-group transfer.

Shared mode was highly beneficial for acquiring knowledge both from each other and from taking new perspectives in exploring the problem space. A significant part of the knowledge that was elaborated in group session were incorporated as a meaningful part of students’ cognitive structures and transferred to individual cognitions.

Students working in Moderated mode incorporated less new concepts in their personal cognitive structure than students in Shared mode. Only those aspects of the group solution that were developed by the personal participation of a particular student were internalised in his/her cognition.

Regardless that students in Distributed mode had a broad access to all other students’ knowledge representation they were not able to gain enough from the externalised experience of the others.

Both the Shared and Moderated mode proved their potential for reconstruction of the individual cognition represented mainly by reshaping of map spatial configuration. Significant interdependence between common group problem solution and the individual outputs was found. Students working within Distributed mode resist on their prior conceptual structure.

No significant difference was found on criteria of knowledge flexibility. The three types of groups were able to explore the problem space from different perspectives and within different conceptual paradigms.

Surprisingly, the individual creativity was not influenced by the mode of group interaction. Nevertheless no significant difference was found (Sig. = .345), it should be stated that students working in Shared mode showed a lower level of retention of their initial concepts than the students in the other two modes.

In summary, the experiment revealed that the learning effectiveness is influenced significantly by the mode of group interaction. In general, Shared interaction scenario proved to be the most effective in collaborative learning and problem solving. These leads to the conclusion that the learning effectiveness depends on the extend to which students share their learning not only as results but also as a process of knowledge acquisition and creation by a direct interaction.

Re-usability problems in large-scale content management of database driven Web based environments

Abstract: The use of databases involves assigning resources to users with changing access rights. How will the information be presented to the right users? How can resources be reused for different audiences and how should access rights be provided. Who has the right to change, who can read it and who is owner of the objects in a resource base?

Introduction
The faculty of Educational Science and Technology started a faculty wide implementation of Telelearning with the TeleTop project in 1997. The aim of the project was to support teachers and students with a web based database driven environment. Two years later the entire university, including ten faculties, is ready to implement the TeleTop system. How reuse of material should be provided is a point of research because content management can make the use of objects more efficient.

The problem of assigning resources to people
Scaling up a course management system means that more information will be stored. Reusing includes retrieving stored information. Finding relevant material and assigning this material to the right users is a problem because of the large amount of objects and the large scale of users. A second point of attention is the use of access rights. Access rights are used to give users rights to read or change objects. Using databases includes controlled access to different objects for different users.

Objects:
Every object has users that can read or use the object, users who are able to change or create the object and users that can actually delete an object. These rights are set in the access control list and every database uses some sort of access control list to control access objects in a database. These objects can consist of (elements of) learning material, course descriptions, assignments, multimedia fragments, HTML pages or any other type of digital content. Controlling access to information is needed so that copyrights or confidential material can be stored in a protected environment; i.e. an environment that is not accessible for unauthorized users.

Users:
Users are mostly unaware of these access control lists, because software developers make these environments as easy as possible by not showing objects that users are not authorized to see. The problem in most cases is that objects may be accessible for one user, but not for another. Resources available for teachers may not be accessible for students. Assigning students to these resources may result in irrelevant links for the students. This makes reuse for different users and audiences a difficult issue. This problem has not earlier been identified because most web-based environments are still pilots or prototypes. A faculty wide implementation includes a large number of users who can create objects and even more users that should be able to use these objects. Dealing with a large scale of objects and really reusing these in database driven courses is a new development.

Solution for large numbers of objects
Maintaining access control for every single object in a very large resource base is not manageable. Managing many (more than 10,000) users over many (more than 10,000) objects is a realistic example in our situation at the University of Twente. Combining a number of related objects in a course is a solution to make control access rights
manageable. In this way it is possible to assign a set of objects to several predefined user groups comprised of
teachers or students. One group can be assigned the role of author and other groups as readers. Copying objects to
new courses can involve reuse of objects. This method has been sufficient until now, because in most cases
instructors wanted to reuse only the material created by themselves. Reuse as described gives the possibility to make
changes to objects for the new audience.

Making objects more flexible
Considering the results of reuse we recently developed a new model for access rights. This model is based on roles
that are assigned to user groups. A user group is a list of people who can access the same functionality in a database.
So the access control of every object in a course depends on the role a user has. Three roles where identified:
Teacher, student and administrator. Using roles makes reuse possible by employing an abstract access level that can
be used over courses and provides a consistent control of rights. Objects can be used in every course without
changing access control lists of involved courses. The development of a resource browser is in progress. In the first
place reuse of objects within a course is being researched, in the second place exchange of objects between courses
will be researched.

Challenge, future plans
In the next years reuse of objects at the university level should be supported. Objects should be reused within
courses, between courses and faculties. Even different universities should be able to reuse objects in courses.
Therefore, interfaces should be developed that support users selecting the right resources. Also, access right models
have to be developed. Another objective of our research should be directed at the ownership of objects; i.e.
copyrights. Ownership can be seen as part of the access rights involved with objects. Is a user who creates an object
the owner and is this user the only one who may reuse or add or edit this object? Who owns such copyrights? All
these points need further research. In this respect it is important to note that a number of organizations involving
standards for learning technology and related issues are aware of these problems and are trying to find solutions, but
until now there is not a standard way to handle large scale resource bases. Examples of these organizations are the
Instructional Management Systems project (IMS)\(^1\), the Alliance of Remote Instructional Authoring and Distribution
Networks for Europe (ARIADNE)\(^2\), the IEEE 1484P Learning Technology Systems Architecture (LTSA)\(^3\),
Advanced Distributed Learning (ADL)\(^4\) and the Aviation Industry CBT Committee (AICC)\(^5\).

Abstract: As the Internet brings new means of presenting information to learners, the need for meaningful assessment increases. We describe the design and development of a computer tool to facilitate a particular form of assessment that can be meaningful in online learning contexts. The tool combines a web browser with an annotation facility, a database, and special means for visualizing assessment data captured with the tool.

Introduction:

As educators explore the many possibilities for delivering instruction online via the Internet, they tend to focus primarily upon delivering presentations of information. The forms of presentation include web pages and web sites, text, images, audio clips, video clips, queries to databases, and Java applets that run simulations. In addition to the information itself, the Internet also enables the online gathering and experience of groups of people who might (or might not) be physically distant from one another. The online communities of learners can be formed such that the members are all at a very similar level of expertise in the subject they are studying. What is largely missing from these innovations, however, is a form of educational assessment that is well adapted to the new patterns of learning.

Assessment is sometimes regarded as the unpleasant part of education, in part because traditional testing is sometimes distasteful to students and because assessment is typically considered less important to the presentation of information. However, studies of assessment in support of learning (rather than in support of administration or of college admission, for example) have lead to recommendations for alternative assessment methods such as performance assessment, authentic assessment, portfolio-based assessment, and continuous assessment (see Tanimoto, 1998). These methods offer the possibility to make assessment a more "natural" part of the learning process, and to permit learning to occur with less stress and in ways more in line with workplace goals. Yet these methods are often difficult to implement because they may require more teacher training, more teachers' time spent on assessment, and because their results may seem to be more subjective than the results of standardized tests. We have developed a software tool for assessment to help us explore one approach to assessing online learning. The tool, called INFACT, permits the assessment to be performed unobtrusively in a manner reminiscent of psychologists' observations from behind the glass wall.

Pedagogical Approach

Our approach to assessment takes place within a particular pedagogical methodology. We have applied the methodology in two subject areas: high-school physics and undergraduate statistics. Students in the class are divided into groups of 4-6 students each. An instructional unit lasts one week. On Monday, a problem that requires conceptual thinking is posed by the teacher. Each student in the class is told to make her/his own interpretation of the problem and suggestion for solving it and to write and post a newsgroup entry using a specially modified version of the HyperNews software from the University of Illinois. The posting is due by 12 noon on Tuesday. This initial post is invisible to other students until a virtual curtain is lifted shortly after noon on Tuesday, at which time it becomes visible to the other members of the student's group. The students are then required to respond to each other's postings in an online discussion, and they are told to come up with a group solution by Friday. Over the course of the week, their postings accumulate, creating an archive which feeds our assessment tool, INFACT.
INFACT stands for "Integrated Networked Facet-Based Assessment Capture Tool." It is used by teachers to view and annotate student newsgroup postings in such a way as to build up a database of assessment information that can be used to track student and group progress in understanding the concepts of the instructional unit. INFACT makes use of catalogs of standard misconceptions that students commonly have about a subject. Each misconception is called a facet, and facets are grouped into clusters such that all facets in a cluster represent misconceptions about the same concept. A facet catalog must be compiled in advance of using INFACT for assessment. However, it is possible to refine a facet catalog in the course of assessment. INFACT makes the assumption that facets can be linearly ordered by their "level of expertise" (see Minstrell 1992 and Hunt and Minstrell 1994 for details).

The Design of INFACT

INFACT comprises the following components: an integrated web browser, a database (currently an MSQL database), dialogs for creating and editing assessment items, and a visualization component. The browser component permits the teacher to load and view HyperNews postings in essentially the same form that the students see when they read and post. This component also supports creating selections of text within the document being viewed. The INFACT software determines (insofar as possible given the limitations of available browser software) the start and end positions within the document where the selection occurs. Selections of this form can then be annotated.

Annotations of two types are permitted: facet annotations and free annotations. A facet annotation represents an atomic assessment item, and it consists of the text selection, a reference to the document in which the text occurs, identification of the student who authored the text, identification of the assessor, reference a particular facet for which this text provides evidence, a certainty value given by the assessor, the date of authoring and the date of assessment. A free annotation is simply a comment associated with the selection. The assessor can check a box associated with each annotation to make it visible to the student. The database is used to keep track of the annotations and to make assessment items retrievable by student, by facet cluster, by date, etc. The database also holds the facet catalog. The visualization portion on INFACT permits the user (usually the teacher) to call up assessment data by student, by group, by date, or by facet cluster. The user can also view graphs that help to reveal trends in the data. Two types of graphs supported by INFACT are (a) histograms of facet frequencies, and (b) facet transition diagrams. The latter show how one or more students' misconceptions about a concept change over time.

As a teacher reads student postings with INFACT and makes annotations, s/he can use INFACT to send feedback to the students. INFACT supports two means of feedback: direct email and student-visible annotations. Direct email permits the teacher to send a message to a student in the context of an assessment item. This can be used to get clarification from the student about something not clear from the posting. It can also be used to commend the student or to make a suggestion. However, its main value over email from ordinary mail programs is the automatic association created between the message and the assessment context in which it originates. INFACT makes it possible for the teacher to include a multiple-choice question in the message that when answered online, provides additional evidence in favor of one facet or another within the facet cluster associated with the assessment item. For a screen shot of INFACT, see http://www.cs.washington.edu/research/metip/crIt/infact-1.gif

Evaluation of an ITS for the Passive Voice of the English Language
Using the CIAO! Framework

Introduction
The primary aim of educational software is to help students learn. Therefore, evaluation of this kind of software is crucial. Its aim is to test the functionality and usability of the design and to identify and rectify any problems (Dix et al. 1993). In particular, formative evaluation is one of the most critical steps in the development of learning materials because it helps the designer improve the cost-effectiveness of the software and this increases the likelihood that the final product will achieve its stated goals (Chou 1999). In this paper, we present and discuss the evaluation of an intelligent tutoring system for the passive voice of the English language using the CIAO! framework (Jones et al. 1999).

The Passive Voice Tutor
The tutoring system that we developed and evaluated is called Passive Voice Tutor (Virvou & Maras 1999a; 1999b). The Passive Voice Tutor complies with the architecture of most ITSs, which consists of the domain knowledge, the student modeller, the advice generator and the user interface (Wenger 1987).

In particular, the domain knowledge of the Passive Voice Tutor comprises knowledge about how to convert a sentence from active to passive voice and vice versa. It also provides the knowledge needed for the dynamic construction of new exercise sentences. Finally, it comprises knowledge about the semantic relation between the words used for the construction of new sentences.

The student modeller checks the student's answer and in case of error, it performs error diagnosis. It contains a bug library of the most common student errors and generic mal-rules that students often apply when they have misconceptions. Another responsibility of the student modeller is to keep a history record concerning each student's progress in learning. This record is used in cases were ambiguity arises, so that the system attributes a particular error to a category of errors that the student seems to be prone to.

The advice generator is responsible for responding in the most appropriate way to a student's error, by informing the user about the cause of the error and by showing to him/her the relevant part of the theory. Finally, the user interface of the Passive Voice Tutor, is a multimedia user interface, which involves animations, sounds and a limited form of natural language so that it can attract the student's interest.

The Evaluation
The CIAO! framework outlines three dimensions to evaluate: (i) context; (ii) interactions; and (iii) attitudes and outcomes. One important aspect of context is the reason why CAL is adopted in the first place, i.e. the underlying rationale for its development and use; different rationales require different evaluation approaches. According to the framework, the reason for looking at students' interactions with the software is in order to understand more about their learning processes; such interactions can provide protocol data for later analysis. Finally, at the "outcomes" stage, information from a variety of sources needs to be used including, pre and post-achievement tests, interviews and questionnaires with students and tutors. The overall emphasis of this framework is on educational issues.

There are many other evaluation techniques, such as the JIGSAW model (Squire & Preece 1996) or the 'set of learning with software heuristics' (Squires & Preece 1999), which also address the problem of integrating both usability and learning issues in the evaluation of educational software. In the JIGSAW model, the evaluation is performed in three levels. In Level 1, the subtasks of the learning and operational tasks are considered independently of each other. As we move from Level 1 to Level 2, integration within the learning and the operational tasks is considered. At Level 3 integration between the learning and operational tasks is considered. On the other hand, the set of 'learning with software' heuristics, are an adaptation of the "usability heuristics" presented in Nielsen (1994), so as to relate them to socio-constructivist criteria for learning. These heuristics include the need to consider appropriate levels of
learner control, the need for the prevention of peripheral cognitive errors and the need for strategies for the
cognitive error recognition, diagnosis and recovery cycle. The CIAO! framework, seemed to be a more
suitable method, in the sense that it also evaluated the students' use of the resource package.

For the evaluation along the dimensions of the CIAO! framework, presented above, we have done the
following:

i) **Context**: The underlying rationale for the development and use of the Passive Voice Tutor is to help
students during the process of learning. Hence, one of the primary aims of the system is to address
individual learners' misconceptions and help them correct their errors. Evaluation in terms of the
context has been addressed by questionnaires to human tutors before their students had ever used the
system. This was done so that the domain knowledge and student modeller could be evaluated. In
particular, tutors were given a set of erroneous answers to questions relating to the domain, which were
generated using the system's domain knowledge and bug library. For each question, each tutor had to
provide an explanation as to what s/he thought the underlying misconception of the error was. Each
human tutor's explanation was compared to the Passive Voice Tutor's explanation. A satisfactory
degree of compatibility was found (45%). However, the comparisons also showed that the explanations
could be improved at a later version of the Passive Voice Tutor.

ii) **Interactions**: On a second phase, tutors were asked to evaluate the system, after their students had
interacted with the Passive Voice Tutor. Protocol data was collected through the individual long term
user model of each student. This kind of protocol data was first automatically analysed by the student
modeller and resulted in information that concerned the student's individual way of learning. Then,
human tutors were also given the same set of students' protocols and were asked to analyse them.
Finally the tutors' analysis was compared to the system's analysis. To a large extent, human tutors had
similar beliefs to the system's beliefs about the students who took part in this evaluation stage.

iii) **Attitudes and Outcomes**: In the case of the Passive Voice Tutor, at the outcomes stage, questionnaires
were given to students and tutors. Students' questions included the following: "Did you consider the
system responses to your errors helpful for understanding your mistakes?" Tutors were also asked to
evaluate the outcome of the use of the system, after their students had interacted with the Passive Voice
Tutor. Therefore, the teachers were asked to provide information about whether the software helped
them to understand better the difficulties that their students had in learning the passive voice of the
English language. Tutors also seemed quite satisfied by the system's student modelling component.
Finally, the progress statistics of each student that had been recorded in his/her long term student model
was also used at this stage of the evaluation. The analysis of this kind of data showed that the majority
of students (57%) made a progress in their learning, whereas only 43% did not seem to have any
progress in their learning of the passive voice. This is an encouraging result in terms of the educational
effectiveness of the system.

**Conclusions**

The CIAO! framework for evaluating educational software has provided insight for several aspects of
the software that needed evaluation at several stages; e. g. before any student had interacted with the
software and after. In this way, both learning effects and usability issues could be evaluated. The results of
the evaluation showed that the Passive Voice Tutor was quite satisfactory but there is scope for
improvement in terms of the explanations provided by the system.

Using A Speech-Driven, Anthropomorphic Agent in the Interface of a WWW Educational Application

Introduction

Web-based education has the obvious benefit of allowing platform independent access to easily updated teaching material. Recently, a large number of educational applications have been delivered through the World Wide Web. Unfortunately, most of these systems are static, they do not maintain a student model and thus they are unable to provide individualised tutoring. Nonetheless, the future of web-based education seems promising since researchers in the field of Intelligent Tutoring Systems have made quite successful attempts to either move existing ITSs to the WWW or build from scratch web-based ITSs (Eliot et al., 1997; Stern et al., 1997). However, the development of an ITS requires the involvement of a large number of people, including experts of the specific domain, instructors and programmers. A way to overcome these problems may be the development of authoring tools, which will help construct cost-effective and reusable ITSs in various domains. One such authoring tool for ITSs is WEAR (WEb-based authoring tool for Algebra Related domains). WEAR incorporates knowledge about the construction of exercises and a mechanism for student error diagnosis that is applicable to many domains that can be “described” by algebraic equations (Virvou & Moundridou, 1999).

WEAR uses a talking head in its interface with the students. Animated characters have often been used in the interfaces of systems (Rist et al., 1997; Stone & Lester, 1996). Such an interface makes a system more appealing and attractive to the user and if talking about an educational application it may also promote the learning objectives. Walker et al. (1994) investigated subjects' responses to a synthesised talking head displayed on a computer screen in the context of a questionnaire study. Their findings showed that compared to subjects who answered questions presented via text display on a screen, subjects who answered the same questions spoken by a talking head spent more time, made fewer mistakes, and wrote more comments. In this paper we describe how the talking head is used in the whole educational application.

Description of the System and its Interface

WEAR aims to be useful to teachers and students of domains that make use of algebraic equations. Such domains could be chemistry, economics, physics etc. In particular the tool accepts input from a human instructor about a specific equation-related domain (e.g. physics). This input consists of knowledge about variables, units of measure, formulae and their relation. When the human instructor wishes to create exercises s/he is guided by the system through a step by step procedure. At each step of this procedure the instructor specifies values for some parameters needed to construct an exercise. Such parameters could be for example what is given and what is asked in the exercise to be constructed. After the completion of this procedure the tool constructs the full problem text and provides consistency checks that help the instructor verify its completeness and correctness.

WEAR assigns to each student a level of knowledge according to his/her past performance in solving problems with the tool. The tool suggests each student to try the problems corresponding to his/her level of knowledge. When a student attempts to solve an exercise the system provides an environment where the student gives the solution step by step. The system compares the student's solution to its own. The system's solution is generated by the domain knowledge about algebraic equations and about the specific domain in which the exercise belongs (e.g. economics). While the student is in the process of solving the exercise the system monitors his/her actions. If the student makes a mistake, the diagnostic component of the system will attempt to diagnose the cause of it.

When interacting with the students WEAR responds through a talking head, representing in some cases the instructor and in some others a co-student. The talking head component of the system uses speech synthesis to automatically produce speech output from text using MBROLA, a freely available speech synthesiser (http://tcts.fpms.ac.be/synthesis/mbrola.html). The talking head renders the interface
quite attractive to students through the sound of speech. Moreover, since WEAR is an authoring tool for ITs there are a lot messages that are dynamically formed during the execution of the application. Therefore, the authoring tool could not use pre-stored material for the speech feature but rather a speech synthesiser.

In the case when the talking head represents the instructor it guides the student to the environment, recommends what problem to solve next and reads the problem text from the database of the authoring tool. Since WEAR is an authoring tool, new exercises are continuously added to its database. When the student begins to solve the problem, s/he may choose to solve it either with a simulated "co-student" or with the "instructor". These two different choices are only on the level of the user interface. This means that they use the same underlying reasoning abilities from the diagnostic component of WEAR.

If the student selects the mode of the "co-student" then the talking head provides very friendly messages as a peer to the student. This simulated student is responsible for providing positive feedback when the student’s actions are correct and for pointing out the student’s underlying misconception in case of an erroneous action. The information concerning which actions are considered correct or not and also the messages that the simulated student should say are provided by the diagnostic component of WEAR. The talking head as a simulated student is aimed at increasing the student’s attention and possibly collaboration attitude (although in a limited form). Indeed as VanLehn et al. (1994) have pointed out peer learning even in a setting where the other peer is a simulated student may increase students’ collaboration skills.

If the student selects the mode of the "instructor" then the talking head provides messages similar to the "co-student" but they are more formal and the diagnosis of misconceptions goes one step further to resolve ambiguities using the long term student model. Indeed, there may be cases where a student’s erroneous action may be attributed to more than one misconception. In such cases, the diagnostic component first consults the long term student model and then through the talking face asks the student a question to determine his/her underlying misconception and resolve the ambiguity. The benefit of directly asking the student is twofold: firstly, the system may find out the real reason for the erroneous action and provide appropriate feedback and secondly, the student through explaining why s/he acted in that way gains more knowledge and understanding. It is a common finding in many researches that explaining things either to oneself or to another student helps one’s understanding (Webb, 1989; Pressley et al., 1992).

Conclusions

In this paper we described the work in progress of the development of a web-based authoring tool for Intelligent Tutoring Systems. The tool, called WEAR, aims to be used by teachers and students working in domains that make use of algebraic equations. In this paper we focussed on the interface of the ITSs that are generated by WEAR: animated talking heads are used to simulate both the instructor and a co-learner of the student solving a problem. In that way, instruction and feedback are more “human-like” resulting in friendlier and more appealing ITSs. Furthermore, the students interacting with WEAR, may gain better understanding of the domain being taught and also improve their ability to collaborate with others; benefits that arise from the peer learning situation in which the students are involved.

mvirvou@unipi.gr

Introduction

Intelligent Tutoring Systems have traditionally been very good at providing dynamic aspects to the educational system's reasoning. This is usually due to the student modelling component that attempts to follow the student's way of learning taking into account possible misconceptions that the student may have. Other important dynamic features of ITSs are due to the advice generator that models the tutoring strategy by which the student is going to be taught the domain.

However, ITSs have often been criticised that they represent immensely complex approaches to building learning environments (Boyle, 1997). A solution to this problem may be authoring tools that provide the facility of building multiple ITSs. In particular, as Murray (1999) points out ITS authoring tools may give the instructional designer a combination of facilities to produce visually appealing, interactive screens and a deep representation of content and pedagogy.

This paper describes an authoring tool for ITSs that incorporates a domain-independent reasoning mechanism. The reasoning mechanism is used for the student modelling and the tutoring strategy of the resulting ITS.

Related Work

The domain-independent reasoning mechanism of the authoring tool described in this paper, is based on an adaptation of a cognitive theory called Human Plausible Reasoning (Collins & Michalski, 1989). Human Plausible Reasoning theory (henceforth referred to as HPR) is a domain-independent theory originally based on a corpus of people's answers to everyday questions. HPR formalises the plausible inferences based on similarities, dissimilarities, generalisations and specialisations that people often use to make plausible guesses about matters that they only know partially. These inferences may lead to either correct or incorrect guesses; in any case these guesses are plausible.

This theory can be used as a domain-independent generator of plausible human errors or as a way of reasoning for open questions. Indeed in previous research we adapted and used HPR in the user modelling component of an intelligent help system for UNIX users (Virvou, 1998; Virvou & DuBoulay, 1999) and in an intelligent learning environment for novice users of a GUI (Virvou & Stavrianou, 1999; Virvou & Kabassi, 2000). In the present research we adapted and used HPR for the student modelling of multiple domains, such as geography, biology etc. and as a tutoring strategy for teaching students how to deal plausibly with open questions. In addition we have provided the facility to human instructors to construct the knowledge - base of the domain to be taught to students.

Operation of the Authoring Tool

The initial input to the authoring tool is a description of factual knowledge of a specific domain given by a human teacher. Then the tool constructs a knowledge base concerning the specific domain in the form of hierarchies, which is compatible with HPR. The human teacher may also construct tests that consist of questions concerning the factual knowledge of the domain.

The resulting ITS may be used by students who can be shown facts from the knowledge base. In addition students may test their knowledge by answering the questions that the human teacher has given. The student modelling component examines the correctness of each student's knowledge and the soundness of the reasoning s/he has used. Information about each student is kept in a long term student model. This kind of information may be used to measure the student's progress and record persistent misconceptions and weaknesses of the particular student.
The tutoring component of the resulting ITS poses questions to the student who is asked to give an answer and an explanation for this answer. For example, in the domain of geography the tutor may pose the question: “Does Italy produce lemons?” Then the student may answer either “Yes” or “No” and give an explanation for his/her answer. An explanation could be “Yes, because I know it does”. If the student does not possess the factual knowledge needed for this answer s/he may say: “My guess is yes. I know Spain produces lemons; Spain is similar to Italy in terms of agricultural products. Therefore, Italy probably produces lemons”. In this case, both the answer and the reasoning are examined by the ITS. There may be cases where the student’s answer may be incorrect but the reasoning reveals that the student has a good knowledge of geography and uses it in a plausible way.

In particular, there may be several cases of combinations in terms of the correctness of the guessed answer and the correctness of the reasoning. One case is both the guessed answer and the reasoning used to be correct. Another case is the guessed answer to be wrong but the reasoning used to be correct. In this case the tutor informs the student about the mistake but admits that the reasoning that the student used was plausible. A third case is the guessed answer to be correct but the reasoning used to be incorrect. In this case the tutor informs the student that the answer was correct by chance. There are also cases where the reasoning used may be correct but the factual knowledge of relevant topics may be incorrect. For example, if the student was asked whether Italy produced coffee and answered “My guess is yes because Spain produces coffee and Spain is similar to Italy in agricultural products”. In this example Spain is similar to Italy but it does not produce coffee.

The learning environments that result from this authoring tool are more open than tutoring systems which do not have any reasoning abilities about correct and incorrect knowledge. For example, Ohlsson (1993) suggests the analysis of epistemic activities (arguing, describing, explaining, predicting, etc.) to be more relevant for higher order learning of declarative knowledge than the study of goal-oriented action. In addition, Andriessen & Sandberg (1999) point out that the process of becoming an expert in a certain domain should no longer be solely viewed as the acquisition of a representation of correct knowledge; the knowledge to be acquired should flexibly manage open problems. In this sense the authoring tool provides support in the student’s learning of factual knowledge and the reasoning that may manage this knowledge.

Conclusion

In this paper we described the work in progress of an ITS authoring tool that incorporates a domain-independent reasoning mechanism. The reasoning mechanism is based on HPR, which is a cognitive theory about how people make plausible guesses. In this way, the resulting ITSs may provide quite open learning environments for the students to practice their factual knowledge on a certain topic, factual knowledge on possibly relevant topics and the reasoning they use to deal with open problems by combining factual knowledge from relevant topics.

The authoring tool is in the process of being evaluated in the domain of geography and biology.

Abstract: This paper reports on the results of the project "Open and Distance Learning Network in Information Technology and Microelectronics - EDIT" run by University "Politehnica" of Bucharest, Technical University of Cluj, Technical University "Gh. Asachi" of Iasi, University of Craiova, Romania and IBM Global Services, Education&Training, La Hulpe, Belgium. The paper focuses on the description of the main objectives, technical infrastructure, course materials, impact/target groups, type of learning environment and further developments. A distributed web-based learning environment has been developed within the EDIT project.

Objectives

The main objective of EDIT Project was to develop the first Romanian academic open and distance education network aimed at training the students and academics from the four partners universities. In the long run the network will extend to link the main technical universities in Romania, including researchers and experts from other institutions. The project is financially supported by the Romanian National Higher Education Funding Council for a period of three years.

The project's specific objectives are: 1) to setup and to develop the technical infrastructure; 2) to design and to implement some good examples of education/training course materials in the field of IT and Microelectronics; 3) to deliver the designed courses to our students/customers; 4) to find the best suited learning environments for a given topic/target group; 5) to support itself through contracts with different customers at the end of the three years period.

The Technical Infrastructure

Because of the unique distance learning environment of the Web and the availability in all Romanian universities the EDIT Project focuses on web-based learning environments.

The Design and Implementation of Course Materials

In 1998, EDIT Distance Learning Network starts to deliver his first course on Modeling and Simulation of Semiconductor Processes and Devices (MSSPD) for the MSc students from Department of Electronics and Telecommunications (Drondoe et al. 1998) using an in-house designed web-based learning environment: EDIT Learning Environment - ELE. Presently, we offer four courses for Department of
Electronics and Telecommunications: Electron, Devices and Circuits, MSSPD, Optimization Methodologies and Particle Simulation in Nanostructures (Drondoe et al. 1999).

**Impact/Target Groups**

The courses are open for undergraduate and graduate students, academics and researchers that can choose between different level of complexity depending on their previous knowledge and personal goals.

**The Type of Learning Environment**

Depending on the topic and/or target group the chosen learning environment used for implementation of the course material was either ELE and/or two well-known distance learning commercial products (i.e. LOTUS Learning Space and IBM Distance Learning Space/DLS).

The main features of ELE are (see Zolti et al. 1999): www dedicated architecture, distributed way of working both in design and exploitation, high degree of reusability, integrated communication system (e-mail and virtual classrooms), web-based publishing system, web-based voting system and secure web access to the database.

**Sustainability**

The sustainability of the project is envisaged through contracts with online continuing education courses on demand dedicated to enhancement of adults' knowledge/skills and/or to professional reorientation of the unemployed people. A special attention is also given to distance training of the work-force in the corporate sector.

**Conclusions and Further Development**

A distributed web-based learning network has been presented. At the basis of this implementation lies WWW dedicated architectures. This has allowed us to reach a high level of reusability and also cost-effectiveness. Currently, there is much work in progress to implement more courses within EDIT Distance Learning Network and to further develop the ELE by establishing some efficient authentication methods that would make awarding certificates more legitimate.

Design Processes Involved in the Creation of Computer Based Learning Environments: Preliminary Results

Steve Wakeham, M.Ed.*
e-mail: swakeh@po-box.mcgill.ca

Robert J. Bracewell, Ph.D.*
email: ed13@musica.mcgill.ca

* Educational & Counselling Psychology, McGill University

This short paper describes dissertation work in progress investigating the cognitive processes and social practices involved in the creation of computer based learning environments (CBLEs). Unfortunately, knowledge regarding the actual design process is very limited. Formal instructional design prescriptions (Dick & Carey 1985; Gagne Briggs & Wager 1988) and design principles based on cognitive psychology (Duffy & Cunningham 1996; Wasson, 1996) do exist but it is not clear how these prescriptions and design principles are used in 'real life'. Research into the cognitive processes involved in instructional design tasks is limited. Studies have examined such things as the extent and nature of alternative designs and stopping rules (Kerr, 1983), expert-novice differences in problem understanding and problem solution (Rowland, 1992) and, expert-novice differences in declarative and procedural knowledge and representations of design (Perez & Emery, 1995). There are very few studies of the design process involved in the creation of CBLEs. The lack of empirical work regarding the design processes and practices involved in the creation of CBLEs is surprising given the important contributions this type of knowledge could bring to future design activities. Studies of the process could indicate where typical difficulties exist and suggest strategies to overcome them. Additionally, it would be interesting to observe the effect of the application of one of design principles on the actual design process.

Theoretical Perspective

The theoretical perspective adopted in this study combines traditional human problem-solving (Newell & Simon, 1972) perspective with an activity theory (Engstrom, 1989) one. Problem-solving research focuses on the internal mental process involved in problem-solving and has been used to investigate instructional design problem-solving process but it has not been used rigorously to study designers of computer material. On the other hand, activity theory investigates how social systems influence human practice. Activity theory has not been used to study the design processes involved in the creation of computer based material but has been used to study other computer design activities. Research that combines human-problem solving and activity perspectives provides a theoretical perspective that recognizes the cognitive and social dimensions of design activities (Bracewell & Witte 1997; Cobb, 1994; Portes 1996).
Questions and Method
(1) What problem-solving processes are involved in developing computer-based learning environments (human-problem solving perspective)
(2) What social practices are involved in the creation of developing computer-based learning environments (activity theory perspective)

A case study of a design team at a local multimedia development firm was conducted over several weeks. Participants included one subject matter expert, an editor and a graphic artist. Data consists of participant observation field notes collected over several weeks, interviews and think-aloud protocols.

Results
Preliminary results indicate that the problem-solving activity of team members is goal directed and involves establishing numerous local plans and frequent evaluations. It is clear that a concurrent analysis that combines problem-solving and activity theory is a very promising approach. It provides data that allows researchers to analyse and interpret the relationship between internal mental processes and social context.

Abstract: This paper describes a case study on the use of community-based low powered FM radio that has been undertaken in Uganda as part of the work of the Commonwealth of Learning. It describes a media solution that employs low-powered FM radio as an effective method of delivering education and information to a rural community. It also describes the inhibitors to proliferation of community radio stations and reflects on the future directions for the use of radio as a delivery system for education.

Introduction

"All available instruments and channels of information, communications, and social action could be used to help convey essential knowledge and inform and educate people on social issues. In addition to the traditional means, libraries, television, radio and other media can be mobilized to realise their potential towards meeting basic education need of all". Final Report World Conference for All: Meeting Basic Learning Needs, Jomtien, Thailand, 1990.

Why Community Radio?

Community radio is an immensely powerful technology for the delivery of education with enormous potential reach globally. Creating opportunities for communities to utilise this delivery system will enable disadvantaged groups to engage in a development agenda, sensitive to their needs and aspirations. In order to serve the underprivileged and rural poor, mass media such as radio must create conditions and mechanisms that provide people with genuine access to useful information. Such mechanisms will offer ways in which people can express their sentiments, opinions, views, dreams and aspirations, their fears and insecurities, their strengths and capabilities, and, of course, their ideas for development.

High illiteracy rates and low levels of schooling among disadvantaged groups, especially women, in many developing countries continues to limit their ability to lift themselves out of poverty. The existing educational system has shown itself to be unable to respond to the massive demand for increased education. This is especially true in many poverty-stricken countries with respect to meeting the massive education needs of the rural poor. Consequently, disadvantaged groups continue to be denied access to information, knowledge, skills and technology transfer.

The answer is to deploy Distance Education techniques and delivery systems such as radio and television based at the community level to address directly local issues and needs.

In order to empower disadvantaged groups as equal partners in development, the limitations of formal and non-formal education are now being challenged. Urgent and new ways to achieve mass education, that can be both efficient and effective, are being sought. In this context, radio, an effective telecommunications medium, was proposed at the Jomtien, Thailand UNESCO Education of All conference in 1990 as one massive solution. Radio can cut across geographic and cultural boundaries. Given its availability,
accessibility, cost-effectiveness and power, radio represents a practical and creative medium for facilitating mass education in a rural setting. However ten years on since Jomtien, radio still continues to be an underutilized technology in education. This is especially surprising because from a learner’s point of view, radio is user friendly, accessible and a well-established medium. From an educational provider’s point of view it is easy to set up, produce and broadcast programmes. After almost hundred years of broadcasting history most nations of the world have more than a respectable level of engineering skills and broadcasting talent to apply the technology in education. In the last ten years, radio has been greatly enhanced by the emergence of new technologies, which have opened up new opportunities for a variety of forms of delivery and access for both broadcaster and listener. For example, portable, low cost FM transmitting stations have been developed and digital radio systems that transmit via satellite and/or cellular are being implemented in many parts of the globe. Internet streaming audio software technology has emerged recently to allow a global audience to listen the news from a distant country. And windup and solar radios have been developed thus freeing radios from expensive power sources. COL is addressing the issue of education for all with creative media solutions that fall under the banner of an initiative called The Commonwealth of Learning Media Empowerment (COLME).

**COLME – A Template for a Media Projects**

COLME is building creative media models for delivery of information and training in the area of non-formal and formal education.

COLME strives to:

- Provide new skills in the use of technology for the disadvantaged
- Provide media models that will stress local participation and transfer of knowledge and skills
- Provide opportunities for disadvantaged groups to participate and benefit from new technology and media based initiatives
- Create a capacity for dialogue among government sectors, institutions and different interest groups
- Create a research base and body of knowledge that can be utilised by Commonwealth governments, organisation and communities as models for media and technology based initiatives.

Media projects in radio stations and projection, video and audio production, and computing solutions have all been part of the work of COLME in the past several years. The focus here is a portable FM radio station that has been used in several developing countries of the Commonwealth such as Uganda, Namibia and South Africa.
Overview of the Station

Radio is a very powerful technology that can allow large sectors of the population to be reached with information, quickly and economically. Due to national broadcast regulations in many countries, community radio stations have not developed. Also the cost of transmitters, infrastructures, and equipment, has placed most potential community broadcasters at a disadvantage, especially those in the remote rural areas. There is a distinct information gap to the rural corners of some countries resulting from the lack of service by national broadcasters who in some cases have weak or non-existent signal coverage. Under COLME, portable FM radio systems have been tested and implemented as part of media project work over the past three years. The station configuration that was first developed has, with input and data gathered from COLME initiatives in the field, have aided the manufacturer in altering the station to address the each community’s need. The station configurations range in price from three for five thousand dollars US including all elements, antenna, transmitter, console, mixer, microphones and CD and tape decks (Figure 1). The stations can run from 12 V DC or 120/240 AC.

Figure 1 – Pictured is a station in its watertight carrying case (on the consul starting on the left top the gooseneck microphone, below is the mixer, top right are two tape decks, below are two CD decks). The transmitter and power supply, not pictured, are housed under the consul. The consul is removed from the carrying case when in operation (see Figure 4 for operational mode).

Keys Elements to Success

There are number technological factors that are important in the initial needs analysis before a station can be considered. First the physical landscape must be conducive to an FM signal to reach the intended target audience especially if rebroadcast of the origin station signal is not possible due to cost or licensing regulations. If the landscape is mountainous then there will be difficulty in the signal reaching a large radius of users. Secondly, the station target audience must have radios or access to radios. Thirdly, there must a situation where there is a steady flow of content and a regular broadcast schedule.
Fourthly, the station must be targeted to the local users so that they can directly relate to the content, language, and situations discussed.

In the feasibility stage before station implementation certain conditions must exist to improve the element of sustainability. In-country stakeholders are identified for each of the stations. Their role is to insure infrastructure is in place for FM radio and that all licensing and issues pertaining to community broadcasting are dealt with.

Another important factor is that the broadcasts are in languages that are used daily in the local community level. The national or regional stations do not have the capacity to aim linguistically or at the level of information detail for rural community issues. Community-based stations can be effective if well managed in providing information and training directly to the community. In the case of the COLME installed community station in Uganda, it was imperative that the station be able, by law, to rebroadcast Radio Uganda in the event of important political announcements. Therefore, among the technological upgrades in the design of the station, in addition to the interface for telephone calls, extra microphone inputs for group discussions, and a more powerful transmitter, a facility for radio rebroadcast of the national government station, (in Uganda, Radio Uganda) and international broadcasters (such as the BBC) was implemented.

The overriding factor to the success of these stations has been the proper community access and ownership, which was paramount in the initial project design. If the station is or becomes an integral part of the voice of the community and local interest groups have an equal say in the information that is disseminated via the station, then there is a lesser risk of failure in the long-term sustainability of the station. This can be achieved with good station management that works with community leaders and committees consisting of both political and community leaders.

The local stakeholders, with the aid of COLME, will provide on going evaluation of the stations via listener surveys and media expert evaluation. Workshops will be given in production and survey techniques that will aid broadcasters with improving programming to suit the needs of the community. Local broadcasters will be tapped to train in advanced broadcasting techniques and programme development that will improve community radio personnel.

**A Solar Station on the Move – A COLME Case Study**

Apac, Uganda is located in the northern region of Uganda. This COLME project was a cooperative effort with the Minister of State and Tourism, The Right Hon. Akaki, to work with community leaders to implement an FM radio station in the Apac region. The COLME feasibility study revealed several limitations with the electrical infrastructure, which was not reliable. This was a result of load sharing throughout the country (Apac would not receive power for several days). The power was also not usable for electronic equipment due to the dramatic power fluctuations. Therefore, it was decided that in order to maintain a reliable broadcasting schedule and develop the station as a center point to community activities by different groups, Radio Apac would be operated entirely by solar power. This would free the project from the constraints of electrical situation and the tariffs associated with it. A configuration was determined, in consultation with a solar distributor in Kampala, to allow the station to stay operational during the eighteen-hour broadcast day. Eight solar panels and seven deep cycle batteries were installed at the station, which now provide lighting and all the station power requirements for daily broadcasting (see Figures 2 to 4). The lifespan of solar installations is over a decade with low maintenance costs.

A committee was organized and a station manager appointed. This person works directly with the community to develop programming and allow the development of community involvement. The station
has a rebroadcast facility incorporated for programmes from the national broadcaster as well as the BBC and WorldSpace. A further radius of listeners will be taken in Spring 2000 with a retransmission unit that will allow the signal to take in other populated areas. It is anticipated that the total potential listening audience will be over one million. A VHF/UHF radio system will also be implemented to act as a community telephone that will interface into the FM radio system. This will allow the broadcasters to out to the community and speak directly to groups live on air thus eliminating the issue of travel to the station by people such as farmers and medical officers. Links have been made to educational programmers in South Africa to supply educational programmes to the station. The station has been used by the government for health related issues and announcements. There is also an element of income generating by the station with the interest of local businesses in advertising their services.

Figure 2 - Receiving the solar panels at the station site

Figure 3 – Installing the panels
Figure 4 – Radio Apac, 92.9 FM on air, powered by the sun

Conclusion

Radio is an effective system for delivery of education to large numbers of people. It facilitates information exchange at the community level, acting as a “community telephone” and can be effective in literacy and formal/non formal education. Analogue systems for radio will be supplanted by digital broadcasting in the coming decade, however digital radio will pose issues including cost of radio receivers and renewal of broadcasting infrastructure. Analogue radio systems, such as the portable solution that COL and others have utilised in community FM radio initiatives, can be effective in delivering education to the masses without the high infrastructure costs associated with radio broadcasting. With community broadcasting not only can broadcasters focus on addressing local needs through their own produced programming, but also have the choice among a tremendous variety of quality educational content that is available via rebroadcast from national and international sources whether it is delivered via satellite or via the Internet. Rebroadcasting also should be balanced with the needs of the local community and the provision of appropriate and relevant programming content.

There is a marriage between the digital and the FM analogue systems that is taking place. The convergence also includes Internet streamed audio based broadcasters that can effectively be employed by the community FM station in a rebroadcast mode. Will we be able to say in ten years that radio’s potential for educational delivery to millions of disadvantaged groups has finally been realised? With the many varied formulas for convergence of digital and analogue technology and the vast selection of content and tools to create original culturally sensitive material for education at the community level, we state clearly - yes. But will the bodies that regulate frequencies for community radio initiatives reform regulations to reflect the current technological developments and pressing need for mass media to meet the goal for education for all in the next ten years? We can only hope. The past ten years and the failure of Jomtien is a heavy burden to bear. The next ten should see the harnessing of radio, analogue, and more so digital, as the powerhouse for delivery of education. Governments should be prepared to adjust broadcasting regulations to adhere to technological developments and realities, and also consider community based mass media delivery as an effective solution for improving a nation’s human resource development towards the goal of education for all.

ABSTRACT The authors will describe the programs used in the preparation of faculty who are participating in an Web-based Integrated Curriculum in Engineering (ICE). The programs are a blend of efforts between faculty and the Educational Technology Team.

The ICE program is a comprehensive effort between engineering faculty, humanities faculty, physics and mathematics faculty. The ICE program includes specifically designed sections of the foundation courses required of all engineering students: the calculus sequence, the physics sequence, the humanities sequence, social science, and introductory engineering courses. What differentiates the ICE program from traditional engineering curricula is that all courses incorporate active and collaborative learning and a reliance on computer and web technology. In addition, the ICE program promotes team learning, team design projects, and a well-documented series of assessment practices.

Background of ICE:

The motivation behind this program includes:

- high attrition rates in calculus, physics, and chemistry;
- perceptions of the faculty that these students do not read and write well;
- a lack of comprehension of the building nature of the foundation courses and their relationship to the engineering curriculum;
- the lack of continuous use of common computer technology;
- failure of students to adjust to the university environment;
- and the isolation that many students feel in such programs of study.

The Integrated Curriculum for Engineers was introduced in 1997 to a volunteer group of 65 entering freshmen selected from a pool of 130 initial volunteers. In succeeding years, similar sized classes have volunteered to enter this program.

This paper describes the programs specifically designed by the Educational Technology Team and the programs put together to teach faculty how to use active and cooperative learning in the various courses which are included in ICE.

Description of ICE methodology
Computer and web technology are crucial to the implementation of the ICE program. Students in this program must have laptops for use in each course. Classrooms have been wired so students have access to the campus network and access to the Internet. Common software in use includes Maple, Microsoft Office, Bentley Microstation, and Internet access. All courses are web-based so that students have access to each course in the program, to reference materials, tutorials, reviews for exams, and to each faculty member and to their peers. Forums, emails, chat rooms and links to other sites are all available to every student. Students can plug their laptops into any campus port as well as their dorm room. The authors will discuss examples of daily classroom usage of a web-course and we will comment on the active and collaborative nature of the courses by showing how these are incorporated.

Another crucial component of the ICE program is the use of cooperative and collaborative learning in each course. Thus, in addition to restructuring the content, all courses have been redesigned for an active and collaborative learning environment. Each course assigns team exercises, daily or weekly, which are to be done both in and outside of the classroom. In any of these courses, it is common to ask a team to present their work to their peers at the end of a daily class. In addition, the mathematics faculty designs external team problems that are reported in class about a week later. For each such team problem it is required that the problem be written using a word processor and the report is graded for composition and exposition as well as the mathematics. Class presentations are oral and each team receives a grade based upon accuracy, style and clarity of exposition.

Students in the program are assigned to a team of four. A team is selected based on the class rank condition. A team stays together through all the courses during that semester. The engineering faculty devote the first week of the introductory engineering course to team building skills and continue to monitor the effectiveness of the teams throughout the semester. This engineering course also serves as a student success course based on the University 101 model and include topics such as time management, study skills as well as adjustment and orientation to the university.

Programs of the Educational Technology Team

Most of the faculty who teach at Embry-Riddle use word processing, spreadsheets, and email. A few of the ICE faculty had some acquaintance with use of the web, but none had ever put a course up on the web and many were apprehensive about trying. A template was designed specifically for the web-based portion of the ICE program, and faculty members were provided with training on how to develop and post materials in the template.

Because the ICE faculty were technically proficient in specialized areas and working with a web template specific to their program, a customized training program was developed for them by the university Educational Technology Team. A description of the ICE web template and training program and ongoing support for the ICE faculty will be presented in this talk.

Programs used to acquaint faculty with Active and Cooperative Learning.

When faculty think of teaching, they think of lecturing - the me-centered model of education. Active learning is participatory - an idea or theme is selected, the students think about it, promote their own understanding, and share it with the class. Collaborative learning is group based - in our case, team-based. It requires the team to work together in and out of class on assignments.

Assessment

Assessment of these training programs include informal and formal components. In this presentation, the authors will comment on each, including what worked and what did not. In addition, we will comment upon some of the measures used by faculty in the ICE program itself. These include attitudinal surveys about use of teams, use of active learning, use of computer technology, use of computer software, use of web-based courses, adjustments to the university, and a variety of other topics. Assessment of use of web-based materials is done by formal assessment at the end of the term. All aspects of assessment will be shared with the audience.
FutureBoard: Supporting Collaborative Learning with Design Activities

Abstract: The FutureBoard system has been developed to support the collaborative learning process, especially design activities in Project Based Learning.

Two kinds of board system have been created: one is a Personal Board for supporting the personal reflective thinking process based on a wireless note PC, and the other is a Collaboration Board for supporting collaborative learning and the creative process based on a 50 inch monitor with pen input support.

Project Based Learning and Design Activities

In Japan, the national curriculum standards will be changed in 2002, and Project-based learning known as “The period of integrated study” will be introduced to elementary and secondary schools. During the process of project-based learning, design activities such as making books and posters are critical because they give students the chance to reflect on their ideas. Computers have been used for the design activities in project-based learning, however they are limited to student’s individual expression when using graphic software and DTP software.

We believe computers can render the process more dynamic when designing activities such as in collaborative design for the social construction of ideas, by many professional designers do.

Design Process of Professional Designers

We have analyzed the design process of professional interface designers (a university professor and two professional designers in a private corporation) in order to clarify points to support the collaborative design process.

1. Using Tracing Paper
All used tracing paper in the collaborative design process. One designer drew an idea on paper, while the other put tracing paper on it, revised and added new ideas to previous ideas.

2. Fast and Interactive Process
This process was fast-paced and interactive. They sketched ideas in a few seconds and talked like a “This is better,” pointing the revised idea.

3. Using Personal Spaces
Sometimes, Personal spaces were used such as on a small memo or a corner of the tracing paper to dot down their ideas.

Outline of the FutureBoard System

Following this analysis, we made design policies for the new system that supports the collaborative design process. We named it “FutureBoard”.

1. Tracing Paper Function
FutureBoard contains 8 layers of tracing paper wherein the level of transparency can be modified. The lowest layer is called the “Master Layer”, a special layer for guiding design activities such as Maps, Axes, Tables, etc.
2. Pen Input and Drawing Tool
A user can employ the pen input (or his/her finger) similar to ordinary paper resulting in the interaction being much quicker. Moreover, the software becomes not just a paint tool but a drawing tool, so that each object drawn can be moved or deleted.

3. Personal Board and Collaboration Board
Two kinds of board system have been developed: one is a Personal Board for supporting the personal reflective thinking process based on a wireless note PC, and the other is a Collaboration Board for supporting collaborative learning and the creative process based on a 50 inch monitor with pen input support.

Personal Board and Collaboration Board

The hardware of the Collaboration Board system (CB) consists of a PC and a 50 inch projection monitor with pen input support and a wireless LAN station.
The software of CB is a simple drawing programme with 7 half transparent layers. The user can control the visible/invisible aspects of the specific layers as well as control the 5 levels of transparency. All operations are assigned to the icons, thereby eliminating the menu bar.
The hardware of the Personal Board (PB) system consists of a pen-based PC and a wireless LAN card.
The software of PB is a subset of the Collaboration Board that has two layers and is optimized for SVGA screen. (The CB is of XGA size)
Initially, students will use the PB, and then send the work to the CB's layer. With the CB, they can lay ideas on the other half of the transparent layers. And CB's data can be downloaded to a PB using the wireless LAN system.

FIGURE 1: Jr.HS students using Personal Board and Collaboration Board

Evaluation

The FutureBoard system was evaluated from November to December of 1999 at Utase Junior High School in Chiba Prefecture, JAPAN. The system was used in project-based learning about "Makuhari Bay Town" where the students live. To meet the goals of the curriculum, Small groups were formed. The students explored and researched many aspects of their town, such as the traffic system and road safety, the soundscape of the town. They reported the result of their research on the Personal Board and transferred the data to the Collaboration Board. Using Collaboration board, They discovered new ideas from the overlapped information and made final presentations to an audience composed of classmates, teachers, municipal officials and parents.

We are now evaluating how these tools supported the collaborative process by protocol analysis and interviewing. The main points of the evaluation center around how 8 half-transparent layers and drawing tools work as a cognitive resource in collaborative process.

Acknowledgements

This research is generously supported by an IPA (IT Promotion Agency, JAPAN) Grant. We deeply appreciate the cooperation of the students and teachers at Utase Junior High School in furthering our research.
Merging Physical Manipulatives and Digital Interface in Educational Software

Anna Zacchi, Nancy Amato
Dept. of Computer Science
Texas A&M University
USA
{zacchia, amato}@cs.tamu.edu

Abstract: In this paper we describe how elementary school students used physical manipulatives in conjunction with the digital interface of educational software for geometry. The blending of physical manipulatives and digital interface may help them to overcome the limits of the representation and interaction modalities of the digital interface.

Introduction

Our study used SuperTangrams (Sedighian & Westrom 1997), a program developed by the EGEMS group at the University of British Columbia. We introduced manipulatives that students could use while playing with the software. The idea was to use manipulatives in conjunction with the software in order to overcome the representational problems of the interface. Manipulatives allow the students to experience what they are doing on the screen in the real world.

SuperTangrams. SuperTangrams is a computer-based learning environment for two-dimensional transformational geometry. Learning of this mathematical domain is situated in the context of the traditional tangram puzzles game activity. The player is challenged to put together several geometric shapes to fill a given outline. To move the shapes on the screen the student selects and applies to them one of three transformations: translation, rotation, and reflection.

Subjects and Settings. The study involved approximately 180 fifth grade students at a College Station, Texas, elementary school. The task of each student was to play with SuperTangrams to solve the tangram puzzles. The student was free to use the tools that we placed on the side of his computer. Data collection techniques included class observations, video-recordings, scratch paper used, pre-tests and post-tests, questionnaires and log files of computer sessions.

Use of Physical Manipulatives

First set of manipulatives
During a first study session (two weeks), we provided the students with the following manipulatives: 1) a set of tangram plastic shapes, 2) a reflection mirror, 3) a colored grid board with a rotating stick. The board had two different drawings on it: a line for reflection and a circle divided in 16 sectors of equal size. This is consistent with the software that allows the minimal angle to be 1/16th of a circle. A stick is connected to a hub at the center of the circle and can rotate 360°. The idea was that the students would place a shape on the circle and then rotate it by pushing against it with the stick. We intended for them to use the reflection mirror with the line drawn on the grid board to find the reflection line.

Rotation. One common use of the shapes was to put them on the screen and animate them. A video recording shows a girl using them for rotation. She started superimposing one plastic shape on the digital shape on the screen, and then she moved the shape along the arc of rotation trying to move and rotate it at the same time. In this operation she paid attention to the position of the shape on the screen, but not to the orientation, or angle of rotation. The students who used the grid positioned the plastic shape on the circular drawing, trying to position the shape in the same orientation as the one on the screen. Then they would push the shape with the stick until the shape could reach the orientation of the target. They would count the number of sectors the stick moved and
move the digital handle accordingly. Some students felt comfortable with the board, while some others preferred to bring the shapes directly to the screen.

Reflection. Students did not use the mirror on the grid board with the plastic shapes as we had expected. Instead, they placed the mirror directly on the screen and looked for the reflected image of the digital shape. The first operation involved was to position the mirror until they could see the reflected image superimposed on the target. Once the position was found, they had to play with the digital handles to position the reflection line along the position found for the mirror.

New Manipulatives
The use the students made of the manipulatives surprised us, since they preferred to use them on the screen, merging the physical operations with the digital ones. Thus, for the second session, with a second group of students, we modified the manipulatives to make it easier for the students to use them on the screen. We eliminated the grid board and built a rotation tool consisting of two popsicle sticks joined together at one end in such a way that they could rotate, and placed some sticky paste on the other ends. The popsicle stick had more success than the grid. The students would stick the chosen shape at the end of one stick, and position the two overlying sticks directly on the digital radius of rotation, with the plastic shape matching the digital shape. Then they would rotate the stick holding the shape and keep the empty stick in the initial position. When the plastic shape reached the target, the opening of the two popsicle sticks represented the sought after angle. In this case they could hold the right "angle" in their hand. Finally, they would recreate the digital angle playing with handles, holding the physical one as a model.

Student reactions
The second set of tools had more success than the first. It was more natural for the children to bring the tools to the screen, and they could physically experiment with the transformations. In the questionnaires we asked children if it was good to have manipulatives, and if they helped them learn. Here are some of the answers:

"They helped because they were 3D;" "they helped you to learn the movement;" "all tools because they helped you think ahead;" "you need some reference to look at;" "because it is important to have stuff you can work with in your hand;" "it helps understand."

Conclusions And Future Work
Software running on a computer is something abstract: when the student drags a handle with the mouse something happens on the screen. In educational software for geometry it is important that the student learns to relate what happens on the screen to the real world. Our preliminary findings indicate that physical manipulatives can be a valuable addition to educational software. We noticed how the use of manipulatives helped students overcome limits of the representation and of the types of interaction allowed by the interface. For example, additional information on the screen whose purpose was to help the students, such as additional lines, actually confused them, causing them to miss important concepts. Using a physical representation of those concepts, such as an angle between two popsicle sticks joined together, helped them to focus on the main aspects of the transformation without being lost in representation details. During our study we collected log files and data relative to pre-test and post-test. The statistical analysis of this data will determine the effect on learning of the different tools.

Contemporary education needs to be connected to the very world it purports to study. In this context, media archives and documents are value-added material that can support both traditional pedagogical practices and media literacy related activities. Public broadcasting archives and related documents can play an edifying role in offering various sources through which to grasp a host of current and historical issues. Recognizing the educational value of its media assets, Radio-Canada is working with schools, colleges, and universities in exploring a variety of pedagogical scenarios in which media content can complement traditional study material. This presentation will illustrate how Canada's public broadcaster can, by means of forging partnerships with various organizations (multimedia, cultural, or educational), and repurposing of media archives, play an active role in the development of educational Web content as part of a constructionist approach to learning.
Learning Code

Suzanne Rhodes, Human Code, USA

Who We Are

The Learning CodeTM development team extends beyond the walls of our studios to include the clients we work with and the learners we work for as well as a passionate and compassionate team of education specialists which includes the following professionals:

- Educators
- Interaction Specialists
- Producers
- Artists
- Technologists

What We Do

At Human Code, our mission is to humanize technology to fundamentally transform the way people learn, work and play. Human Code's Learning Technology Group meets this challenge by designing spectacular learning environments.

Our approach affords the Learning Technology Group with the discipline to manage the complexity of tasks that characterize each design stage, as well as the flexibility to provide appropriate consideration to the six interrelated components that define each of our spectacular learning environments. These components include:

- Setting
- Community
- Content
- Pedagogy
- Tools and Technologies
- Assessment

How We Do It

Derived from years of best practices and research in the field of learning technologies, our Learning CodeTM approach to educational environment design is an iterative process that motivates our team of specialists through the following comprehensive design stages:

- Envision
- Design
- Produce
- Implement
- Integrated, On-going Reflection

Who Benefits?

Targeted learners

Learning Code TM engages the learner in an experience that is personal, relevant and meaningful. Our environments engender a love of learning, content mastery, higher-order thinking, and inspire life-long learning.

Clients and Educational Partners
Learning Code's collaborative nature transforms clients into development associates. Skillfully managed projects, delivered on-time and on-budget meet the needs, goals, and expectations of our client partners.

**Human Code**

Each project affords our company teams with heightened knowledge, skills, and abilities that inform future designs and techniques. The result is continually evolving processes, products, and services.

**About Human Code**

Human Code is a leading developer of interactive experiences for e-commerce, games, learning systems and marketing communications. The company's approach combines creativity, consulting and technology to create user-centered solutions that change the way people learn, work and play. Human Code's creativity and client-service focus are maintained through the company's Studio Network, which includes Austin Studios, Presage Studios in San Rafael, CA, Human Code Japan in Tokyo, and Human Code Shanghai. The company was founded by industrial designers in Austin, Texas in 1993, and received venture investments from Austin Ventures and Applied Technology in 1995 and 1999. Additional information on Human Code can be found at www.humancode.com.

Human Code’s Learning Technologies Group is emerging as a market leader in creating spectacular learning environments. From a statewide initiative in Idaho to programs that provide entry-level technology workers with training in hard and soft skills, Human Code is becoming known as a true total solutions provider for educational technologies.
Teaching and learning in a virtual campus:
The model of the Universitat Oberta de Catalunya

Albert Sangrà  
e-Education Laboratory  
Universitat Oberta de Catalunya  
assangra@campus.uoc.es

Lourdes Guardia  
Head of Instructional Design Unit  
Universitat Oberta de Catalunya  
lguardia@campus.uoc.es

By combining the latest technologies with both a solid pedagogical foundation and continuous evaluation, the Universitat Oberta de Catalunya has built a Virtual Campus: an electronic communications environment that provides the means to effectively support the tutoring of students, and the provision of university resources and social activities.

It has presently a total of 13,000 registered students. Eight main degree programs are offered, as well as Master programs, postgraduate courses and a wide offer of continuous education programs.

The organization is also working on the Metacampus, which mission is to demonstrate the global, virtual cooperation of universities; a concept known as the flexible university which is achieved by interconnecting the partners virtual services and infrastructures.

It will be able to capture, register, invoice, teach, assess and accredit courses and provide all the administrative services in a global scale, using the Internet as the only medium to support all these educational processes.
Deploying Web-Based Assessments
Eric Shepherd

Learn the principles of creating and administering Web-based tests and assessments using Question Mark™ Perception™ software. Find out how to use Perception's authoring wizard to create questions in a variety of formats: multiple choice, multiple response, hot spot, text, numeric, selection, and matrix questions as well as explanation screens that can include text, graphics, and multimedia. Participants will also learn how to create multiple question banks from which to assemble tests, surveys, and questionnaires. Other topics include how to set up interactive feedback, create adaptive tests, analyze test results, and create reports. Example questions will be presented from various applications including competency testing, employee recruitment, customer satisfaction questionnaires, study aids, diagnostic tests, skills assessments, product knowledge exams, course evaluations, and certifications. The presentation will cover such issues as test security, linking with learning management systems, and the use of Perception Secure Browser for high-stakes tests.

The LearningStation.com

The LearningStation.com is dedicated to providing a realistic and cost-effective way to manage technology and make it available to the teachers, students, and administrators who will transform the educational process to meet the expectations of the information economy.

The LearningStation.com is the leading and largest Application Service Provider (ASP) and portal in the educational market, providing online access to educational content, tools, and applications, on a subscription basis. With The LearningStation.com, a managed and maintained library of applications is made available to PCs, Macintosh systems, and thin-client devices across the school’s network and over the Internet. The LearningStation.com Chief of Innovation and Co-Founder Jim Pennington states, "Schools are extremely excited to hear that they can get out of the software management business, and focus on using software rather than delivering it," says Pennington, "and the fact that they can make good use of their installed base of cross-platform computers has a significant impact on their ability to make technology accessible to more students and teachers."

The Education Market Opportunity

Technology is now accepted as an integral part of education in Canada. As awareness of the importance of preparing students for the information age grows, school boards are turning an increasing amount of attention to this process. Educational spending now accounts for 8% of Canada’s budget, and technology is fast becoming a priority, including significant investment in hardware, software, and cabling. In the 1997 - 1998 school year, $230 million was invested in bringing computer technology into Canadian classrooms.

Despite a high level of spending, most schools are equipped with a collection of computers ranging from Apple II to x386 to Pentium-based computers. This presents an implementation nightmare. It is currently impossible for schools to incorporate new software applications into their curriculum without consistently upgrading their hardware, a situation which is neither desirable nor cost-efficient. Regular overhauls of computer equipment is financially impossible for schools with limited budgets. This issue is probably the single largest barrier to institutional technology integration.

The LearningStation.com presents a solution to this problem. It has the potential to completely reorganize instructional computing as we know it. It would allow schools to run brand new applications, as well as provide web access and e-mail, while removing the financial burden of having to constantly upgrade hardware. It would also allow schools to use equipment donated through programs such as the Computers for Schools Program, which provides schools with recycled business and government computers.

What is thin-client computing?

Citrix Systems, the world leader in server-based computing, reports over 2,000,000 ports in place supporting over 10,000,000 users today. The idea behind the thin client is simple: concentrate computing power, storage, applications, and data on "servers" (powerful computers) and provide users with a simple "client" computer that is easy to install and maintenance-free. Users connect to The LearningStation.com servers over the Internet to process applications, access files, print, and perform all other services available to ordinary computers. Since the applications and data are kept on a server, only keystrokes, mouse clicks and screen updates travel the network, so just a fraction of the normal bandwidth is required to run applications. Thin-client delivery has the flexibility to support any device—from full-featured computers like PCs, Macintosh systems, and UNIX workstations, to Windows-based terminals and hand-held information appliances.
How do schools benefit from using an Application Service Provider (ASP)?

- **Reliability and Ease of Use**
  ASPs allows teachers and students to spend more time working on technology projects such as accessing information on the Internet and using educational software—rather than spending class time fixing and upgrading PCs or adjusting software programs to suit each individual workstation. Users simply log on and access their applications and data.

- **Simplified, Centralized Management**
  The LearningStation.com's servers are managed by skilled network administrators, removing this responsibility from educators. Updates and additions are made only once at the server and are immediately available to all users.

- **Lower Cost of Technology**
  Zona Research, a technology research firm, estimates that organizations will save 54-57% of their systems administration costs over a period of 5 years with a thin-client computing approach. Using the services of an ASP further reduces costs by eliminating software upgrades and inefficient purchasing volumes.

- **Security**
  Vital data and applications may be kept on The LearningStation.com servers creating a higher level of security. Sensitive applications and data are made available to authorized users only via password protection. Data is effectively secured and backed-up in one central location either on a local customer server or at The LearningStation.com.

- **Universal Access**
  Since applications and data are stored on the server, access is available to students and faculty from any machine at any location and at any time via an Internet connection and the desktop appearance is always consistent.

**Strategic Alliances**

The LearningStation.com has created a network of strategic partners supporting thin-client delivery of applications to the education market. The LearningStation.com is continually looking for new strategic partners to enhance its offering to education customers.

Software Publishers and Online Content—The LearningStation.com has strategic agreements to offer products from:

- Microsoft
- The Learning Company
- Sunburst Communications
- Saratoga Group
- Infonautics
- Schepp-Turner Productions
- CBT Training
- Lotus
- Learning Outfitters
- Steck Vaughn
- MediaSeek
- Webivore
- Fog Cutter
- SkillsBank
- And many others

Technology Partners—The LearningStation.com has strategic agreements with:
Server Access Accounts

The LearningStation.com customers use Server Access Accounts (SAA) that allow access to the LearningStation.com server farm via the Internet. Users have access to a basic package of applications and services that include:

- Reference.Center, a customized version of Infonautic's Electronic Library
- Adventure Online, real world-based core learning materials
- Star Office Suite, an online suite of productivity tools
- Facilitator, conferencing tools for collaborative learning
- Internet filtering and virus protection utilities

Additional products and services can be added as desired including:

- Microsoft Office or Works
- SkillsBank or Cornerstone basic skills software
- Classroom Planner, a comprehensive teacher productivity tool
- Webivore, a directory of educationally reviewed web content
- Explorasource, a curriculum correlation tool for teachers.
- Many, many more

Schools require a Local Area Network (LAN) to provide users access to The LearningStation.com. A T-1 line, or a fast broadband connection like high speed cable modems, is recommended for school site access, while an individual account can gain access over a modem. SAA's are for concurrent usage, so schools only need to purchase as many accounts as they will use at one time. Access is 24 hours a day, seven days a week, allowing teachers, students and parents to gain access from home and after hours as well.

Total Cost of Ownership

Typically, educational technology purchase decisions are made on the basis of acquisition cost and compatibility. As technology usage becomes more pervasive, educators will need to pay more attention to the Total Cost of Ownership (TCO) which includes support and maintenance costs, reliability, and lifecycle replacement costs. And in these areas, thin clients continue to outperform new PCs in cost effectiveness by a wide margin.

Zona Research, a technology research firm, estimates that organizations will save 54-57% of their systems administration costs over a period of 5 years with a thin-client computing approach. And this cost savings is in addition to the lower cost thin-client devices and ability to leverage your current computing infrastructure—hardware, applications, networks and training—to extend the reach of your thin-client network.

A study by the Gartner Group released in June 1999 estimated that thin-client applications require 80 percent less management than traditional PC deployment (Computer Reseller News Online, 6/1/99).
Here are some details of the Gartner Group Study for annual PC cost of ownership:

- Actual cost of the PC Three-year depreciation $677
- Non-Labor Expenses Software, network connectivity, etc. $1677
- Technical Support Service, Maintenance, Help desk $1089
- Network Capital Cabling, Servers, etc. $585
- Network Support Management, virus control, etc. $544
- End User Admin Backups, upgrades, productivity loss $981 from downtime, etc.

**Total Cost of Ownership $6507**

Thin-Client Computing Cost Savings

While schools typically cannot provide the type of support that is described above, the information serves to illustrate the cost savings that thin client computing provides. In fact, the lack of resources available to support PCs makes an even stronger case for thin-client devices in education. The cost savings of thin-client computing in education are just starting to be quantified:

- Thin client devices can have an effective life of 5 - 10 years
- Your current PC’s can be easily utilized as Thin client devices
- Software is a fixed annual expense without hidden version upgrade expenses
- Network support can be provided centrally on servers instead of desktops
- End users have a common, easy-to-learn desktop environment
- Downtime loss from viruses, hardware failures and vandalism are all but eliminated
- Universal access enhances productivity and leverages the technology to more users
SPECIAL INTEREST GROUPS
Campus Notebook Computer Programmes

Craig Blurton, University of Hong Kong, China

Notebook computer programmes are proliferating as many universities move from "corporate" ownership of computing resources to individual ownership. Benefits of such programmes have been widely touted by universities and commercial notebook computer vendors including enhancement of universities marketing position, decreased IT expenses because of cost-sharing between institutions and students, extended learning opportunities, and enhanced IT skills.

But how each individual programme is implemented is highly contextualized on local goals, needs, and circumstances. This special interest group meeting will give representatives from tertiary institutions an opportunity to interact, share success stories, identify common concerns, and perhaps develop collaborative efforts around the issues of "assured access" and "mobile computing."

Issues that may be discussed include:

* Planning and implementing such programmes.
* Multiple or single vendor solutions
* Cost-effectiveness
* Bridging the gap between academia and business
* Managing vendor relationships
* Equity of implementation
* Staff support and development
* Barriers to success
* Programme evaluation
Providing Quality Distance Education in an Outcomes-Oriented Program

Dr. Ginny Engman
Fort Lewis College
52 Hesperus Hall
Durango, Colorado 81301...
engman_v@FORTLEWIS.EDU

Abstract: Providing on-line programs for pre-service teachers has presented many issues. Assessing the effectiveness of one's teaching in the classroom is difficult under the best of circumstances; doing so through distance education is even more challenging. The program at Fort Lewis College has addressed these issues and, while resolving many of them, has developed some concerns that require further study.

Quality Distance Education in an Outcomes-Oriented Program

The development of an on-line program in elementary and early childhood licensure has raised many issues. It has also caused some dissension among the faculty. The program consists of all courses in the traditional program being offered through Top Class and Web CT. Currently two faculty (of the 10 full-time faculty) have been responsible for the majority of the program delivery. There has been an increase in the number of students who have opted for this avenue since its inception three years ago. Students are admitted to the program in the same way that students are admitted to the on-campus program: minimum GPA of 2.5, proof of having worked with children, pass a state basic skills test, pass oral exam, and adequate ACT/SAT score.

Causes For Concern

There are three major causes for concern. First, after an initial orientation meeting on campus, the faculty have little or no face-to-face contact with the students. They must rely on the written evaluations and comments of the public school teachers with whom the students are placed. Historically, these assessments have been somewhat skewed toward the positive. In fact, the teachers are willing to be more objective if they do not have to put their observation in writing. However, for legal purposes we need to keep a “paper trail”. The problem arises when we face a disconnect between what the teachers are writing and the actual effectiveness of the student (teacher candidate). It comes to a head at the student teaching experience—after the student has finished all course work and pre-student teaching practica. The dilemma we face is that the students are out of our service and (hence, the term distance education) so that it is not possible for our faculty to observe and evaluate them on-site. When predicted teacher How do we balance this with our commitment to preparing qualified, caring and competent teachers?

Second, besides the teacher education courses, there is a need for courses outside the department to be delivered online. There are auxiliary courses in Exercise Science, Art and Music that our students need as part of their licensure program. Additionally, if the are seeking a degree in Arts and Sciences, they will need to take classes in they major. There has been much resistance on the part of faculty to develop an electronic delivery of their courses. How can we break through the barrier that keeps faculty from taking a risk in the area of distance education?

Third, and lastly, until recently, the upper level administration has been reluctant (not necessarily resistant) to invest significantly in distance education. There is a skepticism about the ability to have high quality and require high standards in an electronically delivered program. How can we educate decision-makers so that we can get their buy-in for distance education?
How to Prepare Teachers for Integrating Multimedia and Technology into K-12 Classrooms

Barbara G. Foster, Ed.D. – Spalding University: Louisville, KY USA bfoster@spalding.edu

Abstract: To meet the needs of diverse learners, teachers must be able to integrate multimedia and technology into K-12 classrooms. Participants will walk away from this session with practical assignments and constructivist activities to enhance professional productivity and support instruction, successful assessment strategies that promote positive attitudes for facilitating the lifelong learning of various technologies by teachers and students, and samples of student work. Topics will include: knowledge of basic multimedia terminology, applications, and technologies; development of basic skills in operating multimedia hardware to support instruction and learning; development of basic skills in using and integrating the Internet and multimedia applications into the curriculum to meet the needs of learners at different age levels and in different subject areas; experience in making presentations using multimedia technologies; experience in designing and planning instruction that integrates multimedia technologies into the curriculum; and awareness of the copyright laws as they relate to educational technology.
Educational Technology and Context: an exploration of values, roles, and concerns from Lecturers, tutors and instructors.

Introduction
Educational and instructional technologies are increasingly becoming part of learning and teaching in higher education institutions. There is no doubt therefore that the adoption of such technologies in this context impacts upon many areas of university life. It could be argued however, that in addition to significant benefits to the institution and its students, the increasing use of educational technologies raise a number problematic issues and areas of uncertainty.

This special interest discussion therefore seeks to get to grips with a number of key issues around the role of educational technology in the learning and teaching equation from the perspective of the lecturer/tutor/instructor. It is considered therefore that by generating discussion around a number of important areas of interest to educational practitioners, some improved awareness of obstacles as well as examples of best practice can be made. From this starting point, greater understanding and progression may be encouraged or developed.
Applications and categorization of software-based scaffolding

Koos Winnips, University of Twente, Netherlands; Catherine McLoughlin, University of New England, Australia

The increasing popularity of computer-based learning environments, combined with a need for time-flexible and self-reliant learning, has caused an increase in the demand for scaffolding embedded in instructional software environments (see for example Acovelli & Gamble, 1997; Guzdial & Kehoe, 1998; Tabak & Reiser, 1997; Rada & Yazdani, 1998). The aim of software-based scaffolding is to provide some of the same kinds of support a teacher could provide in a classroom setting, but now in a computer-based learning environment. In this setting it is assumed that face-to-face contact between student and teacher is reduced or impossible. Software scaffolding can be defined by the following three characteristics (Guzdial, 1995, Zhao, 1997, Winnips, 1998):
- Modeling: the desired behavior is modeled by providing a kind of structure, communicating what is desired, or presentation of an expert model.
- Support is given to the learner so that the learner can perform a task independently.
- Fading takes place so that students become self-reliant.

While many applications and examples of software scaffolding are now known, a categorization of these examples has not emerged yet. Applications of scaffolding can be categorized according to who regulates the scaffolding (teacher, peer-student, computer, self), technology used, pedagogy used, or according to its intended learning outcome. An example of a categorization, based on types of support given is found below:
- Providing examples: ideally these examples should not only focus on products, but also on a process. Providing examples links to the concept of modeling as Bandura (1965) described it, where a teacher would serve as a role model.
- Helping students, by giving away (physical) parts of the solution. This can serve to help students with a solution, or the help may just serve to support students on very time-consuming tasks that are not absolutely necessary for learning (Acovelli & Gamble, 1997).
- Providing a model for design, or a structure to design in. For example providing design guidelines (Collis & Winnips, 1998).
- Cueing/hinting: helping students with a solution by providing a hint or cue to a possible path of the solution (Acovelli & Gamble, 1997).
- Coaching comments (Jonassen, 1998). These comments are intended for motivation, providing feedback and advice on performance, and provoking reflection.
- Asking questions, pointing out weaknesses, asking for a motivation, in order to enhance reflection.
- Metacognitive support: stating why the above types of support are given, in order to model the type of metacognition that experts would use.
- Providing a timeline, with fixed dates and goals built in. This structure could be present, to help students appearing to be very goal directed to build in multiple evaluation moments into the actual experience of studying.

Aim of this SIG discussion is to reach consensus about a number of categories for scaffolding and to construct guidelines about the relationship of learning outcomes to particular forms of scaffolding. This in order to provide structure for future research and to be able to better link previous experiences in software scaffolding to future experiments.

PLANNING ONLINE COURSES and LEARNING RESOURCES

Andrew Litchfield
Lecturer in Learning and Teaching
Centre for Professional Development
Macquarie University
SYDNEY NSW 2109

Tel: +61 2 9850 9780
Email: andrew.litchfield@mq.edu.au

Session Number: 5553
Maximum Participants: 20
Duration: 3 hours

WORKSHOP OBJECTIVES

By the completion of the workshop participants should be able to:

1. understand the processes, phases and activities involved in planning online courses and learning resources

2. develop a persuasive proposal for project funding including concept, rationale, team formation, learner profile, timeline and budget

3. locate potential sources of project funding

4. understand the pedagogic principles of designing online courses and learning resources

5. identify project learning and teaching strategies

6. develop the content for online courses and learning resources

7. understand the legal issues involved with the design of online courses and learning resources

INTENDED AUDIENCE/EXPERTISE LEVEL

This tutorial is for faculty and staff developers who want to fund, design, develop, implement and evaluate online courses and multiple media learning resources. The tutorial is set at an introductory and moderate level.
ABSTRACT

In this tutorial we discuss and commence the crucial planning tasks required to successfully fund, design, develop, implement and evaluate online courses and learning resources. The tutorial will be of most benefit to participants who come with a specific project idea they want to develop further.

We discuss a learner-centred project framework that consists of proposal, media production and educational design processes, phases and activities. You will use the framework to start developing a persuasive proposal including the project concept, rationale, objectives, team formation and learner profile. You then use the framework to develop sound project timelines and a justifiable budget. Potential sources of project funding are identified.

Design principles for online courses and learning resources are discussed based on the instructional design process, Bigg’s concept of ‘alignment’, and Laurillard’s ‘conversational model’ of the learning and teaching process. You will commence identifying your project’s learning and teaching strategies. We discuss methods of developing the content for your project and the relevant legal issues.

TUTORIAL OUTLINE

1. Introduction - participant's projects
2. Learner-centered project proposal, media production & educational design processes, phases and activities
3. Activity #1: Develop project concept, rationale, objectives, team and learner profile
4. Timelines for online educational projects
5. Activity #2: Develop project timeline
6. Budgeting for online educational projects
7. Activity #3: Develop project budget
8. Funding sources
9. Design principles for online courses and learning resources
10. Activity #4: Identify project learning and teaching strategies
11. Developing educational content
12. Relevant legal issues

13. Plenary Discussion

14. Conclusion and tutorial evaluation

**PRESENTER’S QUALIFICATIONS & EXPERIENCE:**

Andrew Litchfield lectures in Learning and Teaching at the Centre for Professional Development, Macquarie University. He is responsible for supporting Macquarie University staff in course design, the use of educational technology, and the planning, design and management of teaching innovations and learning resources. His academic experience also includes lectureships in Media Communications and in Educational Technology.

Andrew’s media company, Positive Image, has produced numerous large-scale educational media projects. He has extensive project management and media design experience and has produced four award-winning projects funded by the Australian Government as 'Projects of National Significance'.

Research & evaluation of online systems for teaching & learning
Anne A'Herran, James Cook University, Australia

Piecemeal adoption of methods of online educational delivery can duplicate effort and waste an institution's resources. Early enthusiasm for online delivery of courses soon fades without strategic initiatives on the institution's part. In August 1999 a Web Educational Development Advisor was appointed at JCU to research and evaluate systems for online teaching and learning, with a view to integrating the selected system university wide. That research and evaluation is the subject of this paper.

The relationship between learners' personality types to their performance in computer-mediated distance education
Justin Ahn, Fairfield University, USA; MiLee Ahn, Hanyang University, South Korea

Many distance education programs tend to be focused on programs rather than on individuals and their characteristics with the goal of improving the learners' performance. More research into the effects of distance education should be oriented toward the individual learners. Little is known about the personal factors that promote or inhibit success in distance education environments. This study examined the relationship between learners' personality types and their performance in computer-mediated distance education. This study found that Perceiving types posted fewer but longer messages, Judging types posted more but shorter messages, Feeling types perceived that they had gained knowledge more than other types, and Sensing types were less satisfied with the CMC experience. There were no significant relationships between personality types to grades, level of small group collaboration, and level of leadership influence. Students indicated that the leadership changed from topic to topic and learning in CMC can be achieved without a leader. They used others' frequency and quality of postings, writing skills, and feedback to postings as a factor in determining the leadership.

Tutoring Skills for Instructors in Distance Delivery
Mohamed Ally, Athabasca University, Canada

The growth in use of the Internet and other telecommunications technologies in education is changing the role of the instructor from that of a provider of information to that of a tutor. This new role of the instructor requires different skills to work with students in a virtual and distributed environment. This session will present the tutoring skills that are required by tutors to function in a distance delivery mode.

Development of an Introductory Financial Accounting Text in Print-based and Electronic Multimedia Environments
David Annand, School of Business, Athabasca University, Canada

Athabasca University is Canada's largest distance-based, open university. Students presently registering in the University's introductory financial accounting course are provided with a paper-based textbook, solutions manual, study guide, and assignment manual. These materials are all developed and printed in-house. The 800-page textbook was recently converted to on-screen presentation format. The amount of material was significantly reduced by moving discussion cases to an on-line instructors' manual. The material was edited for on-screen use by altering backgrounds, screen breaks, and page size. The files were then converted into Authorware Professional®. Information presentation was streamlined and interactive elements were incorporated. Feedback for selected text problems was inserted at appropriate points. Audio/visual segments, two computer simulations, and navigation and index systems were developed. The final product will be packaged on a CD-ROM, included with each print-based course package sent to students, and incorporated into the University's Virtual Teaching and Learning (ViTAL) electronic environment.

The Biotechnology Project: A Case Study on Integrating the Use of The Internet for Research and On-Line Communication in a Brazilian School
Cristiana Assumpção, Columbia University, USA

This project was developed in a model private school in Brazil, Colégio Bandeirantes, having the reputation for its high academic level and vision for the future. Using an advanced topic in Biology, students were challenged to go beyond normal academic activities, acquiring skills to integrate technology and become lifelong learners. They have had the opportunity to interact with researchers in the field of Biotechnology, as well as with peers in New York. Students have learned to use the Internet as a research tool as well as a place for collaboration and content building. This is a study of the role of technology in empowering students to become active learners and researchers, as well as adaptation to these new methods of communication. Interesting patterns have emerged on how students communicate online versus face to face. The study continues on how to create pedagogically sound best practices for technology integration.
Utilization of BBS for ESL class
Hideyuki Baba, Keio Gijuku Girls High School, Japan

We introduced the usage of a BBS system into ESL learning to enhance English reading and writing competence of our high school students. The BBS system can enable our students to learn English in a totally relaxed and comfortable way. They are expected to find an English file by using a Web browser and write down their reaction on a page designed in the BBS. Students are also expected to name the URL on the top of the reaction writing so that we can easily trace back what kind of file our students have read and what kind of viewpoint they have taken. The BBS system itself is not so complicated. The program was originally created by a Japanese college student and made to adapt our learning goals later. The good points of this system is (1) it is quite easy to grasp the several stages of developing process of our students' English learning only by giving a look at the writing page, (2) students can read and write English in a non-stressed way, (3) the English the students are likely to write is not so intimate or personal, which is one of the disadvantages of "pen-pal, or mail-pal" type of writing, (4) anyone concerned can write comments to the writings so that a kind of dialogue is possible among the people inside the system.

The eMINTS Project: Enhancing Missouri’s Instructional Networked Teaching Strategies - - Promising Developments and Projected Outcomes
Adam Bickford, OSEDA/University of Missouri Extension, USA; Bill Elder, OSEDA/University of Missouri Extension, USA; Barbara Hammer, OSEDA/University of Missouri Extension, USA; Patrick McGinty, OSEDA/University of Missouri Extension, USA; Priscilla McKinley, OSEDA/University of Missouri Extension, USA; Susan Mitchell, OSEDA/University of Missouri Extension, USA

The eMINTS Project is an ongoing cooperative initiative between the Missouri Department of Elementary and Secondary Education (MoDESE), the Missouri Research and Education Network (MOREnet) and 98 elementary classrooms in 44 school districts. eMINTS classrooms are provided with an extensive technological infrastructure: high-speed internet connectivity, enough student computers to provide one computer for every two students, a high capacity teacher workstation with video conferencing capabilities, and a computer projector and a Smart Board. In addition to the computing infrastructure, participating teachers receive extensive training in constructivist, inquiry-based teaching methods which are supported by the University of Missouri College of Education, which provides full-time assistance in locating and using online instructional resources. Results from the first wave of this project, the MINTs Project, have demonstrated that well trained teachers working in technologically rich classrooms, can focus student interest and improve student scores on measures of academic achievement.

LEZI: a Tool for Easy Development of Interactive Video for Education
Mario A. Bochicchio, University of Lecce, Italy; Roberto Paiano, University of Lecce, Italy; Paolo Paolini, Politecnico di Milano, Italy; Elisabetta Andreassi, University of Lecce, Italy; Tiziana Montanaro, University of Lecce, Italy

The design and implementation of complex multimedia application is an extensive effort, requiring time, technical skills and sizable budgets. In few cases, therefore, in educational environment it's possible to realize complete hypermedia applications. It's true, nevertheless, that within several academic institutions there is the capability of developing high quality educational content, traditionally delivered as paper, while it could be more efficiently delivered in multimedia format. Our Laboratory is devoted to development of Multimedia applications, some of them concerning educational subjects in collaboration with several professors from the Humanities. Many of them asked for developing their own "cultural" application, but may be they don't have the budget, human resources or technical skills to carry on the job. With this requirements in mind we conceived LEZI, a tool that requires a minimal computer expertise in order to develop in a quick manner educational multimedia application based on interactive video and electronic documents.

New Views on Community and Collaboration: Building and Sharing Dynamic Worlds in Cyberspace
Paula Bonta, LCSi, Canada; Richard Borovoy, MIT Media Lab, USA; Susan Einhorn, Consultant, Canada; Brian Silverman, MIT Media Lab, USA

Abstract: The Internet has the potential to provide an unprecedented dynamic, interactive learning environment - one in which students from around the globe can collaborate in the construction of exciting new worlds. Despite the Internet's capabilities, there is a lack of applications geared towards fulfilling this need. This poster session will present a prototype, the Kids Internet Construction Kit (KICK), that allows K-12 students to create and share dynamic worlds on the Internet.
Reeves Ten-Dimensional Model: Application for the Design and Development of Web-Based Learning Scenario on Learning Theories
Caroline Brassard, Universite du Quebec a Chicoutimi, Canada; Jacqueline Bourdeau, Universite du Quebec a Chicoutimi, Canada; Pauline Minier, Universite du Quebec a Chicoutimi, Canada
This poster presentation covers the design and development of a media-based learning scenario and Web environment with a view to implementing a pedagogical design that integrates new technologies. The scenario responds to concerns regarding pedagogical innovation in "Teachers Training". It tries to facilitate the development of the skills required within the larger framework of courses where theoretical content is high and cooperative learning methods must be supported. The focus was therefore placed on the ability to "make links" and on the socio-constructivist approach. The results showed the importance of design, the need for cognitive strategies, the inherent pedagogical value of cooperative learning and developing the ability to "make links". The creation of links can go beyond the context to encompass any training session that contains a wide range of theories and a broad body of knowledge. It appears that the need for a design that produces the most appropriate overall educational formula may lead to proven pedagogical effectiveness.

The Creative Network: the development of a collaborative learning community for mature professionals
Helen Brown, University of Central England, Birmingham Institute of Art and Design, England
The hypothesis underlying the formation of the Creative Network is that a radical approach to Continuing Professional Development in the U.K. is needed to prepare those employed in the Creative Industries for:
1. the portfolio career
2. short term contracts
3. rapidly changing technologies/materials
4. structural changes in the companies, flatter hierarchies, featuring multi-skilling and cross functional teams
5. e-business (e-commerce and e-volution)
The Creative Network web site is the gateway to a learning community. There is no standard course or assessment. Instead the Creative Network tutors work with each individual learner or company to analyse their development needs and structure a training plan. The Creative Network aims to facilitate deep learning based upon a spirit of facilitation which helps learners to contextualise new learning and construct personal relevance and meaning.

Breathing New Life Into The Classroom
Lawrence Bundy, Nebraska Department of Education, USA
Two Nebraska projects, funded by grants from the United States Department of Education, will work together to prepare teachers to use technology in the classroom. The Connections Project, a five-year Education Technology Innovation Challenge grant, works with in-service teachers. Introductory, intensive five-day summer workshops focus on classroom uses of technology, brain-compatible teaching strategies, life skills, multiple learning styles, and integrated curriculum models. On-going staff development follows the workshops at local sites throughout the academic year. The teachers create curriculum units incorporating the strategies they have learned and post them on the project Web site—http://ois.unomaha.edu/connections. They also create CD-ROMs of the workshop presentations, which will be distributed to over 6,000 teachers. The Catalyst Project, a three-year Preparing Tomorrow's Teachers to use Technology (PTTT) grant, involves seventeen higher education institutions that are engaged in active systemic changes to prepare pre-service teachers to use educational technology. The two projects will work together to identify and develop a cadre of K-12 teachers who are leaders in the use of educational technology. This cadre will act as resources in the higher education classroom and as cooperating teachers for teacher education programs.

Improving Collaboration in Face-to-Face Groups using Technology
Robert W. Cavenagh, Jr., Dickinson College, USA
Abstract: Face-to-face collaborative work is an essential tenet of much contemporary teaching, especially within constructivist models. The practical use of technology by small intact groups has received relatively little research attention. Observation of learners in existing settings suggests that commonplace computing facilities may limit effective collaborative work by more than two individuals. The design of facilities and strategies specifically for collaboration has been demonstrated to improve the effectiveness of such work. This PosterDemo reviews applicable research, presents design and cost criteria for and photographic examples of purpose-built facilities, and delineates pedagogic strategies found useful, including both assignment and assessment strategies. It summarizes findings and future topics to explore. It also simulates the look and feel of one such collaborative facility.
Educational Applications of Hypervideo
Teresa Chambel, University of Lisbon, Portugal

Video clips can greatly enhance the authenticity of a computer based learning environment. Something constructivists have been strongly arguing for. Broadcast television does not afford composition or the time to reflect. But, television and video, when properly constructed, can be a powerful tool for reflection. If the user can select what is to be seen and control the pace of the material, and it is easy to go back and forth, to stop, to make annotations, to compare and to relate to other materials. Effective reflection requires some structure and organization, the main issues in hypermedia. Hypervideo refers to the integration of video in truly hypermedia documents, taking into account its spatial and temporal dimensions, and defining the semantic and mechanisms to link and navigate video and other media. In this presentation, different mechanisms for the integration and navigation of video in educational applications are demonstrated. These were developed using HTIMEL, an extension to HTML and existing Web tools, being developed and used in the Unibase project on distance learning.

Collaboration between T&T3 Project Team and ETU/CeLTS at HKIEd in Promoting Teaching Skills and IT for HE
Thomas YH Chan, Lingnan University, Hong Kong, China; Julianne WY Wong, Hong Kong Institute of Education, Hong Kong, China; Elson Szeto, Hong Kong Institute of Education, Hong Kong, China

We are presenting the fruit of our collaboration in the context of the T&T Project --- a publicly-funded inter-institutional collaborative initiative for all academic and professional staff in Hong Kong's HE institutions. Project mission is to pull together human and instructional resources from all institutions in a collaborative effort in promoting, fostering and advancing quality teaching and learning. We are going to share with conference participants the following:

- Designing and conducting sessions on IT in teaching and learning for academic and professional staff from all tertiary institutions in Hong Kong, in particular on:
  - formatting and layout of text
  - digital graphics
  - perfecting presentation skills
  - other digital media for enhancing teaching and learning
- Designing and producing for colleagues' use self-instructional multimedia packages for enabling IT self-sufficiency (in CD-ROM format)
- Initiating audio and video streaming for the “T&T Project Website” and related on-line multimedia packages

Teaching Symbol Recognition with Interactive Java GUI
Li Chao, University of Houston-Victoria, USA

Abstract: The ease of learning Java, its reliability, and its portability make this programming language more and more popular among students and faculty. It has gained much attention through its power of multithreading, networking, and computer graphics. As an assistant in teaching computer vision such as symbol recognition, Java has the flexibility needed to develop classroom demonstrations which are accessible through Internet. The objective of this paper is to present an interactive Java based GUI to assist the teaching of symbol recognition.

Kabisa: A computer-based training program for diagnostic reasoning in tropical medicine
Geraldine Clarebout, University of Leuven, Belgium; Jan Elen, University of Leuven, Belgium; Joost Lowyck, University of Leuven, Belgium; Jef Van den Ende, Institute of Tropical Medicine, Belgium; Stefano Laganà Italy

A shift took place in educational goals from knowing everything in a certain domain, to knowing how to deal with complex problems. The reasoning process has become more important than the amount of information to memorize. In medical education the same evolution took place. A computer-based training program that is developed to guide and help to develop diagnostic reasoning skills in tropical medicine is KABISA. In this poster, the program will be presented and all its functionalities, as well as a user-test that was performed. This test was done to identify whether KABISA really contributes to the development of reasoning skills in tropical medicine. The main aim of this test is to determine what has to be changed to the program to provide students with an efficient learning environment to learn diagnostic reasoning and to optimize the program. Use was made of a thinking aloud method and log file analysis.
WEB-LIT: Web-Based Support for Learning Theory and Instructional Design
Ken Clinkenbeard, University of Bergen, Norway; J. Michael Spector, University of Bergen, Norway
The primary objectives of our project include creating an open and flexible web site to host materials on learning theory and instructional design. We will find and evaluate existing web-based materials on these topics which reflect a wide variety of perspectives, applications and lessons learned and organize the site so that materials can be posted and easily accessed. Interactivity also plays a key role. Opportunities are provided for users to comment on existing materials and/or submit new materials. Our goal is not to create an online course in the area of instructional design of learning theory, but to augment the design of these courses by offering support resources. A secondary goal of this site is to create a web-based set of resources that can provide a source of evaluation data on the use of web-based materials in graduate education.

Realism and Credibility in a Simulation-Based Virtual Physics Laboratory (VPLab): An Empirical Study
Marc Couture, Télé-université, Canada; Alexandre Francis, Université de Montréal, Canada
Realism and effectiveness of computer simulation-based learning or training environments have been examined in several studies. It was shown that under certain conditions, simulations can be as efficient as real experiments, and that increased realism may result in gains in 'practical appreciation'. However, few have investigated the relationship between realism and credibility, or between credibility and effectiveness. The VPLab is a simulation-based learning environment featuring many characteristics and constraints normally associated with real experiments. These include uncertainty in measurement, random fluctuation of parameters, and limitations in user control over the simulation. This approach distinguishes the VPLab from most existing simulation-based laboratories. We will present first results of an experimentation with first-year university science students, in which we sought to identify the factors, most notably those associated with our approach of realism, that may enhance the credibility of such an environment and/or its perceived relevance as a tool for learning laboratory skills as well as science concepts.

A Web-based Tutorial on Optical Communications
Ignacio de Miguel, University of Valladolid, Spain; Carlos Jesus Fuertes, University of Valladolid, Spain; Abel Prieto, University of Valladolid, Spain; Patricia Fernandez, University of Valladolid, Spain; Miguel Lopez, University of Valladolid, Spain; Fernando Gonzalez, University of Valladolid, Spain; Juan Carlos Aguado, University of Valladolid, Spain; Ruben M. Lorenzo, University of Valladolid, Spain; Evaristo J. Abril, University of Valladolid, Spain
We are developing a tutorial on optical communications in order to increase the interest of the students in this area and to clear up some concepts. The tutorial is divided into four didactical units: Propagation of Signals; Components and Devices; Optical Communication Systems; and Optical Communication Networks. Within each unit, basic information is provided as well as simulators and animations. The students can also perform self-evaluations to check their progress. The self-evaluations are randomly generated from the contents of a database according to the students' preferences (topics, difficulty and kind of items: questions and/or short problems). The tutorial is being developed at http://pesquera.tel.uva.es/tutorial. The utilization of web technologies allows the students to access the tutorial from their homes, and we hope it will facilitate the collaboration with other groups working in these topics. This work is partially supported by Consejeria de Educacion y Cultura (Junta de Castilla y Leon).

Posting Visual Cues on Threaded-Message Boards in Science Curricula: Enhancing Transfer of Theory Knowledge to Clinical Practice
Gregory A. DeBourgh, University of San Francisco, USA
Results of a pilot study (16 baccalaureate nursing students) suggest posting thematic, integrated photographs, graphic, and text data on asynchronous, threaded-message boards facilitates transfer of theory knowledge to clinical practice and supports the acquisition of skills in clinical reasoning (pattern recognition, critical analysis, problem solving, and identification of therapeutic interventions). Visual cues provide powerful representations of reality that enable students to recognize manifestations and patterns of clinical pathologies. Text-based learning prompts stimulate reflective thinking and collaborative problem solving. Used synergistically, they create clinical context, authentic complexity, and scaffold learning. Provided both words and pictures during instruction, learners encode information in such a manner that recall is facilitated and transfer of knowledge enhanced. Students report on-line interaction results in the positive experience of belonging to a professional community during learning, affords support and opportunities for collaboration, and increases access to the instructor to clarify "accuracy of learning" and provide feedback. Using visually-enriched on-line conferencing is an enjoyable, convenient, and satisfying way to amplify and enhance learning, and "brings the course content alive".
The «BacVert» or «Blue Box» - A Knowledge Recycling Bin for Students
Céline Desjardins, Centre de recherche LICEF, Canada; Éfoe Wallace, Centre de recherche LICEF, Canada; Claude Ricciardi-Rigault, Centre de recherche LICEF, Canada

While it has become common to provide students with a list of documents to peruse on the Internet, information gathering, net-surfing and annotation all have an exploratory, individual and work-in-progress quality. Sharing insights gained through these activities, especially in distance education, is complicated and requires highly structured settings. The INF9002 «BacVert» web-based dispositif at Télé-université supports such sharing. The natural language parsing performed by Nomino provides flexible automatic structuration, both of the core Internet material proposed by the teacher to which the students gradually add their findings, and of the comments about these documents produced by the students. By allowing a group of students to constitute an evolutive information base, to comment on it and to compare notes, the INF9002 «BacVert» constitutes a step towards tackling the complexity and heterogeneity of the information environment, while supporting exchanges among peers about the material at hand.

Building Global Information Communities: the University of Iowa Center for Electronic Resources in African Studies (CERAS)
Barbara Dewey, University of Iowa Libraries, USA

This poster session provides a case study of the issues and lessons learned regarding development of the University of Iowa's Center for Electronic Resources in African Studies (CERAS) (http://sdr.lib.uiowa.edu/ceras/). The Center is a “virtual” space for creating, disseminating, and accessing scholarly electronic resources in text, multimedia, and interactive format, and a “virtual” place for further development of electronic resources (textual and multimedia-based) pertaining to Africa created by scholars from the United States as well as from Africa and other parts of the world (http://sdr.lib.uiowa.edu/ceras/). CERAS is part of the University Libraries' Scholarly Digital Resources Center supporting students and faculty engaged in African Studies research and teaching at the University of Iowa, and scholars nationally and internationally. CERAS is also a venue for U.S. and African scholars for creating and disseminating African Studies scholarship and information resources in electronic format. Several CERAS initiatives have focused on image creation, particularly in the field of African art, a strength at the University of Iowa. CERAS will serve as a venue for digitizing projects related to Africana scholarship (i.e. museum collections, selected non-copyrighted collections, archival materials, and documents). Other goals include bringing high quality African Studies scholarly electronic collections and web sites currently in existence into a user-friendly digital library web page; providing a venue for “publishing” original materials, including pre-prints, (articles, books, conference proceedings) as well as creating significant thematic textual and multimedia collections of materials in electronic format; and developing an electronic international community of Africana scholars where dialogue about issues, research, and projects can take place. This latter feature is intended to provide a broader opportunity for Africana scholars to post drafts of research papers and projects for critique and discussion by other Africanists from around the world. The University of Iowa Libraries is seeking collaborative projects and partnerships with institutions and Africana scholars from around the world.

Introducing a Distance Learning version of a Postgraduate Program on Networking in Argentina
Dean Javier Diaz, University of La Plata, Argentine; Maria Alejandra Osorio, University of La Plata, Argentine; Ana Paola Amadeo, University of La Plata, Argentine

The great popularity of the Internet and the widespread use of the World Wide Web are promoting a new methodology for distance learning. The main advantage of the Internet based courses is possibility to promote a bi-directional communication between the students and the professor and to highly motivate the student due to an adequate feedback. This poster describe the introduction of Internet tools (such as www, e-mail, IRC, FTP, mailing list) in the distance learning postgraduate program of the ‘Magister de Redes’ (http://www.linti.unlp.edu.ar/master) of the UNLP. The ongoing experience was successful due to certain facts that are stated in the poster which also mentions some drawbacks and the strategy for overcoming them. The distance-learning version of the program started in 1998 as way to reduce the obstacles for he students (professionals from the engineering and the computer science field in the networking area), mainly the traveling expenses and the time it takes due the large geography of our country and the long distances.

The Bones Of The Skull: Creating Anatomical Models With Quicktime Vr
Marilyn Dispensa, The University of Iowa, USA; Jim Duncan, The University of Iowa, USA; Jerry Moon, The University of Iowa, USA

This electronic demonstration will provide an overview of QuickTime Virtual Reality (QTVR) and its utility in the development of virtual anatomical models which can be used alone or integrated into computer-based-learning (CBL) software. The Bones of the Skull: A 3-D Learning Tool is a CD-ROM-based module designed to help
college-level anatomy students learn the bones and important landmarks of the skull. The software has two main features: 1. A collection of Quicktime VR movies that allow the user to rotate and view the skull and its bones in three dimensions. 2. An interactive "textbook" that contains high quality 2-D images, descriptive text and many embedded activities to encourage interaction with the content. This presentation will demonstrate the product and provide an overview of QuickTime VR, including technical requirements and hardware/software costs. The Bones of the Skull won the 1999 Sandoz/Slice of Life Student Software Award.

The impact of establishing a virtual university: a case study at NUST
Nomusa Dlodlo, National University of Science and Technology, Zimbabwe

The purpose of establishing any university is to cater for the educational needs of the surrounding community. In developing countries universities fail to cope with large numbers of applicants. The reason is that the number of universities in such countries is limited due partly to historical circumstances and partly due to financial constraints. The exercise of building brick and mortar universities and acquiring skilled staff to run them is expensive.

A Distributed Maritime Simulation Training Environment based on HLA
Mirko Dobermann, Computer Graphics Center ZGDV, Germany; Harro Kucharzewski, MarineSoft GmbH, Germany

A new approach for advanced training systems is the integration of computer simulation into such applications, allowing students to experiment in complex scenarios. The presentation introduces a distributed simulation-based training scenario, generated in a distributed environment, which offers extended functionality for interaction and demonstration within a maritime training scenario. The main objectives of the solution are threefold: to set up and establish a distributed simulation-based training environment, to provide real-time interaction functionality during run-time, as well as to integrate already available simulators that are currently on the market. The infrastructure for this simulation is based on HLA/RTI, while which already offers functionality to couple embedded applications with networked simulation applications. The Computer Graphics Center in Rostock (ZGDV) currently focuses on maritime scenarios related to competency training for crews aboard and ashore. The development of the simulation environment is part of a research project in collaboration with regional enterprises in the Maritime sector.

Human Anatomy Predissection Lecture-On-Demand at The National University of Singapore
Gilles Doiron, National University of Singapore, Singapore

The NUS Integrated Virtual Learning Environment (IVLE) was developed so that staff and students could use this information technology infrastructure to communicate, exchange documents and information, discuss, chat, and access custom learning materials and course related web sites. IVLE also enabled the university to consider new pedagogical approaches, which would utilise its campus-wide broadband access to meet specific teaching and learning needs. A "lecture-on-demand" (LoD) delivery was seen as a viable tool that would allow students to take more responsibility for their learning and enable them to have greater control over their time schedule. With the collaboration of the Faculty of Medicine, the Center for Instructional Technology and the Centre for Development of Teaching & Learning, a prototype anatomy pre-dissection LoD, "The Abdominal Wall & Inguinal Canal", was produced. This paper examines the design and development issues addressed in building the prototype. Field test data on the technical reliability, and ratings, and comments from student feedback are presented.

ExploraGraph and CINEMA
Aude Dufresne, Univ. of Montreal, Canada; Claire Isabelle, Univ. of Montcton, Canada; Roger Nkambou, Univ. of Montreal, Canada; Yan Laporte, Univ. of Montreal, Canada; Frank Ferront, Univ. of Montreal, Canada

The ExploraGraph interface was designed to facilitate interaction in the context of distant learning. It was developed as an alternative to simple web interaction, in order to increase flexibility, visibility, and structure in the learning environment. It may be used as a front end to existing courses on the web and to support learner in them. The ExploraGraph Navigator makes it possible to navigate through conceptual graphs with automatic arrangement of elements, zoom and "fish eye" effects. Each node of the graph may have a description attached to it and may give direct access to an application, a document or an Internet site. Graphic structures may thus be used to represent the organization of tools, activities, concepts or documents. The Navigator offers each user a tool to specify his goals and the system can support him, using multiple modalities: Hypertext, graphical cues, Ms Agents avatars, voice, visual demonstrations and force feedback guiding.
Future Special Education Teachers' Abilities to Integrate New Technology Into Teaching Reading Comprehension
Catherine Dumoulin, Universite du Quebec a Chicoutimi, Canada; Jacqueline Bourdeau, Universite du Quebec a Chicoutimi, Canada

This study questions future teachers' abilities to integrate new technology into their teaching. A pedagogical scenario based on a cognitive approach was proposed to graduating students of the bachelor of Special Education program in order to teach Grade 3 students with reading comprehension difficulties. This pedagogical scenario integrated new technology via the "Village Prologue", a computerized environment. Future teachers were found to organize pedagogical activities, create learning situations suitable for teaching reading comprehension, help motivate children to read, and finally, guide children in their learning processes within the computerized environment. Furthermore, the pedagogical scenario helped in motivating future teachers to include new technology in their future teaching. The computerized environment also permitted the future teachers to adapt their teaching to the specific needs of children with reading comprehension difficulties.

School Festival on the Internet - Project-based and cooperative learning -
Hironori Egi, Keio University, JAPAN; Yoshitomo Tsutsui, Kamogata High school, JAPAN; Yuuki Nishimura, Keio University, JAPAN; Keiichirou Ishibashi, Keio University, JAPAN

We report a case of project-based and cooperative learning activities, School Festival on the Internet, Okayama 1999 (SF99) in Japan. Three public high schools in Okayama, Keio University and Kurashiki University of Science and the Arts participated in SF99. The goal of SF99 was to put the school festivals held at each of the high school on the web so that the students efforts could be widely appreciated. School festivals are considered as an educational event in Japan, and we implemented SF99 as a project-based and cooperative activity. The festival provides students with opportunities to present achievements of their research or their other interests. Video streams and online communication through a Bulletin Board System (BBS) were the main applications used to achieve the end. SF99 is one of the few examples were extra-curricular activities such as school festivals were digitalized. Information-based learning and extra-curricular activity have similar goals. We also analyzed the achievements of SF99 and discussed the educational effect of information-based learning using the Internet.

The ParlEuNet-project: Problems with the validation of socio-constructivist design principles in ecological settings
Jan Elen, University of Leuven, Belgium; Geraldine Clarebout, University of Leuven, Belgium

Instructional design aims at generating indications about optimal relationships between learner-related and instruction-related variables in view of the attainment of instructional and/or learning goals. In this poster, a study is presented in which it was started from socio-constructivist view on learning and instruction to identify a number of design principles. These principles were used to design and develop a concrete and innovative rich technological learning environment, the ParlEuNet learning environment. The main features of the this environment can be described as follows:

- A variety of technologies
- A problem-based learning environment where use is made of ill-structured tasks
- International collaboration

It was hypothesized that such an environment would have an influence on certain learning environment. In this poster the environment and the results of the research will be presented, which indicate that there is an influence of the learning environment, however in a different direction than was expected.

Examining Medical Students' Attitudes and Learning Experiences in BioWorld
Sonia Faremo, McGill University, Canada; Susanne Lajoie, McGill University, Canada; David Fleiszer, Faculty of Medicine, McGill University, Canada

This poster presents BioWorld (Lajoie et al., 1998), a computer-based learning environment (CBLE) that engages learners in realistic problem solving as they attempt to diagnose medical cases. Its design is consistent with both problem-based learning (PBL) and cognitive principles of instruction. Solving a BioWorld case involves interpreting case history information, ordering diagnostic tests, developing diagnostic hypotheses, and reflecting on one's own performance. As part of a larger study, the data for this poster consisted of measures of the attitudes and learning experiences of medical students using BioWorld. The experimental procedure involved having medical students individually diagnose a set of BioWorld cases and complete a questionnaire concerning their experiences. Students rated several aspects of the system (level of interest, difficulty, utility of learning activities, etc.). The results have implications for the design of CBLEs for complex domains. They also suggest that BioWorld is an effective learning environment.
CyberARTS: A Integrated Arts Curriculum
Tito Faria, Don Mills Collegiate Institute, Canada; Sholom Eisenstat, Don Mills Collegiate Institute, Canada

The CyberARTS program is offered at a number of school sites in Toronto. CyberARTS uses a constructivist methodology to deliver visual integrated arts, media communication, computer technology and now Gr. 9 Geography credits. Students have constant access to labs of Macs and PCs and a range of peripherals. Teams of teachers work collaboratively creating and delivering the curriculum. Senior students complete the program with a co-op experience. Their placements include: Alias Wavefront, Web Feat, Apple, Microsoft, the Design Exchange and Nelvana. Our partners include: Waterloo University, Apple, Kodak, Rogers Cable and SoftImage. Our senior class was involved in designing and producing the first edition of "RE: DESIGN", a web "zine" about design for teachers and students by students. www.dxnet.net. Currently a number of senior co-op students have placements at the Design Exchange where they are working on the website for Toronto's Olympic bid. Our program has won an Apple School of Distinction Award and some of its teachers have won a 1999 Prime Minister's Award for Achievement. We will focus on:

- problem oriented curriculum projects and units
- subject integration and authentic learning assessment techniques
- real-world connections and business partners

Managing Electronic Resources - Auto-registration for Distance Learning
Richard Fasse, Rochester Institute of Technology, US; Damon Betlow, Rochester Institute of Technology, US; Randy Overbeck, Rochester Institute of Technology, US

Electronic resources used in distance learning are often restricted to registered students through login ids and passwords. As electronic resources proliferate, so do the problems with managing these accounts for both students and administrators. One option is a form of auto-registration with "course keys" that allows users to select their own login id and password, but restricts registration to only those who received the "course key" in a handout or email.

Interactive Training Materials for Early Childhood Educators: Cases, Tools, and Reflection
Gail Fitzgerald, University of Missouri-Columbia, USA; Louis Semrau, Arkansas State University, USA

Materials to assist early childhood educators in working with young children with behavioral problems are currently in high demand. Multimedia programs offer an effective method for providing instruction based on authentic cases for developing necessary knowledge and skills. In the multimedia program, "Trisha," users can seek professional knowledge from an information database, watch Trisha in multiple settings, interview her teachers and other care providers, read case records, listen to expert commentators discuss theoretical approaches and care recommendations, and carry out a series of real-world activities related to Trisha's needs. Following problem-solving activities, users engage in a series of reflective prompts to review their decisions based on best practices. The program contains electronic performance support tools that can be used within the program as well as in actual job situations. "Trisha" is designed for implementation with workers in childcare settings and preservice courses. Additional information is available at http://www.coe.missouri.edu/~vrcbd/.

Integrating computer ethics into the computer science and computer engineering curricula
John Fodor, Educational Media Resources, Inc., USA

This demonstration will show how to integrate computer ethics into the computer science and computer engineering curricula by using the interactive CD-ROM Understanding Computer Ethics. (UCE was made possible by grants from the National Science Foundation and has won AXIEM, Communicator and International CINDY Awards.) We will discuss such topics as computer privacy, computer security, ownership of intellectual property, software piracy, hacking and professional responsibility. We will examine ways of developing skills, sensitivities, and understandings to "human value" issues and problems raised by computing and information technologies, including ways to elicit more reflective performance understandings. We will analyze four ways specific ways of integrating computer ethics into the computer science and computer engineering curricula:

1) as a stand-alone class,
2) incorporating computer ethics into existing cs & ce classes,
3) as part of a capstone senior project, and
4) as an independent study class.
Development and Implementation of Computerized Instructional Materials: The Mismatch Between Formal and Informal Technology Support Structures in a Medical College
Cynthia Frank, The University of Arizona, U.S.A.

This study focused on the development and implementation of instructional computer materials in the everyday teaching environment of a southwestern U.S. medical college. What happened between the time an instructor voluntarily decided to implement computer technologies in a course and the time a student could actually use the technologies? The existence of formal technology support structures led to the assumption that instructors would utilize professional help. This turned out not to be the case. The majority of instructors used informal support structures to develop and implement their materials. Much of the work was done by students who had no training in instructional design, multimedia programming, or graphic design. This preliminary finding indicates a fundamental mismatch between the type of support professors selected and the type of support offered by the institution.

Putting Curriculum in Control: Interactive Courseware Development with the TechDisc Instructional Design Template
Traig Friedrich, Sencore, Inc., United States; Bill Wann, Sencore, Inc., United States; Karen Korth, University of South Dakota, United States; Mike Hoadley, University of South Dakota, United States; Dan Eastmond, University of South Dakota, United States

The Technology for Training and Development division at the University of South Dakota has joined forces with Sencore, Inc., a multimedia application provider, in the development of an innovative multimedia authoring tool. Designed specifically to apply recognized instructional design techniques to "drag-and-drop" multimedia development, this tool puts interactive courseware authoring into the hands of the classroom educator. This approach to multimedia application development benefits everyone involved in K-12 education by enhancing the classroom teacher's control of course curriculum and specific course content. During this demonstration of the TechDisc Instructional Design Template, participants are welcome to engage in open discussions of the tool, trends in multimedia project authoring, and other issues surrounding interactive courseware development.

Using Virtual Reality to Assist Air Travelers With Disabilities
Clark Germann, Metropolitan State College of Denver, USA; Jane Broida, Metropolitan State College of Denver, USA

Getting to the airport, checking our luggage, going through security, boarding the plane—these are all tasks most of us take for granted each time we fly. But to persons with physical disabilities who use a wheelchair, the above tasks can be difficult and intimidating. No two airports are exactly the same, and procedures for air travelers with disabilities differ with each air carrier. To help ease the anxiety, faculty and students at Metropolitan State College of Denver have used computer technology to duplicate one major airport into virtual reality. Now, future air travelers can preview the experience first on the computer prior to going to the airport in person. With 135,000 people in wheelchairs in Colorado alone, provision of resources for air travel is especially pertinent. Survey research and anecdotal evidence has shown that these virtual representations can be helpful in reducing anxiety in persons with disabilities by providing a preview of a location prior to visiting it in person.

Gender and Race: The Accuracy of Internet Clip Art
Carol Gilley, University of Arkansas, USA; Elaine Terrell, University of Arkansas, USA

Abstract: Computers are being used to create various print media as well as multimedia. Some questions are being raised in developing these media materials. Is there a supply of free clip art on the Internet that represents the real world? Do viewers see themselves in clip art used in print and computer-based multimedia? This study explores the issues of equity and stereotyping with regard to the images in free Internet clip art by investigating the following two hypotheses. 1) There is no significant difference between the proportion of men, women, boys, and girls represented in free Internet clip art and the proportion of men, women, boys, and girls in the general population. 2) There is no significant difference between the proportion of White, Blacks, and other minorities represented in free Internet clip art and the proportion of White, Blacks, and other minorities in the general population.

How To Be Innovative Designing Educational And Interactive Environments For Children
Gloria Elena Gomez Escobar, University of Los Andes, Colombia

LUDOMATICA PROJECT looks to effectively attend children's educational needs. It seeks to help them to creatively think and act, validating their rights to high-quality education and to actively participate as social change agents. This validation is accomplished through innovations in formal, non-formal and informal education, using Information and Telecommunication Technologies within a non-conventional pedagogical. We want to develop the intellectual potential and cognitive abilities of children who live in high-risk situations, taking advantage of their adverse learning to stimulate creative potentials, communicative resources and have them discover their own adventurous spirit and creative capabilities. The interactive game THE FANTASTIC CITY is one of the
environments created for these purposes. This is a digital multimedia microworld that motivates and develops children's fantasy and creativity by means of enigmas and puzzles, seeking to generate cognitive and affective imbalances. This interactive environment leads children to action. It promotes curiosity and experiential learning; it allows speculating, discovering, learning from mistakes; and it stimulates the desire to learn.

**Teaching Dynamics of Dairy Herd Health and Management**
Claudia Haferkamp-Wise, Cornell University, USA; Heather G. Allore, Cornell University, USA; Yrjo T. Grohn, Cornell University, USA; Lorin D. Warnick, Cornell University, USA

Cornell University offers "Dynamics of Dairy Herd Health and Management" (http://courseinfo.cit.cornell.edu/courses/vetmed745) - a newly designed web-based distribution course to its on-campus veterinary students and to students at 9 off-campus test sites within the United States and abroad. This course uses a computer-based instructional delivery system (DairySim) to teach basic concepts of epidemiology and economics of dairy cattle disorders, experimental design, and statistics. The courseware provides two simulation models - SIMHEALTH and SIMMAST - with an interactive user-friendly interface and output analysis - thus making research tools accessible to a broader audience. DairySim and its accompanying user guides are available online. Lectures can be attended in person on-campus or viewed via the internet. Students can print handouts for use in computer laboratory sessions, take on-line quizzes and download homework assignments. Completed assignments are handed in by uploading the documents. Instructor-student and student-student communication for off-campus students takes place via email and an on-line discussion board.

**A Comprehensive Model for Improving Technology in Teacher Education**
Robert (Bob) Hannafin, College of William and Mary, US; Robert (Bob) Hanny, College of William and Mary, US.

This paper identifies the professional development model developed at the College of William and Mary to close the gaps between its strategic vision for the teacher education program and its capacity. The College's vision is to produce teachers who seamlessly integrate technology by designing and assessing authentic student-centered learning activities. Three areas were identified as requiring parallel effort: faculty development, institutional development, and clinical faculty/PDS development. Goals were established that addressed capacity shortfall and advance the program to the point where significant innovation could occur. Both our students and faculty needed to master both basic technology skills and the subtler art of practicing creative integration strategies. It also required placing our students with teachers who are competent technology users and encouraging in technologically-adequate classrooms. Institutional changes were necessary on two fronts: upgrading the technology available in School classrooms, and instituting incentives to entice faculty to use and integrate technology.

**Web-Based Tools For Courses On Transport Phenomena**
Bernardo Hernandez-Morales, Universidad Nacional Autonoma de Mexico, Mexico; Rafael Fernandez-Flores, Universidad Nacional Autonoma de Mexico, Mexico; Jorge Tellez-Martinez, Universidad Nacional Autonoma de Mexico, Mexico

Even though multimedia applications have been extensively used in many courses, the field of transport phenomena has received comparatively less attention. Thus, we are developing interactive tools, to be accessed through Internet, to solve problems observed when traditional teaching techniques are used. The material consists of modules to solve typical problems in transport phenomena. Each module is a Webpage that includes the theoretical background (with hyperlinks to all course material) and an interactive worksheet to solve a particular problem. The worksheets are built with Java applets (JDK 1.1. compatible) and may be used in any of three modes: example mode (fixed set of values), training mode (variable set of values), and exploration mode (range of values of a key independent variable). Thus, unlike problems found in traditional textbooks, the student may explore a range of values for key independent variables to establish its influence on the dependent variables.

**Shaknoma: A collaborative tool for shared knowledge management**
Oriel Herrera, Pontificia Universidad Catolica de Chile, Chile; Sergio Ochoa, Pontificia Universidad Catolica de Chile, Chile; Vidal Rodriguez, Pontificia Universidad Catolica de Chile, Chile; David Fuller, Pontificia Universidad Catolica de Chile, Chile

Nowadays, the amount of scientific knowledge produced is overwhelming and it is clear that it will grow even more. Shaknoma (Shared Knowledge Manager) is a tool useful to make available and share the people's individual knowledge. The activities carried out on this tool respond to a model that ensure the input, validation, use and evolution of the knowledge. The process is implemented through four major components: the shared repository, the management model (see Herrera et al. 2000), the representation language of the knowledge, and the collaborative environment. The knowledge management model provides decision-making mechanisms, which mainly includes discussion and voting activities. As a way of structuring and graphic representation, Shaknoma uses a language based on conceptual maps (Novak 1984). The information repository does not store only knowledge, but also the information of its use and evolution.
Teachers and Computer Technology Training
David Hofmeister, Central Missouri State University, USA; Gerry Peterson, Central Missouri State University, USA

The poster session provides an overview of the processes and materials used to advance the integration of computer technology into student learning in K-12 schools.

Results and conclusions from a Learning Software Design Competition
Brad Hokanson, University Of Minnesota, USA; Simon Hooper, University Of Minnesota, USA; Paul Bernhardt, University Of Minnesota, USA

The University of Minnesota's Design Institute is sponsoring a competition to recognize the design of innovative educational software. The competition was open to professional and not-for-profit educational software designers in such areas as higher education, K-12 education and commercial training. Prizes will be given in each category, and entries for the competitions were due February 15, 2000. Winners of the competition were announced April 10, 2000. One of the competition's goals is to establish a bank of exemplary educational software that can be examined by designers and students of educational software design. To facilitate this goal, winning designs (and others selected for inclusion) will be compiled and made available to the public. We will present the results of the competition in a workshop format at ED-MEDIA 2000. The intended audience is educators and practitioners in the field of educational technology.

Constructive Hypertext for Learning
Hsi-chi Huang, The Ohio State University, USA

This study focuses on teachers as designers using constructive hypertext and teachers' perspectives on the use of the World Wide Web in educational contexts and its implications. Constructive hypertext encourages the participants not only to be users of hypertext, but also to be designers of hypertext. The study describes the participants' experiences as designers and their thoughts on designing hypertext for learning. In designing Web-based hypertext learning environments, educators can make use of the Web from three approaches: the Web as a resource for information, the Web as a medium of expression-representation, and the Web as a space for dialogue. The distribution perspective takes advantage of the Web as an information network. The expression-representation perspective uses the Web as a space for publishing, and expressing ideas and creativity. The Web as a space for dialogue has the capacity to encourage and embrace different voices. To participate in the dialogue is to create voices. The dialogue space provides possibilities for students to converse and exchange learning experiences.

Internet Infrastructure with ATM for Small Countries; Case Studies
Neddet ICIL, Eastern Mediterranean University, TURKIYE

Rapid development on communication technologies, become easy to support QoS (Quality of Services) application on Internet. As a case study, North Cyprus which is a small country with 5 small cities, develop a project to connect all cities with ATM BackBone. The purposes of the project is to connect all the local government offices to the cities node and to use all multimedia and information facilities on the BackBone. All governmental documentation will be send electronically between the offices. Virtual meeting will be possible by using video conferencing facilities. Also all schools will connect to the Ministry of Education to use educational facilities which are prepared by the trainers.

NACSIS-ILL Distance Training System in IDLE Distance Learning Project
Tomo'o Inoue, National Institute of Informatics, Japan; Haruki Ueno, National Institute of Informatics, Japan

We have started the distance learning project named IDLE (Integrated Distance Learning Environment) in 1998. The primary motivation of beginning the project is to meet the social needs. There are not many practical and sustainable DL systems in Japan, while on the other hand DL is already recognized as a natural form of getting education in the US. Current core product of IDLE is NACSIS-ILL Distance Training System, a WWW based system for training NACSIS-ILL operators. NACSIS-ILL is a system that our institute offers to nearly 700 university libraries to support exchange of information for the inter-library loan service. Our institute also offers NACSIS-ILL Training Courses to train the staff in the inter-library loan sections of the participating libraries. We have put emphasis on its practicality in the project and applied DL to the training course. The system will be in actual use this year.
Linking Active Learning to Web-based Instruction: Students Teaching Students through Multimedia Productions
James S. Javenkoski, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA; Elizabeth F. Reutter, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA; James E. Painter, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA

Instructors (academic teachers and corporate trainers) recognize the value of video as an educational medium. Video provides learners (students and trainees) with opportunities to observe phenomenological examples that reinforce the concepts that are verbally described during classroom and laboratory sessions and on-the-job-training. Until recently, educational video production was a multi-step, multi-component process requiring at the minimum a camera or VCR, a computer (with a high speed processor, very large hard drive, and video editing and processing software installed), and a high speed serial I/O connection to transfer the video data between hardware devices. The new Apple® iMac™ DV desktop computer and iMovie™ software offer a simple, accessible, and affordable solution to instructors who wish to create continuous media (audio and video) for use in their courses. Our demonstration will showcase the QuickTime streaming videos produced in UIUC’s FSHN 199: Business Etiquette and Protocol and FSHN 355: Fine Dining Management courses.

Using Tailored, Interactive Soap Operas for Breast Cancer Education of High-Risk Hispanic Women
Maria Jibaja, Baylor College of Medicine, USA; Paul Kingery, Hamilton Fish Institute, USA; Nancy Neff, Baylor College of Medicine, USA; Quentin Smith, Baylor College of Medicine, USA; Jennifer Bowman, USA; J. David Holcomb, USA

While Hispanic women have lower rates of breast cancer than other groups, among women from all ethnic groups, they are the least likely to undergo screening exams. This study evaluated a culturally sensitive and linguistically appropriate tailored computer-based educational program on breast cancer early detection aimed at high-risk Hispanic women. Spanish-speaking Hispanic women from an inner-city community health clinic were recruited and randomly assigned to either a computer intervention with an interactive soap-opera format (n=118) or a comparison group (n=60). True-false pre- and post-tests were used to identify any change in breast cancer related knowledge/beliefs. Both younger (18-40 y.o.) and older (41-65 y.o.) women in the intervention group increased significantly their knowledge/beliefs as compared to the younger and older women in the comparison group (p<.05). Computer-based tailored and interactive soap operas that are linguistically and culturally appropriate are effective in increasing breast cancer screening knowledge/beliefs in high-risk Spanish-speaking Hispanic women.

webStract - a Distributed Tool for Collaborative, Project-driven Learning on the Internet
Werner B. Joerg, NetEssence / U of Alberta, USA

webStract is a combined software tool that supports the construction and delivery of Internet based courseware. It embodies a project-driven paradigm - a problem based learning approach guided by the needs of student projects. It allows content providers to make effective use of the vast knowledge source of the World Wide Web and to present the students with qualified material in a structured manner. It takes advantage also of the interaction capabilities of the Internet, to enable focused synchronous and asynchronous communication among distributed teams and team members. Following a brief introduction of the motivation and the learning paradigm, our presentation centers on the three principal areas of service covered by webStract: knowledge qualification and structuring tools for the content provider, collaboration and management tools for the teams, and knowledge management tools for the individual student. webStract is currently being used in experimental courses. We’ll report feedback from those experiments.

Digital Learning System: Web’s Cool
Myunghee Kang, Ewha Womans University, Korea

Web’s Cool (can also be pronounced Web School) program with SRL(Self-Regulated Learning) principles, PBL(Problem Based Learning) approaches and Keller’s ARCS model for motivation has been designed by the author and developed by Samsung Electronics Company in Korea. Now, all the contents and study modules are completed in CD-ROM and the total service including Q&A and real tutorial help is now available on the UNITEL web service.
Learning Amidst A Sea Of Information In The New Millennium
Dan Kauwell, University of Illinois, Urbana-Champaign, USA; Jim Levin, University of Illinois, Urbana-Champaign, USA; Daniel Schiff, University of Illinois, Urbana-Champaign, USA; Young-Jin Lee, University of Illinois, Urbana-Champaign, USA
Visualization can improve our ability to access information and construct knowledge. Information visualization is particularly well suited for the location and analysis of information found on the Internet and, for the construction of knowledge from that information. Our research has led us to develop VisIT, a tool for the visualization of Internet based information and the analysis of that information. Instead of lengthy lists of search results, the user is presented with a graphical, spatial representation of the search space. Now the user can "see" the hits returned by the search engine as well as other pages from the same site. When any of the pages are clicked, the appropriate page is displayed in the browser window. Furthermore, VisIT facilitates the knowledge construction process by allowing its graphical displays to be edited, saved and re-opened later.

An@tomedia: A New Approach TO Medical Education Developments In Anatomy
David M. Kennedy, Monash University, Australia; Norm Eizenberg, The University of Melbourne, Australia; Chris Briggs, The University of Melbourne, Australia; Ivica Grkovic, The University of Melbourne, Australia; Priscilla Barker, The University of Melbourne, Australia
Evaluations have indicated that students find An@tomedia very engaging (Kennedy, Eizenberg, & Kennedy, In this volume). An@tomedia supports students actively in their learning tasks, fostering a deeper understanding of human structure, with a stronger basis for clinical diagnosis and procedures. The new medical course has focused less on traditional teaching, instead emphasising on focussed dissection, problem-based and self-directed learning. An@tomedia provides multiple perspectives of the human body. Each module is independent and of equal importance. The modules are:
1. Back,
2. Abdomen,
3. Thorax,
4. Neck,
5. Upper Limb,
6. Lower Limb,
7. Head, and
8. Pelvis.
The first 3 of the 8 modules, the Back, Abdomen, and Thorax have been completed, each organised into 4 major perspectives.
1. 'Dissection' includes practical (including emergency) procedures.
2. 'Imaging' incorporates sectional and endoscopic anatomy.
3. 'Regions' incorporates surface and functional anatomy.
4. 'Systems' incorporates conceptual and clinical anatomy.

References

Offering Online Degree Programs: A Case Study Issues, Challenges, Successes, and Lessons Learned
Gerard Kickul, University of St. Francis, USA; Laurel Jeris, University of St. Francis, USA; Michael LaRocco, University of St. Francis, USA
Offering degree programs online offers an attractive option in the higher education environment. As schools confront this opportunity, familiar issues of quality, access, participation, retention, and assessment take on new meaning. Online delivery systems parallel traditional classrooms, including discussion and assignment areas, chat rooms, and online assessments. After experiencing high student dropout rates the University focused on several solutions to reduce its student dropout rate. These included online support systems with a centralized approach to addressing faculty and student technical concerns, complaints, and requests for assistance. A new assessment procedure consists of a two-phase process, a pre-course assessment and a more traditional assessment occurring during the final three weeks of the course. Finally, feedback from faculty on the various instructional design challenges including learning curve, time commitment, recommended class size, ethical issues, adaptability of subject matter content, and practical suggestions for reconceptualizing syllabi and assignments for online learning will be included.
Developing a Distance Education Infrastructure
Gerard Kickul, University of St. Francis, USA; Mark Snodgrass, University of St. Francis, USA

Development of distance learning infrastructure is a multifaceted project, from the desktop to the far reaches of the Internet. Attention must be focused on the outgoing data and information, as well as, incoming data and information. There are four basic areas of concern when designing an infrastructure to facilitate Internet distance education solutions: hardware, software, support, and security. Providing the proper hardware to developers and support personnel is crucial in creating a productive and efficient work environment. Reliable and efficient Internet access is essential, with 24-hour availability and minimal down time. Software components for development and support are key ingredients to success. From a student and faculty standpoint, the course software must be user friendly with a high degree of stability. Support must be considered from both a human and a technological standpoint. Essential to any online endeavor is secure access and distance learning demands the highest levels of security.

Content Management for Web Based Learning
Thomas Kleinberger, TECMATH AG, Germany; Paul Müller, University of Kaiserslautern, Germany

With the help of the newest information and communication technology all the needs of modern educational systems can be met for the first time in one tool: the computer. Computer based solutions provide the technological support necessary for the whole teaching and learning process. The greatest advantage of this tool is the possible combination of all its usable instruments, their flexibility and configurability. With new technologies and new media types it will be possible to support all kinds of training, self-study and continuing education. It is clear that these new methods and technologies require new methods and solutions for the tasks content creation, delivery and archiving. Especially the use of new media sets high requirements on these tasks. This article describes how content management systems, a technology already used in other kinds of business, can support these tasks in web based teaching and learning. A definition of content management is made and refined for the area of web based learning. The main building blocks and features of content management systems are described and the improvements for web based learning are highlighted.

Computer-Mediated Communication for Distance Education: Developing and Teaching a Second Language Course in Academic Reading
Esther Klein-Wohl, Open University of Israel, Israel

The Open University of Israel is searching for ways to improve its distance education methods. Taking advantage of the flexibility of computer-mediated communication (CMC), we will describe the application of CMC to academic reading. We chose e-mail support, which allows students to work on texts, and to receive feedback and help when needed. Reading - a mode of language use, and distance education - a mode of language instruction, feature striking parallels: the reader (in “real life”) and the learner (when learning to read) each functions in isolation when interacting with a text. Discourse is enacted at a distance, a disassociated first person (the author or the instructor) is actively present, and no reciprocity is manifest, within the interactive context. Therefore, reading instruction and distance education seem very well-suited. Because CMC is particularly learner-centered, it seemed appropriate to adopt this more motivating medium of instruction to our traditional reading program.

The Major Promise of Distance Education Is On Campus
W. R. (Bill) Klemm, Texas A&M University, USA

Distance Education (DE) is reforming on-campus instruction. DE's impact extends beyond the mere use of technology to put more razzle-dazzle into classroom presentations and beyond the advantages of assisted learning via computer simulations, drills, and animations. DE should force teachers to re-examine teaching philosophies, style, and tactics. Distance Education shows that learning need not depend on classroom lecturing. Indeed, we should now re-examine the whole purpose of the classroom environment. DE prompts us to re-examine accrediting criteria of "contact hours" and "credit hours." Teachers, now freed from the lecturing straight-jacket, can explore creative ways to show students how to find, comprehend, manage, integrate, and apply information. DE reveals the value and need in teaching for more interpersonal communication, between teachers and students and among students. I see a revival of interest among teachers in group work. Specific strategies for this new kind of classroom teaching are illustrated in the poster.

Interactive Ophthalmic Pathology Tutor
Gordon K. Klintworth, Duke University Medical Center, USA; Anthony N. Benson, Duke University Medical Center, USA; Ann L. Bushyhead, Duke University Medical Center, USA

A CD-ROM interactive, instructional course on ophthalmic pathology and relevant anatomy with hundreds of high quality images has been developed for users with different knowledge backgrounds.
Cognitive Idea Processor --- Modified Mandal-Art
Kagemasa Kozuki, Konami Co, Japan; Atsushi Tsubokura, Osaka Electro Communication Univ., Japan; Shogo Harima, Osaka Electro Communication Univ., Japan; Noboru Ashida, Osaka Electro Communication Univ., Japan; Katsuhide Tsushima, Osaka Electro Communication Univ., Japan

The new idea processor called modified Mandal-Art which can assist a user in his associative thinking between given item have been developed in which a user can communicate with the system using eye movement, finger-hand motion and voice. A user of this idea processor is forced to associate by seeing only nine items on the matrix called Mandala on CRT at a time. We have measured this information retrieve behavior from item pool of our testee putting on eye mark recorder and data gloves. Human associative thinking in his problem solving is accelerated by using this cognitive idea processor. This type of idea processor may brings us innovation of educational style on the computer by using the student model which take account the real time associative behavior of a learner.

Dilemma of Inquiry and Reflection Through and With Technology: New Directions for Research in Post-Secondary Teaching
Olga Kritskaya, Michigan State University, USA; Tony Clay, Michigan State University, USA

The study explored the issues of pedagogy for teaching reflective inquiry in the undergraduate program in Educational Psychology. The analysis focused on the role of the learners' imagination and the use of instructional hyper-media texts in construction of meanings associated with the course content. Particular attention was paid to the development of student design ideas that they use for the arrangement of images, which reflect, as a special form of narrative, on their understanding of the disciplinary concepts, personalities and life experiences. The data illuminate the instructional conditions when the student's act of arranging information becomes an act of insight. The computer-based student projects (Teacher's Portfolio, Multi-Media Gallery), along with the instructional hyper-media texts, reveal a critical instructional shift in the pedagogy of teaching reflective thinking-from structure to process, from enforcing students' competence to engaging them into performance-that fosters a deeper understanding of the dialectics of socio-cultural processes.

Assessing and Training Admunct Faculty with Technology: Enhancing their Classroom Learning
Karen Krupar, Metropolitan State College of Denver, USA

Increasing numbers of adjunct faculty at all major institutions of higher education has made it imperative that institutions examine the technology competencies of this large contingent of faculty who now instruct 40% of the courses on the undergraduate level. Very little effort is being made to provide development or training for these faculty in technology applications that would keep their students current in the rapidly altering global world of the 21st century. Metropolitan State College of Denver reviewed their 650 adjunct faculty and found many interesting factors that will be reported during this poster session. It is evident that adjunct faculty need assistance in both learning specific technology programs and in applying the technology into their coursework.

Design an Enhanced Virtual Experiment Environment Using Science Process Skills on WWW
Li-Ping Kuo, Chung Yuan Christian University, Taiwan, R.O.C; Da-Xian Dong, Chung Yuan Christian University, Taiwan, R.O.C; Chang-Kai Hsu, Chung Yuan Christian University, Taiwan, R.O.C; Jia-Sheng Heh, Chung Yuan Christian University, Taiwan, R.O.C

This paper proposes a methodology of applying a proper distance learning system following Seven Steps of Problem Solving and Science Process Skills. To complete this process of distance learning, this paper also suggests some tools for student undergoing all the process needed in the problem solving. Virtual Experiment Environment and Experiment Record are presented for some new notions in this paper. In Virtual Experiment Environment, Visual Lab is a new idea to operate experiment in Internet and show the reality of experiment. Experiment Record solves the difficult of implementing sheet and chart in HTML document. An environment for teacher design Science Process Skills is also presented in this paper.

Analysis of messages on the Only One Earth Club; TV-based collaborative learning site on the Internet
Haruo Kurokami, Kanazawa University, Japan; Tatsuya Horita, Toyama University, Japan; Yuhei Yamauchi, Ibaraki University, Japan

Messages sent to our BBS for collaborative learning can be classified to 10 categories. Each of these categories has some types of interactions among participants and site-staffs. The types of interactions are promotion of in-depth learning, discussion, and question & answers.
Aged and Disability Care training: A CD-ROM based project
Mark Laidler, RMIT UNIVERSITY, Australia

This demonstration has been developed to highlight one solution for delivering high quality work-based training in a multimedia environment.

Civilization in the 21st Century
David F. Lancy, Utah State University, USA; David DeBry, Utah State University, USA; Megan Andrew-Hobbs, Utah State University, USA

We will report on the evolution of an on-line course. The Civilization/Humanities course had its origins in the reform of the university's General Education curriculum in 1994-95. It was one of several classes created to replace existing requirements. The reform effort was designed to create interdisciplinary classes that would put the emphasis on universal aspects of inquiry rather than the narrow focus of typical introductory classes. Other expected features of these new courses were an emphasis on writing and the integration of technology. The initial Civilization/Humanities class met these criteria and was, by several measures, quite successful. In developing his version of the class, Dr. Lancy digitized his very large slide library and students were thus able to more readily access the collection for study and review. Another milestone occurred in 1998 when the library adopted an Electronic Reserve policy. Forced to incorporate this system into his class, Lancy went further and adopted many of the built-in features of ERes such as the "Bulletin Board." Civilization/ Humanities was moving towards the new millennium as it were. It became clear in the second year of implementing the new Gen Ed program (referred to as University Studies) that not enough faculty were signing on to teach the new courses. A bottleneck emerged which provided further incentives to adapt the few classes that had been developed to meet the new criteria for delivery to a larger audience. The most recent stage in this evolutionary process we will report on is the transformation of the Civilization course from a (primarily) classroom to (primarily) on-line delivery. In concluding we will generalize about this evolutionary process from cases gathered across the curriculum on our campus.

Wired for Learning
Donna Landin, West Virginia Department of Education, United States; Roberta Taylor, IBM, United States; Lynn Blaney, Wheeling Park High School, United States; Susan Alkire, Romney Junior High School, United States

The Reinventing Education project was established under a $2 million dollar grant from IBM to the West Virginia Department of Education. Its purpose is to define and validate criteria for creating instructional plans that use the power of the Internet to address the West Virginia Instructional Goals and Objectives and improve student achievement and learning. A Criteria for Excellence was created, then employed by a group of pilot teachers to develop lesson plans that would be peer reviewed, validated by field testing, observed during classroom implementation, and repeatedly revised. The resulting lesson plans have resulted in significant learning improvement and have been placed in the Best Practices database and shared with all teachers in West Virginia. Instructional plans have been developed for K-12 classrooms in the areas of math, language arts, social studies and science by teams of teachers, pre-service teachers and college instructors. On line professional development facilitates implementation of the instructional-collaborative environment.

Redesigning An Individualized Paper-Based Course
Stéphane Lavioie, SOFAD, Canada; Jo-Ann Stanton, SOFAD, Canada

Web-based courses that are an adaptation of a paper-based version rarely take full advantage of the Internet and related technologies. Taking this into account, we developed a successful interactive web version of a French grammar course. This poster session will show how "Du français sans fautes" was reengineered to avoid the pitfalls of shovelware using an Oracle database created with Visual Basic applications. We will offer an insight into the most challenging aspect of the process: the development of interactive exercises. We will focus on how we worked around technical constraints in order to maintain our pedagogical goals. More than 1500 students have enrolled in the course since it went online in September 1998. You may access "Du français sans fautes" at http://www.dfst.com.

Team-paced versus Self-paced: The Effects of Educational Game Design on Collaboration, Learning and Attitude towards Information Technology
Edith Law, University of British Columbia, Canada; Maria Klawe, University of British Columbia, Canada; Cristina Conati, University of British Columbia, Canada; John Meech, National Research Council, Canada

Avalanche is a multi-player game where players must cooperate to achieve a common goal. Using Avalanche, a pilot study was conducted to investigate (a) the effects of cooperative (team-paced) and independent (self-paced) learning on communication patterns, performance, learning and attitude of the players, and (b) whether there exists any gender differences in how boys and girls interact with the computer and their teammates in a cooperative gaming environment. 16 elementary school children, in same-gender groups of four, played Avalanche for two-hour
sessions. Results suggest that although team-paced learning foster a positive, cooperative team dynamics, self-paced learning has a more significant effect on learning itself. In addition, boys and girls react to the two versions of the game differently. In particular, the self-paced female group demonstrates more cooperative and help seeking/giving behavior than the team-paced female group, while the reverse was observed among the boys.

**Assured Quality Strategies in Web-based Accredited Programs**

**Judy Lee, University of Central Florida, USA**

Distance learning poses a challenge to voluntary accreditation. Quality assurance in emerging technology mediated distance learning is a central issue for accredited programs. The Council for Higher Education Accreditation report (CHEA, 1998) defines "quality assurance" as the means by which the institutions or providers set their accredited programs goals and measure results against those goals in distance learning. Regional and specialized accrediting organizations are currently engaged in assuring quality in distance learning as part of their ongoing review of institutions and programs. "Distance learning is seen by many as transformative vehicle for increasing the pace of change and reform in higher education. For these and other reasons, analysis of quality assurance is an essential topic for national, state and institutional policy development (CHEA, 1998)." Areas of interest regarding Quality Assurance Strategies include course and program concerns and needs, faculty and student concerns and needs, technical needs, and administrative support.

**Reference**

**Training Students to Be Self-Learners in Educational Hypermedia and Technology Courses**

**Amy S. C. Leh, California State University San Bernardino, USA;**

Modern technology is changing our education paradigm. Due to technology advancement, instructors can no longer play the role of "information-giver", rather have to become a facilitator. Facing tremendous amount of technology information, students in Educational Technology need to feel comfortable of learning technologies by themselves. The presenter employed a variety of instructional strategies in her graduate courses to train her students to be technology self-learners. In the courses, her students searched for Internet tools useful for instruction, selected computer applications that they would like to study, learned the selected tools in a team, and trained other class members the use of the tools they learned. In this poster session, the author will present teaching strategies, instructional activities, and course assignments that are related to the training. She will also report students' feedback on this kind of training.

**Effective Use of Client-Server Software and Teaching Strategies in Online Courses**

**Amy S. C. Leh, California State University San Bernardino, USA; Laura Howzell Young, California State University San Bernardino, USA**

In the field of education, many professors are incorporating online teaching into traditional courses. What is the impact? The authors received a university internal grant to convert two education courses—an instructional technology course and a course in adolescent development—to include online components. They report the benefits and challenges of using WebCT (course tools) with a variety of teaching methodologies. The poster session reflects results of a pre- and post- survey used in both courses to determine teacher attitudes toward online coursework. Students in both courses appreciated the flexible schedule of online work and time saved by not having to commute. The majority of teachers in both classes had not previously taken online courses; many liked the threaded group discussions and online testing, but a few who did not believe at the outset that on-line teaching is beneficial continued to reject it. For most of the participants, technology improved learning and achievement.

**Stepnet: quality newspapers and web-based learning in the Netherlands**

**Jan Lepeltak, Meulenhoff Educatief, The Netherlands**

Stepnet is a web-based newspaper-project in the Netherlands. Due to some educational reforms students in the upper grades of the Dutch secondary schools are to study partly individually, which implies that teachers are obliged to provide them with proper assignments. The results of these are part of the students' final examination. The use of ICT should also be part of their activities and a relation with daily (world-) news-events is strongly recommended. In order to facilitate the above approach for teachers and students, PCM, a Dutch publishing company consisting of newspaper and educational publishing houses, developed a web-site. This site contains a D-base filled with assignments related to the contents of two daily national quality newspapers. Every three weeks during the annual schoolterm a special magazine is published. Schools will pay a fee and will receive a licence in return, which entitles all participating students and teachers to receive a copy of this magazine called the "@krant", as well as access to the assignment D-base and the @krant D-base containing the newspaper articles. In addition, teachers will receive a half a day on-the-job training about working with Stepnet.
Custom-Authoring Hypermedia Exercises for Use in College Classrooms

Amy Lobben, Central Michigan University, USA

Continuously improving technology now allows educators new opportunities to move beyond traditional lecture style methods to create custom-authored multimedia, hypermedia, and animation presentations for use in classroom demonstrations or as computer-run student exercises. The development of new software programs and faster, more powerful computers, is beginning to change the creation process of dynamic presentations (multimedia, hypermedia, and animation). The once time consuming, programming intensive, and complicated methods of authoring such presentations have become manageable tasks through the use of improving computer programs, many of which are easy to learn and use. A series of computer-administered lessons have been created using Macromedia Director and Freehand. Each interactive lesson is designed to explain a specific topic and includes animation, graphics, photographs, quizzes, while maintaining stringent design guidelines. Applications such as these could have profound effects in large college classrooms, where traditional lecture-style approaches limit the individual, active learning by students.

Groupware Tools: Web File System Allows Students to Access Information Anywhere, Anytime

Tyrone Lobo, SiteScape, Inc., Canada

This poster/demo is based on SiteScape's Web File System and will explore how the Web File System allows users to securely store and manage large volumes of information entirely over the Web, giving students the freedom to access information from any industry-standard web browser.

A Web-based Hypermedia Pedagogical Course

Alla N. Makarova, St-Petersburg State Pedagogical University, Russia

The success of any hypermedia distance-learning course strongly depends on its psychological and pedagogical aspects. A study was made of the practical realization of some common pedagogical/psychological criteria in a Web-based hypermedia course. As a result of this study a template was developed which includes these criteria. This template may be included as a building block for many different hypermedia courses devoted to a particular subject. Some open problems with the template are discussed and analyzed.

Info Pursuits

Kerrie Manning, Leichhardt High School, Australia; Rosemary Ward, UTS, Australia; Tony Ward, Award Consulting Enterprises, Australia

Info Pursuits is an interactive CD-ROM game designed to teach and practice Library Information Skills. Students will answer Trivial Pursuits style questions and will be offered Information/Research Skills hints and suggestions as part of the feedback. These will include such things as techniques for finding resources, using encyclopaedias, dictionaries, non-print resources, Internet, statistical resources, telephone books, indexes, directories, interviews etc. Positive experience in using these resources may stimulate students to use them again in a different research task. The same skills are practiced many times with different resources and in different contexts, to facilitate transfer. The questions will be arranged in teaching area groups, to be used by teachers in ordinary lessons within the standard curriculum, or as extension work within standard curriculum areas. Many questions will practise general skills, but each curriculum area will provide experience with subject-specific resources.

Content Area Integration: A Step Toward Emiratisation

Reo H. McBride, Dubai Women's College, United Arab Emirates; Michael Ford, Dubai Women's College, United Arab Emirates; David Thomson, Dubai Women's College, United Arab Emirates; Raymond Yarsley, Dubai Women's College, United Arab Emirates; Lai la Hawker, Dubai Women's College, United Arab Emirates

The Higher Colleges of Technology (HCT) is dedicated to the delivery of technical and professional programs of the highest quality to the citizens of the United Arab Emirates (U.A.E.). This is the goal of "Emiratisation": an affirmative action policy of employing nationals in larger numbers in the workforce, which is currently dominated by ex-patriot workers. The authors of this article state that the most effective way to better prepare our students in fulfilling their roles in the task of emiratisation, is to integrate the skills taught in English, Math and Basic Computing in the classroom, and NOT teach them as completely separate entities. In essence, integrating the skills taught in English, Math and Basic Computing develops in students greater linguistic abilities, technical skills, intellectual capacities, and leadership potential. This study describes efforts made toward accomplishing such a daunting yet absolutely necessary task for college students in the U.A.E.

High Tech Classrooms-Going The Distance with Distance Education

Patricia McNames, Indiana University Southeast, USA

The rapidly evolving paradigm of interactive distance education is changing the learning environment on and off campuses and schools nationwide. Educators are suddenly surrounded by not only the opportunities of distance
education, but also by its demands. Thus, when educators begin using these boundary-spanning technologies to enhance the learning process, it does dramatically require teachers and students to change what they do. The purpose of this paper and poster/demo is to serve as a resource for educators who may be considering incorporating distance education approaches into their courses. In cyberspace, time and place are fourth dimensional. The four dimensions that will be discussed in this presentation are 1) defining the appropriate distance education system, 2) designing the interactive course, 3) developing a virtual learning community, and 4) dealing with technical difficulties.

An on-line introduction to quantitative methods
Moira McPherson, Lakehead University, Canada; William Montelpare, Lakehead University, Canada

This poster/demo describes the development, implementation, and evaluation of an "on-line" introduction to an undergraduate course in quantitative methods. The virtual curriculum modules developed for the course provided a forum in which information, knowledge, expertise, and questions could be explored and updated throughout the course. Working asynchronously, the user completed six assignments. Questions which arose during the user's session were passed to "experts" that provided feedback, electronically. The "question - feedback" loop was a dynamic component of the organizational structure and used different modes of communication, including e-mail, electronic conference rooms, bulletin boards, and on-line help pages. The assignments were submitted electronically to teaching assistants who evaluated the submissions and provided feedback directly to the users. The inclusion of direct feedback communication between experts and users reduced the impersonal characteristics that might arise within an asynchronous learning-environment.

Principles Of Cognitive Evaluation For An Educational CD-ROM For History
Christina Metaxaki-Kossionides, University of Thrace, Greece; Eleftheria Gonida, University of Thrace, Greece; Stavroula Lialiou, University of Athens, Greece; Georgios Kouroupetroglou, University of Athens, Greece

The evaluation of CD-ROMs and multimedia products used in educational environments is a major topic. One of the erasing problems is the formation of a set of pedagogical principles or concepts and their technological implementation. We present the formation of a set of cognitive principles. Those are included in the set of evaluation, concerning a CD-ROM developed by us. The topic was a history lesson about the Homer period. We have selected two types of principles which, together with the ones for software development, should form the set for the formative evaluation. The one sub-set included the pedagogical requirements for the lesson of history. The other sub-set included the principles delivered by the cognitive scientists. These last ones were developed for the specific topic. They mainly refer to the nature and processes of learning and instruction. The set of the cognitive requirements were added explicitly as fields for a database for software evaluation.

Authoring Multimedia, Designing Animations for Physics Education
Donald J. Metz, University of Winnipeg, Canada

Computer animations used in high school physics instruction are demonstrated. The programs are written using Asymetrix Multimedia Toolbook and are designed to address the specific needs of the students and their learning environment.

Dynamic Communication Layer Between Virtual Laboratory and Intelligent Agents
Kaufmann Meudja, UniversitT de Sherbrooke, Canada; Roger Nkambou, UniversitT de Sherbrooke, Canada

In the last few Years, virtual laboratory has become an important part in online courses. Some of those virtual labs involve intelligent behaviour. However, this intelligent behaviour is usually hard-coded in the virtual lab and therefore, limit the possibility of using reusable intelligent agents that are completely separate from the virtual lab and which can control most users actions in the virtual laboratory environment. We propose a way to separate intelligent behaviour from the virtual lab by the implementation of a communication layer between the virtual laboratory and intelligent learning agents.

Design, Delivery, and Evaluation of Online Courses: A Primer
Jerold Miller, United States International University, USA

Online learning environments can be highly interactive and student-centered. Incorporating the contributions and experiences of each member of a learning community into the coursework encourages students to contribute more of themselves to the course and allows them to learn more from their teachers and peers. Creation of functional online learning environments is contingent upon the effective design, delivery, and evaluation of online courses. This session will address the design of online courses and adaptation of traditional courses to the online delivery mode. Participants will understand appropriate online delivery methods, explore teacher-centered vs. student-centered learning, understand effective strategies for communication online, know how to adapt content and curriculum for online teaching, discover new assessment strategies for distance learning, and learn how to create an online community of learners.
Discovering xyAlgebra: Intelligent Interactive Internet Instruction
John Miller, The City College of CUNY, USA

Abstract: Passive activities such as watching presentations, listening to explanations of general principles and watching experts solve sample problems are helpful, but peripheral, to the mathematical learning process. For students the indispensable step is solving problems for themselves. Yet most commercial mathematics software still concentrates on presentations and sample problems, while sending students off line to do practice problems on paper without interactive support. Answers are either multiple choice or limited to a single simplified final step. Early Internet courses are even less interactive. In contrast, students using xyAlgebra can enter each step of each problem solution. They enjoy intelligent support at every step as xyAlgebra’s suggested solution strategy changes in response to their steps in simplifying expressions, solving equations and even in setting up and solving verbal problems. The next version of xyAlgebra will support instruction over the Internet, yet the entire package can be downloaded without cost at math0.sci.ccny.cuny.edu/xyalgebra.

Problem-based Learning and Flash 4.0: An Experiment in Science Education
Leslie Miller, Rice University, USA; Janice Mayes, Rice University, USA; Donna Smith, Rice University, USA

How does one design learning resources that will reach large audiences, capture the imagination, and compete with the game environments that are popular among of middle school students? The Reconstructors is a new episodic adventure series, designed for the Web, with a substantive educational message. See http://reconstructors.rice.edu where a student enters a futuristic world in which he or she assumes the role of a "reconstructor." In the interactive mystery format, a student learns science and history relevant to the discovery and use of opiates. Over the course of four episodes or missions, students "solve the problem." The concepts of neurotransmission, the neurobiology underlying drug addiction, drug tolerance, and analgesia, as well as the history of opium use are presented.

On-Line Education Using Video Broadcasting Delivered from Perth Campus, Algonquin College
Maike Luiken Miller, Algonquin College, Canada; Dave Osborne, Algonquin College, Canada; Ian McCormick, Algonquin College, Canada

As part of the LCN (Lanark Communications Network) TAP project, Algonquin College at Perth Campus engaged in a video broadcast/conferencing pilot to deliver a course, "The History and Philosophy of Architectural Conservation" (ARC9001), simultaneously in 2 modes: lectures with electronic slides and traditional black board work and, in parallel, video broadcasts (IN@SEC VP Broadcaster) with e-mail feedback. This pilot demonstrated successfully that on-line co-delivery allows to teach students simultaneously at different locations employing video, audio and text via a network using relatively inexpensive broadcasting/conferencing software with minimal set-up requirements at the clients' site. Course delivery improved. Students enjoyed the choice of delivery modes to suit their learning styles. Professor appreciated more time for interacting with the students. Re-broadcasting at a later time possible. The delivery model - independent of the specific broadcasting tool - provides a means to reach remote connected students everywhere - be it rural or elsewhere around the world.

TLC : Teachers’ And Learners’ Collaborascope – A Platform For Analysing And Evaluating Online Education
Michelle Montgomery Masters, University of Glasgow, UK; Stewart Macneill, University of Glasgow, UK; Prof Malcolm Atkinson, University of Glasgow, UK

Millions is being spent on installing networks, computers and assembling distance learning material and ICT (information and communications technology) software. Yet the network technology is not being used to assemble databases which researchers, managers and politicians can "data mine" to guide their investment. In the TLC project we are pioneering techniques for assembling and querying educational data. Our goal is to initiate research into the best methods of rapidly assessing the effectiveness of resources deployed and then interpreting the data to improve our educational performance. We are not trying to reinvent the wheel and produce yet another online learning environment like WebCT or Virtual-U. Instead we are building tools which will work in collaboration with these existing learning environments and provide teachers and students with valuable information about the usage of their learning environment. The TLC project aims to utilise the emerging standards such as those from the IMS project.

The Third Dimension For World Of Knowledge: An Acceptable Way To Get In
Mikhail Morozov, Mari State Thechnical University, Russia; Aleksander Markov, Mari State Thechnical University, Russia

Educational CD-ROMs should be as interesting and attractive for children as computer games. The approach offered by the authors allows to reduce the existing gap between multimedia for education and for entertainment. It is achieved due to the unusual design of 3D interface and by using a special technique of development. As a general metaphor for organisation of multimedia environment the metaphor of theatre with all appropriate attributes was
chosen: the stage with visual educational content, side-scenes, a curtain, etc. For presentation of educational material in addition to traditional multimedia components, the new integrated forms are used. Because of complexity and richness of information of the CD-ROM model, its realization is based on a graph of program transitions and application of script paradigm, which is accepted for the description of structure of the educational and navigating information. These solutions can be recommended for creation of a new generation of "three-dimensional" educational multimedia CD-ROMs.

**Using a Web Site to Increase Student Motivation to Write and Enhance the Reading/Writing Relationship**

Susan Nelson, Elm Street Elementary School, USA; Harrison Yang, State University of New York at Oswego, USA

This action research project is an example of how Internet technology is being used in an elementary classroom as a means to increase student achievement. The project explores the relationship between writing and reading and its effects on early literacy development. It also explores the concept of motivating students to write by publishing student work for real life audiences. The project uses the current technology of an Internet web site as a source for publishing student writing. It explores the effects that this type of publication has on student attitude, motivation to write, and literacy development.

**TELSi, Web-Based Software For Collaborative Learning**

Graciela Nielsen, Norwegian State Center for Adult Education, Norway; Boo Hever, Majornas Vuxengymnasium, Sweden; Aase Steinmetz, Undervisningsministerium, Denmark

The TELSi software has been developed with the support of the European Union under the SIMULAB-project. SIMULAB is a concept for Web-based collaborative tasks. TELSi has been created to cater for the needs of this type of activity, and is a flexible and user-friendly environment.

**Development of Speech Input System for Web-based Courseware**

Ryuichi Nisimura, Nara Institute of Science and Technology, Japan; Shoji Kajita, Nagoya University, Japan; Kazuya Takeda, Nagoya University, Japan; Fumitada Itakura, Nagoya University, Japan

We propose WebSPEAC (Web SPEech Acquisition for Courseware) System that provides a speech-input function for Web-based online education system. WebSPEAC has the following three features: (1) easy to maintain the system by the use of a simple speech input program in Web browsers, while the other speech processing are performed on the Web server, (2) a natural interactivity between Web server and users by using the server push technology, (3) a simple installation and no needs of external programs on client machines. To show the effectiveness, an Web-based speech analysis system, a speech recognition system and a student identification system are developed as the examples of WebSPEAC System. By using the speech analysis system, it is clarified that WebSPEAC System can significantly reduce task steps, error steps and elapsed time for speech-input task, compared with the conventional method (file upload).

**The Instructional Portal Project**

Kevin Oliver, Virginia Tech, USA

The Instructional Portal is a clearinghouse of information, resources, tools, and services at Virginia Tech, designed to facilitate practical instructional design among faculty. Faculty can increasingly adopt and easily utilize educational technologies in their courses. While some faculty use technology to modify and improve teaching and learning practices, too many rely on tools to simply make their existing teaching practices more efficient. The portal is designed to help faculty integrate technology more effectively by applying three instructional design components. The analysis component outlines strategies and instruments to account for environmental and learner characteristics, and provides information about structuring course content. The strategy component describes instructional methods and models that utilize technology effectively, and provides teaching modules covering popular web-based instruction and interface design issues. The evaluation component describes evaluation methods and models and provides tools to help faculty revise and improve their technology innovations. Visit the portal at: http://www.edtech.vt.edu/edtech/portal/index.html

**Integrating and Adapting Multimedia Resources**

Mary Panko, UNITEC Institute of Technology, New Zealand

In UNITEC students enrolled on an Automotive Trades course have access to a series of 32 CDX disks, entitled The Automotive Trainee Series that provides them with a learning resource in addition to their basic theoretical and practical teaching. This study attempted to:

- discover what beneficial learning effects the students perceived as being currently provided by the multimedia component;
- examine the extent to which the tutors integrated and adapted the multimedia material as part of their teaching;
compare patterns of current disk utilization with those of the previous year.

Results showed that although both staff and students thought the multimedia material valuable, its overall utilization by students had diminished over time. The reason for this appears to be the lack of integration of the resource by tutors into their teaching. Furthermore, tutors had generally not adapted the material for their own needs although where workbooks had been provided, this seemed to increase the students' satisfaction.

DISCETECH-BIMBOTECH: An Experimental Project For Introducing Innovative Technology Within The Italian School System
Paolo Paolini, Politecnico di Milano, Italy; Pierluigi Della Vigna, Politecnico di Milano, Italy; Francesca Collina, Politecnico di Milano, Italy; Paolo Magatti, Politecnico di Milano, Italy; Silvia Moiola, Politecnico di Milano, Italy

Since 1996 Politecnico di Milano has launched a program for experimenting, within the Italian school system, the use of advanced technology for teaching and learning. Two projects (in Como and Lecce) have involved more than 700 teachers and more than 8,000 pupils, being the largest of this kind in Italy, both in High Schools (Discetech project) and grammar schools (Bimbotech). The project emphasizes the role of the teachers, who are trained on multimedia and Internet technology first. Secondly they are "guided" and assisted in shaping up specific activities with usage of either multimedia CD-ROM's or Internet Sites. A large collection of CD-ROM's has been created and several hundreds educational Websites, on different subjects, have been classified. The project has been very successful with the teachers (many of them have never used advanced technology before) and the pupils, the learning and the interest of which has been evaluated as sharply improved.

Learning Experiences in New Learning Environments
Heli Pekkala, University of Jyvaskyla, Finland

One of the outcomes of a departmental action research project at our language centre is a modernised Learning Centre, where students and staff of the university have access to learning materials in over 30 languages. The philosophy and pedagogical framework underlying the operations of the centre is to support and encourage students in developing their learning skills and self-directiveness for continuous language learning and for making effective use of new learning environments. This paper presents the Learning Centre (interactive studios, writing studio, multimedia studio etc.) and reports student experiences of learning a new language independently. One part of this learner training course Learning to Learn Languages was a self-access project during which students were requested to reflect upon the kinds of qualities and procedures that self-directed language learning requires from a learner. They also evaluated what areas of language were possible to access without external structuring and teaching.

Microsoft Office as a Learning and Teaching Tool
Craig Place, Acadia University, Canada; Michael Shaw, Acadia University, Canada

Many useful features in popular software applications often go unnoticed by many users. Often thought of as a business application, Microsoft Office is one such suite of applications that is often overlooked as a tool for use in the teaching and learning environment at most grades, and at the university and college level. With just Word, Excel and PowerPoint, MS Office can be used as a tool to develop the basic understanding and expertise for a number of other applications including photo-editors, drawing and animation programs, multimedia authoring and web-development tools. Used as a stepping stone to more advanced applications in this way, the interface of each of these 3 applications can be simplified to be useful at a number of different grade levels, or levels of expertise. Using a combination of examples and hands-on exercises the workshop will illustrate to the participants how MS Office can be used to easily and effectively create multimedia hyper-documents, dynamic learning-objects, student review exercises and interactive non-linear presentations. Specific examples will be the use of PowerPoint as a concept-mapping tool and as a multimedia authoring and animation tool. Using Excel to assist in language learning and create dynamic graphs for interactive what-if scenarios, and using Word to develop hypermedia templates and collaborative writing documents. Several examples of the usefulness and creation of macros will also be shown.

Students' expectations and perceptions of efficacy for self-regulated learning in mediated learning environments: Partial results of an evaluation
Laura Helena Porras, Universidad de las Americas, Puebla, Mexico

This paper discusses partial results of an evaluation applied to an educational teleconferencing system in a Mexican higher-education institution. Courses offered through the system are based on a pedagogical model, which emphasizes the active role of the learner as responsible of her own learning. Therefore, perceptions of the self, and self-regulatory processes become key components in this learning environment. Conclusions here presented correspond only to: (i) students' expectancies, (ii) perceptions of efficacy for self-regulated learning, and perceptions of the course, and of the teacher and learner's work. Results indicate students' expectancies focus on "learning more than in face-to face situations", followed by "using technology", and "having freedom and initiative". Perceptions of efficacy for self-regulated learning were high overall. Nevertheless, analyses of individual items identify specific areas
of improvement. Qualitative data on perceptions of the course, and teacher's and learner's work suggest that these courses are more demanding than the face-to-face ones they are taking. Students' responses include attitudinal and cognitive adjustments needed for these learning environments. These results have led to improvements, which are presently being applied.

**An Online Model For Precalculus**

Hari Pulapaka, Valdosta State University, USA; Denise Reid, Valdosta State University, USA

Some of the greatest challenges to designing and delivering a completely online mathematics course are effective and efficient uses of the leading technologies that are available for this purpose. The authors have just completed designing the first version of a precalculus course that is being delivered through a combination of synchronous and asynchronous environments. Precalculus was chosen over other mathematics courses for several reasons. The course has been planned as a model online course for any mathematics course (especially at the early levels). Future versions of this course and related courses will undoubtedly incorporate additional technologies and components in an effort to improve student learning, interactivity, and end-user feasibility. Future plans for the course include development and refinement of the unfinished sections of the course and tighter integration with graphing calculator and/or mathematical software.

**IMAGUS: An Environment To Design Video Applications For Digital Libraries**

Andre Luis Alice Raabe, Pontificia Universidade Catolica do Rio Grande do Sul, Brasil; Lucia Maria Martins Giraffa, Pontificia Universidade Catolica do Rio Grande do Sul, Brasil

This poster presents the description of the IMAGUS environment. IMAGUS has tools to built video applications supported by Internet. This environment has being developed in order to contribute for the construction of the PUCRS digital library collection.

**Art, Poetry, and Instructional Media**

Thomas Reinartz, Rosemount High School, USA; Brad Hokanson, University of Minnesota, USA

In many high school English courses, students are trained to seek out proper form and work toward clarity in their writing assignments. They are taught to write using complete sentences and complete thoughts, fix their punctuation and grammar, and strive for polish in all written work. That is what English is all about. On one level, we can be pleased with their concern. However, this quest for excellence and perfection seems to interfere with the poetry writing process. Many successful poems lack complete sentences, defy traditional uses of punctuation, and contain word combinations that require readers to make inferential connections, often sacrificing the writing clarity that English teachers work so hard teach. We have taught them to be concise, clear, and correct in all writing endeavors, which in most cases, is sound advice. Writing poetry, however, demands skills that require us to play with words and dwell in areas where word juxtapositions and combinations are limited only by one's imagination. The many choices in this "zone" of possibility are frighteningly endless, so it is no wonder students resist entering. They may get lost. To help foster an awareness about word choice and imagery, we developed an interactive program to generate "found" poetry with student input and used it in a twelve week American literature class taught by T. J. Reinartz, one of the authors. The program evolved from discussion between the authors regarding the use of computers to inspire poetry writing. A multi modal qualitative research study was undertaken involving classroom observation, video taping, survey questions and analysis of poetry segments. The findings of that research and analysis will be presented, with broader observations of the use of computers 'in the service' of poetry, and their appropriate use in the high school classroom.

**Students as Producers: Changing the Way we Teach and Learn**

Gail Ring, University of Florida, USA; Sebastian Foti, University of Florida, USA; Melissa McCallister, University of Florida, USA; Tamara Pearson, University of Florida, USA; Ebraheem Alkazeemi, University of Florida, USA

Educational technology courses at the University of Florida are modeling the concept of students as producers. Through student-based projects such as an online support center, educational software, student portfolios, and documentary-type CD-roms our students are producing educational products. These 'real' activities are improving our courses as students learn by doing, thereby creating a constructivist learning environment. Relevant, contextual projects such as these provide students with an increased sense of empowerment and ownership. In our presentation we will share how the traditional roles of instructor and learner may no longer appropriate.

**The GPB project; A successful PHD seminar using Videoconference in real time and a list to communicate between the classes**

Claire Roberge, University of Quebec in Montreal, Canada

This winter 2000, a seminar was offered at the PHD level in the department of Communication at the University of Québec in Montréal. Three teachers participated, one from Montréal, one from Paris and one from Grenoble. Seven sessions were offered in videoconference to all students enrolled. A website and a list were added tools offered to the students to communicate between the sessions. The sessions in videoconference were in real time.
Teachers and students made presentations and periods of questions were planned at the end of each of those presentations. The experience which will be renewed next winter was a success. Technology was used wisely, the teachers made sure the environment available enhance the learning process of their students. The differences in cultural habitus and in the uses of technology were taken in consideration. An evaluation was made taking seriously all factors.

**Multimedia Training, Virtual Instrumentation and Remote Laboratory a New Approach to the Electronic Courseware**

Nicoletta Sala, Academy of arch. University of Italian Switzerland, Switzerland

This work describes a project developed at the Department of Electronic Politecnico of Torino in the field of multimedia technologies in educational process. The goal was to allow the students to carry out a pre-training activity outside the laboratory and possibly at home; each student could thus individually adequate the learning rate to his own capabilities. After this pre-training phase, students who enter the laboratory require reduced assistance and less time to complete the training activity. This approach can reduce the qualified assistance that is not easily found. For this reason several hypermedia modules have been developed (using Multimedia Toolbook) to assist the students to acquire the fundamentals of the basic electronic instrumentation. The subjects developed are:

- fundamentals of the analog and digital oscilloscope, which includes practical exercises;
- fundamentals of the analog and digital voltmeters and their operating theory;
- the IEEE488 standard interface for programmable instrumentation;
- the logic analyzer;
- the spectrum analyzer.

Virtual instruments are implemented in order to allow simple simulations of the real instruments during the self-training phase. A client-server system has been designed in order to allow the students to operate on a remote laboratory for experimental training. The idea is to design a laboratory that is simultaneously and remotely accessible to several students, who concurrently share the same instrumentation, but not necessarily the same experiment. The instrumentation and the other hardware resources are accessible in a sort of time sharing process, which is managed by a server and transparent to the user. The virtual laboratory architecture is composed of two kinds of subsystems: the measurement Server and the measurement clients.

**Strategies for Teaching and Learning: Lessons Gained from an Ethnography of Graduate Classes in an Interactive Distance Learning Studio**

Lorraine C. Schmertzing, University of West Florida, USA; Richard W. Schmertzing, Valdosta State University, USA

This poster session is based on data collected during a one-year ethnographic case study of graduate education classes during the inaugural year of a 2-way audio/2-way video interactive distance learning classroom at a regional university in the southern United States. Cultural anthropology and symbolic interactionism acted as guide to uncover and describe the processes through which adult learners transformed traditional classroom culture as they implicitly redefined that culture during their initial exposure to a specific distance learning environment. This poster session addresses the often un-addressed complexities inherent in re-defining ones learning environment so that effective learning can occur and offers strategies for teaching and learning based on these complexities. Strategies include ideas for the first night of class, cultural awareness activities, feedback forums, and rules of engagement.

**Use of Telecommunications Technology in Radiation Accident Simulation**

Domenic Screnci, Boston University School of Medicine, USA; Kirsten Levy, Boston University School of Medicine, USA; Erwin Hirsch, Boston University School of Medicine, USA; Richard Aghababian, University of Massachusetts Medical School, USA; Tracey Russo, Boston University School of Medicine, USA

Radiation accidents are rare but increasing in frequency. Partners in a regional project are providing training on radiation accident preparedness in Eastern Europe and the New Independent States. Recently, the partners devised a radiation accident exercise to simulate radiation exposure and test inter-regional cooperation among eight nations. A variety of multimedia, communication and distance learning technologies was used to execute the exercise. This poster describes:

- Objectives
- Design
- Procedures
- Communication Plan
- Educational Technologies

The exercise demonstrates a live response to a simulated radiation accident; the ability to exchange information among peers, request resources and notify appropriate agencies; and the use of communication technologies to
debrief the experience. Also demonstrated is the use of distance learning technology to cultivate regional harmonization of response in a field in which preparedness is essential but practical exercises lacking.

**Teaching data analysis using thin client technology for remote access**

Robert Seidman, San Diego State University, USA; K. Michael Peddecord, San Diego State University, USA

This poster describes implementation and outcomes of using thin client technology to provide remote access in a data analysis course. All software applications run on the course server, so no downloading of data or software is required. Results from statistical analyses are transmitted to students’ client machines. Students were able to launch applications and complete assignments from any location that had Internet access. In addition to 7/24 access, students were able to use software they did not own and large data files they did not have on their own computers. While they generally expressed satisfaction with this remote access capability, drawbacks included initial programming time and cost of the server software, lack of familiarity with operating in a networked environment, frustration with server-side disconnects or ISP interruptions, and occasional inability to print at home because the server software does not include all old printer drivers.

**Multimedia Guide to Fractal Geometry**

Vladmir Shlyk, Belarusian State Pedagogical University, Belarus

Fractal geometry has changed our view of natural processes and geometric forms. The Guide is a software kit supporting a university course on this science. It contains an introductory electronic textbook, annotated list of publications, favorite Internet links and provides facilities to run programs. One program of the project visualizes the mechanism of birth of classical and IFS fractals. A student can grow fractals by himself and explore their features by trying different generators and mappings. Another program demonstrates connection between the Mandelbrot and Julia sets. It throws a bridge from fractal geometry to nonlinear dynamics and chaos theory by showing different variants of behaviour inherent in underlying quadratic process. Having advantages over analogous programs, it is already being used at several universities. To create the most complete educational software on fractal geometry we would be pleased to collaborate with other specialists and enthusiasts.

**Project-Based Learning + Multimedia: Adding Value to Students’ Education**

Michael Simkins, Silicon Valley Network, USA; William R. Penuel, SRI International, USA

"Does technology really make a difference in student learning?" Definitely, according to the Challenge 2000 Multimedia Project, one of the original Technology Innovation Challenge Grants funded by the U.S. Department of Education. The Project has demonstrated significant educational results when technology investment includes teacher training, technical support staffing, and curriculum materials development. In a five-year evaluation of the $6.2 million project in California’s Silicon Valley, SRI evaluators found that technology-using students surpassed their non-technology-using peers in developing some of the most critical skills for the new economy of the 21st century. These skill advantages included better communication, teamwork and problem-solving. Researchers also found important positive changes in teachers’ classroom practices that support a constructivist approach to learning. In addition, these same students equaled their non-technology-using peers in learning the basic skills measured in standardized tests. In short, students in technology-using classes not only "got the basics," they got more.

**The Search for the Skunk Ape: An Information Literacy WebQuest**

Charlotte Slater, The Walden Institute, USA; Pamela Sawallis, Florida Gulf Coast University, USA

A web-based instructional resource for distance and on-campus learners uses elements of goal based scenarios (Schank, 1994) and WebQuests (Dodge, 1997) to provide a "fun," story-based environment for learning information literacy skills. This project represents a partnership between instructional technology and library services at a state university.

**Online Learning in a 3-D Robotics Workshop: The NASA ROVer Ranch**

Stephanie Smith, NASA/LinCom, USA

The ROVer Ranch is an online environment based on NASA’s mission as it relates to robotics engineering. Students are situated where they learn about robots and then build and run simulated robots in a 3-D virtual world. The robotics workshop has all the components to build a "soft" version of a robot and the tools needed to instruct the robot to complete its mission. Student engineers or teams select a mission, review the mission goals then design a robot with the appropriate attributes (power source, navigation planning, tools, etc.) based on the mission objectives. Once the robot is constructed, students plan a navigation path and then place the robot in the simulation to execute the mission. This simplified design and programming exercise is an interactive method to learn science and math skills both individually and in a team setting as students share their experience in journals and team message boards.
OATS: Operational Amplifier Tutorial Simulation; a dynamic presentation
Sarah Sniderman, Concordia University, Canada; Gary Boyd, Concordia University, Canada; Geza Joos, Concordia University, Canada

Abstract: Operational Amplifiers are among the most important components used in analog electronic devices. They are complex and initially counter-intuitive in behaviour. Electrical engineering and electrotechnology students frequently need special tutorial help to understand them and configure them to work properly in various circuits. The main advantage of simulation programs for higher education in technical fields is that, when carefully designed, they can promote higher level instructional goals of prime meta-cognitive value, especially those involving the autonomous active construction and exploration of knowledge at a pace appropriate for the learners. Note, however, that such free exploration of knowledge at a responsive pace is not a quality inherent in multimedia instruction. High-level interactivity involves more than guided clicking through branched instruction. A truer understanding requires a learning environment which accommodates the testing, falsifying, validating, and elaboration of understandings.

The Munchhausen-Trick: Learning Internet by Internet
Ralph Sontag, TU Chemnitz, Germany; Dietrich Thie, TU Chemnitz, Germany

The Chemnitz University of Technology is the first one in Germany, which is able to offer an internet-based study about information and communication technology. The participants of the courses are able to collect fundamental and applicable knowledge about internet-related technologies using it - a problem comparable to the baron of Munchhausen, which drags himself at his tuft out of a marsh. After two introducing lessons the communication between learners and teachers is strictly internet-based. Stepwise the students are qualified to understand and maintain complex situations in management of ip-networks and servers. The knowledge can be proofed in a remote managed, but actually existing laboratory. Moreover we had to consider the very heterogenous working times of our participants. We prefer asynchronous communication with short turn-around-times in conjunction with online-tools like "virtual seminars", tests or experiments. The consequently platform-independent project uses open protocols and standardized document formats like HTML or XML.

In defence of ‘shovelware’: A powerful tool in staff development for online teaching and learning
Heather Sparrow, Edith Cowen University, Australia; Jan Herrington, Edith Cowen University, Australia; Tony Herrington, Edith Cowen University, Australia

A significant challenge for universities creating effective online learning environments is educating and empowering teaching staff. Those who are not confident using technology are frequently unconvinced about the benefits and are concerned that it will force unwanted changes on their current practices. This poster outlines a project which introduced a large number of variously experienced academic staff to online teaching, whilst maintaining or enhancing effective learning. The project included the simple conversion of print-based external units to an online mode, as one of several strategies of development. Whilst this process is often referred to derogatively as shovelware, some of the positive and immediate outcomes achieved will be described, and challenges will be made to extremely negative attitudes towards such conversions.

An Evaluation of Video Compression Schemes for Teleteaching Applications
Ognjen Stanovcic, Open Systems AG Zurich, Switzerland; Thomas Walter, Swiss Federal Institute of Technology Zurich, Switzerland; Bernhard Plattner, Swiss Federal Institute of Technology Zurich, Switzerland

Synchronous, interactive teleteaching is demanding with respect to required network bandwidth and short end-to-end delays. An uncompressed digital video, e.g., requires a data rate of 261 MBit/s. Video compression is a method to reduce required network bandwidth. Efficient video compression is almost lossless with respect to perceived video quality at the receiving site, but it is time intensive. In support of interactivity, however, response times must be short to allow participants to audio-visually communicate like being in the same room. This implies that the end-to-end communication delay should be less than 150 ms. This requirement puts a hard constraint on video compression since compression time is only one factor that adds to the overall end-to-end delay. We present a framework for the evaluation of video compression schemes. We define evaluation criteria such as compression delay and compression efficiency. The video compression schemes evaluated are Motion JPEG, MPEG, H.261 and H.263.

Multibook: making web based learning resources personal
Achim Steinacker, TU Darmstadt, Germany; Cornelia Seeberg, GMD IPSi, Germany; Ralf Steinmetz, GMD IPSi, Germany

Considering the amount of knowledge accumulated on the Web, the discussion of an effective use of the web resources becomes urgent. The main question is how to find the relevant information. In our web based teaching
system Multibook we use modularized learning content stored in a knowledge base and describe these modules such that the combination of modules can be matched to the users preferences, represented in a user profile. In this demo we will show our knowledge base containing both the actual multimedia learning resource and the metadata in form of a terminological ontology, attributes for the resources and relations between the resources. Then we sketch the user profile and finally we show how these components are matched together.

**Math and Science Curriculum Revision: A Collaborative Approach to Improving Preservice Teachers' Use of Technology Knowledge and Instructional Skills.**

David Stokes, Westminster College, USA; Carolyn Jenkins, Westminster College, USA; Lorel Huhnke, Westminster College, USA; Gothard Grey, Westminster College, USA; Cheryl Manning, Bryant Intermediate School, USA

Reports on a Preparing Tomorrow's Teachers to use Technology Capacity Grant project, a consortium comprising Bryant Intermediate School, and Westminster College, both of Salt Lake City, Utah. The consortium participants engaged in collaborative curriculum development to provide preservice teachers greater exposure to the instructional uses of technology in education. Skills in the application of communication, presentations, and CLE technologies were explored. Teaching units integrating sound curriculum with technologies including video-microscopes, CBL probes, graphing calculators, Excell, PowerPoint, various software programs, and the Internet were developed. Outcomes suggest improved teaching with technology skills, better real-world collaborative inquiry, greater focus upon multiple learning styles; and gains in extending the power of scientific inquiry into mathematical and scientific reasoning.

**Integrating pedagogy, content and technology into your curriculum**

David Stokes, Westminster College, USA; Wanda Carrasquillo-Gomez, Westminster College, USA

Perhaps there are fewer more daunting tasks to teacher educators than to find the time, means, and information to begin to more fully integrate technology as an instructional and learning tool into their courses. Over the past year the authors conducted a thorough curricular revision of technology courses offered in the Master of Education program at Westminster College in Salt Lake City. Courses were redesigned focusing curriculum upon technology as a communication rather than a presentation medium. Outcomes suggest this approach is beneficial to generating increased understanding of the role technology can play in teaching and learning, and in strengthening key linkages between constructivist theory and teaching practice.

**SMILE Maker - An Intelligent Learning Environment for Problem Solving**

Svetoslav Stoyanov, University of Twente, The Netherlands

This poster introduces SMILE Maker - a web-based tool supporting ill-structured problem solving activities of students involved in problem-based learning. SMILE Maker stands for Solution, Mapping, Intelligent Learning Environment. It is both a problem solving and a learning tool. As a problem solving tool it proposes a method for creative problem solving based on the synergy of some mapping approaches like concept mapping, mind mapping, cognitive mapping, flowscapping, and process mapping, and a systematic creative problem solving methodology. The method facilitates elicitation of tacit knowledge, an effective organization of the explicit knowledge, and avoidance of some negative individual problem solving syndromes like analysis-paralysis, functional fixedness, premature judgment, and etc. As a learning method it provides an individualized learning environment for studying and applying this method. It adapts learning to four personal constructs such as learning styles, problem solving styles, learning locus of control and prior knowledge.

**An Adaptive Web-based Course in Financial Engineering with Dynamic Assessment**

Alberto Suárez, Universidad Autónoma de Madrid, Spain; Estrella Pulido, Universidad Autónoma de Madrid, Spain; Rosa Carro, Universidad Autónoma de Madrid, Spain

The increasing relevance of interdisciplinary skills calls for the design and implementation of novel strategies to address the problem of teaching a corpus of knowledge to a heterogeneous audience. We have chosen a problem in financial engineering, the valuation of European options, whose mastery requires the interplay of mathematical, computational and financial tools. The target audience in financial engineering courses is generally composed students of either financial background or of a scientific, non-financial area (mathematics, computer science, physics). The course is designed within the framework of the TANGOW system (http://www.ii.uam.es/esp/investigacion/tangow/present.html), which provides the necessary mechanisms to construct a web-based course whose contents are dynamically generated according to the student's profile and actions. The system includes the possibility of dynamic assessment, which involves testing not only the student's ability to understand static knowledge, but also his/her ability to actively design procedures (programming analytical formulas, realization of simulations) to achieve the prescribed goal.
Building Learner and Teacher Autonomy for New Learning Environments
Leena Subra, University of Jyvaskyla, Finland; Liisa Kallio, University of Jyvaskyla, Finland; Ulla Lautiainen, University of Jyvaskyla, Finland

The poster reports on the experiences of our departmental action research project aiming to explore the use of ICT-enhanced methods in promoting both learner and teacher autonomy/self-directedness in discipline-based language learning and instruction. The action research approach involves continuous staff development, needs identification and aims-setting, teacher and learner self-assessment, learner training, and development of a variety of learning tasks suitable for self-directed learning in both authentic and virtual learning environments. It also involves an attempt of creating a set of ICT-enhanced course formats which - without significant, time-consuming and technically demanding modifications - could be used in teaching and learning languages. The poster describes pilot courses which use different approaches, materials and programmes, and are aimed at different kinds of learners. They cover a variety of possibilities and combinations but remain within the same pedagogical framework, since learner and teacher autonomy are the basic guidelines in all the pilot courses.

Development of a Computer Aided Cooperative Classroom Environment
Akira Suganuma, Kyushu University, Japan; Ryunosuke Fujimoto, Kyushu University, Japan; Yutaka Tsutsumi, Kumamoto Gakuen University, Japan

In the educational domain, a popularization of computers and the Internet enable us to hold lectures using Web contents as a teaching material. We propose CACCE, Computer Aided Cooperative Classroom Environment, which is an WWW-based supporting system for a classroom teaching. CACCE consists of a server-software and a client-software, that is to say, a teacher's browser and a student's browser. These browsers are connected together by a socket connection, sends and receives some messages such as a URL and the CACCE's command. There are three main features of CACCE. First, CACCE automatically refreshes student's browsers. Secondly, CACCE displays a cooperated mark and text on these browsers. Finally, student's browsers automatically report an URL of page shown by them to teacher's browser. This information is used as one of the guidelines for teaching. It is concluded that CACCE is not only a tool that broadcasts the document on a teacher's browser to students, but also a cooperative environment.

Using Knowledge Models in Intelligent Tutoring Systems
Stephen G. Taylor, Champlain Regional College, Canada

The Virtual Tutee system will be introduced as a prototype of an intelligent tutoring system. The user of this system adopts the role of the tutor and studies photosynthesis by tutoring a virtual tutee residing within the software. The system was produced as a simulation based on a model of the tutoring learning situation called the Knowledge Modelling Approach, which will also be introduced. Fifty college students participated in a test of the system.

An Evaluation of Interactive Studio Physics I
Holly Traver, Rensselaer Polytechnic Institute, USA; Michael Kalsher, Rensselaer Polytechnic Institute, USA; Karen Cummings, Rensselaer Polytechnic Institute, USA; Keith Hmieleski, Rensselaer Polytechnic Institute, USA

Rensselaer Polytechnic Institute has implemented an innovative physics course ("Studio Physics") that promotes collaborative interaction. Students work in groups of 2-4 on computers connected to the local network and Internet. Class time is spent on short lecture and group exercises. This research study evaluated Studio Physics in terms of grades and alumni responses. An examination of course grades from students who took the first courses of Studio Physics yielded no significant difference between traditional lecture and studio courses. However, as the studio course has evolved, learning has improved. Alumni were contacted and asked for their opinions on all types of courses, including studio. Alumni indicated working collaboratively with others helped them to improve communication, interpersonal, and computer skills, as well as the abilities to work with others, learn new material, and perform at their current job. This finding is important for work organizations, since much of work today is group-based.

Grasp of Few body element's correlative operation using Multi points measure data-Compair with 2 kind selection-
Atsushi Tsubokura, Osaka Electro-Communi nation Univ., Japan; Kiyoshi Masui, Osaka Electro-Communication Univ., Japan; Noboru Ashida, Osaka Electro-Communication Univ., Japan; Kagemasa Kozuki, Konami Co., Japan; Katsuhide Tsushima, Osaka Electro-Communication Univ., Japan

Expert Operator has any skill for machine operation.But novice has a little skill.The novice do and error operate when try need to new operation skill.Our target is to trace the Operator's skill learning process and the task identify for the skill learned.The newer operation skill based another already learned operation skill.These Operator's skill was changing during Try Operating.The changed operation can show operation timing and used skill for operation. We used few body's measure data and identify his operation using symbolic way.Measure
device is Eye Mark Recorder, 3D position or degree sensor (for Arm Motion), Data Grove. This paper proposes the symbolic way for Multi Points Measure data's correlation and single measure data's characteristic, and evaluate the measure data using these ways. This paper is introduction of these research.

**Offline projects for cross-cultural competence improvement**

Victoria Tuzlukova, Rostov State Pedagogical University, Russia; Irina Rozina, Rostov State Pedagogical University, Russia; Cyndy Woods, Arizona State University, USA

Russian and US faculty members from the Department of Foreign Languages, Rostov State Pedagogical University RSPU, Russia and Arizona State University, Phoenix, USA, developed off-line writing projects designed to increase language proficiency, cross-cultural awareness, computer and networking skills. Targeting EFL students (English as a Foreign Language), the project has demonstrated that students not only increase English language proficiency, but students learn more about the way of life, basic values, and cultural background of the people, whose language they study.

**Analyzing Artists’ Interaction with an Artificial Reality**

Elpida Tzafestas, National Technical University of Athens, Greece

Our long term goal is to understand how humans build models of biological phenomena. To this end, we are studying the relation between an artificial reality and the model of it that an observer deduces. The study is currently based on the observation of how Digital Art students interact with "Painter Ants", an educational simulation software that is used for laboratory work on intelligent and complex systems. The software is a special-purpose ant population demo that tries to convey and teach regulation principles using graphical means. Artists have shown a high motivation to experiment with the system, partly because they tend to regard it as a simple abstract art tool.

They manage to create a functional model of complexity, without really understanding the underlying models. Few experiments with users of different background, have shown that humans, independently of background knowledge, tend to find complex top-down explanations to apparently complex phenomena.

**Supporting Virtual Classrooms through Extranet technology: the Eurydices system**

Kostas Bovilas, University of Patras, Greece; Aspasia Kanta, University of Patras, Greece; Nikos Piskopos, University of Patras, Greece; Bill Vassiliadis, University of Patras, Greece; Athanassios Tsakalidis, University of Patras, Greece; John Tsaknakis, University of Patras, Greece; Evangelos Sakkopoulos, University of Patras, Greece; Christos Makris, University of Patras, Greece

This work describes how collaborative, extranet-based services can be used to teach virtual classes to geographically-dispersed academic participants. Eurydices is an extranet-based training application, whose aim is the efficient management of the great variety of users and courses provided by the Greek Universities Network (GUNet).

**A Web-based educational tool for solving equations**

Maria Virvou, University of Piraeus, Greece; Maria Moundridou, University of Piraeus, Greece; Michael Loizos, University of Piraeus, Greece; Athanasios Papachristou, University of Piraeus, Greece; Nikolaos Polyzotis, University of Piraeus, Greece

This paper describes a web-based intelligent authoring tool for constructing problems in the area of equation solving. The main objective of this tool is to be useful to teachers and students of high school level in the area of algebraic equations. The teacher using this tool is able to provide the information needed to construct an exercise through a user-friendly interface on the web. Every exercise that has been constructed is immediately available to students. The tool also monitors students closely while they are solving the exercises through its student modelling component. The aspects we consider important in this tool are:

- The authoring capabilities it embodies. Teachers can continuously add new exercises and be assisted at their construction. Therefore the tool can be very useful for the construction of student assignments and/or exam tests.
- It is a Web-based tool. Therefore it can be used as a support tool for distance learning. It can also be used in classrooms and/or home as homework, exam tests, student practice or tutorial.
- The tool has ITS features such as the diagnostic capability. In this sense the tool can help the teacher to assess his/her students' progress and level of knowledge. It can also be very helpful at marking the assignments and/or exam tests. In addition it can be very useful to students in two ways. First for the self-assessment of their skills and second for the practice they can have with the provision of individualised feedback.
Constructing a Learning Environment for Knowledge Advancement
Feng-Kwei Wang, University of Missouri - Columbia, USA

The purpose of this research is to introduce the use of technology to construct a learning environment for knowledge advancement through three levels of knowledge -- know-what, know-how, and know-why. Know-what is concept-based domain content which is prepackaged and generalized. Know-how translates know-what into action-oriented skills. Know-why permits one to renew know-what and know-how and thus to solve larger and more complex problems. Different levels of knowledge require different learning methods and entail different learning activities. The most efficient approach to acquiring know-what is through comprehension and feedback. The process-based know-how can be best achieved through practices in simulation and case studies. Know-why can only be built over time through personal encounters with many different problems and solutions in real-world projects. This poster session will depict the theoretical grounds of this knowledge advancement framework and show how technology is employed to construct a learning environment based on this framework.

The Use of Cooperative and Collaborative Learning in a Web-based Integrated Curriculum for the First Two Years of an Engineering Program of Study
John Watret, Embry-Riddle Aeronautical University, USA; Charles Martin, Embry-Riddle Aeronautical University, USA

The authors will describe and present the results of an innovative Integrated Curriculum in Engineering (ICE) designed for the first two years of an engineering program. Entering freshmen engineering student volunteers are placed into specifically designed sections of the foundation courses required of all engineering students: the calculus sequence, the physics sequence, the humanities sequence, social science, and introductory engineering courses. What differentiates the ICE program from traditional engineering curricula is that all courses incorporate cooperative and collaborative learning and a reliance in computer and web technology. In addition, the ICE program promotes team learning, team design projects, and a well-documented series of assessment practices. Although our program was written for an engineering curriculum, the underlying philosophy is applicable to a wide spectrum of programs of study as well as the general education component of many degrees.

Distance Learning For Government Agencies / Online Academies
Joseph Wilczak, American West Enterprise, USA

Government agencies are turning to online presentation formats for computer based instruction related to distance learning. CBT lends itself well to innovative visual curriculum and realtime information sharing. The educational / training implications that combine computer technology, the internet, email, and telecommunications are enormously untapped. CD Rom, online student / instructor interaction through chat rooms, or both are utilized. Material is presented in text supported with voice overs, and graphics. While writing screen text, voice over scripts should be written simultaneously, and graphics last. Lectures can be conducted online supported by video telecommunications. A final online exam is provided at the completion of each course with follow up sessions scheduled depending on course content. Presentations are suitable for newly enrolled student course material as well as recertification or ongoing certification requirements of the particular agency.

The Management of the Telecommunications Function: The Impact on Organizational Support, Planning and Training Quality
John Willems, Eastern Illinois University, USA; Karen Ketler, Eastern Illinois University, USA

This article reports the results of a survey of marketing managers in order to obtain information from the end user about the impact of the management structure of the telecommunications function on 1) the importance of the function within the organization, 2) the formalization of planning practices and 3) the quality of training on thirty issues. While the information systems manager was the most common form of management of the telecommunication function, the organizations with a distinct telecommunications manager reported greater satisfaction with top management support and a more formalized telecommunications planning and implementation process than the other organizations. The respondents from the organizations with a telecommunications manager also indicated better telecommunications training (although still somewhat unsatisfactory) than the other respondents. This was especially true in the managerial issues with a long term focus such as the use of telecommunications to gain a competitive advantage, and managing innovation and technology.

Online Learning Communities: Vehicles for Collaboration in
Stephanie Woolley, University of Colorado at Denver, United States; Stacey Ludwig-Hardman, University of Colorado at Denver, United States

Learning communities are environments that encourage mutual exchange between community members to support their individual and collective learning. Learning communities are founded on the social negotiation of meaning. Collaboration is the key tenet of constructivism and small-group theory (Springer Springer, Stanne, & Donovan,
1999; Grabinger, 1995; Duffy & Jonassen, 1992) that explains the social component of learning and demonstrates that “conceptual growth comes from sharing perspectives and modifying our internal representations in response to that sharing” (Grabinger, 1995, p. 669). Online learning communities provide the means for achieving “shared creation” and “shared understanding” (Shrage, 1991, p. 40). They are an excellent tool for integrating collaboration in online learning environments. The authors’ poster demonstration defines collaboration and learning communities and addresses their theoretical foundations. The authors will discuss the benefits of collaboration and learning communities in online learning environments and provide a case study of a new online learning community at Western Governors University.

The Construction of World-Wide-Web Resource for Chinese Medicine and Acupuncture
Fan Wu, China Medical College, Taiwan; Shao-Fu Huang, China Medical College, Taiwan

As the information technology makes great strides in recent years, Internet has irresistibly reached into every aspect of our daily life. With its unique capability of well-integrating text, image and video, World-Wide-Web has been pervasive in the dissemination of medical discovery, the promotion of medical education and the application of clinical medicine. The issue of capitalizing on the state-of-the-art web technology to build Chinese medicine and acupuncture multi-media web resource is well addressed in this thesis. It is organized around:
1. The largest Chinese medicine news web site domestically.
2. The Chinese-medicine-centric high resolution multi-media Video on Demand in the field of Chinese medicine.
3. The electronic journal on Chinese medicine in the field of Chinese medicine.
4. The virtual classroom with complete features on Chinese Medicine and group-learning systems.

In addition, all the relevant web sites on Chinese medicine will be listed and linked for the benefit of the public. Integrated with Chinese medicine database, this set of medical resource helps to present teachers and researchers with an informative environment surrounded by Chinese medicine data. And it gives students the chance of individual learning and the space for the development for voluntary acquisitiveness for knowledge as well as paves the way for academic exchanges and pervasion of the information on Chinese medicine.

Automatic Generation of the Optimal Tutorial-Plan in Adaptive Educational Hypermedia System
Haiyan Xu, University of Science & Technology of China, P.R.China; XueHai Zhou, University of Science & Technology of China, P.R.China

Adaptive hypermedia system provides a good framework for web-based education. An ideal adaptive educational hypermedia system adapts to different learners during the whole period of the study. Aiming at the automatic generation of the adaptive tutorial-plan, we simply introduce the architecture of the KDAEHS: an adaptive educational hypermedia system based on structural computing, propose the concept of knowledge structure graph represented by AND/OR graph and then discusses the algorithms used to obtain optimal tutorial plan. Combined with the pedagogical strategies specified by the instructors, KDAEHS generates the optimal tutorial-plan which adapts to different learners based on the knowledge structure graph and the learners’ knowledge level. Every tutorial-plan is well suit to the individual learner and can help the learner to fulfill the study goal efficiently.

Virtual Reality in astronomy teaching
Yoav Yair, CET / The Open University, Israel; Rachel Mintz, CET / Tel-Aviv University, Israel; Shai Litvak, CET / Tel-Aviv University, Israel

A new 3D model of the solar system with virtual reality (VR) features. It is based on powerful scientific visualization techniques and can be used as an effective aide in capability of learning within astronomy teaching is presented. The model allows for a powerful learning experience, and facilitates the mental construction of three-dimensional space, where objects are varied and different, but share common features and obey the same physical principles. The learner “enters” a virtual model of the physical world, journeys through it, zooms in or out as he wishes, changes his view point and perspective, as the virtual world continues to “behave” and operate in its usual manner. The new view helps to overcome the inherent geocentric view and ensures the transition to a scientific, heliocentric view of the solar system.

Uncovering cognitive processes in discourse synthesis using hypermedia
Shu Ching Yang, National Sun Yat-Sen University, Taiwan ROC

An exploratory study was undertaken to uncover the cognitive process of discourse synthesis within a hypermedia learning environment. The focus was on learners’ discourse synthesis behavior and the problem solving strategies they employed using the Perseus database. The data for the study was transcribed from tape recordings of the ‘thinking aloud’ protocols as the learners attempted to work on their tasks. All protocols were transcribed verbatim and categorized according to each strategies content. A functional taxonomy were developed to characterize the cognitive operations and thinking processes of the learners’ interactions with Perseus. The proposed taxonomy characterizes their cognitive engagement within hypermedia from a broader context. It is a multifaceted construct
which entails thick cognition with many highly correlated factors. The study is concluded with practical and theoretical concerns emerging out of this focus on discourse synthesis within hypermedia.

Integrating Technology Into the Curriculum
Rosanne Yost, University of South Dakota, USA; Ray Thompson, University of South Dakota, USA

This session describes a teacher education course designed to help K-12 educators integrate technology into their curriculums. The Technology for Training and Development (TTD) Division at the University of South Dakota has developed the course by using the same curriculum planning process that the course is designed to teach. The overall goal of TTD 782: Technology Integration, is to help teachers develop an understanding of the potential for technology to transform school curriculum so that it is student centered and future orientated. As the professors have modeled the curriculum planning process they teach to their students they have themselves become better at using technology. The benefits to both teacher educators and classroom teachers have included classrooms where active learning occurs and where students gain some control over there own learning. A variety of learning styles and needs are now being met as teachers and students learn "how to learn" together.

Using Web Resources to Enhance the Interdisciplinary Nature of Freshman Preceptorial Course
Kesheng Yu, Union College, USA

The purpose of this poster is to demonstrate the design and development of the web-based set of materials designed to help instructors become familiar with topics or readings in which the preceptors' group has little expertise. The focus of Freshman Preceptorial is on cultural difference and on contemporary issues seen in historical or philosophical perspective. Three Freshman Preceptorial projects were funded in 1998 and 1999. While two of these projects are still in the progress, the Resources for Teaching the Bible are finished. This website is designed for faculty teaching and students taking Freshman Preceptorial, though others are certainly welcome to use it. While the demonstration of the design and development of the web resources, the effect of web resources on Freshman Preceptorial course and student attitude toward the use of the web resources would be discussed as well. The URL for the web site: http://www.union.edu/RESOURCES/curriculum/fpbible/

Development of an Virtual University Online Course Using an Interprofessional Approach to Teach Qualitative Research
Cheryl Zaccagnini, Shippensburg University, US; Denise Anderson, Shippensburg University, US; Kent Chrisman, Shippensburg University, US

Using an interprofessional approach, a qualitative research course was designed and taught as a virtual university course. Professors from the disciplines of early childhood, special education, and social work developed a qualitative research online course to utilize virtual university resources to reach graduate and undergraduate students at distant education sites. It was developed to implement the course as an interactive research course with web-based programming and video conferencing sites to enhance the quality of the course and to provide sufficient web-based content but most importantly to create an atmosphere of communication and connectedness with the professors and students at other sites. Syllabi was developed using a team teaching approach with access to the professors via video conferencing, e-mail, and web-based instruction. Formative and summative evaluation results indicate that teaching qualitative research through virtual university resources can be an effective alternative.

Going the Distance:Offering Design Curriculum in the University of Utah’s Distance Learning MFA in Directing/Theatre Education
David Zemmels, University of Utah, USA

In the fall of 1999, the University of Utah’s Department of Theatre, in collaboration with Sundance Institute/Sundance Theatre Lab admitted the first cohort to its pilot distance learning MFA in Directing/Theatre Education. The intent of this session is to provide an overview of the pilot program—its underpinnings, its infrastructure—and examine one solution to offering a theatrical design course within the parameters set by the program. Demonstration and examples of assignments and delivery methods will help conference participants envision ways to use distance learning technologies as part of program development at their home sites.

Merging Fine and Performing Art with Digital Technology:An Exploration of the University of Utah's Arts Technology Certificate Program
David Zemmels, University of Utah, USA

Successfully integrating traditional forms of artistic expression with digital technology is an ongoing challenge in the fine and performing arts. In the 21st Century, digital art forms will likely become even more important. Computer technology has become a pervasive and necessary aspect of the arts, whether you are a music therapist, art historian, actor, musician, designer, photographer, or painter. This past fall, the University of Utah’s College of Fine Arts began the Arts Technology Certificate Program, an interdisciplinary pilot program offering classes in digital...
technology as a tool for artistic expression across all art forms. The intent of this session is to provide an overview of the pilot program and the methods and strategies used to implement it, and to showcase representative examples of student work. Demonstration participants will also explore ways to integrate digital technology curriculum as part of program development at their home sites.

**Comprehensive Examinations via e-mail**

David Zimmerman, James Madison University, USA

This paper will examine the electronic administration of the written comprehensive examination for the Masters Degree in School Library Media Services from James Madison University. Prior to the fall semester, 1998, all students traveled to the main campus in Harrisonburg, Virginia to take the three hour exam. Beginning in November, 1998, four students were sent the exam via e-mail and returned their responses via the same method. The following paper will include a comparison of the two methods of administration, the results of a seven-item questionnaire and a review of the James Madison University Honor System.
